MiR-96-5p is involved in permethrin-promoted proliferation and migration of breast cancer cells

Yi Yan, Tian Wen Long, Xi Niu, Jia Fu Wang and Sheng Li✉

Key Laboratory of Plant Resource Conservation and Germplasm Innovation in Mountainous Region (Ministry of Education), Collaborative Innovation Center for Mountain Ecology & Agro-Bioengineering, CICMEAB, College of Life Sciences/Institute of Agro-Bioengineering, Guizhou University, Guiyang 550025, Guizhou Province, China

MicroRNAs (miRNAs) are major players in cellular responses to xenobiotic compounds and toxins. However, the role of miRNAs in pyrethroid pesticide-induced cancer progression remains unclear. This study aimed to investigate the function of miR-96-5p in permethrin-induced proliferation and migration in breast cancer cells. In our study, the expression of miR-96-5p was upregulated in permethrin-treated MCF-7 cells. MiR-96-5p promoted MCF-7 cell proliferation and migration, accompanied by changes in the expression of proteins involved in cell proliferation, migration, and apoptosis. Homeobox A5 (*HOXA5*) was identified as a direct target of miR-96-5p. *HOXA5* silencing had the opposite effects with miR-96-5p inhibition. In conclusion, these results suggest that miR-96-5p is involved in permethrin-promoted proliferation and migration of breast cancer cells by targeting *HOXA5*.

INTRODUCTION

Permethrin is a synthetic pyrethroid pesticide widely used in agriculture. Permethrin typically disturbs the nervous system of insects through slackening sensitiveness toward voltage on the intramembrane and extramembrane of axons in the nervous system of insects (Park *et al.*, 2021; Wang *et al.*, 2016). Due to the efficient insecticidal properties of permethrin, it is not only applied to control crop diseases and pests but also used in mosquito killing and malaria treatment (Richards *et al.*, 2017; Richards *et al.*, 2018; Thievent *et al.*, 2019). However, the residual toxicity of permethrin has attracted great attention from the public. In vitro studies indicated that permethrin competitively combined with estrogen receptor (ER) against estradiol (E2) (McCarthy *et al.*, 2006) and promoted the proliferation of breast cancer cells, which could be blocked by estrogen antagonists (Kim *et al.*, 2004; Sun *et al.*, 2014). In addition, the wet weight of the uterus of female rats increased after being injected subcutaneously with permethrin, which was similar to the effect caused by E2, and permethrin-induced weight increase he the uterus could be inhibited by antiestro-gens. When male mice were given permethrin *per os*, their luteinizing hormone (LG) significantly increased, while testosterone (T) level and sperm vitality dramatically decreased (Kim *et al.*, 2005). These studies indicate that pyrethroid pesticides such as permethrin have estrogen effects and belong to environmental hormones. According to epidemiological observation, workers exposed to low-dose permethrin for a long time have higher risks of colorectal cancer, breast cancer, lung cancer, and leukemia (Rusiecki *et al.*, 2009). However, the underlying mechanisms remain elusive.

MicroRNA (miRNA) is a kind of non-coding small RNA and regulates protein expression by binding to the 3'-untranslated region (3-UTR) of target genes (Burnett *et al.*, 2021; Cao *et al.*, 2021). miRNAs play an essential role in regulating the organismic response to toxic effects caused by xenobiotic compounds, including pesticides. For example, miR-22 restrained endothelial cell dysfunction caused by the pesticide endosulfan (Xu *et al.*, 2017). MiR-513 protected renal cells from DDVP-induced apoptosis by targeting *BCL-2* (Li *et al.*, 2018). MiR-96-5p was initially identified as a 23-nucleotide miRNA and abundant evidence has shown that miR-96 is related to cell proliferation and apoptosis. For example, overexpression of miR-96-5p was shown to induce gastric adenocarcinoma cell apoptosis through targeting *FOXO3* (He & Zou, 2020), and it also inhibited hepatocellular carcinoma cell apoptosis (Iwai *et al.*, 2018). MiR-96-5p inhibited the expression of the target gene *MTSS1* and enhanced the growth of glioma cells (Zhang & Guo, 2019). These findings indicate that miR-96-5p is involved in tumor cell proliferation, migration, and apoptosis. However, the role of miR-96 in the cellular response to exogenous toxicants remains unclear.

HOXA5 is a member of homeobox gene clusters, which is involved in the regulation of cell differentiation. The role of *HOXA5* in tumorigenesis is controversial. *HOXA5* is generally regarded as a tumor suppressor in many cancers, such as cervical cancer and breast cancer. In these cancers, *HOXA5* is normally the target of various miRNAs. On the other hand, *HOXA5* is reported to be capable of promoting tumor progression, which needs further investigation.

Notably, the mechanism by which permethrin promotes breast cancer is not fully understood, and the role of miR-96-5p in breast cancer remains elusive. Therefore, in this study, we aimed to determine the regulatory role of miR-96-5p in mediating the estrogen effect of permethrin. Our study confirmed that miR-96-5p targeted *HOXA5* to promote breast cancer induced by permethrin.

MATERIALS AND METHODS

Cell line and main reagents

MCF-7 cells were obtained from China Center for Type Culture Collection (CCTCC, China). Cell lines were cultured and maintained in Dulbecco's modified Eagle's medium (DMEM) (Gibco, USA) supplemented with 10% fetal bovine serum (FBS) (Gibco, USA), 1% penicillin and 1% streptomycin (both from Solarbio) under 5% CO2 at 37°C. Permethrin standard (purity 99.1%) and 17β-estradiol standard (purity 99.2%) were purchased from China Center for Standard Substance; Trypsin was purchased from Sigma (USA); CCK-8 kit, Apoptosis-HOECHST staining kit, RNA Extracting Kit, PBS buffer, enhanced RIPA lysis buffer, BCA protein assay kit, and Lipo8000TM were purchased from Beyotime Technology (China), The primary and secondary antibodies were obtained from Beijing Quailityard Biotechnology (China); U6 snRNA Real-time PCR Normalization Kit was purchased from Shanghai GenePharma (China).

Cell proliferation assay

MCF-7 cells were seeded into 96-well plates at a density of 3×10^3 cells/well. After overnight incubation, the cells reached about 70% confluency. Different concentrations of permethrin (10^{-4}, 10^{-5}, 10^{-6}, 10^{-7} mol/L) and estradiol (10^{-6}, 10^{-7}, 10^{-8}, 10^{-9} mol/L) were used to treat MCF-7 cells for 48h or 72 h. Each treatment has five repeats and the medium with different drugs was refreshed daily. Cells untreated with drugs were set as the control group, and wells added only with the medium were set as the blank group. CCK-8 reagent allows the sensitive colorimetric assay to determine the number of viable cells in the cell proliferation assay. Therefore, 20 μL CCK-8 reagent was added to each well after different periods. After 30 min of incubation, the OD values of the solution in each well at 450 nm were measured to calculate cell viability according to the formula:

$$\text{Cell viability(\%)} = \frac{OD_{\text{treated group}} - OD_{\text{blank group}}}{OD_{\text{control group}} - OD_{\text{blank group}}} \times 100\%$$

Cell transfection

MCF-7 cells were seeded into 6-well plates. After 70% confluency was reached, the cells in the control group were treated with 100 pmol scramble miRNA (marked as miR-NC group), while the cells in the experimental group were treated with 100 pmol miR-96-5p inhibitor or miR-96-5p mimic (marked as miR-96-5p inhibitor group or miR-96-5p mimic group) (GenePharma, China) using Lipofectamine 2000 (Invitrogen, USA). The medium was refreshed after 4 h, followed by 24 h incubation.

Quantitative Real-time PCR

Total RNA was extracted with RNAeasy™ Animal RNA Isolation Kit and was reverse transcribed into cDNA using GenePharma RT Reagent Kit. The expression of miR-96-5p was measured with GenePharma qRT-PCR Kit. U6 snRNA was used as an internal reference for miRNA analysis. QRT-PCR was conducted using the CFX96 system. Primers were listed as follows: miR-96-5p, forward: 5'-CGAACTTTGGCACTAG-GCACATT-3', reverse: 5'-TATGGTTTTGACGACT-GTGTGAT-3'; U6, forward: 5'-CAGCACATATAC-

TAAAATTGGAACG-3', reverse: 5'-ACGAATTT-GCGTGTCATCC-3'.

The relative expression of target genes was quantified using the $2^{-\Delta\Delta Ct}$ method.

Luciferase reporter assay

The targets of miR-96 were predicted by Target Scan Human (http://www.targetscan.org), miRDB (http://mirdb.org), and miRTarbase (http://mirtar-base.mbc.nctu.edu.tw/php/index. php). For the luciferase reporter assay, the wild-type (WT-*HOXA5*) or mutant 3'-untranslated regions (MUT-*HOXA5*) of *HOXA5* were subcloned into the luciferase reporter gene vector (pMIR-REPORTER Luciferase, cat. # QYV0423, Qualityard, China). MCF-7 cells were cultured in 24-well plates, and co-transfected with miR-96-5p or miR-NC and WT-*HOXA5* or MUT-*HOXA5* plasmids using Lipofectamine 2000. The luciferase activity was calculated through the ratio of firefly and renilla luciferase activity following the manufacturer's instructions.

In vitro wound healing assay

Cells were cultured in 12-well plates at a density of 3×10^5 cells per well. After transfection with miR-NC, miR-96-5p mimic, and miR-96-5p inhibitor, cells were inoculated until 95% confluency was reached. A sterile 200-μL pipette tip was used to scratch the cell layer manually, and the time point was set as 0 h. Next, the cells were rinsed with PBS 3 times to remove all cellular debris. Fresh complete medium was then added. The subsequent colonization of the denuded surface was quantified with Image J, and the relative migration distance was calculated by subtracting the width at 0 h from the width at each migration time point.

Western blot analysis

Cells were collected after 48 hours of transfection. Radio immuno-precipitation assay (RIPA) lysis buffer was used to extract total proteins and Bicinchoninic acid (BCA) protein assay kit was used to measure the concentrations of total proteins. Proteins of different molecular weights were separated by SDS-PAGE and transferred onto the membranes. After blocking with 5% skim milk for 1 h, proteins were incubated with primary antibodies, rabbit anti-HOXA5, and rabbit anti-β-actin at 4°C overnight. Subsequently, the membranes were washed with TBST solution, incubated with the secondary antibody goat anti-rabbit IgG coupled with HRP at room temperature for 2 h, and washed with TBST solution. The membranes were exposed using an ECL kit and Gel Imaging System. Each experiment was repeated 3 times.

Statistical analysis

Data analysis, graph generation, and statistical analysis were performed with the software GraphPad Prism 8.3 (GraphPad Software Inc., Philadelphia, USA). Data were represented as mean ± standard deviation (S.D.). The comparison between the two groups was analyzed by *t*-test and the comparison of multiple groups such as different concentrations were analyzed by One-way analysis of variance (ANOVA). *P* values less than 0.05 were considered significant.

RESULTS

Low-dose permethrin promoted the proliferation of MCF-7 cells

To determine the effect of permethrin on MCF-7 cell viability, the cells were treated with different concentrations of permethrin for 48 h or 72 h. The results showed that permethrin promoted MCF-7 cell proliferation in a dosage range from 10^{-7}M to 10^{-4}M (Fig. 1A). The maximum viability in MCF-7 cells was seen when cells were treated with 10^{-4} M permethrin for 72 h. Hoechst staining showed that cells in treatment groups had higher viability. The nuclei were evenly stained, compared with the control group (Fig. 1B). IWH assay showed that MCF-7 cell migration was significantly promoted after treatment with 10^{-4} M permethrin for 72 h (Fig. 1C). These results indicate that low-dose permethrin promotes MCF-7 cell proliferation and migration.

Permethrin promoted ER-α and STAT3 expression and upregulated miR-96

Next, we investigated whether permethrin regulated the expression of genes involved in cell proliferation, employing estradiol as the positive control. As is shown in Fig. 2A, after treatment with low-dose estradiol and permethrin for 72 h, the expression of estrogen receptor-α (ER-α) and Signal Transducer and Activator of Transcription (STAT3) in MCF-7 cells increased.

We performed a qRT-PCR assay to detect miR-96 expression in MCF-7 cells treated with different concentrations of permethrin. The results showed that miR-96 expression in MCF-7 cells in the permethrin-treated group increased in a dose-dependent manner (Fig. 2B).

HOXA5 was a target of miR-96-5p in MCF-7 cells

HOXA5 gene was predicted to be the target of miR-96-5p by the TargetScan program (Fig. 3A). To verify the prediction, we constructed a luciferase reporter containing either the wild-type *HOXA5* 3' UTR or a mutated *HOXA5* 3' UTR and then co-transfected into

Figure 2. Permethrin promoted ER-α and STAT3 expression and upregulated miR-96.

Figure 3. *HOXA5* is a target of miR-96-5p in MCF-7 cells.
(**A**) The predicted position of the miR-96-5p target site in the 3' UTR of *HOXA5*. The miR-96-5p seed sequence was shown in the box. (**B**) Luciferase report assay in cells co-transfected with *HOXA5* or HOXA-5 mutation reporter and miR-NC or miR-96-5p. (**C**) Western blot analysis of protein levels of HOXA-5 in miR-NC or miR-96-5p transfected MCF-7 cells. Data were mean ± S.D. (n=3). *$P<0.05$, **$P<0.01$ versus NC groups.

MCF-7 cells with miR-96-5p mimic or negative control (NC) miRNAs. A significant decrease of luciferase activity was detected in cells co-transfected with *HOXA5* 3' UTR construct and miR-96-5p mimics, compared with cells co-transfected with miR-NC or mutant *HOXA5* 3' UTR (Fig. 3B). Compared with the miR-NC group, a significant decrease of *HOXA5* expression in miR-96-5p mimic group was observed (Fig. 3C). These results indicate that *HOXA5* is a direct target of miR-96-5p.

miR-96-5p promoted permethrin-induced proliferation and migration of MCF-7 cells by targeting *HOXA5*

To further investigate the mechanism of miR-96-5p in permethrin-induced MCF-7 cell proliferation and migration, the miR-96 inhibitor was transfected into permethrin-treated MCF-7 cells. IWH assay showed that permethrin-induced migration of MCF-7 cells was increased and *HOXA5* expression was upregulated after miR-96

was inhibited, compared with cells treated with permethrin only. In rescue experiments, permethrin-induced proliferation and migration of MCF-7 cells were decreased by silencing *HOXA5* expression (Fig. 4A, B, C). These results suggest that miR-96 regulates the proliferation and migration of MCF-7 cells by targeting *HOXA5*.

DISCUSSION

Estrogens are crucially involved in the development of breast cancer (Yi *et al.*, 2009; Chaudhuri *et al.*, 2021). Estrogen activates the ER dimer in the promoter domain of the target gene to regulate gene expression in cells (Krieg *et al.*, 2001). Estrogen also promotes the phosphorylation of related transcription factors (Sengupta *et al.*, 2019). Human breast cancer cell line MCF-7 is capable of expressing estrogen receptor and is sensitive to estrogen. Therefore, in the present study, we employed

Figure 4. miR-96-5p promoted permethrin-induced proliferation and migration of MCF-7 cells through targeting *HOXA5*.
(**A**) Wound of permethrin-treated MCF-7 cells immediately after scratching and after 72 h culture in control or miR-96 inhibitor transfected group or miR-96 inhibitor/si*HOXA5* co-transfected group. (**B**) Statistical analysis of wound healing of MCF-7 cells. (**C**) Western blot analysis of *HOXA5* expression after permethrin exposure in MCF-7 cells of the control group, transfected group, or co-transfected group. the MCF-7 cell line as the experiment model and found that low-dose permethrin promoted the proliferation and migration of estrogen-sensitive MCF-7 cells. Moreover, we found that permethrin increased ERα protein expression as E2 did, indicating that permethrin plays a role in enhancing the metabolism of the estrogen receptor.

As a critical downstream transcription factor of ER, phosphorylated STAT3 passes through the nuclear pore to activate the transcription of target genes (Kettner *et al.*, 2019; Wang *et al.*, 2021). In our study, when MCF-7 cells were treated with low-dose permethrin, the expression of STAT3 and ER-α increased, compared with E2 treatment as the positive control. These results suggest that permethrin has an estrogen effect and promotes cell proliferation by activating the estrogen receptor and STAT-related estrogen pathway.

STAT3 is an important transcription factor of the miR-96-182-183 family (Lei *et al.*, 2021; Xiao *et al.*, 2021). MiR-96 was reported to influence the cell cycle (Xu *et al.*, 2018). miR-96 inhibitor arrested the cell cycle at the G1 phase, while fewer cells entered the S phase, suggesting that inhibition of miR-96 induces cell arrest in the G1 phase. Therefore, we speculated that miR-96 might promote cell proliferation and migration induced by permethrin. Our results showed that the miR-96 inhibitor attenuated permethrin-induced proliferation and migration of MCF-7 cells, which confirmed our speculation.

Next, TargetScan, miRDB, and miRTarbase were employed to predict the target genes of miR-96 (Guo *et al.*, 2021). *HOXA5* is highly correlated with cell proliferation and tumorigenesis. *HOXA5* is a member of the homeobox gene family encoding homologous proteins, and its biological function is to control embryonic development and cell differentiation. *HOXA5* is regulated by AKT/mTORC1/S6K1 signal pathway (Feng *et al.*, 2017), and inhibits cell progression by regulating AKT/p27 pathway (Wang *et al.*, 2019). *HOXA5* expression was closely related to tumor histological grade (Dziobek *et al.*, 2020; Aubin *et al.*, 2002). Inhibition and overexpression of *HOXA5* promoted proliferation and apoptosis of osteosarcoma cells through the p53 and p38α/MAPK pathways (Chen *et al.*, 2019). Inhibition of *HOXA5* significantly enhanced viability and proliferation in U2OS and MG63 cells, while overexpression of *HOXA5* promoted cell apoptosis and caspase-3 activity. Knockdown of *HOXA5* in HCC cells provoked capillary tube formation, while overexpression of *HOXA5* inhibited cell proliferation and invasion and promoted cell apoptosis. Based on the luciferase assay, we confirmed that *HOXA5* was a target gene of miR-96. When *HOXA5* was overexpressed, proliferation and migration in MCF-7 cells induced by permethrin were inhibited. Therefore, overexpression of *HOXA5* could reverse the effects of miR-96. These results suggest that miR-96 promotes permethrin-induced proliferation and migration in MCF-7 cells via the downregulation of *HOXA5*. A recent study reported the potential of miRNAs as biomarkers of breast cancer (Shaaban *et al.*, 2022). It would be interesting to evaluate the application of miR-96 in the early diagnosis of breast cancer.

This study has certain limitations. First, the downstream mechanism of Permethrin, miR-96-5p, and *HOXA5* in promoting breast cancer is still obscure. In addition, we need to perform *in vivo* experiments to confirm our conclusion in future studies. Beyond these limitations, this is the first study to demonstrate that miR-96-5p targeted *HOXA5* to promote cancer progression.

In conclusion, our results suggest that permethrin, as a pseudo estrogen, upregulates ER-α and STAT3 expres-

sion in MCF-7 cells. STAT3 activates the transcription of miR-96, which specifically inhibits *HOXA5* expression and promotes the proliferation and migration of MCF-7 cells.

Conflict of Interest

The authors declare that there are no conflicts of interest.

Spinal cord injury (SCI) is a common disease of the central nervous system. Circular RNAs (circRNAs) play an essential role in neuron disorders. This study aimed to investigate the role and regulatory mechanism of circ_0013613 in promoting functional recovery of spinal cord injury (SCI). The mRNA and miRNA expressions were calculated by RT-QPCR. The characteristics of circ_0013613 in nerve cells was determined by actinomycin D and RNase R assay. Protein expression was detected using Western blot. Lactate dehydrogenase (LDH) activity assay was performed to determine cytotoxicity. ELISA was conducted to detect the release of cytokines. MTT assay and flow cytometry were applied to measure cellular functions. In SCI patients and lipopolysaccharide (LPS)-induced primary spinal cord neurons circ_0013613 was increased. Knockdown of circ_0013613 suppressed LPS-stimulated cytotoxicity, inflammation and inflammation-induced pyroptosis. Additionally, circ_0013613 negatively regulated miR-370-3p, downregulation of which degraded cellular functions of spinal cord neurons. Moreover, miR-370-3p targeted Caspase1 (*CASP1*), overexpression of which promoted the inflammation and pyroptosis of spinal cord neurons. circ_0013613 can promote the recovery of SCI by regulating miR-370-3p/*CASP1* to mediate neuronal pyroptosis.

INTRODUCTION

Spinal cord injury (SCI) is a serious disease of the central nervous system and an important cause of disability and death in patients. Its prevention, treatment and rehabilitation have always been the focus of attention and research by clinicians and related scholars (Lu *et al.*, 2020; Kumar *et al.*, 2019).

Circular RNAs (circ RNAs) are a kind of non-coding RNAs with closed circular structure widely existing in eukaryotic cells. It is formed by reverse splicing and plays an important role in cell proliferation, apoptosis and inflammation through microRNA (miRNA) sponges, RNA-binding proteins, regulatory gene transcription and peptide translation. Some studies have pointed out that circRNAs with abnormal expression exist in the process of SCI, which may be a potential target for the treatment of SCI (Yao *et al.*, 2020). Some scholars have found that circRNA plays a role in the pathogenesis and treatment of SCI based on circrNa-mirNA-mrna network. The expression of circ_0003801, circ_0014620, circ_0013613 and circ_0007259 is up-regulated in rats after SCI (Peng *et al.*, 2020). Based on previous studies, we analyzed serum samples and SCI cell models of patients with SCI. Among the four circRNAs, circ_0013613 was the most significantly up-regulated. At the same time, the mechanism of circ_0013613 in SCI recovery is not completely clear.

CASP1 is a member of the Caspase family. It is also the core executor of scorched cell death. It plays an important role in the process of cell death and inflammatory process. (Man *et al.*, 2017; Sun & Scott, 2016). Some studies have pointed out that miR-370-3p is low expressed in SCI cell model *in vitro* and plays an important role in the process of neuronal apoptosis (Li *et al.*, 2021). *CASP1* activation mediated sorosis is closely related to SCI (Li *et al.*, 2020). However, it is not clear whether miR-370-3p participates in the occurrence and development of SCI by regulating the *CASP1*-mediated sorosis pathway. Based on this, this study aims to explore the role of circ_0013613 in promoting SCI function recovery, and to observe whether the mechanism of action is related to the regulation of miR-370-3p/*CASP1* pathway mediated neuronal pyroptosis.

MATERIALS AND METHODS

Experimental materials

This study was approved by the Ethics Committee of Ningxia Hui Autonomous Region People's Hospital. A total of 40 SCI Patients and healthy subjects with similar age and gender distribution were enrolled in the spinal surgery department of our hospital from October 2020 to May 2021. The participants' informed consent was obtained from all of the participants. The serum was collected by centrifugation at 3000 r/min for 10 min at 4°C and stored in the refrigerator at −80°C for detection. DMEM medium, fetal bovine serum and horse serum were purchased from Sigma Company in the United States (MA, USA). IL-18 (SP10189), IL-1 β (SP10180), IL-6 (SP10234) and TNF-α (SP10205) ELISA kits are purchased from Wuhan Saipei Biotechnology Co., Ltd (Wuhan, Chi-

an). The LDH test kit was purchased from Nanjing Jiancheng Bioengineering Research Institute (A020-2-2, Nanjing, China). Reverse transcription kits, Lipofectamine 2000 and TRIzol reagents were purchased from Invitrogen Company in the United States (MA, USA). SYBR Green Mix was purchased from TaKaRa Company in Japan (Tokyo, Japan). Biotin-labeled circ_0013613 probe was purchased from Shenggong Bioengineering (Shanghai) Co., Ltd (Shanghai, China). CircCCS WT, circCCS MUT, circCCS siRNA and siRNA control were constructed by Shanghai Albus Biotechnology Co., Ltd (Shanghai, China). miR-370-3p mimic, miR-370-3p inhibitor and their corresponding negative controls were purchased from Guangzhou Ruibo Co., Ltd (Guangzhou, China). miR-370-3p mimic, miR-370-3p inhibitor and their corresponding negative controls were purchased from Guangzhou Ruibo Co., Ltd (Guangzhou, China). GSDMD-N (69469), NLRP3 (13158), ASC (67824) and GAPDH (5174) antibodies are purchased from Cell Signaling Technology Company in the United States (MA, USA). The double luciferase detection kit was purchased from Promega Company in the United States (CA, USA). BCA protein quantitative kit is purchased from Thermo Company in the United States (MA, USA).

Cultivate and identification of primary spinal cord neurons

Spinal cord tissue isolated from pregnant mice was cut into small pieces according to references (Lan W *et al.*, 2021) and digested using 0.125% trypsin for 25 min. The cells density was 6.0×10^5/mL and inoculated with 10% FBS on the petri dish of DMEM medium with 10% horse serum. After being cultured in a 5% CO_2 incubator at 37°C for 6 h, the medium was replaced with a serum-free medium containing 1% glut amylamine, 2% B27, 1% N_2 and 96% Neurobasal. After 7-9 days of culture, high purity primary spinal cord neurons were obtained by observing the number of tubulin β-positive cells under a microscope.

Construction of SCI cell model, experimental grouping and cell transfection

SCI cell model was constructed by stimulating primary spinal myeloid neurons with 100 ng/mL LPS according to the literature (Li *et al.*, 2021). The experiment was divided into 1) Control group: no treatment was done; 2) LPS group: treated with 100 ng/mL LPS for 24 h; 3) NC inhibitor group: negative control transfected with miR-370-3p inhibitor; 4) NC mimic group: negative control was transfected with miR-370-3p mimic; 5) Inhibitor group: transfected miR-370-3p inhibitor; 6) Mimic group: transfected miR-370-3p mimic; 7) LPS+ Si-circ_0013613 + NC inhibitor group: 100 ng/mL LPS was added to si-circ_0013613 and miR-370-3p inhibitor negative irradiation after 24 h co-transfection for 24 h; 8) LPS+ Si-circ_0013613 +inhibitor group: After co-transfection of Si-circ_0013613 and miR-370-3p inhibitor negative control group, LPS treatment was added; 9) oe-nc group: transfection of empty plasmid; 10) oe-*CASP1* group: transfection of *CASP1* overexpression vector plasmid; 11) LPS+mimic+oe-nc group: co-transfection of miR-370-3p mimic and empty plasmid was given LPS treatment, 14) LPS+mimic+oe-*CASP1* group: co-transfection of miR-370-3p mimic and *CASP1* overexpression vector plasmid was co-transfected with LPS treatment.

The transfection method was carried out according to the Lipofectamine 2000 instructions for 24 h.

RT-qPCR detection

After collecting the serum or cells to be detected, the total RNA was extracted by Trizol method. The purity of RNA was detected by ultraviolet spectrophotometer. After reverse transcription, cDNA was synthesized, and then PCR reaction was carried out with SYBR Green Premix Ex Taq: The 20 μL reaction system consisted of 2 μL cDNA, 10 μL TB Green Premix Ex Taq, 1μL forward and backward primers and 6 μL ddH₂O. The 40 cyclic reaction conditions are: 94°C 30 s, 94°C 5 s, 60°C 30 s. circ_0013613 was calculated by $2^{-\Delta\Delta Ct}$ method (*GAPDH* as internal parameter). Expression levels of miR-370-3p (with U6 as internal reference) and *CASP1* (with GAPDH as internal reference). Primers for circ_0013613, miR-370-3p and *CASP1* were provided by Shanghai Shenggong Biological Co., LTD.

MTT detection

The cells were inoculated 100 μL (density: 1×10^7/mL) in each well into 96-well plates. Cells were conventionally cultured in 37°C, 5% CO_2 incubator. 10 μL MTT was added and incubated at 37°C for 4 h. Next, they were incubated at room temperature for 10 min with 150 μL dimethyl sulfoxide solution. Determination of optical density of 490 nm was done with the use of an enzyme labeling instrument. The survival rate of control cells was 100%. The ratio of experimental treatment group to its group represents the cell viability of this group.

LDH activity detection

The culture medium of the cells to be detected in each group was collected, and the LDH activity of the cells was detected using LDH detection kit according to the instructions.

ELISA detection

After collecting the cells to be detected in each group, the supernatant was collected by trypsin digestion and centrifugation. The contents of IL-18, IL-1 β, IL-6 and TNF-α were detected with specific ELISA kits according to the instructions.

Western blot detection

After collecting the cells to be detected in each group, cell lysis solution was added and placed on ice for full lysis. Then, protein concentration was quantified by BCA method. The sample size of 50 μg per well was transferred onto membrane after SDS-PAGE electrophoresis. Next, the PVDF membrane was sealed with 5% skim milk powder for 2 h and incubated with the first antibody (GSDMD-N, 1:1000; NLRP3, 1:600; ASC, 1:800; GAPDH, 1:2500) overnight at 4°C. After being washed by TBST 3 times, the secondary antibody diluent (HRP labeled secondary antibody diluted according to 1/5 000) was incubated at room temperature for 2 h. ECL was used to develop color and Bio-Rad was used to take pictures. GAPDH was set as a reference to observe the grayscale of the target protein.

Flow cytometry detection

The cells were collected, washed twice with PBS solution, and then added to 100 μL Annexin V Binding Buffer suspension cells. Then, 5 μL Annexin V-FITC

and 5 μL PI were added. After being mixed, cells were incubated for 15 min in the dark. After the 400 μL Annexin V Binding Buffer was added, flow cytometry was performed within 60 min.

Double luciferase reporter gene assay

Circular RNA Interactome (https://circinteractome.nia.nih.gov/index.html), TargetScan 7.2 (http://www.targetscan.org/vert_72/) and miRcode data libraries were used to analyze the complementary binding sites between miR-370-3p and circ_0013613/*CASP1*, circ_0013613/*CASP1* containing miR-370-3p binding sites were used to construct wild-type double luciferase reporter gene carrier, labeled WT. The mutated vector constructed by the sequence of circ_0013613 containing miR-370-3p binding site and *CASP1* site-directed mutation was used as MUT. Wt and MUT were co-transfected with miR-370-3p mimics (mimics) and negative control (NC mimics) for 48 h. To detect the luciferase activity of cells, refer to the double luciferase reporter gene detection kit for specific steps.

RNA Pull down experiment

Trizol reagent was added to 100 μg circ_0013613 or *CASP1* overexpression cells to extract the total RNA. After washing the streptavidin magnetic beads, 200 pmol biotin labeled miR-370-3p mimic was added. After setting for 5min at room temperature, shake it upside down. Next, it was added to the extracted total RNA and incubated for 30 min at room temperature. After the elution buffer was added, the pulled RNA complex was collected in the magnetic field. The expression of circ_0013613 or *CASP1* was detected by RT-qPCR.

RNase R and actinomycin D test

After the total RNA of circ_0013613 overexpression cells was extracted, 5 mg and 3 U/mg RNase R were incubated at 37°C for 15 min. circ_0013613 expression was detected by RT-qPCR. Nerve cells were treated with 2 g/L actinomycin D for 0, 4, 8, 12, 24 h. The total RNA was extracted and the expression of circular and linear in circ_0013613 was detected by RT-qPCR.

Statistical analysis

SPSS26.0 software was used to analyze the experimental data. Data results were calculated as means ± standard deviation ($\bar{\chi} \pm s$). Single factor variance is used to compare multi-group differences. *T*-test corrected by Bonferroni was used for pairwise comparison of data between groups. The difference was accepted as statistically significant at $P < 0.05$.

RESULTS

circ_0013613 expression increased in SCI

RT-qPCR showed that compared with the control group, the expression of circ_0003801, circ_0014620, circ_0013613 and circ_0007259 was significantly up-regulated in LPS-induced neuronal cells, and circ_0013613 had the highest expression ($P < 0.001$, Fig. 1A). Meanwhile, circ_0013613 was also found to be highly expressed in peripheral blood samples of

Figure 1. circ_0013613 expression in SCI cell model and patients.
(**A**) The expression of circ_0013613 was the highest in SCI cell model, compared with Control, *$P < 0.05$, **$P < 0.01$, ***$P < 0.001$; (**B**) The expression of circ_0013613 was the highest in SCI cell model, compared with Control, *$P < 0.05$, **$P < 0.01$, ***$P < 0.001$; (**C**) Line RNase R is processed to confirm the closed-loop structure of circ_0013613, compared with Mock, **$P < 0.01$; (**D**) Actinomycin D analysis to evaluate the stability of circ_0013613 closed-loop structure, compared with Linear, **$P < 0.01$.

40 patients with spinal cord injury (Fig. 1B). The expression of circ_0013613 was not affected by RNase R digestion. The abundance of linear RNA decreased significantly. The results showed that the closed-loop structure circ_0013613 was not easily degraded by exonucase (Fig. 1C). In addition, actinomycin D analysis showed that circ_0013613 was more stable than linear transcription in nerve cells (Fig. 1D).

circ_0013613 down-regulation promotes SCI recovery by alleviating pyroptosis of nerve cells

RT-QPCR results showed that compared with Si-NC, the expression of circ_0013613 was down-regulated after transfection with SI-circ_0013613-1 and Si-circ_0013613-2 ($P < 0.05$), and si-circ_0013613-1 has a more significant effect ($P < 0.01$, Fig. 2A). The results of MTT assay showed that the down-regulation of circ_0013613 significantly weakened the inhibitory effect of LPS on the viability of nerve cells (Fig. 3B). Additionally, the LDH activity of nerve cells induced by LPS was significantly higher than that of control ($P < 001$). However, the down-regulation of circ_0013613 could attenuate the effect of LPS on the activity of LDH in nerve cells ($P < 0.01$, Fig. 3C). The contents of IL-18, IL-1 β, IL-6 and TNF-α in the supernatant of nerve cells treated with LPS were significantly higher than those of control. However, the above-mentioned effects of LPS on nerve cells were significantly weakened after transfection with Si-circ_0013613 ($P < 0.01$, Fig. 3D–G). The protein expression of pyroptosis biomarkers (such as GSDMD-N, NLRP3, and ASC) was decreased by circ_0013613 knockdown (Fig. 3H). The pyroptosis rates of neuronal cells were significantly decreased after transfection of Si-circ_0013613 ($P < 0. 01$, Fig. 3H–I).

miR-370-3p is the target gene of circ_0013613 and has low expression after SCI

It was predicted by Circular RNA Interactome that there were complementary binding sites between circ_0013613 and miR-370-3p (Fig. 3A). Dual-luciferase reporter gene assay confirmed that miR-370-3p mimics reduced luciferase activity of circ_0013613-WT (Fig. 3B). circ_0013613 was highly enriched in the biotin-miR-370-3p group compared with the Biotin-NC

group ($P<0.01$, Fig. 3C). In addition, transfection of Si-circ_0013613 significantly induced the upregulation of miR-370-3p (Fig. 3D). Meanwhile, miR-370-3p expression was significantly decreased in SCI cell model and patient plasma (Fig. 3E~F).

miR-370-3p low expression can reverse the promoting effect of circ_0013613 downregulation on SCI recovery

Compared with the corresponding control, nc inhibitor and NC mimic, transfection with miR-370-3p inhibitor and mimic successfully induced low expression and overexpression of miR-370-3p in nerve cells (Fig. 4A). We further verified whether circ_0013613 plays a role in promoting SCI recovery by directly regulating miR-370-3p expression. Compared with LPS+ SI-circ_0013613 + NC inhibitor, cell viability of LPS+ Si-circ_0013613 +inhibitor group was decreased. The contents of IL-18, IL-1β, IL-6 and TNF-α in cell supernatant, as well as the gray level of protein expression of GSDMD-N, NLRP3 and ASC, LDH activity and pyroptosis rates were significantly increased ($P<0.01$, Fig. 4B–I).

CASP1 is the target gene of miR-370-3p

It was predicted by TargetScan that there were complementary binding sites between *CASP1* and miR-370-3p ($P<0.01$, Fig. 5A). Dual luciferase reporter gene assay, RNA pull-down assay and RT-QPCR detection were found. miR-370-3p mimics can reduce luciferase activity and *CASP1* mRNA expression of *CASP1*-WT, and *CASP1* was highly enriched in the biotin-miR-370-3p group ($P<0.01$, Fig. 5B and C). Moreover, miR-370-3p overexpression significantly decreased the expression of *CASP1* ($P<0.01$, Fig. 5D). In addition, RT-QPCR detection showed that miR-

Figure 4. Low expression of miR-370-3p attenuated the promoting effect of circ_0013613 downregulation on SCI recovery.
(**A**) RT-QPCR confirmed the effect of miR-370-3p low expression and overexpression: compared with NC inhibitor, **$P<0.01$; Compared with NC mimic, ##$P<0.01$; (**B**) MTT assay for cell viability, (**C**) LDH activity detection results, (**D–G**) ELISA detection results of coke death pathway related genes in cell supernatant: Compared with Control or LPS+ SI-circ_0013613 + NC inhibitor, **$P<0.01$; Compared with LPS+ SI-circ_0013613 + NC inhibitor, #$P<0.05$, ##$P<0.01$; (**H**) Western blot analysis of GSDMD-N, NLRP3 and ASC protein expression; (I) pyroptosis results of cells detected by flow cytometry compared with Control or LPS+ SI-circ_0013613 +NC inhibitor,**$P<0.01$; Compared with LPS+ SI-circ_0013613 + NC inhibitor, ##$P<0.01$.

Figure 5. The targeting relationship between miR-370-3p and CASP1 and the expression of CASP1 in SCI cell model and patients.
(**A**) Binding site of CASP1 to miR-370-3p; (**B**) Luciferase activity, compared with NC mimic, **$P<0.01$; (**C**) RNA pull-down results, compared with biotin-NC, **$P<0.01$; (**D**) miR-370-3p regulation of CASP1, compared with NC mimic, **$P<0.01$; (**E**) CASP1 was highly expressed in SCI cell model, compared with Control, **$P<0.01$; (**F**) CASP1 was highly expressed in plasma of SCI patients, compared with Healthy, **$P<0.01$.

370-3p was highly expressed in SCI cell model and SCI patients ($P<0.01$, Fig. 5E–F).

Up-regulation of CASP1 induced the degradation of neuronal cells

As shown in Fig. 6A, the expression of CASP1 was significantly increased in CASP1 OE group ($P<0.01$),

suggesting that cells were successfully transfected. Overexpression of CASP1 suppressed the cell viability of neuronal cells ($P<0.01$, Fig. 6B), and promoted cytotoxicity ($P<0.01$, Fig. 6C), inflammatory response ($P<0.01$, Fig. 6D–G) and pyroptosis ($P<0.01$, Fig. 6H and I).

DISCUSSION

Previous studies have shown that there are abnormal circRNAs in SCI. Restoration of its expression can inhibit secondary injury and promote functional recovery after SCI, which is expected to be a potential molecular marker for the diagnosis and treatment of SCI (Dai *et al.*, 2019). In this study, the expression of circ_0003801, circ_0014620, circ_0013613 and circ_0007259 was upregulated, especially that of circ_0013613. Therefore, this study focuses on circ_0013613. Scorched cell death is one of the important ways of programmed cell death. Including the classic CASP1-mediated inflammasome pathway and/or the non-classical caspase-11/4/5 pathway, inhibition of pyroptosis may be a promising treatment for SCI (Chalfouh *et al.*, 2020; Dai *et al.*, 2019). In this study, it was found that circ_0013613 had good stability in the nerve cells. Knocking down the expression of circ_0013613 can improve the activity of nerve cells by inhibiting the expression of IL-18, IL-1 β, IL-6, TNF- α and related proteins GSDMD-N, NLRP3, ASC and scorch death to reduce SCI damage and promote SCI recovery. The results showed that circ_0013613 down-regulation may promote SCI recovery by alleviating pyroptosis of nerve cells. The results suggest that circ_0013613 may be a potential therapeutic target for SCI.

Figure 6. Up-regulation of *CASP1* can reverse the promoting effect of Mir-370-3p overexpression on SCI recovery.

As is known to all, circRNAs are rich in specific binding sites with miRNAs. CircRNA is a new type of regulatory molecule that regulates the function of miRNA. The role of competitive endogenous RNA can be exerted by targeted adsorption of miRNA to relieve its inhibitory effect on target genes (Chen *et al.*, 2021). In this study, we used bioinformatics software to screen the cirC_0013613 target gene. MiR-370-3p is a miRNA closely related to neurosystemic diseases and tissue damage. It has been reported that it can inhibit the occurrence and development of glioma by targeting β-catenin to regulate cell proliferation and cycle. It can reduce neuronal damage in rats with depression and play an important role in the protective effect of paclitaxel on acute renal injury induced by LPS (Mamun *et al.*, 2020; Shi *et al.*, 2021). In addition, in LPS-induced acute kidney injury, Mir-370-3p can be targeted by LNC-MALAT1 to play a positive role in the protection of paclitaxel against renal tissue injury (Du & Andrea, 2013). We found that Mir-370-3p is the target gene of circ_0013613, and its low expression can promote the recovery of nerve cell scoria inhibition SCI. This is because there are complementary binding sites between circ_0013613 and Mir-370-3p. Double luciferase reporter gene assay and RNA Pull down assay confirmed that circ_0013613 could competitively bind miR-370-3p. RT-qPCR confirmed that down-regulation of circ_0013613 could increase the expression of miR-370-3p. In addition, low expression of miR-370-3p could reverse the down-regulated effect of circ_0013613 on the recovery of SCI. This suggests that circ_0013613 may regulate cell pyroptosis by regulating Mir-370-3p and thus affect SCI recovery. Our results may provide new insights into the molecular regulation of circ_0013613 on the circRNA/miRNA network, thus regulating the progression of SCI.

In order to further explore the mechanism of Mir-370-3p in regulating SCI injury, we used bioinformatics software to predict its potential target genes. *CASP1* is a cysteine aspartate specific proteolytic enzyme that cleaves the N-terminal and C-terminal domains of the executive protein GSDMD. The activation of N-domain can promote the release of IL-1β and IL-18, which play an important role in the process of inflammation and cell death (Peng *et al.*, 2016). The decrease in Caspase-1 activity causes a decrease in the amount of IL-1β because caspase-1 activates pro-IL-1β to IL-1β (Malik & Kanneganti, 2017). Some studies have pointed out that inhibition of Caspase-1 can reduce the expression of IL-1 β and IL-18 after SCI, reduce the secondary injury after SCI, and may play a positive role in the repair of SCI (Nadaradjane *et al.*, 2018). We found that *CASP1* is the target gene of miR-370-3p. Its overexpression can promote the scorched death of nerve cells and inhibit the recovery of SCI. This is because we found that there are complementary binding sites between *CASP1* and miR-370-3p. At the same time, double luciferase reporter gene assay and RT-qPCR confirmed that miR-370-3p could target the regulation of *CASP1*. In addition, upregulation of *CASP1* expression could reverse the promoting effect of miR-370-3p overexpression on SCI recovery. The results suggest that miR-370-3p can promote the recovery of SCI through targeted regulation of *CASP1*-mediated neuronal necrotic death.

In conclusion, circ_0013613 expression was increased in SCI. circ_0013613 sponged miR-370-3p promoted degradation of neurons by promoting *CASP1*-mediated inflammatory response and inflammation-induced pyroptosis. Circ_0013613/miR-370-3p/*CASP1* axis may be a therapeutic target for SCI.

The cadherin protein CDH19 mediates cervical carcinoma progression by regulating AKT/NF-κB signaling

Jia Yu, Xin Sun, Yani Yu and Xiaorong Cui✉

Department of Gynecology, Zibo Central Hospital, No. 54 Gongqingtuan West Road, Zibo 255036, Shandong, China

The cell adhesion protein cadherin 19 (CDH19) has been reported to be involved in various types of cancer, but its role in cervical carcinoma remains unknown. We collected and analyzed the patients' data using the GEPIA Kaplan-Meier plotter databases. CDH19 was overexpressed in cervical carcinoma cells to assess its effect on cell proliferation and activation of AKT and NF-κB signaling pathways. A xenograft mouse model was established to study the function of CDH19 *in vivo*. We found that CDH19 expression was significantly downregulated in cervical carcinoma tissues compared to adjacent normal tissues. Patients with high expression of CDH19 had a significantly better overall survival rate than those with low CDH19 expression. CDH19 expression was negatively correlated with the expression of the proliferation marker Ki-67, and overexpression of CDH19 significantly inhibited cervical carcinoma cell proliferation. Furthermore, overexpression of CDH19 suppressed the activation of the AKT and NF-κB signaling pathways, and CDH19-overexpressing cervical carcinoma tumors exhibited significantly slower growth *in vivo*. CDH19 plays an important role in cervical carcinoma by suppressing both cell proliferation and the activation of AKT and NF-κB signaling pathways. Therefore, CDH19 may be a potential therapeutic target for cervical carcinoma.

INTRODUCTION

Cervical carcinoma is a type of cancer that typically develops in the cervix of women, which is the lower part of the uterus that connects to the vagina. It is caused by the uncontrolled growth of abnormal cells in the cervix. These abnormal cells can spread to other parts of the body and invade nearby tissues and organs. Cervical cancer is one of the most common cancers in women worldwide, with more than 500 000 new cases and over 300 000 deaths reported annually. It is mostly diagnosed in women aged 35 to 44 years, but it can occur in women of any age (Kaur *et al.*, 2003; Lazo, 1999).

The main cause of cervical cancer is the human papillomavirus (HPV), which is sexually transmitted. Cervical cancer often develops slowly over many years, and the early stages of the disease may not cause any noticeable symptoms. However, as cancer progresses, symptoms may include abnormal vaginal bleeding, unusual vaginal discharge, pain during sex, and pelvic pain. But cervical carcinoma can often be successfully treated if detected early (Petereit *et al.*, 1995). Current treatment options for cervical cancer may include surgery, radiation therapy, chemotherapy, or a combination of these approaches, depending on the stage and extent of cancer. However, these treatments might be physically taxing, so it is worthwhile to explore the mechanisms of cervical cancer development can help find new potential therapeutic targets.

Cadherin 19 (CDH19) is a type II classical cadherin protein, which is a cell adhesion molecule that plays an important role in the formation and maintenance of cell-cell contacts. CDH19 protein is expressed in various tissues throughout the body, including the brain, lungs, heart, and kidneys. It is believed to play a crucial role in the development of the nervous system and in the regulation of cell growth and differentiation (Woods *et al.*, 2021). Mutations or alterations in the CDH19 gene have been associated with several different diseases and conditions (Avila & Southard-Smith, 2022; Niu *et al.*, 2008; Tervasmäki *et al.*, 2014). A genetic variation in CDH19 has been linked to a rare neurodevelopmental disorder known as CDH19-related X-linked intellectual disability syndrome. This syndrome is characterized by intellectual disability, seizures, delayed speech and language development, and other neurological and developmental abnormalities. Additionally, CDH19 has been implicated in the developing and progression of certain types of cancer. For example, several studies have reported that CDH19 expression was decreased in cancers including colorectal cancer, gastric cancer, and ovarian cancer. In these cases, reduced CDH19 expression has been associated with poorer outcomes, such as increased tumor invasiveness and poorer survival rates (Blons *et al.*, 2002; Gao & Yang, 2022; Koski *et al.*, 2009; Niu *et al.*, 2008). On the other hand, other studies have reported that CDH19 expression was increased in cancers such as esophageal squamous cell carcinoma and non-small cell lung cancer (Bailis *et al.*, 2019; H. Wang *et al.*, 2021). Overexpression of CDH19 may contribute to cancer growth and metastasis by promoting cell proliferation, invasion, and migration. In these cases, increased CDH19 expression has been associated with more aggressive tumor behavior and poorer prognosis. Overall, the relationship between CDH19 and cancer appears to be complex and may vary depending on the specific type of cancer and other factors. Further research is needed to fully understand the role of CDH19 in cancer development and progression.

Furthermore, there is limited research on the relationship between CDH19 and cervical carcinoma, but some studies have suggested that the expression of CDH19

may be altered in cervical cancer. One study found that CDH19 expression was significantly decreased in cervical cancer tissues compared to normal cervical tissues. Another study reported that CDH19 was upregulated in a group of cervical cancer patients compared to healthy controls (Gu *et al.*, 2021). However, more research is needed to fully understand the role of CDH19 on cervical carcinoma.

The AKT (Protein Kinase B)/NF-*κ*B (Nuclear Factor kappa B) signaling pathway is a crucial pathway involved in cell survival, proliferation, and inflammation. Abnormal activation of this pathway has been implicated in various diseases, including cancer. In cervical carcinoma, studies have shown that the AKT/NF-*κ*B pathway is frequently activated, which leads to the proliferation and survival of cancer cells (Vara *et al.*, 2004). Specifically, activation of the AKT pathway promotes cell survival by inhibiting apoptosis and promoting cell cycle progression, while activation of the NF-*κ*B pathway promotes inflammation and cell proliferation. Moreover, the HPV, which is the primary cause of cervical carcinoma, has been shown to activate the AKT/NF-*κ*B pathway (Bossler *et al.*, 2019). HPV-mediated activation of AKT/NF-*κ*B signaling is thought to contribute to the development and progression of cervical carcinoma by promoting cell survival, proliferation, and inflammation. Overall, the AKT/NF-*κ*B signaling pathway plays a critical role in the development and progression of cervical carcinoma, and targeting this pathway may offer a promising approach for the treatment of this disease. Therefore, our study aimed to explore CDH19's functions and potential therapeutic applications in cervical cancer through AKT/NF-*κ*B signaling pathway.

MATERIALS AND METHODS

GEPIA database and analysis

The expression of CDH19 in cervical carcinoma was collected and analyzed using GEPIA (Gene Expression Profiling Interactive Analysis) database (http://gepia2.cancer-pku.cn). Correlation analysis of gene expression was performed using the Correlation Analysis tool available in the cancer public database GEPIA (http://gepia2.cancer-pku.cn/#correlation).

qPCR

Total RNA was extracted from cells or tissues using a total RNA kit (Invitrogen), followed by the examination of the RNA purity and concentration. The RNA was then reverse transcribed into cDNA using Moloney Murine Leukemia Virus Reverse Transcriptase (BioTeke, China). RT-PCR analysis was performed using the SYBR-Green method. GAPDH was used as an endogenous control for normalization. The relative expression levels of RNAs were calculated using the 2-ΔΔCT method. Details of the gene primers used in the study are provided below.
CDH19 F: 5'-CATTTGTAGGCGTGGTGT-3';
CDH19 R: 5'-GTGGCTGTAATACTTAGGTTGT-3';
GAPDH F: 5'-GGT ATCGTGGAAGGACTCATGAC-3';
GAPDH R: 5'-GGT ATCGTGGAAGGACTCATGAC-3'.

KM Plotter database analysis

We analyzed the overall survival of cervical carcinoma patients with high and low levels of CDH19 expression using KM (Kaplan-Meier) Plotter database online

(http://kmplot.com) as previously described (Nagy *et al.*, 2021).

Cell culture

The CaSki and C-33A cell lines were purchased from ATCC and cultured as previously described (Liu *et al.*, 2021). Briefly, the frozen cells were thawed rapidly in a water bath at 37°C and transferred immediately to a culture hood where the vial contents were quickly transferred to a sterile tube containing pre-warmed growth medium. Using a hemocytometer or an automated cell counter, the cells were counted to determine the density. Plate or flask choice depended on the experimental requirements and growth characteristics. For routine maintenance, a T25 flask or a 6-well plate was suitable. The cells were seeded and placed in a 37°C incubator with 5% CO_2, creating a controlled environment mimicking physiological conditions. The cells were regularly checked under a microscope to monitor growth and passaged when they reached 70–80% confluency.. To this end, the cells were detached using trypsin-EDTA, next neutralized with the growth medium, and the desired number of cells was transferred to new plates.

Western blot

Protein was extracted from cells or tissues using RIPA lysis buffer, and protein concentration was determined in the lysate. Western blot was performed as previously described (Liu *et al.*, 2012). Briefly, the same amount of protein from different treatment groups were loaded into SDS-PAGE gels, subjected to electrophoresis, and then transferred into PVDF membrane. Then membranes were blocked using 5% milk, then incubated with primary antibody overnight. The primary antibodies against CDH19, *p*-AKT, AKT, GAPDH were purchased from Abcam. GAPDH was used as a loading control.

Cell Counting Kit-8 Assay

Cell proliferation was evaluated using the Cell Counting Kit-8 (CCK-8) assay (Boster, China), following the manufacturer's instructions. In brief, $3×10^3$ cells in 100 μL medium were seeded into each well of a 96-well plate, while wells without cells were used as blank controls. Cells in each well were incubated daily with 10 μL of CCK-8 solution for 2 hours at 37°C for 4 consecutive days. Subsequently, absorbance was measured at a wavelength of 450 nm using a microplate reader. The intensity of absorbance is positively correlated with the number of surviving cells (Hou *et al.*, 2022).

Construction and virus packaging of PLVX-CDH19

The full-length human CDH19 gene was amplified via PCR and then inserted into the pLVX-AcGFP lentiviral vector from Thermo Fisher Scientific. Lentiviral particles were produced using a specific protocol that has been previously described (Wang *et al.*, 2017). Cells were transfected with PLVX-NC (negative control) or PLVX-CDH19 for 48 hours.

Nude mouse xenograft model

After transfecting with PLVX-CDH19 for 48 hours, $2×10^6$ tumor cells were suspended in 0.2 ml serum-free DMEM and injected subcutaneously into the left flank of each 4-6-week female BALB/c nude mouse. The same number of PLVX-NC-transfected cells was injected into the right flank of each mouse as control. Tu-

mor size was recorded every three days. On day 21, the tumors were collected, weighted, and lysed for further analysis as previously described (Liu *et al.*, 2020; S. Wang *et al.*, 2021). The animal-related protocols were approved by the ethics committee of Zibo Central Hospital. This study was performed in strict accordance with the NIH guidelines for the care and use of laboratory animals (NIH Publication No. 85-23 Rev. 1985).

Statistical analysis

The data was presented as means ± standard deviation, and analyzed with Student's *t*-test, or two-way ANOVA analysis with a post hoc test using GraphPad software. The result was considered statistically significant when the *p*-values were less than 0.05.

RESULTS

CDH19 is downregulated in cervical carcinoma

We used the public cancer database GEPIA to investigate the expression levels of CDH19 in gynecological tumors, including cervical squamous cell carcinoma and endocervical adenocarcinoma (CESC); ovarian serous cystadenocarcinoma (OV); uterine corpus endometrial carcinoma (UCEC)m and uterine carcinosarcoma (UCS) and matched normal tissues The overall expression of CDH19 was low in gynecological tumor tissues, with significant downregulation observed in cervical carcinoma tissues compared to matched normal tissues ($p<0.01$) (Fig. 1A). To confirm these findings, we collected 20 pairs of cervical carcinoma and adjacent non-cancerous

tissues and examined the expression of CDH19. We observed significant downregulation of CDH19 in all 20 cervical carcinoma tumor tissues (Fig. 1B). These results suggest that CDH19 may play a role in the development or progression of cervical carcinoma and could potentially serve as a diagnostic or therapeutic target for this disease.

CDH19 predicts a positive index for cervical carcinoma

Next, we used the public cancer database Kaplan-Meier plotter to perform an online analysis of the overall survival of cervical carcinoma patients with diverse levels of CDH19 expression. As shown in Fig. 2, patients with high CDH19 expression had significantly higher overall

Figure 2. CDH19 predicts a positive index for cervical carcinoma.
The overall survival of cervical squamous cell carcinoma with low or high CDH19 was analyzed by Kaplan-Meier Plotter online based on pan-cancer RNA-seq data (http://kmplot.com/).

Figure 3. CDH19 overexpression inhibits cervical carcinoma cell proliferation.
(**A**) The correlation analysis between Ki-67 (MKI67) and CDH19 in cervical carcinoma (http://gepia2.cancer-pku.cn). (**B–D**) CaSki and C-33A cells infected with PLVX-NC or PLVX-CDH19-derived lentivirus were lysed for immunoblotting against CDH19 and GAPDH (**B**), and the optical density of the blots was analyzed (**C & D**). E & F. CaSki (**E**) and C-33A (**F**) cells infected with PLVX-NC or PLVX-CDH19-derived lentivirus were prepared for CCK-8 assay at indicated time. **p<0.01, ***p<0.001, ****p<0.0001.

survival rates than those with low CDH19 expression. These findings suggest that CDH19 expression may be a prognostic biomarker for cervical carcinoma and could potentially be used to stratify patients for more personalized treatment strategies.

CDH19 overexpression inhibits cervical carcinoma cell proliferation

To investigate the potential association between CDH19 and cervical carcinoma cell proliferation, we used the public cancer database GEPIA to analyze the correlation between CDH19 and the proliferation marker Ki-67 in cervical carcinoma tissues. We found a significant negative correlation between CDH19 expression

Figure 4. CDH19 overexpression inhibits AKT and NF-κB signaling in cervical carcinoma cells.
(**A & B**) CaSki and C-33A cells were infected with PLVX-NC or PLVX-CDH19-derived lentivirus for 73 hours and then cells were lysed for immunoblotting against p-AKT and AKT (**A**). GAPDH was used as a loading control. The optical density for the blots was also analyzed (**B**). C & D. The above cells were also lysed for immunoblotting against p-p65 and NF-κB p65 (**C**), and the optical density of the immunoblotting was also analyzed (**D**). **p<0.01, ***p<0.001, ****p<0.0001.

Figure 5. CDH19 overexpression inhibits tumor growth of cervical carcinoma.
(**A & B**) The tumor growth curves. (**C**) At the end of the animal study, tumors were excised and weighed. (**D**) Tumors were lysed for QPCR against CDH19 and GAPDH. *p<0.05, ***p<0.001, ****p<0.0001.

and Ki-67 expression (Fig. 3A). Furthermore, we over-expressed CDH19 in cervical carcinoma cells, which was confirmed by Western blot and PCR (Fig. 3B–D), and observed a significant inhibition of cell proliferation in comparison with negative control (Fig. 3E and F). These findings provide further evidence of a close association between CDH19 and cervical carcinoma cell proliferation, suggesting that CDH19 may play a role in regulating the proliferation of cervical carcinoma cells.

CDH19 overexpression inhibits AKT and NF-κB signaling in cervical carcinoma cells

We further investigated the activity of signaling pathways closely related to cell proliferation and found that overexpression of CDH19 significantly inhibited the activation of the AKT pathway as reflected by the decreased AKT phosphorylation both in CaSki and C-33A cells (Fig. 4A, B). In addition, overexpression of CDH19 significantly inhibited the activation of the NF-κB pathway as evidenced with the decreased phosphorylation of NF-κB p65 subunit (Fig. 4C–D). These findings suggest that CDH19 may be involved in regulating cervical carcinoma cell proliferation through the modulation of AKT and NF-κB signaling pathways.

CDH19 overexpression inhibits tumor growth of cervical carcinoma

Finally, to further validate the functional role of CDH19 in cervical carcinoma, we constructed a xenograft tumor model in nude mice. We found that cervical carcinoma tumors overexpressing CDH19 had significantly slower growth rates *in vivo*, as evidenced by the significantly smaller tumor volume (Fig. 5A, B) and weight (Fig. 5C). Also, CDH19 mRNA expression was significantly upregulated in both CaSki and C-33A cells after transfection (Fig. 5D). These findings provide strong evidence of the inhibitory effect of CDH19 on cervical carcinoma tumor growth and suggest a potential therapeutic target for cervical carcinoma.

DISCUSSION

Cadherins (CDHs) are a family of calcium-dependent cell adhesion molecules that play important roles in the maintenance of tissue structure, and cell-cell communication. CDHs are involved in several key cellular processes, including cell adhesion, migration, proliferation, differentiation, and apoptosis. There are several types of cadherins, including E-cadherin, N-cadherin, P-cadherin, and VE-cadherin. These proteins are expressed in different tissues and play a significant role in embryonic development, tissue morphogenesis, and maintenance of tissue integrity.

Previous studies have shown that alterations in the expression and function of cadherins are associated with various types of cancer In particular, the loss of E-cadherin expression is a common event in many types of epithelial cancers, including breast, gastric, colon, and prostate cancers. E-cadherin is a tumor suppressor protein that helps to maintain cell-cell adhesion, and its loss leads to reduced cell adhesion and increased cell motility, which are important events in cancer metastasis (Li *et al.*, 2020). Additionally, mutations in the genes encoding cadherins have been reported in some cancers, including stomach and breast cancer. For example, mutations in the CDH1 gene, which encodes E-cadherin, have been identified in familial gastric cancer and hereditary diffuse gastric cancer syndrome. These mutations can impair E-cadherin function and lead to an increased risk of developing gastric cancer.

Moreover, changes in the expression and function of other cadherin family members have also been associated with cancer. For instance, N-cadherin is upregulated in many types of cancers and plays a role in promoting cancer cell migration and invasion. Similarly, P-cadherin has been found to be upregulated in certain breast cancers and is associated with a more aggressive tumor phenotype. It is believed that upregulation of N-cadherin and P-cadherin, found in some types of cancer, is associated with a more aggressive tumor phenotype.

In summary, alterations in the expression and function of CDH family members are closely related to the development and progression of cancer. The loss of E-cadherin expression, in particular, is a common event in many types of epithelial cancer and is associated with an increased risk of cancer metastasis (Lechner *et al.*, 2013). Understanding the molecular mechanisms underlying these alterations may provide new insights into cancer pathogenesis and may also offer new therapeutic targets for cancer treatment.

CDH19, a member of the cadherin family of cell adhesion molecules, has been implicated in various types of cancers. However, its role in gynecological tumors, especially cervical carcinoma, has not been studied sufficiently (de Mello *et al.*, 2017). In this study, we first analyzed the expression of CDH19 in gynecological tumors (CESC, OV, UCEC, and UCS) using the GEPIA database and found that CDH19 expression was overall downregulated in these tumors, including cervical carcinoma.

To further investigate the role of CDH19 in cervical carcinoma, we analyzed the overall survival of cervical carcinoma patients with high or low CDH19 expression levels using the Kaplan-Meier plotter database. We found that patients with high CDH19 expression had significantly better overall survival than those with low CDH19 expression. This data suggested that CDH19 expression was associated with the overall survival rate of cervical carcinoma patients.

Cervical Intraepithelial Neoplasia (CIN) is a grading system used to classify the severity of abnormal cell growth in the cervix. CIN is divided into three grades based on the degree of abnormal cell growth: CIN1 (mild dysplasia), CIN2 (moderate dysplasia), and CIN3 (severe dysplasia or carcinoma in situ). The CIN grading system is widely used in clinical practice to guide management and treatment decisions for patients with abnormal cervical cell growth. In the future, performing the correlation of CDH19 expression with CIN, may better elucidate its role in cervical carcinoma development.

To explore whether CDH19 is associated with cervical carcinoma cell proliferation, we analyzed the correlation between CDH19 and the proliferation marker Ki-67 in cervical carcinoma patient tissues using the GEPIA database. We found that CDH19 expression was negatively correlated with Ki-67 expression. To validate this observation, we overexpressed CDH19 in cervical carcinoma cells and found that CDH19 overexpression significantly inhibited cell proliferation. That means, loss of the CDH19 expression caused abnormal cell growth, and additional CDH19 can significantly inhibit the abnormal growth. These data further give us a hint that CDH19 might be a potential therapeutic target of cervical carcinoma.

We also investigated the activation of signaling pathways that are closely related to cell proliferation and found that CDH19 overexpression significantly inhibited the AKT and NF-$\varkappa$B signaling pathways. There are several studies supporting potential connection between CDH19 and AKT. For example, in prostate cancer, CDH19 has been found to regulate the AKT/mTOR signaling pathway and promote cancer cell migration and invasion (Qian *et al.*, 2019). In addition, in breast cancer, CDH19 has been shown to interact with the extracellular matrix protein laminin-511, which activates the AKT signaling pathway and promotes tumor growth (Gudlaugsson *et al.*, 2010). These studies suggest that there may be crosstalk between CDH19 and the AKT signaling pathway in various types of cancer. However, so far

there are no studies that directly investigate the relationship between CDH19 and the AKT signaling pathway in cervical carcinoma.

Finally, we constructed a xenograft model in nude mice and found that CDH19 overexpression significantly reduced the growth rate of cervical carcinoma tumors *in vivo*. These results further provide evidence that CDH19 might serve as a therapeutic target of cervical carcinoma.

The findings on CDH19 in cervical carcinoma are quite significant in clinic. It not only provides a prognostic marker of cervical carcinoma, but also proposes a therapeutic target. Understanding that CDH19 suppresses the AKT and NF-$\varkappa$B signaling pathways provides crucial insights into the underlying mechanisms of cervical carcinoma. This knowledge could help in developing more targeted and effective therapies that focus on these pathways. Moreover, the *in vivo* studies in a xenograft mouse model validate the potential therapeutic relevance of CDH19. The slower growth of tumors in mice with CDH19-overexpressing cervical carcinoma cells indicates the potential for further exploration in preclinical models, which could eventually lead to human clinical trials. Overall, these findings suggest that CDH19 could have multifaceted clinical implications in the diagnosis, prognosis, and treatment of cervical carcinoma. However, further research and validation are crucial to determine if targeting CDH19 could indeed be a viable approach in clinical settings.

The study shows promising results in cell cultures and xenograft models. However, cellular responses *in vitro* may not always replicate the complexities of human physiology accurately. The behaviors observed in a controlled lab setting might not fully represent the actual response in human patients. Furthermore, this study primarily relies on data collected from databases such as GEPIA and the Kaplan-Meier plotter. While these resources provide valuable insights, they may have inherent limitations, including data quality, biases, or potential errors in the data collection or analysis methods used in these databases. The number and diversity of samples used in the study is limited to 300 (GEPIA dataset) and 400 (TCGA dataset). The findings might not be universally applicable across different demographic or genetic backgrounds. For comprehensive and robust conclusions, a larger and more diverse sample pool should be considered. The findings show correlation between CDH19 expression and patient survival as well as direct influence of CDH19 expression on cell proliferation, and activation of signaling pathways. It's crucial to continue mechanistic studies to further test the cause-effect relationship between CDH19, activation of the cell signaling pathways and patient outcomes to validate the role of CDH19 in cervical carcinoma and to determine its potential as a therapeutic target. While the findings presented in our study are promising, they represent a stepping-stone for more in-depth research before any clinical implications can be drawn.

CONCLUSIONS

Taken together, our findings suggest that CDH19 plays an important role in cervical carcinoma, potentially through its regulation of the AKT and NF-$\varkappa$B signaling pathways and inhibition of cell proliferation. Further studies are needed to fully elucidate the underlying mechanisms and potential therapeutic implications of CDH19 in cervical carcinoma.

Declarations

Ethical Approval. The animal-related protocols were approved by the ethics committee of Zibo Central Hospital. This study was performed in strict accordance with the NIH guidelines for the care and use of laboratory animals.

Consent for publication. Current study is available from the corresponding author on reasonable request.

Disclosure of potential conflicts of interest. The authors declare that they have no competing interests.

Funding. None.

Data availability statement. The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Acknowledgment. None.

Objective: Major depressive disorder (MDD) is one of the most common psychiatric issues in hemodialysis population. However, the research on proper diagnostic tools and its treatment is still insufficient. The study was performed to investigate the safety and effectiveness of sertraline and agomelatine in a group of hemodialysis patients. **Patients and Methods:** 78 adult patients from one dialysis centre in Poland were included into the study. The Beck Depression Inventory II (BDI-II) was used to screen for depressive symptoms and was followed by the clinical interview with the psychiatrist. Nine patients diagnosed with major depressive disorder received antidepressant treatment with sertraline or agomelatine, according to the best clinical practice. The additional treatment with vortioxetine was used if the initial one was not effective. The time of observation was 24 weeks. The psychiatric follow up as well as the laboratory data were obtained during the course of observation. **Results:** All patients receiving sertraline achieved remission of depressive symptoms. In patients receiving agomelatine no remission was observed despite dose augmentation. The side effects of antidepressants were mild and did not result in treatment discontinuation. No abnormalities in liver enzymes levels were observed. In five cases the significant decrease of haemoglobin level was noticed, with no cases of bleeding reported. **Conclusion:** In patients receiving sertraline the antidepressant effect was satisfactory. No remission of depressive symptoms was observed in patients taking agomelatine. The side effects of antidepressants were mild and transient. Further research on depression treatment in hemodialysis patients is needed, including newer medications.

Keywords: hemodialysis, depression, sertraline, agomelatine

INTRODUCTION

Chronic kidney disease (CKD) and depression plays a significant role in global health (GBD Chronic Kidney Disease Collaboration, 2020; GBD 2019 Diseases and Injuries Collaborators, 2020). Patients suffering from end-stage renal disease (ESRD), requiring renal replacement therapy, are at a high risk of major depressive disorder (MDD) (Kimmel *et al*., 2019). According to the studies, around twenty to forty percent of maintenance hemodialysis patients suffer from major depressive disorder, depending on the methodological approach used (Palmer *et al*., 2019). Individuals with chronic kidney disease have significantly lower quality of life (QoL) (Fletcher *et al*., 2022) and higher mortality rate (Ozieh *et al*., 2021). Furthermore, depression is the known independent risk factor of decreased QoL (Belayev *et al*., 2015) and mortality (Farrokhi *et al*., 2014), as well as higher nonadherence in hemodialysis population (Gebrie *et al*., 2019). Patients undergoing hemodialysis are often excluded from clinical trials, due to the safety reasons, as pharmacokinetics of antidepressants in hemodialysis are not fully explored (Constantino *et al*., 2019). The European Renal Best Practice (ERBP) suggests treatment with serotonin reuptake inhibitors (SSRIs), as the first line in patients who meet depression criteria (Nagler *et al*., 2012). However, the recognition and treatment of depression in ESRD patients remain insufficient (Lopes *et al*., 2004; Pena-Polanco, 2017).

Sertraline is known to be safe and does not require additional doses after the dialysis session (Schwenk *et al*., 1995; Constantino *et al*., 2019). However, its effects in hemodialysis patients may be heterogeneous (Kubanek *et al*., 2021). Studies evaluating safety and efficacy of this SSRI in ESRD patients usually had small samples and lacked placebo control (Palmer *et al*., 2016). In the randomized, controlled trial by Friedli *et al*. there were no significant differences between sertraline and placebo group in improving depression symptoms. (Friedli *et al*., 2017).

Agomelatine is the atypical antidepressant with melatonergic agonism and 5-HT2c antagonism. It was shown to be effective and well tolerated in treating major depressive disorder in general population (Cipriani *et al*., 2018). It is not contraindicated in patients with severe renal impairment, however the data considering CKD population is scarce (Chen *et al*., 2018). One of the side effects of agomelatine is liver enzymes elevation and it

requires aminotransferase monitoring in the course of treatment. Vortioxetine is an antidepressant with multimodal activity used in major depression disorders treatment, recognized as having the best efficacy and safety in head-to-head studies (Koesters *et al.*, 2017; Cipriani *et al.*, 2018).

METHODOLOGY

Patients over eighteen years old from one dialysis centre in Gdańsk (Poland), who had been receiving hemodialysis treatment for at least three months, were recruited. The study received approval of the Independent Bioethics Committee for Scientific Research of the Medical University of Gdańsk. All patients gave their written informed consent. Dialysis Center provides public health services for approximately 200 patients. There is no psychiatric or psychological assistance provided in patients' routine. Individuals suffering from major psychiatric disorders other than depression were excluded. The study group received the high-flux hemodialysis or hemodiafiltration three times per week. Cognitive functions were evaluated using Mini Mental State Examination (MMSE) and assessed clinically by the psychiatrist (Folstein *et al.*, 1975). MMSE was completed subsequently at the end of observation. Patients diagnosed with moderate and severe cognitive impairment were excluded from the further depression diagnosis. The clinical and laboratory data of the study group were also obtained.

The depression screening was performed using Beck Depression Inventory II (BDI-II), followed by the psychiatric assessment (Beck *et al.*, 1996). The diagnosis of major depressive disorder was based on the Diagnostic and Statistical Manual of Mental Disorders 5 (DSM-5). Psychiatrists were using Montgomery-Asberg Depression Rating Scale (MADRS), Clinical Global Impression- Severity scale (CGI-S) and Personal and Social Performance Scale (PSP) to evaluate the severity of depression symptoms and psychosocial functioning of patients (Montgomery *et al.*, 1979; Morosini *et al.*, 2000; Busner *et al.*, 2007). MADRS is a standard in monitoring depressive disorders and improvement during treatment. Tests were performed in the middle of the dialysis session, at least one hour after the initiation and one hour before the termination of the procedure.

Individuals who were diagnosed with major depressive disorder by the psychiatrist and agreed to receive the antidepressant treatment were subjected to further observation. The medications were chosen according to the best clinical practice guidelines. Six patients received treatment with sertraline in the daily dose of 25-100 mg. One patient had been already receiving sertraline (50 mg/day) before the study. Two patients received agomelatine treatment (25–50 mg/day). The time of observation was twenty-four weeks. Psychiatric evaluation, laboratory and dialysis parameters control were performed every six weeks. The additional treatment and dose changes were adjusted during the time of observation. ERBP guidelines suggest that trials with SSRIs in patients, who meet criteria for moderate MDD, should last for eight to twelve weeks, followed by medical evaluation (Nagler *et al.*, 2012). However, the psychiatric clinical practice's assessment for depressive and anxiety patients is usually done after four weeks.

RESULTS

The cognitive functions were rated in 82 patients. According to the MMSE screening and clinical assessment mild cognitive impairment (MCI) and mild dementia were observed in thirty two percent of patients, while moderate dementia in four percent. Patients that agreed to remain in the study and were not diagnosed with moderate or severe dementia were subjected to further evaluation. 78 patients underwent the depression screening and clinical assessment of the psychiatrist. The percentage of individuals with depressive symptoms using BDI-II alone was forty-three. In the clinical interview, performed by the psychiatrist, the criteria of MDD requiring antidepressant treatment were fulfilled in thirteen cases. Two patients did not agree to receive antidepressants. Three patients had been already treated for depression before the study. One person, who had been receiving sertraline, was monitored for possible adverse events. In the group treated with antidepressants there were five women and four men. The age range was between 36

and 76 years and the comorbidity index in most patients was over 4 points. (Table 1).

During the observation two patients resigned from the follow up and one received kidney transplantation. Five patients receiving sertraline achieved remission according to MADRS, CGI-S and clinical evaluation. However, two patients required treatment modification and switching to vortioxetine (10–15 mg). Patients treated with agomelatine had no remission during the observation (one person was observed for 24 weeks and the other for 6 weeks, since the treatment was started during the study). Both required the agomelatine dose augmentation. One

had quetiapine and the other vortioxetine added to the treatment. In the sertraline group the dose of 50 mg was the minimal one to achieve remission, one patient required 100 mg dose. One person receiving agomelatine reported dizziness after 12 weeks of observation, but the treatment was continued. One patient treated with sertraline reported headaches after 6 weeks; the effect was transient and disappeared after splitting the dose into twice a day regimen. In the other individuals we observed no side effects. All patients that agreed to perform dementia screening using MMSE in the end of observation improved or had the equal test result. In the

I, result at the beginning of observation; II, result after 24 weeks of observation; Kt/V (K, dialyzer clearance of urea; t, dialysis time; V, volume of distribution of urea; approximately equal to patient's total body water). Ca x Pi, calcium phosphate index; Hb, haemoglobin; F, female; M, male; WBC, white blood cells; PLT, platelet count; ALT, aminotransferase

patient that refused undertaking the test no clinical features of cognitive decline were observed (Table 2).

The laboratory results were also monitored during observation (Table 3). No abnormalities in liver transaminase levels were observed and the albumin level remained within the normal range in all the patients. In all individuals either no significant changes or the decrease in Kt/V were observed. White blood cells count decreased during the antidepressant treatment but remained within or slightly below the norm. The platelet count stayed within or above the normal range. We noticed the decrease of the haemoglobin level (above 1 g/dl) in five cases- in both patients treated with agomelatine and three patients receiving sertraline in the daily dose of 50 mg. No bleedings were reported in the study group.

DISCUSSION

The prevalence of depressive symptoms and cognitive impairment in the observed group of hemodialysis patients was significant. However, when the gold standard methodological tools in diagnosing major depressive disorder are used and age, coexisting diseases, dementia screening are taken into consideration, it is similar to other elderly populations with high comorbidity rate (Luppa *et al.*, 2012; Wang *et al.*, 2017). It is important while analysing the effectiveness of self-reported questionnaires, which may over-diagnose depressive symptoms. Thus, the psychiatrist examination remains a crucial point in diagnosing depression in a dialysis centre. Increasing its availability for the dialysis patients might have a positive impact on their quality of life and compliance. Moreover, it could upgrade the motivation to proceed in kidney transplantation process.

Taking into consideration the small study group, the number of patients that refused antidepressant treatment or resigned from the follow up was high. The results are consistent with the National Kidney Foundation survey, referring that half of the hemodialysis patients do not adhere to the dialysis regimen (Estrella *et al.*, 2013). Hemodialysis patients suffer from numerous comorbidities and often require polypharmacy, which may be one of the reasons of the incompliance. It might be the group of patients that would agree to psychotherapy or other nonpharmacological approach.

All patients treated with antidepressants that agreed to perform MMSE in the end of observation improved the cognitive functions or achieved the equal test result. It may indicate that some of the observed cognitive disorders in dialysis patients are functional, related to mood disorders. During the treatment, the regular laboratory testing is needed. The decrease of haemoglobin level might be triggered among others by the platelet dysfunction and bleeding caused by the antidepressant agent. The decrease of white blood cells count might be connected with the potential anti-inflammatory effect of antidepressants suggested in previous studies (Taraz *et al.*, 2013). Kt/V is used to evaluate dialysis adequacy; however, its interpretation should be individual due to its limitations as a single parameter (Jones *et al.*, 2018).

The treatment tolerance was good, and the adverse effects of the antidepressants were mild and transient. The antidepressant effect of sertraline in the observed group was satisfactory, however two patients required treatment with vortioxetine. Sertraline is known to be safe to use in the end-stage kidney disease population, but its effectiveness requires further research. Individuals that received treatment with agomelatine did not achieve re-mission according to psychiatrist evaluation. More studies considering newer antidepressant agents, causing less adverse effects (Cipriani *et al.*, 2018), including agomelatine and vortioxetine, are needed.

CONCLUSIONS

In patients receiving sertraline the antidepressant effect was satisfactory. No remission of depressive symptoms was observed in individuals treated with agomelatine. The side effects of used medications were mild and transient. All patients treated with antidepressants improved or had equal cognitive performance at the end of the follow-up. Further research on depression treatment in hemodialysis patients is needed, including the newer antidepressant agents.

Circ_PWWP2A promotes lung fibroblast proliferation and fibrosis *via* the miR-27b-3p/GATA3 axis, thereby aggravating idiopathic pulmonary fibrosis

LiQing Su[1#], Ying Nian[1#] and TianJi Zhu[1✉]

Department of Respiratory and Critical Care Medicine, Affiliated Hospital of Inner Mongolia Medical University, Hohhot City, Inner Mongolia Autonomous Region, 010050, China

Objective: This paper was to investigate the effect of circ_PWWP2A-mediated miR-27b-3p/GATA3 axis on idiopathic pulmonary fibrosis (IPF). **Methods:** circ_PWWP2A expression in lung fibroblasts MLg2908 induced by different concentrations of TGF-β was detected. The relationship between circ_PWWP2A or GATA3 and miR-27b-3p was analyzed by RNA immunoprecipitation and dual-luciferin reporter assay. The proliferation of MLg2908 cells was determined by MTT. GATA3, α-SMA, Collagen-I, and Collagen-III in cells were detected by RT-qPCR and Western blot. The rat model of IPF induced by bleomycin (BLM) was constructed and treated with circ_PWWP2A siRNA injection. HE and Masson staining were of utility to evaluate the pathological conditions of rat lung tissue, and circ_PWWP2A, miR-27b-3p, and GATA3 levels in lung tissues were detected by RT-qPCR. Immunohistochemistry was used to detect the staining of α-SMA, collagen I, and collagen III in the lung tissues of rats. **Results:** circ_PWWP2A in MLg2908 cells induced by TGF-β decreased in a concentration-dependent manner. MLg2908 cells transfected with circ_PWWP2A siRNA were induced by 5 ng/ml TGF-β, decreasing circ_PWWP2A and GATA3 levels, increasing miR-27b-3p expression, and suppressing cell proliferation. The targeting relationship between circ_PWWP2A and miR-27b-3p, as well as miR-27b-3p and GATA3, was confirmed. Depleting miR-27b-3p reduced the inhibitory effect of circ_PWWP2A down-regulation on the proliferation of TGF-β-treated MLg2908 cells, accompanied by increased expression of α-SMA, Collagen 1, and Collagen 3, and increased expression of GATA3. The *in vivo* results showed that BLM-induced fibrosis in rat lung tissue was obvious, accompanied by increased expression of circ_PWWP2A and GATA3, decreased expression of miR-27b-3p, and deepened staining of α-SMA, collagen I, and collagen III, but circ_PWWP2A siRNA could improve these phenomena. **Conclusion:** Silencing circ_PWWP2A can inhibit the proliferation of lung fibroblasts induced by TGF-β through the miR-27b-3p/GATA3 axis, and reduce BLM-induced pulmonary fibrosis in rats, which may be a potential therapeutic target for IPF.

INTRODUCTION

Idiopathic pulmonary fibrosis (IPF) is a diffuse parenchymal lung disease, which is a group of interstitial lung diseases (Martinez *et al.*, 2017; Xaubet *et al.*, 2017). IPF is a representative interstitial lung disease (Sgalla *et al.*, 2016) that is pathologically featured by diffuse alveolitis, pulmonary fibrosis, and progressive scarring. The clinical manifestations are mainly no obvious cause, and the initial symptoms are exertional dyspnea and chronic cough without sputum (Konigsberg *et al.*, 2021; Wolters *et al.*, 2014).

At present, there are mainly anti-inflammatory drugs (such as prednisone) for inflammation, and immunosuppressants (such as cyclophosphamide) for immune response. However, the application of these two types of drugs can affect the inflammatory response of IPF, but not improve the progress of immune response and immune response much, or increase the survival rate of patients (Hewlett *et al.*, 2018; Somogyi *et al.*, 2019). These include nintedanib (Ofev®) and pirfenidone (Esbriet®). These medications are called anti-fibrotic agents, Nintedanib inhibits inflammation and fibrosis by blocking a variety of tyrosine kinase receptors, including platelet-derived growth factor, vascular endothelial growth factor, and fibroblast growth factor (Hilberg *et al.*, 2008). The main antifibrotic effect of pirfenidone is to downregulate transforming growth factor-β (Nakayama *et al.*, 2008). Such as Tananchai et al data confirm that multicenter phase III randomized controlled trial of pirfenidone and niintedanib (ASCEND and INPULSIS Q7) showed a similar reduction in lung function decline compared with placebo (King *et al.*, 2014).The long-term effects of antifibrotic therapy on mortality are unknown. Real-world and registry-based studies have been published describing the long-term use of antifibrotic drugs in clinical practice (Nathan *et al.*, 2017). These studies showed that about 40 percent of patients had drug-related adverse effects, including diarrhea, gastrointestinal distress, and elevated transaminases. However, only 5% of patients receiving antifibrotic therapy permanently discontinue treatment(Cerri *et al.*, 2019). Such studies also add to the growing number of reports on the long-term efficacy of antifibrotic drugs.Therefore, IPF has a poor prognosis and a high mortality rate (Wakwaya & Brown, 2019). IPF generally affects men after the age of 60 years and a median survival time of 2–4 years, even worse than many cancers (Vancheri *et al.*, 2010; Sgalla *et al.*, 2016). It was reported that the survival rate is as low as 2–5 years after diagnosis of the IPF(Richeldi *et*

al., 2017).Therefore, how to prevent and treat IPF more effectively is a difficult problem faced by clinicians.

Circular RNA (circRNA) closed circular RNA molecules formed by covalent bonds (Kristensen et al., 2019). Studies have proved that circRNAs exerts a regulatory role in eukaryotic life activities and disease developments, such as cardiovascular diseases (Altesha et al., 2019), tumors (Lei et al., 2020; Li et al., 2020), kidney-related diseases (Jin et al., 2020), and lung-related diseases (M. et al., 2020), including IPF (Li et al., 2018). For example, hsa_circ_0058493 knockdown inhibits fibrosis by affecting the epithelial-mesenchymal transition (EMT) process in IPF (Cheng et al., 2022). Has_circ_PWWP2A, also known as hsa_circ_0074837 (Zhang et al., 2018), was found to be associated with promoting liver fibrosis (Liu et al., 2019). A reliable function of circRNAs is to directly or indirectly bind target miRNAs to inhibit miRNA function through a process commonly referred to as miRNA sponge adsorption (Huang et al., 2020). Through ENCORI comprehensive database, we found that circ_PWWP2A has a potential binding site with miR-27b-3p. miR-27b-3p has been discovered to be correlated with renal fibrosis (Conserva et al., 2019). Microarray analysis revealed that downregulation of miR-27b-3p is associated with fibrosis (Kim et al., 2017). Furthermore, miR-27b-3p expression alters significantly during lung exacerbation in cystic fibrosis patients (Stachowiak et al., 2020).

Therefore, this article targeted to reveal the mechanism related to circ_PWWP2A and the regulatory network of circ_PWWP2A/miR-27b-3p/GATA3 in IPF, with the purpose to develop molecule-based therapy.

MATERIALS AND METHODS

Cell culture and treatment

The murine lung fibroblast cell line MLg2908 (ATCC, CCL-206, USA) was maintained in EMEM (30-2003, ATCC, USA) containing 10% FBS and treated with different concentrations of recombinant human TGF-β (10 ng/ml; PeproTech, USA; 0, 5, 10 ng/ml) for 24 h (Y. J. Li et al., 2006). circ_PWWP2A siRNA#1, circ_PWWP2A siRNA#2, and NC siRNA were transfected in MLg2908 cells according to Lipofectamine 3000 reagent (L3000001, Thermo Fisher Scientific), and the more effective siRNA was selected for later experiments. MLg2908 were treated with TGF-β at an optimal concentration of 5 ng/ml for 24 h. Before induction, Cells were cultured in 6-well plates with a concentration of 4×105 cells/well, the cells were transfected with the following plasmids, including circ_PWWP2A siRNA#2 and miR-27b-3p inhibitors (#AM17000, Thermo Fisher Scientific).Cells were incubated with 2 ml Opti-MEM medium (GIBCO, USA) containing plasmids (1 μg) and Lipofectamine 3000 (2.5 μl). The medium was changed after 6 h, and the RNA extraction was performed at 48 h to verify the transfection efficiency.

RNA immunoprecipitation (RIP)

Protein-A/G-coated magnetic beads were resuspended in 100 μl NT-2 buffer and let stand with 5 μg AGO2-labeled antibody(Millipore, Billerica, MA, USA). Cells were centrifuged, and 100 μl of the supernatant was added to 900 μl of magnetic beads resuspended in NET-2 buffer. Appropriate antisense probes were designed according to the unique trans-cleavage site of circRNA, and the corresponding sense sequences were used as control negative

probes. Briefly, cells were lysed in RIP lysis buffer, then supernatants were transferred to nuclease-free tubes, magnetic beads conjugated to Ago2 or IgG antibodies were added and incubated for 6 hours at 4°C. The immunoprecipitates bound to the beads were eluted with elution buffer, and the purified RNA fragments were analyzed by RT-qPCR.

MTT experiment

Cells were taken after trypsinization and centrifuged to prepare a cell suspension at $5×10^4$ cells/mL. Seeded into 96-well plates to 45 Wells, 200 μL of cell suspension was cultured for 24 h and centrifuged at 1000 r/min (supernatant was removed). Afterward, 200 μL of serum-free culture medium and 20 μL of 5 mg/ml MTT were added to each well for an additional 4 h, centrifuged at 1000 rpm/min (supernatant was removed), and reacted with 200 μL DMSO to record OD_{490} value on a microplate reader.

Luciferase activity assay

Bioinformatics software predicted the binding sites of circ_PWWP2A and miR-27b-3p, as well as miR-27b-3p and GATA3, and a miR-27b-3p recombinant firefly luciferase reporter plasmid containing the circ_PWWP2A/GATA3 binding sequence was designed and synthesized. circ_PWWP2A WT/circ_PWWP2A MUT/GATA3 WT/GATA3 MUT was co-transfected with mimic NC or miR-27b-3p mimics into MLg2908, respectively. After 48 h, the luciferase activity of the cells was detected according to the instructions of the Dual-Luciferase reporter system kit (Promega).

Immunoblot analysis

Proteins were extracted by lysing cells with RIPA buffer (Sigma, USA) containing protease inhibitors and subsequently quantified by a BCA protein concentration assay kit(Beyotime Biotechnology, Nanjing, China). Total protein was loaded onto PVDF membrane (ThermoFisher Scientific, USA) after 10% SDS-PAGE gel electrophoresis, then blocked with 5% nonfat milk powder, and with primary antibodies at 4°C overnight, including α-SMA at 1 μg/ml (ab5694, Abcam), collagen I (1:5000, ab260043, Abcam), collagen III (1:5000, ab7778, Abcam), GATA3 (1:1000, ab199428, Abcam) and GAPDH (1:2500, ab9548, Abcam). The next day, secondary antibodies were added and incubated for 40 min, the membrane interacted with HRP-conjugated goat anti-rabbit IgG secondary antibody (#31460, Thermo Fisher Scientific). Immunoblots were visualized in IBright FL1500 Intelligent Imaging System (ThermoFisher, USA) and GAPDH was used as an internal control.

Establishment and treatment of IPF rat model

Twenty-four SD male rats, weighing about 200 g, were treated accordingly (6 rats in each group). The rats were anesthetized by intraperitoneal 10% chloral hydrate and fixed in a supine position to expose the trachea. After anesthesia, 1 mg BLM was added to 0.5 ml PBS for intratracheal administration (Otsuka et al., 2017), while the Sham group was only given 0.5 ml PBS. Fourteen days after modeling (day 15), 1 μl/g siRNA was intravenously injected into rats at 0.75 mg/kg/day, three times every other day. Twenty-four hours after the last injection, rats were euthanized by pentobarbital sodium, and lungs were harvested for HE staining and Masson stain-

ing (Milara *et al.*, 2018; Otsuka *et al.*, 2017). Fibrosis was scored according to the Ashcroft assay.

Immunohistochemistry

Fresh paraffin tissues (4 μm) were placed in an oven at 65°C for 2 h, deparaffinized to water, and microwaved in EDTA buffer. Sections were placed in 3% hydrogen peroxide solution for 10 min, blocked with 5% BSA for 20 min, added about 50 μl of diluted primary antibody overnightincluding α-SMA at 1 μg/ml (ab5694, Abcam), collagen I (1:5000, ab260043, Abcam), collagen III (1:5000, ab7778, Abcam), GATA3 (1:1000, ab199428, Abcam) and GAPDH (1:2500, ab9548, Abcam), and 50-100 μl secondary antibody for 50 minthe (membrane interacted with HRP-conjugated goat anti-rabbit IgG secondary antibody (#31460, Thermo Fisher Scientific). After the addition of DAB solution, the sections were counterstained with hematoxylin, differentiated with 1% hydrochloric acid alcohol, immersed in ammonia, dehydrated with gradient alcohol, cleared with xylene, and mounted with neutral gum.

RT-qPCR

Cell and tissue RNA was extracted by the Trizol method, and the concentration and quality of the RNA solution were determined on a DU730 instrument. RNA was reverse transcribed into cDNA using SuperScript IV Reverse Transcriptase (#18090010, Invitrogen) and treated with qPCR according to the SuperScript III Platinum SYBR Green One-Step qRT-PCR Kit (#11736059, Invitrogen). The primer sequences are shown in Table 1. Transcription level of the target gene was calculated by $2^{-\Delta\Delta Ct}$ method.

Statistical analysis

SPSS 19.0 software was of utility for statistical analysis and Graphpad 6.0 was for drawing graphs. One-way analysis of variance, along with Tukey's HSD test was suitable for assessing data collected from multiple groups. Differences were considered statistically significant at $P<0.05$.

RESULTS

circ_PWWP2A can affect the proliferation of TGF-β-treated MLg2908

To investigate the function of circ_PWWP2A in MLg2908 cells, we first knocked it down by transforming the cells using two lentiviral vectors encoding independent shRNAs targeting circ_PWWP2A.

Figure 1. circ_PWWP2A can inhibit the proliferation of mouse lung fibroblasts treated with TGF-β
(**A**) circ_PWWP2A expression after MLg2908 cells were treated with different concentrations of TGF-β (0, 5, 10 ng/ml), *vs. 0 ng/ml TGF-β, P<0.05; #vs. 5 ng/ml TGF-β, P<0.05; (**B**) circ_PWWP2A expression in MLg2908 cells co-treated with circ_PWWP2A siRNA and 5 ng/ml TGF-β; (**C**) Proliferation of MLg2908 cells after co-treatment with circ_PWWP2A siRNA and 5 ng/ml TGF-β; *vs. Control group, P<0.05; #vs. TGF-β group and NC siRNA + TGF-β group, P<0.05; &vs. circ_PWWP2A siRNA + TGF-β group, P<0.05. (**D**) qRT-PCR analysis of circ_PWWP2A levels in MLg2908 cells infected with a lentiviral vector encoding circ_PWWP2A siRNA#1 or circ_PWWP2A siRNA#2

A

Figure 2. circ_PWWP2A can adsorb miR-27b-3p
(**A**) ENCORI found that circ_PWWP2A and miR-27b-3p have potential binding sites; (**B**) RIP to further verify the interaction relationship between circ_PWWP2A and miR-27b-3p; (**C**) dual luciferase reporter experiment to verify the targeting relationship between circ_PWWP2A and miR-27b-3p; *vs. other three groups, P<0.05.

RT-qPCR analysis confirmed that circ_PWWP2A levels were suppressed to a greater degree by expression of circ_PWWP2A (Fig. 1D), which was then utilized in subsequent experiments. In MLg2908 cells treated with different concentrations of TGF-β (0, 5, 10 ng/ml), circ_PWWP2A was increased in a concentration-dependent manner (Fig. 1A), indicating that circ_PWWP2A is promoted during lung fibroblast activation. MLg2908 cells were transfected with circ_PWWP2A siRNA and then induced by 5 ng/ml TGF-β, and it was found that circ_PWWP2A in the cells was decreased (Fig. 1B), After 48 h of TGF-β treatment accompanied by a decrease in prsoliferation activity (Fig. 1C). It indicated that the low expression of circ_PWWP2A could inhibit the proliferation of lung fibroblasts induced by TGF-β.

circ_PWWP2A can adsorb miR-27b-3p

Bioinformatics analysis ENCORI found that circ_PWWP2A has a potential binding site with miR-27b-3p (Fig. 2A). Next, RIP assays in MLg2908 cells further verified the interaction between circ_PWWP2A and miR-27b-3p. circ_PWWP2A was richly precipitated with anti-AGO2 after overexpressing miR-27b-3p in cells (Fig. 2B). Dual-luciferase reporter gene assay results showed that miR-27b-3p can reduce the luciferase activity of circ_PWWP2A WT (Fig. 2C) but not circ_PWWP2A MUT, indicating that circ_PWWP2A has a direct interaction with miR-27b-3p.

Consumpting miR-27b-3p enhances the proliferation of TGF-β-induced MLg2908 cells

Figure 3A showed that 5 ng/ml TGF-β can inhibit miR-27b-3p expression in MLg2908 cells, and after co-treatment with miR-27b-3p inhibitors, miR-27b-3p expression was further reduced, and the accompanying cell proliferation was further activated. circ_PWWP2A siRNA could reduce TGF-β-regulated inhibition of miR-27b-3p, that is, circ_PWWP2A siRNA augmented miR-27b-3p expression in TGF-β-treated MLg2908 cells.

Silencing miR-27b-3p affects fibrosis-related genes in lung fibroblasts

α-SMA, collagen I, and collagen III in cells were determined by RT-qPCR and immunoblot analysis (Fig. 4A, B), demonstrating an increase α-SMA, collagen I, and collagen III increased in MLg2908 after TGF-β induction, which was promoted α-SMA, collagen I, and collagen III express after co-treatment with miR-27b-3p inhibitors, but alleviated α-SMA, collagen I, and collagen express III after circ_PWWP2A siRNA co-treatment. miR-27b-3p inhibitor co-treatment lessened circ_PWWP2A siRNA-regulated suppression of these fibrosis-related genes.

circ_PWWP2A can regulate GATA3 expression through miR-27b-3p

ENCORI database showed that GATA3 was a direct target gene of miR-27b-3p (Fig. 5A). The interaction between the two was further verified by luciferase experiments, as the results showed that miR-27b-3p mimic reduced the luciferase activity of GATA3 WT without affecting that of GATA3 MUT (Fig. 5B). Our test results also found that circ_PWWP2A siRNA could inhibit the increase of GATA3 in MLg2908 cells induced by TGF-β, while miR-27b-3p inhibitors did oppositely. GATA3 was down-regulated in MLg2908 cells co-treated with TGF-β and circ_PWWP2A siRNA, but this phenomenon was reversed by miR-27b-3p inhibitors (Fig. 5C–E).

Therapeutic effect of circ_PWWP2A siRNA on IPF rats

HE staining and Masson staining showed (Fig. 6A): in rats receiving sham operation, lung structure was normal, the alveolar interval was uniform, no obvious exudation was seen in the cavity, and a small number of collagen fibers dyed in light blue can be seen in the alveoli, but without obvious pathological change. However, BLM injection destroyed the alveolar structure, reduced the alveolar cavity, exfoliated alveolar epithelium and protein exudate, and caused obvious collagen deposition and fibrosis areas. circ_PWWP2A siRNA-treated rats consti-

tuted mild hyperplasia of fibroblasts, deposition of collagen fibers in the pleura and alveolar septa, and mild to moderate pulmonary fibrosis. Ashcroft scores indicated that BLM-induced rats had higher Ashcroft scores, but circ_PWWP2A siRNA reduced Ashcroft scores in BLM-treated rats (Fig. 6B). BLM-induced increased expression of circ_PWWP2A and GATA3 in rat lung tissue, while decreased expression of miR-27b-3p, was reversed by circ_PWWP2A siRNA treatment (Fig. 6C). BLM rats had enhanced immunohistochemical staining results of α-SMA, collagen I and collagen III in lung tissue, but the staining degree was reduced after circ_PWWP2A siRNA injection (Fig. 6D).

DISCUSSION

In humans, IPF is a progressive disease associated with aging caused by uncontrolled proliferation and dif-

ferentiation of fibroblasts resulting from sustained damage to the alveolar epithelium. These myofibroblasts are responsible for hyperproliferation, EMT, ECM production, and contribute to collagen deposition in the affected organ (King *et al.*, 2011). Transforming growth factor-β1 (TGF-β1) is a key member of the TGF-β superfamily. It was discovered in 1983 for its ability to stimulate the growth of rat fibroblasts cultured in soft AGAR and has been identified as a master cytokine in liver fibrosis (Xu *et al.*, 2016). In fibrosis, increased TGF-β signaling significantly affects the behavior of the fibroblast population, which represents the majority of cells in fibrotic lesions. In addition, low levels of TGF-β promoted fibroblast proliferation (Zhang *et al.*, 2017). These activities may explain the number of fibroblasts in fibrotic lesions. Tgf-β-induced mesenchymal characteristics enable epithelial and endothelial cells to contribute to fibroblast popula-

Figure 6. Therapeutic effect of circ_PWWP2A siRNA on IPF rats

tion in fibrotic diseases, which has been revealed in a mouse model of fibrosis (Katsuno et al., 2021).

With the rapid development of deep transcriptome sequencing technology, the research on noncoding RNAs is growing exponentially(Matsui et al., 2017),Although in some cases ncrnas lack protein-coding capabilities and appear to lack biological functions, increasing evidence confirms that they play a critical role in controlling gene expression through multiple mechanisms, such as targeting transcripts (Liu et al., 2012). Reports have demonstrated that several lncRNAs and miRNAs play critical roles in the progression of IPF. For instance, Li and others (Li et al., 2020) reported that circTADA2A could repress fibroblasts activation and proliferation via miR-526b/Cav1 and miR-203/Cav2 pathway, thus alleviating IPF. Anotherhsa_circ_0044226 was markedly higher in lung tissues from IPF patients than from healthy controls. which RLE-6TN cells and in a bleomycin-induced mouse model of IPA and diminished TGF-β1-induced fibrosis.these findings indicate that downregulation of hsa_circ_0044226 attenuates pulmonary fibrosis in vitro and in vivo by inhibiting CDC27, which in turn suppresses EMT. This suggests hsa_circ_0044226 may be a useful therapeutic target for the treatment of IPF (Qi et al., 2020). In addition, lncRNA H19 (Lu et al., 2018), MEG3 (Gokey et al., 2018) have been also confirmed to paly critical roles in IPF.

At present, previous studies have found that circ_PWWP2A plays a role in various diseases. For example, in OB-6 osteoblasts and primary human osteoblasts, overexpression of circ_PWWP2A can effectively inhibit dexamethasone-induced cell death and apoptosis (Hong et al., 2019). circ-PWWP2A is up-regulated in mouse fibrotic liver tissue and is positively correlated with HSC activation and proliferation (Liu et al., 2019). Similarly, MLg2908 cells were treated with TGF-β (0, 5, 10 ng/ml) and circ_PWWP2A expression was analyzed to be increased in a concentration-dependent manner. Animal

experiments also found that circ_PWWP2A was also up-regulated in BLM-induced rat lung tissue, suggesting that circ_PWWP2A involves the activation of lung fibroblasts and may be a pathogenic factor for IPF. After inhibiting circ_PWWP2A expression in TGF-β-induced MLg2908 cells, cell proliferation ability was reduced, which verified our speculation.

The most important function of circRNA is to play as miRNA "sponge" (Shi et al., 2020). The present study proved that circ_PWWP2A could adsorb miR-27b-3p. In this study, miR-27b-3p expression in MLg2908 cells induced by TGF-β was decreased, which is consistent with previous reports: for example, exosomal miR-27b derived from human umbilical cord mesenchymal stem cells can ameliorate subretinal fibrosis (Li et al., 2021). Also, miR-27b-3p knockout can reduce cardiac hypertrophy, fibrosis, and inflammation induced by a pathological cardiac hypertrophy model (Li et al., 2021). Furthermore, miR-27b-3p overexpression attenuates renal fibrosis by downregulating α-SMA and collagen III (Bai et al., 2021). All of the studies indicate that miR-27b-3p is a fibrosis-related gene, and its overexpression the role can beanti-fibrotic. Our data further described that low expression of miR-27b-3p could reverse the effect of circ_PWWP2A siRNA on TGF-β-induced mouse lung fibroblast proliferation, and circ_PWWP2A siRNA could reduce the expression of miR-27b-3p in lung tissue of IPF rats, indicating that circ_PWWP2A could adsorb miR-27b-3p thus promoting TGF-β-induced proliferation and activating MLg2908 cells. α-SMA, collagen I and collagen III, as fibrosis-related genes are overexpressed in various tissue fibrosis, such as experimental pulmonary fibrosis (Huang et al., 2020), cardiac fibrosis (Zeng et al., 2019), liver fibrosis (Cheng et al., 2019), and kidney fibrosis (Zheng et al., 2019). Here, the expression patterns of α-SMA, collagen I, and collagen III in MLg2908 cells induced by TGF-β were increased, which were similar to the results of previous studies (Cheng et al., 2019; Liu et

al., 2017), but circ_PWWP2A siRNA can inhibit its increase. circ-PWWP2A depletion can alleviate mouse liver fibrosis, accompanied by decreased α-SMA and collagen I expression (Liu et al., 2019). In vivo experiments from the present study clarified that low expression of circ_PWWP2A can improve BLM-induced pulmonary fibrosis in rats, accompanied by decreased expression of α-SMA, collagen I, and collagen III, indicating that the inhibitory effect of circ_PWWP2A on IPF may be through the reduction of fibrosis-related genes.

miRNAs are endogenous small non-coding RNAs (Chen et al., 2019), which can bind to the 3'UTR of target gene mRNA (Bartel, 2009). miR-27b-3p can target the regulation of GATA3 located at 10p14 (Enciso-Mora et al., 2010). T cells regulate the activation of skin fibroblasts, which is in part achieved by GATA3-mediated unique tissue-restricted transcriptional program (Kalekar et al., 2019). GATA3 is also involved in pulmonary fibrosis development (Iturra et al., 2018).

On the whole, the study only discusses the mechanism from experimental tests, and future clinical experiments are required to verify our results; how GATA3 is involved in circ_PWWP2A-mediated adsorption of miR-27b-3p regulating IPF needs to be done as funds and time allow.

CONCLUSION

circ_PWWP2A expression in MLg2908 cells induced by TGF-β decreases in a concentration-dependent manner. Silencing circ_PWWP2A can inhibit the role of TGF-β in the activation and proliferation of lung fibroblasts through the miR-27b-3p/GATA3 axis, and reduce BLM-induced IPF in rats, potentially renewing therapeutic targets for IPF.

The specific role of extracellular matrix metalloproteinases in the pathology and therapy of hard-to-heal wounds

Joanna B. Trojanek✉

Department of Microbiology and Clinical Immunology, The Children's Memorial Health Institute, Warsaw, Poland

Matrix metalloproteinases (MMPs) are zinc-dependent endoproteases responsible for the metabolism of extracellular matrix (ECM). MMPs can degrade the various ECM components as a variety of non-ECM molecules. Hyperactivity of MMPs and improper regulation or inhibition could lead to certain disorders, like non-healing chronic wounds. In chronic wounds, unlike in acute ones, there are always higher levels of MMPs due to the accompanying inflammation. Different proteases are responsible for this condition; nonetheless, blocking MMPs can help restore the wound's healing ability. The level of MMPs can help indicate the prognosis of chronic wounds. In some cases, the healing process is delayed by microbial wound infections. Bacterial proteases may up-regulate the levels of MMPs produced by host cells. That means that both host MMPs as proteases secreted by the infecting bacteria need to be targeted to increase the healing capacity of the wound. MMPs activity modulating treatments by superabsorbent polymer dressings can improve healing rates of chronic wounds. The main goal of this review was presentation the specific role of metalloproteinases in the pathology and therapy of hard-to-heal wounds.

INTRODUCTION

Matrix metalloproteinases (MMPs) belonging to the zinc-dependent endoproteases family are crucial molecules responsible for extracellular matrix (ECM) metabolism by the ability to degrade all kinds of extracellular matrix proteins. Besides degradation of the various ECM components like collagens, fibronectin, or elastin, MMPs can also process several non-ECM molecules, including cytokines, growth factors, their receptors, and ligands. In this way, MMPs are involved in the most physiological and pathological remodeling processes in tissues (Trojanek et al., 2014; Trojanek et al., 2020). The excessive production and hyperactivity of MMPs, and lack of proper regulation and inhibition could lead to certain disorders, like non-healing chronic wounds. Therefore,

this article presents how the level of MMPs can be used to indicate the prognosis of chronic wounds and how protease-modulating treatments can improve healing rates of chronic wounds with examples of specific wound dressings.

In a physiological state, most MMP expressions remain at a very low level, sometimes even close to zero. Their induction occurs in response to tissue damage, enhancing the process of extracellular remodeling. During the extracellular matrix degradation, also many growth factors are released. These growth factors can then be bound to different matrix components, thereby regulating their availability and activity in the tissues. For the proper process of wound formation, a balance between the synthesis and degradation of the extracellular matrix components is necessary. In the pathological state, the components of the ECM are accumulated. Through uncontrolled MMP expression and activation, fibrosis is formed, which may significantly delay or even entirely disturb the healing process (Lazaro et al., 2016). In chronic wounds, unlike in acute ones, there are always higher levels of MMPs (especially gelatinases) due to the accompanying inflammation. It was reported that MMP-9 and MMP-8 were synthesized by inflammatory cells and presented in excess could affect the healing process (Westby et al., 2020). Not only metalloproteinases were responsible for this condition (Harding et al., 2018; Westby et al., 2018), but blocking MMPs can help restore the wound's ability to heal, especially in combination with a good standard of care (including compression therapy, cleaning and removal of hyperkeratosis). The healing process is additionally complicated by the possibility of infection and coexisting diseases such as diabetes, cirrhosis or liver failure, renal failure, active tumor, tumor treatment, anemia, malnutrition, obesity, smoking, a prolonged hospitalization period and the advanced age of the patient (Anderson & Hamm, 2012).

WOUND HEALING STAGES

Wound healing is a physiological process after an injury to restore tissue structure and function. This process may be divided into several phases: fibrin clot formation, inflammatory response, granulation and epithelial formation, angiogenesis and fibroblast proliferation, regeneration of a functional connective tissue matrix with remodeling, and scar tissue formation (Lazarius et al., 1994). The fibrin clot stores cytokines and growth factors released from injured cells and platelets during the activated coagulation cascade, initiating an inflammatory response. Incoming neutrophils secrete pro-inflammatory cytokines, activating local keratinocytes and fibroblasts. After completion of the inflammatory state, the granu-

lating tissue starts forming. Proteases are active in all phases of wound healing (homeostasis, inflammation, proliferation, and remodeling) and, therefore, could play several roles in the normal wound healing process (Velnar et al., 2009; Patel et al., 2016). During wound healing, MMPs participate mainly through the degradation of ECM, enabling cellular migration, facilitating the fresh epidermis formation and angiogenesis, the new extracellular matrix formation, and remodeling of wound scar tissue (Le et al., 2007).

CONCISE MMPs CHARACTERISTIC

Currently, there are twenty-three variable matrix metalloproteinases in humans like MMP-1 to MMP-28 but not included four: MMP -4, -5, -6, -22 (discovered simultaneously by different research teams). Typically, the MMPs family consists of several distinct domains conserved between MMP family members. These domains are predomain, propeptide, catalytic, and hemopexin domains. The propeptide domain consists of approximately 80 aa and contains a highly conserved sequence: PRCG-VPG constituting the so-called "cysteine switch". This regulatory element contains a conserved cysteine residue, which interacts with the zinc in the active site and prevents binding and cleavage of a substrate, keeping the enzyme in the inactive site. The catalytic domain consists of about 170 aa and contains two zinc ions (catalytic and structural) and 1-4 calcium ions Ca^{2+}. In the active center, the zinc ion is coordinated by a very conserved three-histidine sequence (for zinc chelation), creating a zinc-binding sequence HEXXHXXGXXH. A typical MMP contains a linker peptide or flexible hinge known as a hinge region of variable 75aa length and haemopexin-in-like-C-terminal domain (Hpx) with a sequence similar to hemopexin related with hem metabolism of approximately 200 aa. The hemopexin domain is a place of interaction between MMPs with their endogenous tissue inhibitors-TIMPs. Only two among all MMPs do not obtain this domain: MMP-7 and MMP-26 (belong to matrylisin), and MMP-12 lost it after activation. Three repeats of fibronectin type 2 in the middle of the catalytic domain enhance substrate binding by gelatinases and are the most important for effectively degrading type IV collagen, elastin and gelatin. Membrane-type MMPs (MT-MMP-1 – MT-MMP-6) contain furin cleavage sites in their propeptide domains (Fig. 1).

Based partly on the historical assessment of substrate specificity and partly on the cellular localization the MMPs family can be divided into seven groups: collagenases, gelatinases, stromelysins, matrilysins, metalloelastases, membrane-type MMPs, and other MMPs (Table 1).

MMPS IN WOUND HEALING

According to the Wound Healing Society, chronic wounds can be classified into four categories: pressure ulcers (PUs), diabetic foot ulcers (DFUs), venous leg ulcers (VLUs), and arterial insufficient ulcers (Simönes et al., 2018). MMP activity is strictly controlled during the post-injury processes. One example of this process disruption stuck in the inflammatory phase and thus preventing the transition to the phase of granulation tissue formation is hard-to-heal chronic wounds. In this state, there is a significant increase in the activity of MMPs, which later self-perpetuates and may increase through the secretion of cytokines. An increase in the activity was found for MMP-2, -8, -9, and -14, while a decrease

for TIMP-1 and-2, compared to the healing group. Poor healing was correlated with increased MMP-9 expression in chronic venous wound biopsy specimens and elevated levels of MMP-9/TIMP-1 in the wound exudates. However, significant differences were found between MMP-1 and other proteases. Because of heterogeneity in protease activity, MMP-1 may be associated with more healing and other proteases with less healing. A higher level of MMP-1 in healing wounds permits the proliferative phase to be completed and allows the progression of the healing process (Westby et al., 2020). Limited evidence suggests correlations between elevated levels of MMPs and delayed healing in PUs (Ladwig et al., 2002), in DFUs (Liu et al., 2009), as well as in VLUs (Serra et al., 2013). Possibly, the association of MMP level with delayed wound healing may be a general wound phenomenon; however, differences between wound types have also been observed (McCarthy & Percival, 2013; Lazaro et al., 2016,). The treatment strategy for such ulcerative wounds has been directed towards decreasing the concentration level of metalloproteinases and regulating their activity. The use of proper inhibitors has become one of the goals of modern wound healing therapy. MMP inhibitors, depending on the type of influence, can be divided into two types – direct or indirect. The most essential direct inhibitors are endogenous tissue MMP inhibitors – TIMPs. Four types of these multifunctional, evolutionarily stable proteins are known: TIMP-1, TIMP-2, TIMP-3, and TIMP-4, with a mass of 22-29 kD. TIMPs differ in specificity and block active MMPs by creating stable and reversible coordination bonds in a stoichiometric ratio of 1:1 or 2:2. The inhibition mechanism involves blocking the access of the substrate to the catalytic site of MMPs (Brew & Nagase, 2010). In the fluid of chronic wounds, TIMP-2 was significantly lower. Also, instead of the concentration of MMPs or TIMPs individually, the MMPs/TIMPs ratio seems to predict better wound healing (Lading et al., 2002). Other direct MMP inhibitors include a broad spectrum of inhibitors like batimastat, marimastat, and ilomastat. Whereas tetracyclines, heparin, glycosaminoglycan (GAG)-sulodexide, pentoxifylline (PTX), reactive oxygen species, and superabsorbent polymers belong to non-direct inhibitors, they can reduce MMP expression indirectly by affecting the inflammatory cascade with immunomodulating or proteolytic actions (Krejner et al., 2016).

Recently, the composite of hybrid dressings has been developed. They combine the properties of different materials (further discussed). Most of these dressings contain gel-forming superabsorbent polymers (sodium polyacrylate or sodium carboxymethylcellulose), which absorb excessive amounts of wound exudates. However, they can decrease the concentration of locally active bacterial proteases and endogenous proteolytic enzymes, including MMPs (McCarthy & Percival, 2012).

A complicated wound is a unique entity and is defined as a combination of an infection and tissue defect. Some researchers believe that every wound is contaminated regardless of the cause, location, size, and management (Velnar et al., 2009).

WOUND HEALING AND INFECTION

Under normal conditions, the human body can heal wounds on its own, so maintenance of the wound in clean and moist conditions and usually used disinfectants are sufficient. However, in some cases, the healing process is delayed, or complications could happen entirely

Figure 1. Diagram of the MMPs domain structure.

Table 1. Extracellular matrix metalloproteinases.

Class	Common name	MMP number	Collagen substrate	Various substrate
Collagenases	Interstitial collagenase	MMP-1	I, II, III, VII, VIII, X	Gelatin, MMP-2,-9, proteoglycans, fibronectin, laminin, pro-TNF
	Neutrophil collagenase	MMP-8	I, II, III, V, VII, VIII, X	Gelatin, fibronectin, proteoglycans ADAMTS-1, pro-MMP-8
	Interstitial collagenase	MMP-13	I, II, III, IV, V, VII, IX, X	Gelatin, laminin, proteoglycans, fibrinogen, proMMP-9, -13
	Collagenase 4 (*Xenopus*)	MMP-18	I	Gelatin
Gelatinases	Gelatinase A	MMP-2	I, II, III, IV, V, VII, X, XI	Gelatin, fibronectin, laminin, elastin, proMMP-9, -13, IGFBPs, IL-1b, TGF-b, a1-antiprotease
	Gelatinase B	MMP-9	I, IV, V, VII, X, XI	Gelatin, elastin, laminin, fibronectin, vitronectin, CXCL5, IL-1b, TGF-b, plasminogen
Stromelysins	Stromelysin 1	MMP-3	III, IV, V, VII, IX, X, XIV	Gelatin, fibronectin, laminin, pro MMP-1, -7, -8, -9, -13, proTNFa, E-cadherin, L-selectin, tenactin
	Stromelysin 2	MMP-10	I, III, IV, V, IX, X	Gelatin, laminin, casein, MMP-1, -8, fibronectin, proteoglycans
	Stromelysin 3	MMP-11	IV	Gelatin, fibronectin, laminin
	Stromelysin 4 or RASI-1	MMP-19	native type IV	Gelatin, laminin, entactin, fibronectin, aggrecan, fibrinogen
Matrilysins	Matrilysin 1or PUMP-1	MMP-7	I, IV	Gelatin, laminin, elastin, fibronectin, proteoglycans, proMMPs, proTNFa, E-cadherin
	Matrilysin 2 or Endometase	MMP-26	I, IV	Gelatin, laminin, elastin, fibronectin, proteoglycans, proMMPs, proTNFa, E-cadherin
Metalloelastase	Macrophage metalloelastase	MMP-12	IV	Elasin, fibronectin, gelatin, proteoglycans, plasminogen
Membrane-type MMPs	MT-MMP-1	MMP-14	I, II, III	Gelatin, fibronectin, laminin, vitronectin, proteoglycans,pro-MMP-2, -13
	MT-MMP-2	MMP-15		Fibronectin, tenascin, enactin, laminin, proMMP-2
	MT-MMP-3	MMP-16	III	Gelatin, fibronectin, vitronectin, MBP, proMMP-2
	MT-MMP-4	MMP-17		Gelatin, fibrinogen, proMMP-2
	MT-MMP-5	MMP-24		Gelatin, fibronectin, chondroitin/ dermatan proteoglycan, proMMP-2
	MT-MMP-6 or Leukolysin	MMP-25	IV	Gelatin, laminin, fibronectin, MBP, fibrin/ogen
Other MMPs	Enamelysin	MMP-20	XVIII	Amalogenin, ameloblastin, aggrecan, laminin, pro-MMP-20
	X-MMP *Xenopus*	MMP-21		Gelatin, aggrecan, casein
	C-MMP Chicken	MMP-22		No matrix substrate defined
Cysteine Array MMP	CA-MMP *Femalysin*	MMP-23		Gelatin, casein, fibronectin
	CA-MMP *Gallus*	MMP-27		Gelatin, casein, pro-MMP-27
	CA-MMP *Epilizin*	MMP-28		proTNFb, casein

disturbing healing. These cases include wound infections or chronic wounds. Microorganisms naturally occurring on the skin cause the most significant risk of wound infections. Among them, Gram-positive bacteria such as *Staphylococcus aureus* or *Streptococcus* spp. occur frequently and after penetrating the wound, significantly delaying or preventing healing. Also dangerous are Gram–negative organisms, like *Escherichia coli* and *Pseudomonas aeruginosa*, as well as anaerobic bacteria – *Bacteroides* spp. *and Clostridium* spp. Wounds can also be infected with fungi

(the most common is *Candida* spp.), viruses like Human Papillomavirus (HPV) or Herpes Simplex Virus (HSV), and parasites; in each case, the wound will heal pathologically (Ding *et al.*, 2022; Diban *et al.*, 2023).

General therapy of infected wounds based on culture with antibiogram is conducted with clinically available antibiotics, including aminoglycosides, β-lactams, cephalosporins, quinolones, and tetracyclines, which interfere with different bacteria structures or metabolic pathways, and for this reason are often included in wound dressings (Simönes *et al.*, 2018; Kaiser *et al.*, 2021). Unfortunately, wounds can become colonized (infection exists, but microbes do proliferate in high numbers) with multidrug-resistant pathogens termed MDROs (Multidrug-Resistant Organisms). They increase the risk of complications because antibiotics have very poor or no effect. The only method seems to be topical antiseptics, which, when used early enough, can stop spreading the infection with fewer side effects than local antibiotics. These are elementary silver, iodophors, octenidine dihydrochloride (ODC), acetic acid (AA), and plant-derived substances like Manuka honey, curcumin, essential oils and many other natural products (Chen *et al.*, 2023).

Chronic wound infections occur due to microorganisms creating biofilm, which adheres to the skin around the wound. Biofilm is a polymicrobial population less susceptible to the human immune defense system, displaying a high level of antibiotic tolerance with intense inter-bacterial communication through quorum sensing (Preda & Săndulescu, 2019; Kaiser *et al.*, 2021). Most chronic wounds are colonized with bacteria. Infections refer to the invasion of tissue by bacteria leading to a clinically evident pathogenic inflammatory response and tissue damage (Persival *et al.*, 2012; Suleman, 2016). The infections may, in some cases, e.g., with a weakened immune system, spread to the surrounding tissues (muscles, bones, joints) and even to the blood, causing systemic infections. Sepsis during chronic wound infection is an infrequent complication, but the possibility of its occurrence should be considered.

Chronic wounds are susceptible to colonization by numerous bacterial species, like *S. aureus* (93.5%), *Enterococcus faecalis* (71.1%), *P. aeruginosa* (52.2%), coagulase-negative *Staphylococci* (45.7%), *Proteus* species (43.1%), and anaerobic bacteria (39.1%). These bacterial species create a biofilm on the wound surface and may secrete bacterial proteases, essential for bacterial growth and virulence (Oldak & Trafny, 2005). Extracellular bacterial proteases can evade the host's immune response and target the immune mediators (Suleman, 2016). Moreover, proteases in wounds could originate from the host or bacteria. It was supposed that host MMPs together with bacterial proteases probably play synergistically causing tissue breakdown on the wound bed. Bacterial proteases may up-regulate the levels of MMPs produced by host cells. Many pathogenic bacteria secrete a range of proteases, of the serine, cysteine, and metallo-type that act as virulence factors. That means both host MMPs and those derived from infecting bacteria need to be targeted to improve the healing capacity of the wound (McCarthy *et al.*, 2012; McCarthy & Percival, 2013).

CHRONIC WOUND TREATMENT

The wound needs to be debrided and dressed correctly. Correct debridement means the removal of nonviable, infected, and hyperkeratotic tissue– it helps to convert a chronic wound into an acute one, which can then progress through the normal stages of healing (Lazaro *et al*, 2016).

In 2002, a group of wound treatment experts described a simple model of chronic wound care. This model with the acronym TIME, which is described as: **T**issue assessment and management, **I**nfection/Inflammation control and management, **M**oisture imbalance and management, **E**dges of wound observation and management (Leaper *et al*, 2012). However applying the above recommendation did not prevent some wounds from failing to heal, and additional efforts were required to resume the healing process.

SELECTED WOUND DRESSING

Wound dressings reduce excess inflammation, allowing chronic wounds to heal more readily. Non-healing wounds often become locked up in the inflammatory phase and cannot progress to produce granulating tissue. Persistent inflammation, in turn, enhances MMP activity. Therefore, one of the main goals of local treatment of wounds, regardless of their etiology, is decreasing the MMPs activity and sequestering host proteases within the wound environment (Krejner *et al.,* 2016; Westby *et al.,* 2020).

Wound dressings have progressed significantly for years, from traditional dry-type gauze or bandages to very sophisticated materials like hydrogels, foams or films. Their application's primary purpose was to maintain a sterile, hypoallergenic, moist, and thermally suitable environment to protect against bacterial infection and promote new tissue growth (angiogenesis) (Verdolino *et al.*, 2021). Some types of dressing especially deactivate elevated MMP activity. The goal was to invent a cost-reasonable dressing, which modulates inflammation and promotes healing. It could be distinguished into several kinds of dressings, which work based on the inactivation of the protease action: skin substitute dressing, collagen-based dressing, cellulose-based dressing, and synthetic dressing based on lipid-colloid technology (TLC).

The first was the skin substitute dressing named Puracol ultraECM, a decellularised porcine mesothelium matrix. It demonstrated high angiogenic potential in vitro and MMP inhibition abilities. Simultaneously, it allowed for a high recovery of growth factor – FGF, VEGF, and TGF-β necessary for quick wound healing (Capella-Monsonis *et al.*, 2020).

The second type was a collagen-based dressing, which compiled the essential requirements for a good dressing: biocompatibility, a lack of toxicity, and a biodegradable material. It could be used for treating chronic wounds, as it demonstrated a decrease in healing times by the ability to inactivate proteases and keep moisture in the wound bed (Holmes *et al.*, 2013; Pallaske *et al.*, 2018). BIOSTEP Collagen Matrix dressing possesses type I collagen and gelatin (denatured collagen). The addition of EDTA to this type of dressing allows binding and irreversibility inactivation of both collagenase (MMP-1), like gelatinases (MMP-2; MMP-9) (Finnegan & Percival, 2015).

The next type was a cellulose-based wound dressing representing the Promogran™ Matrix family, which contained oxidized regenerated cellulose (ORC) besides collagen. This type of dressing presented both antimicrobial and anti-inflammatory properties. The studies proved that the ORC/collagen dressing and silver-ORC (Promogran Prisma™-Matrix) represent antimicrobial properties inhibiting MMP-2 and MMP-9 expressions in wound fluid, and increasing healing rates. Importantly, tEDTA demonstrates antimicrobial and antibiofilm properties, but clinical trials using a synthetic inhibitor MMP (Promogran) showed only 13% effectiveness (Cullen *et al.*, 2001; Verdolino *et al.*, 2021).

Table 2. Summary of MMPs and their role in wound healing – an overview of findings.

Main points	References
In chronic wounds, there are always higher levels of MMPs due to accompanying inflammation.	Patel *et al.*, 2016; Lazaro *et al.*, 2016; Westby *et al.*, 2018
Poor healing is correlated with increased MMP-9 expression and elevated levels of MMP-9/TIMP1 in wound secretion probes.	Ladwig *et al.*, 2002; Serra *et al.*, 2013 Westby *et al.*, 2020; Chen *et al.*, 2023
During infection, bacterial proteases may up-regulate the levels of MMPs produced by host cells.	McCarty *et al.*, 2012; Suleman *et al.*, 2016; Westby *et al.*, 2020
The treatment strategy for chronic wounds is directed towards decreasing the concentration level of MMPs and regulating their activity.	McCarty & Percival, 2013; Krejner *et al.*, 2016
The essential requirements for wound dressing were maintaining a sterile, hypoallergenic, moist, and thermally suitable environment promoting new tissue growth with antimicrobial and antibiofilm properties.	McCarty & Percival, 2013; Kaiser *et al.*, 2021
The modest wound dressing type additionally inactivated the protease action and allowed for high growth factor recovery, which was necessary for quick healing.	Meaume *et al.*, 2012; Meaume *et al.*, 2017; Sigal *et al.*, 2019; Verdolino *et al.*, 2021

Another type was the synthetic dressing Urgostart from a polyester mesh saturated with a sucrose octasulfate potassium salt (Nano Oligo Saccharide Factor – NOSF) embedded lipido-colloid matrix (Technology Lipido-Colloid, TLC). Manufacturer's patents protected NOSF and TLC compositions. Oligosaccharides (NOSF) reduce MMP levels and restore growth factor biological functions, whereas the TLC matrix creates a moist wound environment. NOSF also restores angiogenesis by migration and proliferation of endothelial cells (growth factors protection against MMPs activity). Their mechanisms of action are still unknown. NOSF probably mechanically blocks, i.e. captures and immobilizes MMP molecules, that are massively secreted during prolonged healing (causing a state of chronic inflammation) and contributes to the reduction of the proteolysis (degradation, enzymatic breakdown) of the ECM components (i.e., collagen fibers) by surrounding epithelial cells (fibroblasts and keratinocytes) and macrophages (Lazaro-Martines *et al.*, 2019). Two prospective, multicentric clinical studies named NEREIDES and CASSIOPEE were focused on patients with non-infected, moderate to strongly exudation leg ulcers of venous or mixed origin treated with a dressing and compression system for 12 weeks. Ensure the rapid transition from the debridement stage to the granulation stage, and finally to closure of the wound. Poly- absorbent fibers of the new type of dressing inhibit the proteases in excess accumulating, restore the impaired biological functions, and stimulate angiogenesis through migration and proliferation of endothelial cells (Sigal *et al.*, 2019).

Both TLC-NOSF and ORC/collagen matrix dressings improved venous leg ulcer healing (1% of the adult population in the Western world suffers from leg ulcers). Four randomized controlled trials assessing these two MMP devices were ongoing (Schultz *et al.*, 2008; Sigal *et al.*, 2019).

Urgo-Clean Ag, which combines TLC technology with silver ions, exhibits a broad spectrum of antimicrobial activity, including *S aureus*, *P. aeruginosa*, vancomycin-resistant *Enterococci* and methicillin-resistant *S. aureus* (MRSA). Additionally, after 24 hours, according to Hieu et al. in 2021, UrgoClean Ag reduced the biofilm population by more than 99,99% (4,6 log reduction).

The application of TLC-NOSF technology to lipocolloid dressings (according to Explorer –NTC01717183 and Challenge clinical trials results) in the experts' opinion significantly shortens the healing time of chronically, non-infected wounds, which reduces the cost of treatment and improves the efficiency and quality of patients' life (*Meaume et al.*, 2012; Meaume *et al.*, 2017; Edmonds *et al.*, 2018).

It should be mentioned that the specific clinical study refers to optical and magnetic stimulation (COMS) therapy on wound-healing-related parameters (tissue oxygenation and water index) that were analyzed by hyperspectral imaging on 11 patients with chronic leg and foot ulcers of different etiology NCT03112395 (according to ICHGCP) (Traber *et al.*, 2023).

SUMMARY

A brief summary of the above observations on the role of MMPs in wound healing is presented in Table 2.

CONCLUSIONS

Generally, MMPs play a crucial role in all stages of wound healing, but it was suggested that non-healing wounds may be associated with prolonged high activity of proteases in the later stages of the wound healing process. This persistent proteolytic activity is due to damage to newly formed tissue and the degradation of growth factors necessary for healing. The primary focus in the future will be finding the selective inhibitors of distinguished members; most clinical trials on small spectrum inhibitors until now had negative results due to the widespread inhibitory effect connected with similar structures of all MMPs. It should be assumed that detailed knowledge of protease substrates, especially non-matrix molecules, could help to understand MMP's involvement in physiology and pathology and find the appropriate therapy for hard-to-heal wounds.

MicroRNA-1179 targets Epiregulin (EREG) regulates the proliferation and metastasis of human multiple myeloma cells

Xiao Liu, Lan Qin✉, Wei Li and Fei Fei

Department of Hematology, The Fourth Affiliated Hospital of Traditional Chinese Medicine, Xinjiang Medical University, Urumqi, Xinjiang, 830000, China

MicroRNA-1179 (miRNA-1179) is an extensively studied tumor suppressor. however, the significance of miR-1179 in multiple myeloma has not been investigated previously. So, there is a need for research to find out about the significance of miR-1179 in multiple myeloma. However, current investigations have examined the significance of miRNA-1179 in multiple myeloma for the first time by targeting epiregulin (EREG). In this study, 26 multiple myeloma specimens and 16 healthy donor specimens were examined. Multiple myeloma cell lines (U266, RPMI-8226, KMS-11, JJN-3, and IM-9) were used. In this study, expression analysis, cell viability, colony formation assay, and transwell assay were carried out by standard methods. The outcomes revealed the down-regulation of miRNA-1179 in multiple myeloma. Overexpression of miRNA-1179 promotes, while its inhibition suppresses, the survival ability and colony formation of the U266 multiple myeloma cells. Investigation of underlying mechanisms revealed apoptosis to be responsible for the tumour-suppressive effects of miRNA-1179. The proportion of apoptosis in U266 cells rose from 5.32% to 34.86% when miRNA-1179 was overexpressed. Additionally, it was discovered that miRNA-1179 directs its tumor-inhabiting activities toward EREG at the molecular level. While EREG knockdown was found to halt the proliferation of U266 cells, its overexpression could overcome the suppressive effects of miRNA-1179 on the survival ability, mobility, and invasion of the U266 cells. This research proves that miRNA-1179 can be used as a new treatment or drug for multiple myeloma.

Keywords: MicroRNA-1179, epiregulin, myeloma cells, metastasis

Received: 01 February, 2023; revised: 13 March, 2023; accepted: 03 April, 2023; available on-line: 17 June, 2023

INTRODUCTION

Multiple myeloma is one of the deadliest disorders, with a high fatality rate. Multiple myeloma made up about 2% of all new cases of myeloma and 2.1% of deaths caused by melanoma in the United States (Pinto *et al.*, 2020). Even though research on cancer diagnosis and treatment has come a long way, multiple myeloma is still one of the hardest cancers to cure (Rajkumar & Kumar, 2020). With just over 5 years of median survival, the majority of the patients are administered four or even more different lines of therapy (Boyle *et al.*, 2021).

Researchers across the globe are looking to develop biomarkers for early diagnosis, identify therapeutic targets for efficient treatment, and identify drugs that are effective and safe.

MicroRNAs (miRNAs) have recently gained significant interest as therapeutic approaches to treat human diseases and disorders. miRNAs are non-coding RNA molecules that have the potential to control the expression of protein-coding genes. At the post-transcriptional stage, every miRNA may influence the production of multiple protein-coding genes (Tan *et al.*, 2018). Several studies on miRNAs found that the progression of many human malignancies was often associated with abnormal expression of miRNA (Ramassone *et al.*, 2018; Vannini *et al.*, 2018). For instance, miRNA-1179 has been found to post-transcriptionally suppress the expression of E2F5 to control the formation and spread of pancreatic cancer (Lin *et al.*, 2018). Song and others (Song *et al.*, 2018) observed that miRNA-1179 regulates the progression and metastasis of non-small cell lung carcinoma. Previously, several researchers investigated miR-1179 and found that it regulates chemical sensitivity in ovarian cancer cells (Zhihong *et al.*, 2020), regulates cell cycle progression in glioblastoma cells (Xu *et al.*, 2017) and the vincristine sensitivity of oral cancer cells (Gao *et al.*, 2020). But the significance of miR-1179 in multiple myeloma has not been investigated. So far, there are no reports available on this; therefore, this study intends to find out the significant influence of miR-1179 in multiple myeloma by examining the changes in epiregulin (EREG). The outcomes of this study may help us find out if miR-1179 could be a new way to treat or cure multiple myeloma.

MATERIALS AND METHODS

Study area

The present study was carried out at the Department of Hematology, The Fourth Affiliated Hospital of Traditional Chinese Medicine from March 2015 to November 2018.

Human tissues

In this study, 26 multiple myeloma specimens and 16 healthy donor specimens were collected at the The Fourth Affiliated Hospital of Traditional Chinese Medicine from March 2015 to November 2018. This research was only performed after the patients provided written permission. The research ethics committee (Reg. No. IA-CUC/EREG/2015/02) also authorised the investigation.

Cell lines

Multiple myeloma cell lines (U266, RPMI-8226, KMS-11, JJN-3, and IM-9) were obtained from the American Type Culture Collection (ATCC, USA) and grown in RPMI-1640 media (Gibco, Ireland) with 10% foetal bovine serum (FBS, Gibco, Ireland), streptomycin (100 g/mL) and 1% penicillin (100 U/mL) in ambient temperature at 37°C with 5% CO_2. Normal plasma cells (NPCs) were isolated and grown from a peripheral blood smear as described in earlier methodologies by Adham *et al.* (2020).

Cell Transfection

The miRNA-NC, miRNA-1179 mimics, siRNA-NC, siRNA-EREG, miRNA-1179 inhibitor, and inhibitor NC were constructed by the modified method of Zhihong and others (Zhihong *et al.*, 2019) as per the manufacturer's instructions (RiboBio, Invitrogen, Carlsbad, CA, USA). The appropriate concentrations of miRNA-1179 inhibitor, inhibitor NC, siRNA-NC, and siRNA-EREG were transfected into U266 cells and treated with Lipofectamine 2000 (Thermo Fisher Scientific, China) based on the kit's guidelines.

Expression analysis

Whole RNA extraction from test specimens and cell lines is performed for mRNA expression analysis by utilizing the TRIzol reagent (Invitrogen). The extracted whole RNA was subjected to RNAse-free DNAse treatment to eliminate the contaminated DNA. Following that, PrimeScript RT Master Mix was used to produce cDNA from the RNA (TaKaRa, Japan). Then miR-1179 expression was compared with snRNA U6, while EREG expression was compared with that Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and actin. Proteins were drawn out of cells using RIPA solution and run on an SDS-polyacrylamide gel for protein expression analysis. Then the proteins were loaded onto a polyvinylidene fluoride membrane and maintained with specific antibodies. The membrane then retreated at room temperature with secondary antibodies and horseradish peroxidase. The proteins of concern were visualized using an increased chemiluminescence solution (Millipore).

Cell viability

In this study, the cell survival ability of treated U266 cells was examined by the MTT test. The U266 cells/well (5×10^3) were cultured for 0, 12, 24, 48, and 96 h. Thereafter, 20 μL of MTT was added to each well, and the plates were again incubated at 37°C for 4 h. Formazan crystals were removed by DMSO. Finally, absorbance was measured by a microplate reader to evaluate cell survival ability at 490 nm.

Colony formation assay

The transfected U266 cells were inoculated in 6-well plates and grown for 2 weeks at 37°C. The grown cells were fixed with 100% methanol for 25 min. After that, 0.1% of the colonies were stained with crystal violet and counted under a microscope.

DAPI staining

Transfected U266 cells were grown in 12-well plates for 24 hours at 37°C at a concentration of 1×10^5 cells/well. Subsequently, the cells were harvested by centrifugation, washed with PBS, and fixed with 70% ethanol. Finally, the U266 cells were then stained with DAPI and observed on a fluorescent microscope.

Annexin V/PI Assessment

The Annexin V/PI assay was to be employed to analyze the percentage of apoptotic U266 cells. Transfected U266 cells (1×10^6) were added into six-well plates and maintained to proliferate for 24 h. After that, the cells were harvested, and the percentage of apoptotic U266 cells was evaluated by an Annexin-VFITC apoptosis detection kit (BestBio) and a Cytomics FC500 flow cytometer using CXP software (Beckman Coulter, Fullerton, CA, USA).

Development of mutant EREG

The complementary nucleotides of miRNA-1179 were mutated using the ThermoFisher Scientific mutagenesis kit to construct the mutant EREG (EREG-MUT) by the modified method of Singh and others (Singh *et al.*, 2013)

Target identification

The fee-based online version of TargetScan (http://www.targetscan.org/version-72/) was employed to assess the miRNA-1179 targets. In this study, the most suitable sequence of the EREG 3'-UTR was selected for further investigation.

Luciferase assay

The 3'-UTR of EREG (EREG-WT) was cloned into the pGL3-control vector (Promega) downstream of the stop codon of firefly luciferase. Following that, cells transfected with EREG-WT or EREG-MUT were co-transfected with miRNA-1179 or miRNA-NC. The Dual-Luciferase Reporter Assay System (Promega) was employed to conduct the interaction investigation, which included 48 hours of cell culture at 37°C. Renilla luciferase was used for evaluation to normalise the luciferase.

Transwell assay

Transwell inserts with 8 μM pore sizes that were plain and matrigel-coated were employed for migration and invasion, respectively. In 24-well plates, the transwell insert was placed, and the bottom chamber receives 500 μL of DMEM containing 10% FBS. Transfected U266 cells were maintained in 100 μL of DMEM in the top chamber. After 24 hours, the cells on the outer side of the membrane were scrubbed away and maintained at 37°C. The U266 cells that were adhered to the bottom side of the membrane were kept in methanol for 9 min before they were stained by using crystal violet (0.01%). Thereafter, the samples were carefully washed and cells were imaged and counted in at least five random fields under a digital microscope.

Statistical analysis

The trials were repeated in triplicate, and the outcomes were described as mean ± standard deviation (S.D.). The GraphPad Prism 7.0 software tool was used to analyse the One-way analysis of variance (ANOVA) and Tukey's tests were carried out for multiple group comparisons. A p-value <0.05 was considered statistically significant.

Figure 1. miRNA-1179 expression in multiple myeloma and normal tissues
(**A**) Relative expression between multiple myeloma and normal tissues; (**B**) Expression between different types of myeloma cell lines; (**C**) Relative expression between miRNA-1179 mimics and miRNA-NC; (**D**) Relative expression between miRNA-1179 inhibitor and inhibitor-NC; (**E**) Survival ability of the different types of myeloma cell lines; (**F**) Colony formation of the miRNA-1179 mimics and miRNA-NC cells; (**G**) Colony formation of the miRNA-1179 inhibitor and inhibitor-NC cells

RESULTS

In this investigation, the expression profile of miRNA-1179 was compared between multiple myeloma (MM) and normal cells (Fig. 1A). The relative expression profile of miRNA-1179 in multiple myeloma cells was 1.75-fold, which is considerably lower ($p<0.05$) than the expression profile in normal tissues (5.5-fold) (Fig. 1A). The expression of miRNA-1179 was assessed in the different types of myeloma cell lines (U266; RPMI-8226; KMS-11; JJN-3; and IM-9) as well as normal plasma cells (NPCs) (Fig. 1B). When compared to NPCs, miRNA-1179 was significantly downregulated ($p<0.05$) in all myeloma cell lines. NPCs express the highest fold (1.1-fold) compared to different types of myeloma cell lines (below 0.2-fold). Figure 1C shows that miRNA-1179 mimics expressed the highest relative expression (11.5-fold), while miRNA-NC was expressed the least (1-fold). Figure 1D depicts the highest relative expression (1-fold) by inhibitor-NC, and the miRNA-1179 inhibitor exhibits a low expression (0.1-fold). Figure 1E exhibits the cell survival ability of the cell lines. The survival ability of miRNA-1179 mimic cells was highly suppressed

Figure 2. Alteration of the structure of the tested cells
(**A**) Nucleus structures of the U266 cells; (**B**) Apoptosis of the U266 cells; (**C**) Expression of Bcl2, Bax, and Actin

($p<0.05$) by miRNA-1179 overexpression, whereas the miRNA-1179 inhibitor showed a low level of suppression. Similarly, Fig. 1F expressed the colony formation potential of the miRNA-1179-overexpressing in the miRNA-NC and miRNA-1179 mimics. The miRNA-NC expressed around 100 colonies, while the miRNA-1179 mimics showed around 40 colonies. Figure 1G depicts the colony formation capability of miRNA-1179 overexpression in NC inhibitor and miRNA-1179 inhibitor cells. The inhibitor-NC expresses around 100 colonies, while the miRNA-1179 inhibitor showed around 130 colonies.

DAPI staining revealed that overexpression of miRNA-1179 altered the structure of the nucleus of the miRNA-NC, miRNA-1179 mimics, miRNA-1179 inhibitors, and inhibitor-NC cells (Fig. 2A). The miRNA-1179 inhibitor seems to not affect the nuclear morphology of cells (Fig. 2A), and annexin V/PI staining revealed that the percentage of apoptosis in cells rose from 5.32% to 34.86% when miRNA-1179 was overexpressed. However, inhibition of miRNA-1179 prevented the apoptosis of the tested cells (Fig. 2B). Similarly, the expression of Bax increased while that of Bcl-2 decreased upon miRNA-1179 overexpression. Nonetheless, inhibition of miRNA-1179 in cells exhibited opposite effects (Fig. 2C).

In the study, the target of miR-1179 was analysed and identified by online TargetScan analysis. In this EREG was selected for analysis for its potential oncogenic role in multiple myeloma, and it has not been studied as the target of miRNA-1179. TargetScan analysis showing EREG 3'-UTR sequence as the target of miR1179 (Fig. 3A). The interaction between miRNA-NC and miRNA-1179 mimics was further analyzed by the luciferase assay (Fig. 3B). The luciferase assay of miRNA-NC is high in EREG-WT, while the luciferase assay of miRNA-1179 mimics is very low. In EREG-MUT, there is little difference in luciferase activity between miRNA-NC and miRNA-1179 mimics. Moreover, significant upregulation ($p<0.05$) of miRNA-1179 was seen in both multiple myeloma tissues compared to normal tissues (Figs 3C and 3D). Multiple myeloma tissues were expressed up to 7-fold, while normal tissues were expressed below that up to 2-fold. However, the expression of EREG was considerably suppressed in miRNA-1179 mimics upon miRNA-1179 overexpres-

Figure 3. Expression of miRNA-1179
(**A**) TargetScan analysis showing EREG 3′-UTR sequence as the target of miR1179; (**B**) Luciferase assay between miRNA-NC and miRNA-1179 mimic; (**C**) Relative expression in between normal cells and multiple myeloma cells; (**D**) Relative expression of the different types of myeloma cell lines; (**E**) Expression of EREG and Actin; (**F**) Relative expression of the siRNA-NC and siRNA-EREG; (**G**) Cell Survival ability of the siRNA-NC and SiRNA-EREG; (**H**) Cell Survival ability of the siRNA-NC, miRNA-1179 mimic and miRNA-1179 mimic + pcDNA-EREG

sion (Fig. 3E). Additionally, the knockdown of EREG inhibited the U266 cell survival ability (Fig. 3F). In this assay, siRNA-NC expressed the highest fold compared to siRNA-EREG. The survival ability of the siRNA-NC and siRNA-EREG cells was expressed in Fig. 3G. The survival ability of siRNA-EREG cells was highly suppressed (*p*<0.05) by miRNA-1179 overexpression, whereas siRNA-NC had a low level of suppression. The survival abilities of miRNA-NC, miRNA-1179 mimics, and miRNA-1179 mimics + pcDNA-EREG were shown in Fig. 3H. This study showed that EREG overexpression eliminated the inhibitory activity of miRNA-1179 on the survival of cells (Fig. 3H).

The impact of miRNA-1179 expression on miRNA-NC, miRNA-1179 mimics, and miRNA-1179 mimics + pcDNA-EREG cell motility and invasion was examined. This study's outcomes revealed that the migration of miRNA-NC, miRNA-1179 mimics, and miRNA-1179 mimics + pcDNA-EREG were inhibited by 69%. However, EREG overexpression restored the motility potential of miRNA-1179 overexpression in the tested cells (Fig. 4A). Additionally, invasion of the tested cells was decreased by 76% compared to the control. Nevertheless, EREG inhibited the inhibitory activity of miRNA-1179 on tested cell invasion (Fig. 4B).

DISCUSSION

Multiple myeloma is one of the most devastating and incurable human malignancies and causes a large number

Figure 4. Motility and invasion of U266 cells by miRNA-1179
(**A**) Activity of miRNA-1179 on U266 cell invasion; (**B**) Motility potential of miRNA-1179

of human deaths (Wong *et al.*, 2020). The current work intends to explain the significance of miRNA-1179 in multiple myeloma and develop it as a therapeutic target for the disease's management. Prior research has shown that miRNA-1179 acts as a tumor inhibitor in various human malignancies. Li and Qin (Li & Qin, 2019) have shown that HMGB1 is the target of miRNA-1179, which slows down the growth of gastrointestinal cancer. Similarly, miRNA-1179 has been revealed to inhibit the formation of breast cancer cells *via* the notch signalling cascade (Li *et al.*, 2018). Consistently, the present study revealed tumour-suppressive effects of miRNA-1179 in human multiple myeloma cells and suggested that its downregulation in multiple myeloma cells might be facilitating the genesis and progression of multiple myeloma.

Cancer involves a diversity of genetic alterations resulting in the conversion of a normal cell into a malignant cell (Li *et al.*, 2018). Apoptosis eliminates the malignant cells and controls tumor progression. The suppression of apoptosis is essential in the development of human malignancies (Wanner *et al.*, 2021). The current study also found that apoptosis is responsible for the tumor-suppressing effects of miRNA-1179. This means that miRNA-1179 could be used to treat different types of myelomas. Several studies showed that MiRNA-1179 can control the development of cancer by targeting a large number of genes. For example, it has been shown to target E2F5 in pancreatic cancer (Lin *et al.*, 2018), PTEN in ovarian cancer (Zhihong *et al.*, 2020), HMGB1 in gastric cancer (Li & Qin, 2019), and ZEB2 in hepatocellular carcinoma (Gao *et al.*, 2019). However, this is the first investigation to identify EREG as a target of miRNA-1179. Previously, EREG has been shown to be elevated in gastric cancer and acts as a predictor of poor prognosis (Xia *et al.*, 2019). Similarly, EREG has already been demonstrated to enhance colorectal cancer proliferation (Vychytilova-Faltejskova *et al.*, 2017). In another study, it was found that EREG makes salivary adenoid cystic carcinoma spread to the lungs (Yang *et al.*, 2017). The expression of EREG was observed to be enhanced in the current investigation. However, miRNA-1179 overexpression inhibits its expression post-transcriptionally to exert its tumor-suppressive effects in multiple myeloma, indicative of its therapeutic implications.

CONCLUSION

The current study found that miRNA-1179 was suppressed in multiple myeloma. Its overexpression suppresses the development and proliferation of human myeloma cells by inhibiting the expression of EREG.

These findings imply that miRNA-1179 might be used as a potential therapeutic agent for the therapy of multiple myeloma. Therefore, more in vivo investigation is necessary for this research area.

Wnt inhibitory factor 1 (WIF1) is frequently downregulated in a variety of cancer due to promoter methylation. However, the methylation status of the WIF1 promoter in cervical cancer remains unclear. This study aimed to elucidate the mechanism by which WIF1 promoter methylation contributes to cervical cancer development. The expression of WIF1 in cervical cancer tissues was examined by immunohistochemistry. The methylation status of the WIF1 promoter in cervical cancer cells was detected by methylation specific PCR. WIF1 mRNA levels and protein levels were detected by PCR and Western blot analysis. We found that WIF1 expression was low in cervical cancer tissues compared to adjacent normal cervical tissues. The WIF1 promoter was methylated in the cervical cancer SiHa cell line but not in the normal cervical epithelial cell line Ect1. Correspondingly, WIF1 mRNA levels and protein levels were significantly lower in SiHa cells than in Ect1 cells. Treatment with 5-aza-2-deoxycytidine (AZA) led to the upregulation of WIF1 mRNA and protein levels in SiHa cells, but the effects were abrogated by treatment with WIF1 siRNA. In addition, AZA treatment induced apoptosis and inhibited the invasion of SiHa cells, and the effects were abrogated by WIF1 siRNA. The protein levels of survivin, c-myc and cyclinD1 were significantly lower in SiHa cells treated with AZA, but their levels were upregulated after treatment with WIF1 siRNA. In conclusion, the methylation of the WIF1 promoter leads to the downregulation of WIF1 and the activation of Wnt/β-catenin signaling in cervical cancer cells. WIF1 is a tumor suppressor that is inactivated in cervical cancer.

INTRODUCTION

Cervical cancer is the second most common malignant tumor in women worldwide, and persistent infection with high-risk human papillomavirus is the main cause of cervical cancer (Halim *et al.*, 2021; Sundaram *et al.*, 2021). Although comprehensive treatment options such as surgery, radiotherapy and chemotherapy can improve the efficacy of cervical cancer therapy, the prognosis of patients with advanced stage or relapse of cervical cancer is poor. Therefore, it is important to further investigate the mechanism of cervical cancer development to improve current treatment strategies (Gao *et al.*, 2020).

The Wnt/β-Catenin signaling pathway is an important pathway that promotes tumorigenesis (Paul & Dey, 2008; Zhu *et al.*, 2021). Wnt inhibitory factor 1 (WIF1) gene is located at 12q14 and encodes a secreted protein that binds to Wnt and acts as a Wnt antagonist to inhibit Wnt/β-catenin signaling (Mazieres *et al.*, 2004). *WIF1* has been shown to inhibit the proliferation of different cancer cells (Kim *et al.*, 2007; Tang *et al.*, 2009). Notably, *WIF1* is frequently downregulated in a variety of cancer due to promoter methylation, indicating that WIF1 is a tumor suppressor (Paluszczak *et al.*, 2015; Karamitrousis *et al.*, 2020; Zhang *et al.*, 2014).

DNA methylation is one important DNA epigenetic modification in eukaryotic cells. DNA methylation transferase leads to the covalency binding of methyl groups provided by S-adenosine methionine (SAM) to specific bases. Aberrant DNA methylation, especially for tumor suppressors, could silence their expression and contribute to the development and progression of cancers including cervical cancer (Lai *et al.*, 2010; Zummeren *et al.*, 2018; van Leeuwen *et al.*, 2019). Consequently, DNA methyltransferase inhibitor 5-aza-2-deoxycytidine (AZA) has been utilized to inhibit DNA methylation of tumor suppressors for cancer treatment (Donia *et al.*, 2021). However, the status of methylation of WIF1 promoter in cervical cancer remains unclear. Therefore, in this study, we aimed to detect whether the WIF1 promoter is methylated in cervical cancer and elucidate the mechanism by which WIF1 promoter methylation contributes to cervical cancer development.

MATERIALS AND METHODS

Clinical samples

The clinical samples were from 5 patients with cervical squamous cell carcinoma confirmed by pathological examinations in the Fourth Hospital of Hebei Medical University from December 2019 to June 2020. All patients signed written informed consent. This study was approved by the Ethics Committee of the Fourth Hospital of Hebei Medical University (Approval No. 2019035).

Immunohistochemistry

The streptomycin avidin-peroxidase method was used to detect the expression of WIF1 in clinical samples. The cervical cancer tissues and adjacent cervical tissues were cut into 5 μm thin sections. Antigen retrieval was performed by the incubation of the sections in 10 mM citrate buffer (pH 6.0), and the sections were heated at 100°C for 1 h to block endogenous peroxidase. Next, the sections were incubated with WIF1 antibody (Abcam, Cat# ab71204, Cambridge, MA, USA; 1:500 dilution) for 1 h at 37°C, washed with phosphate buffered saline (PBS), and then incubated with SP-9001 kit (Zhong Shan Golden Bridge, Beijing, China) to visualize the staining. PBS instead of the primary antibody was used as the negative control.

Cell culture

Human cervical cancer cell line SiHa and normal ectocervical cell line Ect1/E6E7 were purchased from American Type Culture Collection and cultured in RPMI 1640 medium containing 10% fetal bovine serum (FBS, Thermo Fisher, CA, USA). The incubator condition was 37°C with 5% CO_2. AZA was purchased from Sigma-Aldrich (St. Louis, MO, USA) and diluted in dimethyl sulfoxide (DMSO). SiHa cells were treated with 1 μM AZA or DMSO as the control for 48 h. In addition, SiHa cells were transfected with siRNA for WIF1 or scramble siRNA as control (Sangon Biotech, Shanghai, China) using Lipofectamine 3000 (Thermo Fisher, CA, USA). Cells were collected 48 h after transfection for further analysis.

Transwell invasion assay

The treated cells were added to the upper chamber of the Transwell (Corning Costar; Oneonta, USA), while the lower chamber was filled with 600 μl of RPMI 1640 medium containing 10% FBS. After incubation for 24 h, the cells were fixed with 95% methanol, stained with crystal violet for 20 min, and photographed under the microscope to count the number of invaded cells.

Flow cytometry

The apoptosis of treated cells was examined by using an Annexin V/FITC apoptosis kit (BD Biosciences, USA) following the manufacturer's protocol. The stained cells were immediately analyzed using FACS Calibur System (Becton-Dickinson). The number of positively stained cells was counted to calculate the apoptosis ratio.

Methylation-specific PCR (MSP)

Genomic DNA was extracted from SiHa and Ect1 cells using a DNeasy kit (Qiagen, Germany) following the manufacturer's protocols. Bisulfite modification of genomic DNA was performed by using a methylation kit (Zymo Research, Orange, CA, USA). MSP was performed with bisulfite-treated genomic DNA as a template and the following primers: unmethylation specific primers 5'-TTGTGGGTGTTTTATTGGGT-3' (upstream) and 5'-AACAAAACC AACAAT-CAACA-3' (downstream); methylation specific primers 5'-TCGCGGGCGTTTTATTGGGC-3' (upstream) and 5'-AACGAAACCAACAATCAACG-3' (downstream).

RT-PCR

Total RNA was extracted from cells and cDNA was synthesized from total RNA using a reverse transcrip-

tion kit. PCR was performed with cDNA as a template and the following primers: WIF1 5'-CCGAAATG-GAGGCTTTTGTA-3' (upstream) and 5'-TGGTT-GAGCAGTTTGCTTTG-3' (downstream). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal control to normalize WIF1 mRNA levels.

Western blot analysis

Total protein was extracted from cells using RIPA buffer and protein concentration was determined by using a bicinchoninic acid assay. Equal amounts of proteins were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis and transferred to nitrocellulose membranes (Bio-Rad). The membranes were blocked in 5% non-fat milk and then incubated with primary antibodies for WIF1 (1:800), survivin, c-myc, CyclinD1 and GAPDH (all from Abcam, Cambridge, UK). The membranes were further incubated with secondary antibodies (Abcam, Cambridge, UK), and detected by chemiluminescence. Densitometry analysis of the bands was performed using Image-J software with GAPDH as a loading control.

Statistical analysis

The data were presented as the mean± standard deviation (S.D.) and analyzed using SPSS statistical software (IBM Corp., Chicago, IL, USA). Comparisons between groups were performed using Student's t-test. The difference was considered significant for $p < 0.05$.

RESULTS

WIF1 expression was low in cervical cancer tissues

First, we compared WIF1 expression in cervical cancer tissues and adjacent normal cervical tissues by immuno-histochemistry. For negative control, we could not detect WIF1 expression in normal cervical tissues because PBS was used instead of WIF1 antibody (Fig. 1A). When we used WIF1 antibody, we detected strong nuclear staining of WIF1 in normal cervical tissues (Fig. 1B). In contrast, we detected weak nuclear staining of WIF1 in cervical cancer tissues (Fig. 1C). These results indicated that WIF1 expression was low in cervical cancer.

WIF1 promoter was methylated in cervical cancer cells

To elucidate how WIF1 is downregulated in cervical cancer tissues, we used cervical cancer cell as the model. First, we detected the methylation status of the WIF1 promoter in cervical cancer cells by MSP. Compared to normal cervical epithelial cells Ect1, WIF1 promoter was methylated in cervical cancer SiHa cells (Fig. 2A). RT-PCR showed that WIF1 mRNA levels were significantly lower in SiHa cells than in Ect1 cells (Fig. 2B).

Figure 1. The expression of WIF1 in cervical cancer tissues.
(**A**) WIF1 was barely detected in adjacent cervical tissues stained with PBS instead of WIF1 antibody as a negative control. (**B**) WIF1 was strongly stained in the nuclei of adjacent normal cervical cells. (**C**) WIF1 was weakly stained in the nuclei of cervical squamous carcinoma cells.

Figure 2. WIF1 promoter was methylated and WIF1 was down-regulated in cervical cancer cells.
(**A**) MSP analysis of WIF1 promoter in SiHa and Ect1 cells. U: un-methylated; M: methylated. (**B**) RT-PCR analysis of WIF1 mRNA levels in SiHa and Ect1 cells. (**C**) Western blot analysis of WIF1 protein levels in SiHa and Ect1 cells. GAPDH was loading control. (**D**) Densitometry analysis of WIF1 protein levels in SiHa and Ect1 cells. Data were expressed as the mean ± S.D. (n=3). *P<0.05 compared to Ect1 cells.

Furthermore, we detected WIF1 protein levels in SiHa cells and Ect1 cells (Fig. 2C). The results showed that WIF1 protein levels were significantly lower in SiHa cells than in Ect1 cells (Fig. 2D). Collectivity, these data indicated that WIF1 promoter was methylated and WIF1 was downregulated in cervical cancer cells.

AZA upregulated WIF1 expression in cervical cancer cells

To examine whether demethylation of the WIF1 promoter can restore WIF1 expression in cervical cancer cells, we treated SiHa cells with the demethylation agent AZA. Compared to SiHa cells treated with DMSO as control, WIF1 mRNA levels were significantly higher in SiHa cells treated with AZA. However, the upregulation of WIF1 mRNA levels by AZA was abrogated by treatment with WIF1 siRNA (Fig. 3A).

Figure 3. AZA upregulated WIF1 expression in cervical cancer cells.
(**A**) RT-PCR analysis of WIF1 mRNA levels in SiHa cells treated with DMSO, AZA (5-aza-2-deoxycytidine), AZA+ scramble siRNA, AZA + WIF1 siRNA. (**B**) Western blot analysis of WIF1 protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. GAPDH was loading control. (**C**) Densitometry analysis of WIF1 protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. Data were expressed as the mean ± S.D. (n=3). *P<0.05 for the AZA group compared to the DMSO group. #P<0.05 for AZA + WIF1 siRNA group compared to AZA group.

Next, we examined WIF1 protein levels in SiHa cells in different treatment groups (Fig. 3B). Densitometry analysis showed that WIF1 protein levels were significantly higher in SiHa cells treated with AZA than in cells treated with DMSO as control. However, the upregulation of WIF1 protein levels by AZA was abrogated by treatment with WIF1 siRNA (Fig. 3C). These results confirmed that AZA targeted WIF1 promoter to upregulate WIF1 expression in cervical cancer cells.

AZA inhibited malignant behaviors of cervical cancer cells

To examine the effects of AZA on cervical cancer cell behaviors, we performed flow cytometry and found that AZA treatment increased the apoptosis of SiHa cells, while the effect of AZA on apoptosis was abrogated by WIF1 siRNA (Fig. 4A). Quantitative analysis showed that apoptosis percentage was significantly higher in SiHa cells treated with AZA than in cells treated with DMSO but was significantly lower in SiHa cells treated with both AZA and WIF1 siRNA than in cells treated with AZA alone (Fig. 4B).

Transwell invasion assay showed that AZA treatment inhibited the invasion of SiHa cells, while the ef-

Figure 4. AZA induced the apoptosis and inhibited the invasion of cervical cancer cells.

(n=5). *P<0.05 for the AZA group compared to the DMSO group. #P<0.05 for AZA + WIF1 siRNA group compared to AZA group.

Figure 5. AZA inhibited the expression of Wnt/β-catenin target genes in cervical cancer cells.
(**A**) Western blot analysis of survivin, c-myc and CyclinD1 protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. GAPDH was loading control. (**B**) Densitometry analysis of survivin protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. (**C**) Densitometry analysis of c-myc protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. (**D**) Densitometry analysis of cyclinD1 protein levels in SiHa cells treated with DMSO, AZA, AZA+ scramble siRNA, AZA + WIF1 siRNA. Data were expressed as the mean ± S.D. (n=3). *$P<0.05$ for the AZA group compared to the DMSO group. #$P<0.05$ for AZA + WIF1 siRNA group compared to AZA group.

fect of AZA on invasion was abrogated by WIF1 siRNA (Fig. 4C). Quantitative analysis showed that the number of invaded cells was significantly lower in SiHa cells treated with AZA than in cells treated with DMSO but was significantly higher in SiHa cells treated with both AZA and WIF1 siRNA than in cells treated with AZA alone (Fig. 4D). Taken together, these results indicated that AZA induced the apoptosis and inhibited the invasion of cervical cancer cells.

AZA inhibited the apoptosis of cervical cancer cells via the inhibition of the Wnt pathway

To investigate how AZA inhibited the apoptosis of cervical cancer cells, we detected protein levels of survivin, c-myc and cyclinD1, which are Wnt pathway target genes and regulate cell proliferation and apoptosis (Fig. 5A). Densitometry analysis showed that protein levels of survivin, c-myc and cyclinD1 were significantly lower in SiHa cells treated with AZA than in cells treated with DMSO as control. However, protein levels of survivin, c-myc and cyclinD1 were significantly higher in SiHa cells treated with both AZA and WIF1 siRNA than in cells treated with AZA alone (Fig. 5B–D).

DISCUSSION

In this study, we demonstrated that WIF1 was downregulated in cervical cancer tissues and cells due to the methylation of the WIF1 promoter. AZA abrogated the methylation of the WIF1 promoter and upregulated WIF1 expression. Consequently, AZA inhibited the invasion and induced the apoptosis of cervical cancer cells. Furthermore, AZA inhibited the expression of survivin, c-myc and cyclinD1, which may be the mechanism by which AZA inhibited tapoptosis and promoted the proliferation of cervical cancer cells.

The development and progression of cervical cancer is a complex process that involves both genetic and epigenetic mechanisms (Albulescu et al., 2021; Wang et al.,

2021). DNA methylation, especially the methylation of tumor suppressor genes, is one of the most important types of epigenetic modification that contribute to tumorigenesis (van Leeuwen et al., 2019). Recent studies have shown that promoter methylation of WIF1 promoted the development of a variety of tumors (Zhang et al., 2014). However, the role of WIF1 promoter methylation in cervical cancer remains unclear.

Using normal cervical epithelial cells as control, we showed that the WIF1 promoter was methylated in SiHa cervical cancer cells. Consistently, both mRNA and protein levels of WIF1 were significantly downregulated in SiHa cells compared to normal cervical epithelial cells. However, AZA treatment led to the upregulation of WIF1 at both mRNA and protein levels, and the effects of AZA on WIF1 could be abrogated by WIF1 siRNA. Taken together, these data indicate that the downregulation of WIF1 in cervical cancer cells is due to promoter methylation.

Wnt/β-catenin signaling plays an important role in tumorigenesis. The activation of Wnt/β-catenin signaling leads to the translocation of β-catenin from the cytoplasm into the nuclei where it interacts with transcription factor TCF/LEF to drive the transcription of downstream target genes such as survivin, c-myc and CyclinD1 (Koushyar et al., 2022). Among a variety of targets of Wnt/β-catenin signaling, survivin is a known anti-apoptosis protein that promotes cell survival. C-myc and CyclinD1 are known to promote cell proliferation and cell cycle progression. The upregulation of survivin, c-myc and CyclinD1 in SiHa cells treated by AZA may explain why the apoptosis percentage was lower in these cells compared to control cells treated with DMSO. In addition, AZA induced apoptosis of SiHa cell was abrogated by WIF1 siRNA. On the other hand, AZA inhibited the invasion of SiHa cells, and SiHa cell invasion could be restored after treatment with WIF1 siRNA. Notably, cancer cell invasion depends on the action of matrix metalloproteinases (MMPs), and MMP9 was recently identified as a target of Wnt/β-catenin signaling

(Ingraham *et al.*, 2011; Lee *et al.*, 2014; Chen *et al.*, 2021). Cervical cancer metastasis remains a big challenge for the effective treatment of cervical cancer in the clinic (Cheng and Huang, 2021). Further studies are needed to identify target genes of Wnt/β-catenin signaling that could be regulated by AZA, which could be novel therapeutic targets for metastatic cervical cancer.

In conclusion, this study provides evidence that the methylation of the WIF1 promoter leads to the downregulation of WIF1 and the activation of Wnt/β-catenin signaling in cervical cancer. AZA treatment reduced the methylation of WIF1 protomer and upregulated WIF1 expression to inhibit Wnt/β-catenin signaling in cervical cancer cells. Consequently, AZA induced apoptosis and inhibited the invasion of cervical cancer cells, which could be rescued by WIF1 siRNA. These findings suggest that WIF1 is a tumor suppressor that is inactivated in cervical cancer, and the development of approaches to restore WIF1 expression is promising for cervical cancer treatment.

Declarations

Availability of data and material. All data and materials are included in this manuscript.

Competing interests. The authors have no conflict of interest.

Authors' contributions. YW, SY, HL, LH, FZ, and XW collected and analyzed the data, and JM designed the study and wrote the manuscript. All authors read and approved the final manuscript.

MicroRNA-196-5p targets Derlin-1 to induce autophagy in human osteosarcoma cells

Department of Orthopedics, Wuhan Puren Hospital, Puren Hospital Affiliated of Wuhan University of Science and Technology, Wuhan, Hubei, 430080, China

Osteosarcoma is a highly prevalent type of primary bone tissues in children and young adolescents. Micro-RNA (miR) dysregulation has been linked to osteosarcoma tumorigenesis. The role of miR-196-5p was investigated in modulating the growth and metastatic behaviour of human osteosarcoma cells, along with exploring its mechanism of action. As shown by RT-qPCR expression analysis, osteosarcoma cell lines exhibited prominent ($P<0.05$) transcriptional repression of miR-196-5p. The latter was thus transiently overexpressed in osteosarcoma cells, which resulted in the loss of cell viability and colony formation via induction of autophagy. The western blot analysis of the autophagy marker proteins revealed that the expression of Beclin 1 and LC3B II proteins was induced by miR-196-5p, whereas that of p62 and LC3BI was repressed. Moreover, osteosarcoma cells overexpressing miR-196-5p showed significantly ($P<0.05$) lower migration and invasion concerning the control osteosarcoma cells. According to the results of the in-silico analysis, Derlin-1 participates in the regulation of miR-196-5p in osteosarcoma, and this prediction has been validated using a dual luciferase assay. The results indicated that miR-196-5p exerted its molecular role by targeting Derlin-1 at the post-transcriptional level. Summing up, the study revealed the modulatory potential of miR-196-5p/ Derlin-1 on osteosarcoma cells and provided insights into the possible implications for the treatment and prognosis of the disease.

Keywords: metastasis, autophagy, miR-196-5p, Derlin-1, osteosarcoma

Received: 11 November, 2022; revised: 14 March, 2023; accepted: 22 March, 2023; available on-line: 23 April, 2023

INTRODUCTION

Osteosarcoma is the most prevalent bone cancer, commonly affecting adolescents and young people (Ferguson & Turner, 2018; Sadykova et al., 2020). This disease has been reported to exhibit a very poor prognosis, and in a considerable proportion of the diagnosed cases, it metastasizes to the pulmonary tissues (Li et al., 2020). Together, these factors make osteosarcoma very lethal and therefore require the formulation of novel and efficient therapeutic measures against osteosarcoma.

Pertinently, elucidation of the tumorigeneses of osteosarcoma on a molecular basis is essential to recognise the potential prognostic and therapeutic targets against this devastating malignancy. The vast majority of localised osteosarcomas are treated with surgery, but with the introduction of multiagent chemotherapy regimens there has been an increase in survival rate to 70% in patients with osteosarcoma (Miwa et al., 2019). Several patients and their families have been reported to have undergone limb salvage surgery. Most patients, more than 85%, choose to salvage a limb rather than have it amputated (Rougraff et al., 1994). It is also possible to employ radiation therapy to aid in the removal of microscopic or marginal residual tumours (DeLaney et al., 2005). It has been estimated that approximately 70% of cancer patients with localized tumors will receive chemotherapy treatment (Chou et al., 2005). There is a compound known as Mifamurtide, which is a liposomal TLR4 agonist that triggers macrophages and monocytes to channel the antitumor immune response against cancerous cells and inhibit malignant metastasis.

Micro-RNAs (miRs) belong to endogenous non-coding RNAs ranging in average size from 20–25 nucleotides (Donlic & Hargrove, 2018) that regulate specific protein-coding genes, mainly at the post-transcriptional level (Loukas et al., 2021). These genes encode proteins that are modulated by miRs that bind to 3'-UTRs (untranscribed regions) of mRNAs post-transcriptionally via the mRNAs' 3'-UTRs (Abdalla et al., 2020). The miRs displayed a vital role in human biology and physiology (Catalucci et al., 2009). Interestingly, several microRNAs' deviations from the normal expression levels were linked to cancer development, among other disorders (Olson et al., 2009). MiRs regulate the proliferation, cell division, apoptosis, autophagy, migratory potential, and invasiveness of human cancer cells (Gao et al., 2020; Lin et al., 2017; Ashrafizadeh et al., 2020). Human osteosarcoma reportedly also exhibits an aberrant expression of several miRs' and regulates the growth, metastasis, and proliferation of osteosarcoma cells (Zhou et al., 2018; Salah et al., 2015).

Currently, miR-196-5p is known to be one of the most important functional molecules in immunity and cancer development in humans (Huang et al., 2014). According to recent evidence, miR-196-5p may suppress the growth of breast cancer and melanoma (Li et al., 2010; Braig et al., 2010). Additionally, in several studies in human cancers like oral and colorectal cancer, miR-196-5p expression is believed to be involved in oncogenesis or tumour suppression, regulating their growth and progression (Xin et al., 2019a; Stiegelbauer et al., 2017; Maruyama et al., 2018). Evidence suggests that the miR-196-5p gene appears to be downregulated in certain hu-

man tumours and acts as a tumour suppressor in regulating tumorigenesis (Zheng *et al.*, 2019b; Lu *et al.*, 2016). Although downregulation of miR-196-5p resulting from long noncoding RNA sponging has been shown in surface osteosarcoma, its regulatory role has not yet been reported (Chen *et al.*, 2019).

Derlin-1, one of the ATPases in the p97 complex, is believed to be involved in ER-associated degradation. The function of this enzyme is to retrotranslocate misfolded or unfolded proteins into the cytosol for degradation by proteasomes (Klopfleisch *et al.*, 2010). Many tumors have overexpressed Derlin-1, which is involved in the progression of tumors (Wang *et al.*, 2008; Dong *et al.*, 2017). There is evidence that Derlin-1 is expressed in several varieties of human carcinomas, and antibodies that target Derlin-1 have been shown to inhibit the growth of colon tumours in mice (Tan *et al.*, 2015). In a study published by Wang and others in 2008 (Wang *et al.*, 2008) it was found that Derlin-1 expression is correlated with tumor grade and lymph node metastasis in breast cancer. There is, however, little information about the biological significance of Derlin-1 in osteosarcoma cancer, and the exact relationship between microRNA196-5p, which targets Derlin-1 to induce autophagy in human osteosarcoma cells, remains unknown. Therefore, a recent study aimed to investigate the effects of miR-196-5p/Derlin-1 pathway at the molecular level involved in osteosarcoma.

MATERIALS AND METHODS

Tissues samples

Fifty five paired osteosarcoma and normal matching human tissue samples were obtained from osteosarcoma subjects during surgical resection in the Department of Orthopedics, Puren Hospital Affiliated to Wuhan University of Science and Technology, Wuhan, China. Two pathologists, blind to the study, conducted the pathological survey of the excised tissue specimens. The ethics committee of our institute approved the study (approval No. OR14PUR256/22). Liquid nitrogen was used to snap-freeze the specimens, and the latter were stored at –80ºC until experimentation.

Cell lines

Three different humans (MG-63; ATCC Catalogue no.: CRL-1427), (Saos2; ATCC Catalog no.: HTB-85) and (HOS; ATCC Catalog no.: CRL-1543) osteosarcoma cell lines were obtained from the ATCC (American Type Culture Collection, USA) and the hFOB1.19 (normal osteoblast cell line; Catalog No.: CL-0353) were obtained from the Elabscience Biotechnology Inc, USA. The culturing of the cell lines was carried out using DMEM (Dulbecco's modified Eagle's medium) added with 10% FBS (fetal bovine serum), penicillin (100 U/ml) and streptomycin (10 μg/L) in an incubator (5% CO_2) at room temperature. The lowest passage numbers for the cell lines were between 3–5, respectively. Colorimetric mycoplasma detection assay using PlasmoTest™ (Catalog code: rep-pt1, InvivoGen USA) for the visual, colorimetric detection of mycoplasma contamination in cell cultures was performed. A positive result indicates the presence of a cell culture contaminant. The results of our tests for mycoplasma contamination in cell cultures were negative.

Cell line transfection

As a result of comparing miR-196-5p expression levels in Saos2, MG-63, and HOS cell lines with the normal osteoblast cell line, we selected the Saos2 cell line due to their relatively significant miR-16-5p expression levels ($P<0.01$).

After reaching 80% confluence, cells were seeded at a density of 1×10^4 cells/cm² into six-well plates. We carried out transient transfection of miRNAs as previously reported (Xin *et al.*, 2019a). Twenty-four hours after seeding, transfection with miR-196-5p mimic (50 nM), miR-NC (50 nM), si-NC (50 nM), pcDNA-derlin1 (50 nM) or si-DERL1 (50 nM) was carried out using Lipofectamine 2000 (Invitrogen, CA, USA) according to the manufacturer's instructions. The presynthesised miR-196-5p mimics, miR-NC or si-NC (negative control) oligos were obtained from the Gene-Pharma Company (Suzhou, Jiangsu, China). To construct the Derlin1 expression plasmid, the mammalian overexpression vector, pcDNA3.1, was cloned with the full-length ORF of derlin1 (pcDNA-derlin1) to obtain Derlin1 whereas control vector-transfected cells were used as the negative control. As a result of using siRNA Derlin-1 sequences (Oligobio, Beijing, China) and pcDNA3.1-Derlin-1 sequences (Oligobio, Beijing, China), we were able to knock down or upregulate the expression of Derlin-1.

A Lipofectamine 2000 (5 μl) solution was placed in DMEM (250 μl) in the absence of serum and incubated for 10 minutes at 37°C. Each 5 μl of miR-196-5p mimic, miR-NC, pcDNA-derlin1, si-NC, and si-DERL1 was placed in DMEM (250 μl) in the absence of serum. Following incubation for 10 minutes, the diluted miR-196-5p mimic, miR-NC, pcDNA-derlin1, si-NC, and si-DERL1 was gently mixed with diluted Lipofectamine 2000, and then incubated at room temperature for 30 minutes. The cells were washed twice in PBS (phosphate buffered saline) after the old medium was removed from the 6-well plate. To each well containing cells and medium, 500 μl of the complexes were added before the plate was gently rocked to mix the solution. A 24-hour incubation period was conducted at 37°C in a CO_2 incubator to test for the expression of transgenes in the cells.

Extraction and quantitative RT-qPCR of RNA

Microfluidics-based Agilent Bioanalyzers (Agilent Technologies Co. Ltd., Beijing, China) classify RNA samples according to their integrity using RNA Integrity Numbers (RIN) ranging from 1 to 10. The RIN value above 8.0 indicates intact, high-quality RNA samples, the value between 5.0 and 8.0 indicates moderately degraded samples, and the value below 5.0 indicates degraded samples (Padhi *et al.*, 2018). It is typically recommended to use RNA samples that have RIN values above 5.0 in order to ensure a reliable measurement of gene expression by RT-qPCR.

Table 1. Primers used in real-time polymerase chain reaction

Primers	Sequence (5′-3′)	Size (bp)
miR196-5p	5′-TAGGTAGTTTCCTGTTGTTGGG-3′	178
	5′-GCGAGCACAGAATTAATACGAC-3′	
derlin 1	5′-TCGGACATCGGAGACTGGTT-3′	186
	5′-AGCCAGTAATCACGATGCAAA-3′	
GADPH	5′-CTTCTACAATGAGCTGCGTG-3′	156
	5′-TCATGATTGAGTCAGTCAGG-3′	

TRIzol reagent (Invitrogen; Thermo Fisher Scientific, Inc.) was used according to the manufacturer's instructions to isolate total RNA from the cells. The expression of mRNA of a cell was detected by a real-time PCR system, which used SYBR Green (Roche Diagnostics, Mannheim, Germany), with two micrograms of total RNA. The cDNA was synthesized with a Transcriptor cDNA Synthesis Kit (Thermo Fisher Scientific, Waltham, MA, USA). In order to normalize the expression of the target gene mRNA, GAPDH expression was used as an endogenous control. The inverse logarithms of the $\Delta\Delta Ct$ levels are used to calculate the relative levels of miR-196-5p. The primer sequence information is listed in Table 1. The specific method is described in the earlier study (Jhan et al., 2022).

CCK-8 assays

A 96-well plate was used to plate the cells (3×10^4 cells) into each of the 96 wells after they had been transfected. After culture of cells for 0, 12, 24, 48, or 96 h at 37°C, the addition of CCK-8 reagent (10 μl, Solarbio Life Science, Beijing, China) was transferred to each well in accordance with the manufacturer's guidelines. The incubation was extended at 37°C for 3 h, and finally, in order to measure the absorbance of the wells at 470 nm, the microplate reader (Agilent Bioscience Co. Ltd, Hangzhou China) was utilized to measure the absorbance of each well at 0 h and at intervals of 24 h until 96 h posttransfection (Xin et al., 2019b).

Colony formation assay

Proliferation of cells was also determined by colony formation assays (Wang et al., 2018). The transfected Saos2 cells (2.5×10^4 cells in each well) were plated in a six-well plate. During the 17 days of culture, fresh medium was changed every day during incubation and cells were incubated at room temperature after 96 hours of culture. The colonies formed were washed with PBS and paraformaldehyde (4%) fixed at 37°C for 15 min. A crystal violet stain of 0.25% was applied to the colonies at 37°C for 15 minutes. The percent colony number (for colonies with > 50 cells) was analysed by two independent researchers (blind) counted under a bright-field microscope with a low-resolution bright field microscope (Olympus, Tokyo, Japan). Image of each plate was scanned using colony counting software (ImageJ, USA)

Analysis of apoptosis in cells by flow cytometry

The FITC-Annexin V Apoptosis Detection Kit (4A Biotech, Nanjing, China) was used to measure cell apoptosis according to the instructions provided by the manufacturer (Badhai et al., 2009). Briefly, 24 h after transfection with 50 nM miR-NC, miR-196-5p mimic and pcDNA-derlin1, the medium was then removed, and the cells were incubated in serum-free medium for 24 hours after removal of the medium. After digestion with trypsin, the cells were washed twice in cold phosphate buffer saline, centrifuged for five minutes at 1200 rpm, and resuspended in phosphate buffer saline (100 μl). The cells were then resuspended in phosphate buffer saline. Incubation was carried out in the dark at room temperature in the presence of 5 μl of FITC-labelled Annexin V and PI. We used flow cytometry to analyze apoptosis five minutes after adding 400 μl of phosphate buffer saline. FlowJo software (Tree Star, Ashland, USA) was used to analyse the data in this study.

The Annexin V/PI assay was developed to differentiate between live and apoptotic cells, but it can also be used to differentiate between apoptotic subpopulations of cells which are in an early or late stage of apoptosis (i.e., healthy cells: (Annexin-/PI-), early apoptotic cells: Annexin V+/PI-), late apoptotic cells: (Annexin V+/PI+), necrotic/dead cells: Annexin V-/PI+). Hence, for the same miR-196-5p treated Saos2 cells, we first removed any cells having a negative value before performing further analyses. We analyzed a total of 10 000 cells per measurement.

Acridine orange (AO) autophagy staining

The acidic vesicles formed during autophagy were visualized with the help of the acridine orange staining protocol (Pierzyńska-Mach et al., 2014). In brief, the transfected Saos2 cancer cells were placed at 5×10^4 in each well of 12-well plate. A 24-hour culture at 37°C was carried out on the cells. After that, the cells were collected, washed with phosphate buffer saline and stained with 0.5% acridine orange (AO). We then removed the acridine orange from the cells, washed them rapidly with fresh medium, and examined them under a fluorescence microscope (Leica, Germany). The imaging conditions were AO-excitation 448 nm, emission 470–550 nm (monomers)and 580–650 nm (stacks); the scanning speed was 7 000 Hz. The cover slip with the live cells were mounted on custom stainless-steel holders. The sample temperature was maintained at 37°C. ImageJ software (Rasband, WS. ImageJ) was used to perform basic image processing and analysis.

The accumulation of acrylidine orange in acidic autophagosomes was detected by fluorescence microscope equipped with a digital camera. The presence of cells with intense red staining indicated that autophagy occurred in these cells.

Western blot

To lyse the cells, ice-cold RIPA lysis buffer (CW-BIO, Beijing) was used after the cells were transfected for 48 hours and the total protein concentration of the transfected Saos2 cells was detected using a BCA Protein Assay Kit (Beyotime, Shanghai, China). Subsequently, 20 μg of protein of each sample was separated by 10% SDS-PAGE gel (Bio-Rad Laboratories Co., Ltd. Shanghai, China) and then transferred onto the PVDF membranes (Millipore, USA). Primary antibodies anti-Beclin1 (Cat#11306-1-AP, Proteintech Group Inc., Rosemont, IL, USA; dilution 1:1000), anti-p62 (Cat#18420-1-AP, Proteintech Group Inc. USA; dilution 1:6000), anti-LC3BI/II (Cat# ABC929, Sigma Aldrich, USA; dilution 1:800), anti-Derlin-1 (Cat#SAB4200148, Sigma Aldrich, USA; dilution 1:2000) were added to the PVDF membrane in blocking solution (10% fat-free milk in TBST (Tris buffered saline/Tween-20), followed by washing three times with TBST and incubated for 3 h at 37°C. Next, PVDF membranes were incubated for two hours with goat anti-rabbit HRP-conjugated secondary antibodies (Proteintech Group Inc., dilution 1:7 000) at room temperature. Chemiluminescent fluid (GE Healthcare Life Sciences, UK) was applied to cover the membranes after they were washed. A chemiluminescence analyzer (Biotech Co., Ltd., Beijing) was used to detect and photograph the bands. Quantity One software was used to quantify protein bands by densitometry. In order to correct for the differences in loading between the groups, the volume per group was divided by the volume of normalized β-actin for each group. A normalization pro-

cedure was then conducted to determine the differences between each group and the control group. Based on the control data, the results were presented as a percentage (Xin *et al.*, 2019a).

Assays of Migration and invasion

It was examined whether miR-196-5p mimics or miR-NC transfected into Saos2 cells could affect migrating and invading cells within the chambers using the Transwell chamber and wound healing assays, respectively. Approximately 2×10^5 transfected cells were placed in each of six wells of a six-well plate to perform the migration assay. Post 24 h cell culturing, the cell surface was scraped by a 200 µl pipette tip. The wound was imaged with the aid of a light microscope. Upon incubation at room temperature for 24 hours, the wound was again visualised and the percent wound closure was analysed using Image J software. For the Transwell chamber invasion assay, 5×10^4 transfected cells suspended in 250 µl of serum-free culture medium were added to the Matrigel-coated upper chamber of a 24-well Transwell plate. DMEM with 10% FBS (650 µl) was placed in the bottom of the cell culture chamber. We fixed and stained the invaded cells in methanol with 0.2% crystal violet after 24 hours of incubation at 37°C. An inverted microscope (Olympus, Tokyo, Japan) was used to visualize the cells. Based on the number of cells counted, two independent researchers (blind) were able to calculate the percentage of cells that invaded seven random fields under the microscope (Xin *et al.*, 2019b).

miR-196-5p target analysis and dual luciferase assay

In silico analysis was conducted to predict the interaction between miR-196-5p and Derlin-1 3'-UTR using TargetScan online (http://www.targetscan.org/vert_72/). The prediction was validated using a dual luciferase assay (Promega, USA) and Microplate Luminometer (BioTek, USA). In an earlier study, the specific method was described (Jhan *et al.*, 2022). Briefly, Derlin-1 3'-UTR with wild-type miR binding site (derlin1-WT) or mutant miR binding site (Derlin-1-MUT) was first cloned in the pmir-GLO luciferase reporter vector. Next, Saos2 cells were co-transfected with 1 ng/µl concentrations of reporter vectors (WT or MUT) and 2.5 µg of miR-196-5p mimics or miR-NC with the help of Lipofectamine 3000. To quantify the luciferase activity of the cells, host cells were isolated, washed, and trypsinized before being assayed with the dual luciferase assay to determine their luciferase activity 48 hours after transfection as directed by the manufacturer following the instructions.

Statistical analysis

Each experiment was presented at least three times independently in order to obtain the best results. Data were shown as means ± S.D. GraphPad version 9.0 was run to accomplish the statistical analysis. A Student's t test was used to assess the significance of differences between the two treatment groups, assuming that the data were normally distributed. One-way ANOVA was used to compare the values of the experimental and control groups. A multiple comparison test was performed between the groups using Tukey's multiple comparison test. A *P*-value less than 0.05 was considered statistically significant.

RESULTS

MiR-196-5p expression is repressed in osteosarcoma

To gain insight into the miR-196-5p expression pattern in osteosarcoma, quantitative RT-qPCR was performed. Interestingly, osteosarcoma tissue specimens displayed a remarkably lower ($P<0.05$) miR-196-5p transcript ($P<0.05$) compared to the normal tissues (Fig. 1A). Expression analysis was also performed from three different osteosarcoma cell lines (MG-63, Saos2, and HOS) with reference to normal osteoblast cell lines. The miR-196-5p expression was shown to be substantially ($P<0.05$) reduced compared to that of normal cells (Fig. 1B). Additionally, miR-196-5p expression was considerably ($P<0.01$) low in Saos2 cells compared to MG-63 and HOS cell lines. Therefore, we selected Saos2 cell lines for transfection. Thus, the results indicate that miR-196-5p is markedly reduced in osteosarcoma, suggesting its possible involvement in its growth and pro-

Significant change in the percentage rate of apoptotic cells (**$P<0.01$) observed from the representative images of apoptotic cells. Cell percentages were calculated based on three independent flow cytometry experiments. Q1 represents death cells, Q2 represents the late apoptosis cells, Q3 represents the normal or live cells, Q4 represents the early apoptosis cells. The statistical result of apoptosis rate (B), which equals to the rate of late apoptosis cells (Q2) plus the rate of early apoptosis cells (Q4) plus the rate of necrotic or dead cells (Q1) respectively.

gression. The Saos2 cell line was therefore used to determine whether miR-196-5p acts in the development of osteosarcoma.

miR-196-5p inhibited osteosarcoma cell growth

To induce miR-196-5p overexpression in Saos2 cancer cells, miR-196-5p mimics were transfected into the cells. The results of RT-qPCR displayed that miR-196-5p mimics transfected Saos2 cancer cells expressed ~8-fold miR-196-5p transcript levels relative to miR-NC transfected Saos2 cells (Fig. 1C). To analyze the effect of miR-196-5p overexpression on Saos2 host cell viability, a CCK-8 assay was carried out. The findings revealed that miR-196-5p overexpressing Saos2 cells showed mark-

edly lower ($P<0.05$) *in vitro* viability ($P<0.05$) compared to negative control cells in different cultures (Fig. 1D). Again, colony formation of Saos2 cells overexpressing miR-196-5p was remarkably lower ($P<0.05$) comparatively to normal cells (Fig. 1E). Colony formation of Saos2 cancer cells overexpressing miR-196-5p was only 32% of that of control cells. As a result of these findings, it might be speculated that miR-196-5p has a growth-inhibitory function in osteosarcomas.

miR196-59-induced apoptosis in Saos2 cells

We evaluated the changes in apoptosis using Annexin/PI staining. The results showed that miR-196-5p transfection significantly ($P<0.01$) increased in the percentage

rate of apoptosis in Saos2 cells (Fig. 2A) compared to negative control (miR-NC). These findings indicate that the miR-196-5p overexpression showed substantial increase in the rate of apoptosis in Saos2 cells (Fig. 2B). Collectively, these results suggest that miR-196-5p overexpression induces triggering cell death in Saos2 cells. In total, 9989 cells were recovered in miR-NC control group, which contained 94.45% live or normal cells (Q3), 2.9% early apoptotic cells (Q4), 2.47% late apoptotic cells (Q2) and 0.18% necrotic or dead cells (Q1). Out of 9972 total cells recovered in miR-196-5p treated Saos2 cells, 33.38% live cells (Q3), 30.66% early apoptotic cells (Q4), 31.83% late apoptotic cells (Q2) and 4.13% necrotic or dead cells (Q1).

miR-196-5p restrained migration and invasion of osteosarcoma cells

Whether miR-196-5p also regulates the migratory ability and invasiveness of osteosarcoma cells, the effect of miR-196-5p overexpression was visualized on the migration and invasion of Saos2 sarcoma cells. The results showed that Saos2 cells over-expressing miR-196-5p migrated at remarkably ($P<0.05$) reduced rates ($P<0.05$), as evidenced by the percent wound closure being markedly lower compared to control cells (Fig. 3A). Furthermore, miR-196-5p overexpression in osteosarcoma cells significantly inhibited *in vitro* invasion considerably ($P<0.05$), and it was shown that percent cell invasion was reduced to less than 20% relative to that of negative control osteosarcoma cells. Thus, the results suggest that miR-196-5p has an antimetastatic regulatory role in osteosarcoma (Fig. 3B).

Osteosarcoma cells overexpressing miR-196-5p exhibited induction of autophagy

To assess whether the reduction in the replication of the Saos2 cancer cell overexpressing miR-196-5p resulted from the induction of cell autophagy, acridine orange (AO) staining was performed, followed by fluorescent microscopy. Cancer cells overexpressing miR-196-5p were shown to accumulate AO stain indicative of the possession of acidic autophagosomes (Fig. 4A). The western blot analysis of the autophagy marker proteins revealed that LC3B II and Beclin 1 expression levels were significantly elevated ($P<0.01$), whereas p62 levels were significantly decreased ($P<0.01$), indicating that miR-196-5p stimulated autophagy (Fig. 4B). Taken together, our findings demonstrated that miR-196-5p overexpression induces apoptosis through autophagy-related proteins (Beclin 1, p62, LC3B) in osteosarcoma cells.

miR-196-5p functionally targets Derlin-1 in osteosarcoma

A comprehensive in silico analysis of miR-196-5p was performed to predict the specific molecular target of miR-196-5p in osteosarcoma. Derlin-1 was recognized as the probable target of miR-196-5p in osteosarcoma, and this miRNA binds to a precise site within the untranscribed region (3'-UTR) of Derlin-1 mRNA (Fig. 5A) corresponding to the seed region of miR-196-5p. TargetScan identified Derlin-1 as a possible target of miR-196-5p with the indicated target sites. Consequently, we assumed that miR-196-5p was regulating Derlin-1 in Saso2 cells.

Further study results revealed that overexpression of miR196-3p could significantly reduce the level of 3'-UTR activity of Derlin-1, which was in contrast to that detect-

ed for mutant Derlin-1 3'-UTR activity (Fig. 5B). Furthermore, the results of the luciferase reporter assay revealed that aberrant cells were identified, which showed that the activity of luciferase in Saos2 cells decreased significantly ($P<0.01$) only after the miR-196-5p mimics were co-transfected with luciferase plasmids containing the 3'-UTR of Derlin-1 with native binding sites. Moreover, the gene expression of Derlin-1 was shown to be considerably increased ($P<0.05$; Fig. 5C) in osteosarcoma cell lines, negatively correlating with that of miR-196-5p expression (Fig. 1A), thus substantially linked with tumor progression. A significant increase in Derlin-1 mRNA and protein levels was also observed in Saos2 cells (Fig. D, $P<0.05$). According to our findings, miR-196-5p targets Derlin-1 by direct binding to predicted sites in the 3'-UTR of Derlin-1 mRNA. The results of our luciferase reporter assay support the hypothesis that miR-196-5p targets the Derlin-1 gene. Again, the expression of the Derlin-1 protein was shown to be repressed in miR-196-5p overexpressing Saos2 cancer cells, which provides further insight into post-transcriptional downregulation of Derlin1 by miR-196-5p in osteosarcoma (Fig. 5E).

Furthermore, it was shown that the effect of miR-196-5p on Saos2 cell migration, invasion, and proliferation was modulated by Derlin-1. The CCK-8 assay showed that Derlin-1 silencing mimicked the antiproliferative effects of miR-196-5p overexpression, suggesting that the latter could be exerting its role in osteosarcoma through post-transcriptional repression of Derlin-1 (Fig. 5F). Besides, Saos2 cancer cells over-expressing Derlin-1

Figure 6. Model showing the molecular mechanism of miR-196-5p/derlin1 axis in osteosarcoma.
miR-196-5p is synthesized and binds to the 3'-UTR of Derlin-1 through the RISC complex. This binding blocks Derlin-1 translation eventually leading to autophagy mediated inhibition of cell proliferation.

did not show proliferative decline when miR-196-5p was overexpressed (Fig. 5G). However, these findings were not noticed between the groups: miR-NC vs. miR-NC+pcDNA & miR-196-5p mimics vs. miR-196-5p mimics+pcDNA (P>0.05). Nevertheless, we observed significant difference in the effects of miR-196-5p overexpression suppressed by Derlin-1 between the groups (P<0.01): miR-196-5p mimics vs. miR-196-5p+pcDNA – Derlin 1 and miR-196-5p mimics+pcDNA vs. miR-196-5p mimics+pcDNA-Derlin 1. The results reveal that miR-196-5p targets Derlin-1 for its post-transcriptional repression to exert its functional role in osteosarcoma (Fig. 6). These findings are consistent with our earlier demonstration about the results of the luciferase reporter assay and the published results on pcDNA (Zhang et al., 2021). The molecular basis of the antiproliferative effects of miR-196-5p overexpression that mediates through the decrease in the expression of Derlin-1 in Saos2 osteosarcoma cells remains unclear and needs further investigation. However, our findings confirmed that miRNA (si-Derlin-1) was silenced in Saos2 cells, thus decreasing the expression levels of Derlin-1. Based on the results of these experiments, we were able to confirm our predictions and suggest that miR-196-5p might regulate Derlin-1 to offer its antiproliferative effects. Consequently, miR-196-5p and Derlin-1 showed a significant correlation in OS tissues, demonstrating the effects of miR-196-5p on cell growth, metastasis, and apoptosis (Fig. 5H).

DISCUSSION

Numerous studies have suggested that miRs might emerge as potential molecular markers in cancer diagnosis and therapy (Iacona & Lutz, 2019). The exact mechanisms by which miRNA regulate tumorigenesis remain unclear, despite several miRNAs found to be downregulated in tissues and cells (Wang et al., 2018). It is possible, however, that miR-196 suppresses tumour growth in breast cancer and melanoma (Braig et al., 2010; Li et al., 2010). Additionally, in several studies in human cancers like oral and colorectal cancer, miR-196-5p expression is believed to be involved in oncogenesis or tumor suppression, regulating their growth and progression (Xin et al., 2019a; Stiegelbauer et al., 2017; Maruyama et al., 2018). Therefore, the present study was planned to show that miR-196-5p could be useful for treating osteosarcoma due to its potential efficacy. Our findings showed that miR-196-5p overexpression inhibited OS cell proliferation, colony formation, and invasion by inducing autophagy, signifying that miR-196-5p functions as a tumour suppressor of osteosarcoma progression (Fig. 1). Similar results from a study were reported, but using a different miRNA in osteosarcoma, showing that overexpression of miR-423-5p suppressed osteosarcoma invasion, colony formation, and proliferation, decreasing STMN1 expression. In osteosarcoma, miR-423-5p appears to act as a tumour suppressor gene (Wang et al., 2018). Another study supporting our findings found that miR-196-5p overexpression worsened HCC (hepatocellular carcinoma) cell proliferation and metastasis in vitro and in vivo (Zheng et al., 2019a). Similarly to the results of our study, recent research demonstrated that overexpression of miR-196b-5p inhibited proliferation, migration and invasion (Wharton's umbilical cord) by targeting Cdkn1b (Meyer et al., 2018).

Autophagy and apoptosis are interrelated processes whose outcomes depend on both cell type and environmental factors. It has been described that autophagy can antagonize apoptosis, but can also act as an agonist (Fan & Zong, 2012). Despite this, autophagy can induce cell death regardless of apoptosis. Consequently, we found a statistically significant difference in the percentage rate of apoptosis of Saos2 cells overexpressing miR-196-5p measured using the FITC-Annexin V Apoptosis Detection Method (Fig. 2). Therefore, we believe that miR-196-5p overexpression increases the percentage rate of apoptosis by down-regulation of Derlin-1 in Saos2 osteosarcoma cells. However, the exact molecular mechanisms underlying the cytotoxic mechanism of miR-196-5p–induced apoptosis remained unclear and warrants further investigation. However, miR-196-5p expression has been reported to be markedly reduced markedly under hypoxic conditions, and overexpression of this miRNA reversed HCC effects of hypoxia on the proliferation and invasion (hepatocellular carcinoma) (Zheng et al., 2019b). Consequently, additional studies are needed to understand the molecular mechanisms of overexpression of miR-196-5p and hypoxic conditions in Saos2 cell lines.

Derlin-1 is upregulated in various human cancers, such as lung, colon, and breast cancer, and activates oncogenic pathways in the body (Dong et al., 2017; Wang et al., 2008; Dong et al., 2013). Derlin-1 overexpression has been linked to aggressive phenotypes in breast, pancreatic, and lung cancers (Dong et al., 2017). There is, however, no evidence of its involvement in human osteosarcoma. The results of our study demonstrated that osteosarcoma cells and tissues expressed low levels of miR-196-5p. Similar to our study findings, a report showed that miR-423-5p overexpression was decreased in osteosarcoma tissues and osteosarcoma (MG-63, SAOS-2, U2OS and SOSP-9607) cell lines (Wang et al., 2018).

However, the effect of the overexpression of miR-196-5p targeting Derlin-1 is still unknown in osteosarcoma. Our results found that the expression of Derlin-1 was upregulated in osteosarcoma tissues and cell lines. The results of the present study revealed that Derlin-1 is a direct target gene of miR-196-5p in osteosarcoma cells. According to this report, miR-196-5p directly regulates Derlin-1 expression in Saos2 cells, and modifying Derlin-1 expression reverses miR-196-5p overexpression/inhibition of Saos2 cell proliferation and metastasis. Based on the results of this study, it appears that the miR-196-5p/Derlin-1 axis is a key pathway that regulates the progression of osteosarcomas (Zheng et al., 2019a). It is in agreement with a study which demonstrated that miR-196-5p targets HMGA2 thus regulating hepatocellular carcinoma progression involving miR-196-5p/HMGA2 axis as a key pathway (Zheng et al., 2019a). Additionally, a study found that miR-30b inhibited breast cancer progression and metastasis by targeting Derlin-1 in vitro, similar to our results.

The autophagy and apoptosis pathways are usually impaired in malignant cells, resulting in the lengthening of their survival (Jain et al., 2013). Autophagy is an intrinsic process which clears off cell debris and assists in maintaining normal cell behaviour (Chua et al., 2022). Our findings clearly indicated that miR-196-5p targets the expression of Derlin-1 and significantly altered the autophagy-related proteins (Beclin 1, p62, and LC3B II; Fig. 3) that demonstrate an increase of autophagosomes formation through increased levels of LC3-II, confirming the increased autophagy formation in Saos2 cells (Murugan & Amaravadi, 2016; Ji et al., 2015). The results were further confirmed by the decreased expression of the autophagic flux-related protein p62 with increa-

sed autophagy (Murugan & Amaravadi, 2016). In light of these results, we hypothesized that miR196-p targets Derlin-1 to induce autophagosome formation in Saos2 cells. Our results demonstrated that the anticancer effects resulting from miR-196-5p overexpression are rising from the promotion of autophagy in osteosarcoma cells which suggests the beneficial activity of miR-196-5p against human osteosarcoma. Furthermore, our findings were supported by a study demonstrating that Derlin-1 expression was elevated in most nonsmall lung cancer cell lines, and silencing Derlin-1 mRNA suppressed autophagic flux in A549 cells that induce autophagy (Cai *et al.*, 2022). Thus, targeting autophagy will be an important consideration in developing novel strategies for cancer therapy (Fan & Zong, 2012).

In the current study, Derlin-1 was post-transcriptionally regulated (repressed) by miR-196-5p, and the former was confirmed to act as a mediator of miR-196-5p role in osteosarcoma. Down-regulation of miR-196-5p would mitigate Derlin-1 silencing at the post-transcriptional level, culminating in Derlin-1 upregulation. The latter, with its established oncogenic function, could be one of the crucial elicitors for osteosarcoma tumorigenesis. Our findings further clarified the involvement of the interactional interplay of miR-196-5p with Derlin-1 to control the progress and subsequent progression of human osteosarcoma. As a consequence, it is speculated that Derlin-1 is involved in miR-196-5p-mediated proliferation, invasion, and colony formation in osteosarcoma (Saos2) cell lines. The results of our research showed that miR-196-5p inhibited the expression of Derlin-1 in osteosarcoma, thus acting as a tumor suppressor gene. However, further studies are warranted to investigate the potential molecular mechanisms underlying its biological effects involving the miR-196-5p/Derlin-1 axis in the regulation of osteosarcoma progression.

However, it is speculated that the cause of the markedly overexpression of miR-196-5p with a decrease in Derlin-1 expression in Saos2 cells in the present study emphasises inhibition of the unfolded protein response (UPR). In addition, the removal of misfolded proteins is crucial for normal cellular functioning. Derlin-1 is a component of the p97 ATPase complex and has been shown to play a deciding role in the elimination of misfolded / unfolded proteins by regulating the ER-mediated degradation response and retrotranslocation of abnormal cellular proteins from the lumen of the endoplasmic reticulum (ER) towards the cytosol for degradation by the proteasome complex (Katiyar *et al.*, 2005).

The accumulation of misfolded proteins in the ER, a sign of disrupted ERAD (endoplasmic reticulum-associated degradation), supports the notion that Derlin-1 acts in the retro-translocation process. It is clear from the fact that loss of Derlin-1 results in lethality that ER homeostasis is crucial for the survival of animals. The results of these studies suggest that Derlin-1 and its associated retrotranslocation machinery (such as the TER94/Derlin-1 complex) are limited without ER stress. ER homeostasis is restored by synthesising additional Derlin-1 and complexing it with existing retro-translocation machinery (Liang *et al.*, 2014).

Overexpression of Derlin-1 causes increased stress in the ER, with the activation of apoptosis-triggering signals. When moderate ER stress is present, Derlin-1 levels that were induced by low levels of ER stress are likely to retrotranslocate misfolded proteins. Severe or chronic ER stress induces Derlin-1 expression, resulting in a population of Derlin-1. It is well recognised that Derlin-1 binds to retrotranslocation components to

restore homeostasis to the ER. However, an unbound Derlin-1 would lead to a worsening of ER stress, ensuring the triggering of pro-apoptotic signals (Liang *et al.*, 2014).

A cell with irreparable ER stress may exhibit a high level of unbound Derlin-1 due to the need to balance proapoptotic and cytoprotective functions during UPR induced by ER stress-induced UPR. It is possible that Derlin-1 serves as a sensor for irreparable ER stress in cells. A prolonged ER stress appears to increase the levels of unbound Derlin-1 in cells, suggesting that UPR upregulates Derlin-1 (Liang *et al.*, 2014). Although there is still a lack of knowledge about the exact mechanism by which excessive Derlin-1 induces UPR and apoptosis in cells, but we provide the evidence that comprises the effects of miR-196-5p overexpression targeting Derlin-1 involving autophagic processes. On the other hand, it is possible that there is an additional microenvironmental factor that induces cellular stress in tumor cells, such as a lack of interaction with the extracellular matrix, or diminishing contact between the cells, in addition to ER-stress (Klopfleisch *et al.*, 2010). However, further detailed molecular investigations will be needed identifying factors that interact with miR-196-5p overexpression to define the mechanism that involves Derlin-1-dependent cytotoxicity for the treatment and subsequent progression of human osteosarcoma.

LIMITATIONS OF THE STUDY

However, interpretation of the results described above should take into account some potential limitations.

First, we used a single Saos2 cell line for the functional experiments. It is because Saso2 showed a higher invasive ability employing miR-196-5p than other used cell lines (MG-63, HOS) in our preliminary study.

Second, although our data found that miR-196-5p overexpression could be beneficial in the treatment of osteosarcoma by inhibiting Derlin-1 expression through autophagic processes, but to validate the specificity of miR-196-5p, it is imperative to investigate the use of miR-196-5p inhibitors to reverse the anticancer effects of miR-196-5p/Derlin-1 axis on cell growth and osteosarcoma metastasis.

Third, our data presented and confirmed the autophagic mechanisms involved in the effects of the miR-196-5p/Derlin-1 pathways on osteosarcoma, but it is fundamental to investigate further the effects of the miR-196-5p/Derlin-1 axis using autophagic inhibitors and different cell lines.

Fourth, although our findings showed the effects of miR-196-5p overexpression on apoptosis and autophagic processes, but further studies are warranted to investigate the cell cycle proteins involved in the processes of apoptosis and autophagy.

A fifth reason is that we were only able to examine Derlin-1 and miR-196-5p expression levels in a limited number of tissue samples to compare the differences between the different tumor specimens.

The sixth aspect is that further studies are required to clarify the molecular mechanisms underlying the relationship between the miR196/Derlin-1 axis and ER stress associated with UPR.

Lastly, *in-vitro* results were not supported by *in-vivo* experiments.

CONCLUSION

The current findings revealed that miR-196-5p over-expression leads to suppression of cell migration and invasion by direct targeting of Derlin-1 in Saos2 cells. Transient overexpression of miR-196-5p in Saos2 cancer cells inhibited cell growth by inducing autophagy *in vitro*. In Sao2 cells, miR-196-5p overexpression could inversely regulate Derlin-1 expression, suggesting that miR-196-5p acts as a tumor suppressor by binding to Derlin-1. Derlin-1 showed a functional post-transcriptional modulatory effect of miR-196-5p overexpression in osteosarcoma. Thus, the findings explored the regulatory miR-196-5p/Derlin-1 axis in controlling the proliferation, movement, and invasion of osteosarcoma cells. Our findings suggested that Derlin-1 may be useful in predicting the prognosis and identifying potential therapeutic targets in osteosarcoma.

Wilforol A inhibits human glioma cell proliferation and deactivates the PI3K/AKT signaling pathway

Zhihan Wang, Li Ren, Hao Xu, Zilong Wei and Hongjun Zeng✉

Department of Neurosurgery, Pudong Hospital Affiliated to Fudan University, Shanghai, China

Objectives: To study the anti-proliferation activity of wilforol A against glioma cells and its possible molecular mechanisms. **Methods**: Human glioma cell lines U118 MG and A172, human tracheal epithelial cells (TECs) and astrocytes (HAs) were exposed to various concentrations of wilforol A and evaluated for viability, apoptosis, and levels of proteins using WST-8 assay, flow cytometry and Western blot analysis, respectively. **Results**: Wilforol A inhibited the growth of U118 MG and A172 cells, but not TECs and HAs, in a concentration-dependent manner and the estimated IC_{50} were 6 to 11 µM after 4 h-exposure. Apoptosis was induced at an apoptotic rate of about 40% at 100 µM in U118 MG and A172 cells, but the rates were less than 3% in TECs and HAs. Co-exposure to caspase inhibitor Z-VAD-fmk significantly reduced wilforol A-induced apoptosis. Wilforol A treatment also reduced the colony formation ability of U118 MG cells and triggered a significant increase in ROS production. Elevated levels of pro-apoptotic proteins p53, Bax and cleaved caspase 3 and reduced level of the anti-apoptotic protein Bcl-2 were observed in glioma cells exposed to wilforol A. The expression of PI3K and p-Akt genes in the PI3K/AKT pathways were significantly downregulated in glioma cells treated with wilforol A. **Conclusions**: Wilforol A inhibits the growth of glioma cells, reduces the levels of proteins in the P13K/Akt signal transduction pathways and increases the levels of pro-apoptotic proteins.

Keywords: glioma; natural product; anticancer activity; apoptosis, P13K/Akt signaling pathways

INTRODUCTION

Gliomas are the most common tumors with extremely broad range of clinical behaviors in the central nerve systems of children and adolescents, although the definitive cell of origin of gliomas still remains elusive (Cahill & Turcan, 2018; Sturm *et al.*, 2017). Gliomas are characterized based on histologic and molecular data into several entities including diffuse gliomas (astrocytoma, oligodendroglioma and glioblastoma) and low-grade gliomas (angiocentric glioma, pilocytic astrocytoma and sub-ependymal giant cell astrocytoma). Genomic profiling of certain gliomas is necessary to define the histologic subtyping and proper use of prognostic and predictive biomarkers for treatment (Ferris *et al.*, 2017; Reifenberger *et al.*, 2017). Early and rational use of drugs that effectively inhibit the proliferation of glioma cells is important to obtain a good prognosis for patients (Morshed *et al.*, 2019). However, a significant portion of gliomas develop over a short period of time and progress rapidly into WHO grade III or IV high-grade gliomas. Despite all therapeutic efforts, gliomas remain largely incurable. Current treatment of gliomas relies on surgery in combination with chemotherapy and/or radiotherapy. However, many tumors show a high resistance to these interventions, and recurrences are very frequent since conventional therapies do not take into full account the unique molecular features of different subtypes of gliomas (Ghotme *et al.*, 2017). Several new therapies have been proposed to better manage the cancer, including immunotherapy that is able to penetrate the blood-brain barrier to deliver drugs to lymphatics with some promising results (Hanaei *et al.*, 2018; Xu *et al.*, 2020), use of IL15Rα-IL15-armed oncolytic poxviruses in combination with adoptive T-cell therapy, rapamycin, and celecoxib (Xu *et al.*, 2020). In addition, several new strategies have been explored to treat glioma. For example, gene therapy based on lipid nanoparticles as non-viral vectors has been attempted to deliver genes across the blood-brain barrier to reach the glioma cell target (Luiz *et al.*, 2021) and ketogenic diets are suggested to induce ketosis to target the glycolytic phenotype to halt the progression of lower grade tumors to more aggressive subtypes (Poff *et al.*, 2019).

In the past decades, there have been growing interest in exploring natural medicinal plants and their bioactive molecules for potential anti-tumor activity, both *in vitro* and *in vivo* (Li *et al.*, 2019; Weng & Goel, 2022). Tripterine, also known as celastrol, is an active ingredient isolated from a vine plant *Tripterygium wilfordii*. It has been proven to have therapeutic effect on inflammatory response and tumors, including hepatoma, multiple myeloma, breast cancer, cervical cancer, prostate cancer and leukemia (Chen *et al.*, 2018b; Li *et al.*, 2021; Yang *et al.*, 2021). Using network pharmacology-based strategy, several components from *T. wilfordii* have been found to impact a number of signaling pathways, such as the Toll-like receptor signaling pathway, NF-kappa B signaling pathway and HIF-1 signaling pathway in acute myeloid leukemia (Fang *et al.*, 2020). Tripterine suppresses the malignancy of breast cancer by upregulating miR-184 (Wang, 2021) and inhibits cell proliferation by increasing the level of Bax in pancreatic cancer cells (Chen *et al.*, 2022). Studies also show that tripterine promotes autophagy and apoptosis *via* the ROS/JNK and AKT/

mTOR signaling pathways in glioma cell lines U251, U87-MG and C6 (Liu *et al.*, 2019) and blocks the PI3K/AKT/mTOR signaling pathway to suppress vasculogenic mimicry formation and angiogenesis (Zhu *et al.*, 2020). On the other hand, wilforol A, a triterpenoid and analog of celastrol from the same plant, has not been characterized for its anticancer activity.

The purpose of this study was to investigate the effect of wilforol A on proliferation of cancer cells and its possible molecular mechanisms underlying the anticancer activity using glioma cell lines U118 and A172.

MATERIALS AND METHODS

Cell lines

Two human glioma cell lines U118 MG, A172, and human tracheal epithelial cells (PCS-300-013, TECs) were purchased from American Type Collection Center (ATCC), USA, and cultured in Eagle's minimum essential medium (EMEM) containing 10% fetal bovine serum (FBS) at 37°C in 5% CO_2. Cells were digested with 0.25% trypsin for 3 min when reaching 80–90% confluence, pelleted by centrifugation at 25°C and subcultured in fresh EMEM medium with 10% FBS under the same culture conditions. Human astrocytes (HAs) were purchased from iXCells (San Diego, CA, USA) and grown in astrocyte medium (cat no. 10HU-035, iXCells) at 37°C in 5% CO_2. Adenovirus with and without the Akt gene (AD00306Z) were purchased from Creative Biogene, USA, and used to infect cells at 1×10^{10} PFU/ml according to the supplier's protocols to generate Akt-overexpressing cells.

Cell viability assay

The viability of cells was measured using Cell Counting Kit 8 (WST-8, Abcam, USA) based on the supplier's instructions. Wilforol A purchased from TargetMol, MA, USA, was dissolved in 1% DMSO (molecular biology grade, Sigma, USA) as stock solution. Cells were seeded in the wells of 24-well black culture plates at the density of 1×10^4 per well in 100 µl EMEM medium and cultured at 37°C in a 5% CO_2 incubator. After incubation for 24 h, 100 µl EMEM medium containing various concentrations of wilforol A and 0.2% DMSO was added to each well and cells were cultured at 37ºC in a 5% CO_2 incubator for another 4 h. EMEM medium containing 0.2% DMSO was used as control. Cells were then added with 20 µl WST-8 solution and incubated in the dark at 37°C for 2 h. The absorbance at 450 nm was measured using a plate reader. The experiments were independently repeated three times and all samples were tested in triplicate.

Soft agar assay

Soft agar assays were performed to assess the colony formation ability as described previously (Horibata *et al.*, 2015). Briefly, U118MG cells (5×10^6 cells/ml) were suspended gently in 0.6% type VII agarose that was maintained at 42°C and prepared in EMEM medium supplemented with 10% FBS and 1% penicillin/streptomycin. The cells were poured to the bottom of 60-mm dishes to form a bottom layer over 1.2% agar. After being solidified at 25°C for 30 min, the plates were sealed and were placed into a humidified incubator for culture at 37°C. Two weeks later, the colonies were stained overnight with 200 µl of 0.1% crystal violet per well at 37°C. The stained colonies were analyzed using a colony counter.

Flow cytometry

After exposure to wilforol A for 4 h, cells (5×10^6) were pelleted by centrifugation at 1000 rpm at 25°C for 10 min and resuspended in 500 µl PBS. For assessment of apoptosis, the cells were washed twice with 500 µl PBS, added with 10 µl Annexin V and propidium iodide (PI) from Annexin V-DY-634 PI Apoptosis Staining/Detection Kit (Abcam) to stain the cells according to the manufacturer's instructions. For assessment of autophagy, cells were stained with autophagy probes in Autophagy Assay Red Detection Kit (cat. no. APO010B, Biorad, USA) according to the manufacturer's instructions. For determination of necrotic cells, GFP-CER-TIFIED Necrosis detection kit (cat. no. ENZ5100225, Enzo Life Sciences, Thermo Fisher, USA) was used to detect necrotic cells with the FL 3 channel as instructed by the manufacturer. The stained cells were loaded and analyzed on a NovoCyte flow cytometer (Agilent, USA). The quantitation of cells was calculated by the built-in CellQuest software. To assess the effect of caspase inhibitor, 50 µM of Z-VAD-fmk (Alexis Biochemicals, San Diego, CA) was added to the culture medium. For reactive oxygen species (ROS) analysis, cells were exposed to wilforol A for 4 h and stained with DCFH-DA (cat. no. S0033S, Beyotime, Beijing, China) in serum-free medium (after 1:1000 dilution) at the final concentration of 10 µmol/L. After incubation at 37°C for 20 min, cells were washed three times with serum-free medium to remove recessive DCFH-DA and loaded to the cytometer for analysis according to the supplier's protocols. The experiments were independently repeated three times and all samples were tested in triplicate.

Western blot

After exposure to wilforol A for 4 h, cells (5×10^6) were pelleted by centrifugation at 1000 rpm at 25°C for 10 min and were lysed in RIPA buffer (Thermo Fisher Scientific, USA) that contains protease inhibitors cocktail to minimize protein degradation. Proteins in the lysates were quantitated using BCA kit (Thermo Fisher Scientific) according to manufacturer's instructions. After denaturing by boiling at 100°C for 5 min, the proteins were loaded onto 12% polyacrylamide gels, separated by electrophoresis and transferred to PVDF membranes (Millipore, USA). The proteins of interest were detected by incubating with primary antibodies against p53 (cat. no. AF7671), Bax (cat. no. AF1270), Bcl-2 (cat. no. AF0060), cleaved caspase 3 (cat. no. AF1213), PI3K (cat. no. AF1549, specific for subunit p110α), Akt (cat. no. AF0045), p-Akt (Ser473) (cat. no. AA329), p-Akt (Thr308) (cat. no. AA331) and β-actin (cat. no. AF5001) (all from Beyotime) and secondary antibody (goat anti-human IgG H&L (HRP) (cat. no. ab97161, Abcam). The immunoreactive bands were captured using Chemi Doc XRS ^{plus} chemiluminescence imaging system (Bio-Rad, USA) after visualization with a chemiluminescence kit (Thermo Fisher Scientific). The gray values of the bands on the blots were determined using Quantity One software.

Statistical analysis

All data were shown as means ± standard error of the mean (SEM) obtained from three independent experiments. Statistical comparisons among groups were

Figure 1. Viability of U118MG cells, A172 cells, tracheal epithelial cells and human astrocytes after exposure to Wilforol A for 4 h.
The viability was measured with the cell Counting Kit 8 (WST-8). 1x10^4 cells/well were seeded cultured overnight in a black wall 24-well plate. Cells were treated with diluted Wilforol A for 4 hours. The absorbance was measured at 460 nm using a plate reader. The experiments were independently repeated three times. One-way ANOVA was used to analyze the differences. ** and *** denote <0.01, and 0.001, respectively, compared to control.

assessed using one-way analysis of variance (ANOVA). A value of $P<0.05$ was considered statistically significant.

RESULTS

Wilforol A reduces the viability of glioma cells

We first tested the effect of wilforol A on the viability of glioma cell lines U118 MG and A172 using WST-8 assays. After 4 h exposure to wilforol A, the viability of cells in both cell lines began to decline at 1 µM wilforol A and decreased from over 95% in controls to 8% in U118MG and 5% in A172 at 100 µM wilforol A, indicating that wilforol A is potently toxic to glioma cells and the viability reduction is concentration-dependent (Fig. 1). The IC$_{50}$ for U118 MG and A172 were estimated to be 11 and 6 µM, respectively, suggesting that A172 is more sensitive to wilforol A. Furthermore, we tested if non-glioma cells could be inhibited by wilforol A within the concentration range using TECs and HAs. No inhibition was observed up to 100 µM wilforol A (Fig. 1), suggesting that wilforol A is more toxic to glioma cells.

Figure 2. Apoptosis (A), autophagy and necrosis (B) of U118MG and A172 cells after exposure to wilforol A (A) and Z-VAD-fmk (C) for 4 h.
The apoptosis, autophagy and necrosis were measured with Annexin V- DY-634 PI Apoptosis Staining / Detection Kit, Autophagy Assay Red Detection Kit and GFP-CERTIFIED Necrosis detection kit. Cells (5x10^6) were seeded overnight in a black wall 24-well plate and were treated with diluted Wilforol A and 50 µM Z-VAD-fmk for 4 hours. The treated cells were stained with relevant probes and analyzed on NovoCyte flow cytometer. Left panel: representative flow cytometry results; right panel: statistical results of apoptosis. The experiments were independently repeated three times. One-way ANOVA was used to analyze the differences. ** and *** denote <0.01, and 0.001, respectively, compared to control.

Figure 3. Colony formation and ROS production of U118MG after exposure to wilforol A for 4 h.
U118MG cells were suspended 0.6% agarose prepared in EMEM medium. The cells were poured to the bottom of 60-mm dishes and cultured at 37°C for weeks. The colonies were stained with 0.1% crystal violet and analyzed. (**A**) left panel: colony formation in soft-agar, right panel: number of colonies. (**B**) U118MG cells (5×10^5 cells/ml) were incubated with 100 μM wilforol A for 4 h and reacted with DCFH-DA in serum-free medium. After incubated at 37°C for 20 m, cells were loaded to the cytometer for analysis according to supplier's protocols. A, left panel: flow cytometry results, right panel: fluorescence density. The experiments were independently repeated three times. One-way ANOVA was used to analyze the differences. *** denotes <0.001, compared to control.

Wilforol A increases apoptosis, but not autophagy and necrosis in glioma cells

Apoptosis is one of the most important mechanisms leading to cell death after exposure to various cytotoxic agents. We therefore analyzed the apoptosis of U118MG and A172 cells after 4 h exposure to wilforol A at different concentrations using flow cytometry. Cells with both early and later apoptosis were detected after exposure to wilforol A, although the majority was later apoptosis at all of the tested concentration levels (Fig. 2A). After exposure to 100 μM wilforol A, over 95% of apoptotic cells were later apoptotic (Fig. 2A). Analysis showed that

Figure 4. Expression of apoptosis-related proteins in U118MG and A172 cells after exposure to Wilforol A for 4 h.
U118MG and A172 (5×10^6) were seeded overnight in a black wall 24-well plate. Cells were treated with diluted Wilforol A for 4 hours. The treated cells were harvested, and total proteins were extract using RIPA buffer and separated on 12% SDS-PAGE. Proteins of interest were detected with relevant antibodies and visualized with a chemiluminescence kit. Upper panel: representative Western blots; lower panel: statistical results of protein expressions. The experiments were independently repeated three times. One-way ANOVA was used to analyze the differences. *, ** and *** denote <0.05, 0.01, and 0.001, respectively, compared to control.

Figure 5. Levels of the PI3K/AKT signaling pathway proteins (A) in U118MG and A172 cells, viability of Akt-overexpressing U118MG cells (B) and levels of the Akt (C) after exposure to Wilforol A for 4 h.
U118MG and A172 (5×10^6), or U118MG infected with Akt overexpression vector were seeded overnight in a black wall 24-well plate. Cells were treated with diluted Wilforol A for 4 hours. The treated cells were harvested, and total proteins were extract using RIPA buffer and separated on 12% SDS-PAGE. Proteins of interest were detected with relevant antibodies and visualized with a chemiluminescence kit. The viability was measured with the cell Counting Kit 8 (WST-8). 1×10^4 cells/well were seeded cultured overnight in a black wall 24-well plate. Cells were treated with diluted Wilforol A for 4 hours. The absorbance was measured at 460 nm using a plate reader. A, Upper panel: representative Western blots; lower panel: statistical results of protein contents. B, results of viability assays; C, Upper panel: representative Western blots; lower panel: statistical results of protein levels. The experiments were independently repeated three times. One-way ANOVA was used to analyze the differences. *, ** and *** denote <0.05, 0.01, and 0.001, respectively, compared to control.

in both cell lines the total apoptotic rates increased from less than 5% to around 40% as the concentration of wilforol A increased from 1 μM to 100 μM (Fig. 2A). Similar to viability reduction, A172 cells had slightly more apoptotic cells than U118MG cells at the same wilforol A concentrations (Fig. 2A). On the other hand, no increase in apoptosis was observed in TECs and HAs after exposure to up to 100 μM wilforol A as compared to the controls (Fig. 2A). Autophagy and necrosis are also important pathways leading to cell death, and were assessed in U118 MG after exposure to wilforol A. The data showed that there was no significant change in autophagic and necrotic cells as compared to the unexposed cells (Fig. 2B).

To further confirm that apoptosis pathway is involved in the observed viability reduction, U118MG cells were treated with caspase inhibitor Z-VAD-fmk. The results showed that this treatment partially reduced wilforol A-induced apoptosis, suggesting that caspase is likely involved in the induced apoptosis (Fig. 2C).

Wilforol A reduces colony formation ability and triggers ROS production in glioma cells

To further assess the cytotoxicity of wilforol A to glioma cells, the colony formation ability of U118MG was assessed using soft-agar assays. The results showed that after treatment with wilforol A, the colony formation ability of U118MG was significantly reduced (Fig. 3A) and ROS production was significantly increased (Fig. 3B).

Effect of wilforol A on the level of apoptosis-related proteins

Western blot analyses showed the levels of apoptosis-related proteins p53, Bax and cleaved caspase 3 were increased, while Bcl-2 level was reduced in both cell lines after exposure to wilforol A (Fig. 4). Statistical analysis showed that the changes in the levels of these proteins were wilforol A-concentration-dependent and the greatest changes in the levels occurred at the highest wilforol A concentration (Fig. 4). While the changes in the protein levels in the two cell lines showed similar trends in response to wilforol A exposure, there were more increases in the levels of cleaved caspase 3 and higher p53 level in U118MG than in A172 cells, while Bax increased more in A172 than in U118MG cells (Fig. 4).

Effect of wilforol A on levels of PI3K/Akt signaling pathway proteins

PI3K/AKT signaling pathway plays a very important role in cancer and the epithelial-mesenchymal transition (EMT) (Xu et al., 2015). Western blot analyses showed that the production of PI3K/Akt signaling pathway protein PI3K, Akt and p-Akt (both p-Akt (Ser473) and p-Akt (Thr308)) was all downregulated after U118MG and A172 cells exposure to wilforol A and the decreases were concentration-dependent, although the downregulation of Akt was not as large as other proteins and was not concentration-dependent in A172 cells (Fig. 5). To consider the contribution of Akt in wilforol A-induced cell death, U118 MG overexpressing Akt was assessed for its sensitivity to wilforol A. Compared with U118 MG and U118 MG infected with an empty vector, U118 MG overexpressing Akt had significantly higher level Akt and p-Akt (both p-Akt (Ser473) and p-Akt (Thr308)) and higher viability, suggesting the Akt pathway is at least partially involved in the wilforol A-induced cell death (Fig. 5B and C).

DISCUSSION

Wilforol A is a pentacyclic triterpenoid with the formula $C_{29}H_{38}O_5$ and is one of the main active ingredients extracted from the medicinal plant *T. wilfordii*. Our experimental data indicated that wilforol A is potently and preferentially toxic to glioma cells with a IC_{50} between 6 and 11 µM in U118MG and A172. It generates apoptosis, ROS; upregulates the production of apoptosis-related proteins and downregulates the levels of PI3K/AKT signaling pathway proteins, suggesting that more studies are warranted to investigate the anticancer activity of this compound and to explore its potential as candidate drug for cancer therapy.

Several molecules have been isolated from *T. wilfordii* that processes anticancer activity. For example, celastrol and triptolide are terpenes purified from *T. wilfordii* and have been demonstrated to be inhibitory to various cancer cells, such as promyelocytic leukemia, T cell lympho-ma and hepatocellular carcinoma cell (Chan et al., 2001; Meng et al., 2011), cervical cancer cell (Kim et al., 2010) and head and neck cancer cells (Cai et al., 2021). However, wilforol A, which is an analog of these terpenes with structural similarity to celastrol, has not been sufficiently characterized for its activity against cancer, although it is recorded to have inhibitory activity against MIA-PaCa2 cells (hypotriploid human pancreatic cancer cells, IC_{50}=3 µM) and A549 cells (adenocarcinomic human alveolar basal epithelial cells, IC_{50}=3 µM) after 72 h exposure (https://pubchem.ncbi.nlm.nih.gov/compound/Wilforol-A#section=Biological-Test-Results). Our experimental data showed that wilforol A has a IC_{50} of 6 to 11 µM for glioma cell lines A172 and U118 MG after 4 h exposure, but is not inhibitory to TECs and HAs, suggesting that there are differences in the toxicity of the compound to cell lines. It is also likely that the IC_{50} would change over the exposure time, with longer exposure generating smaller IC_{50}. Previously, it was reported that the IC_{50} of triptolide and celastrol are 0.21 and 2.58 µM for glioma cell line SHG44 after 48 h exposure (Zhou et al., 2002). The difference in the response of cell lines to wilforol A might be attributed to their different cellular and molecular characteristics, such as cell membrane permeability and metabolic activity, because these cells were derived from different patients. After exposure to wilforol A, the colony formation ability of U118 MG was significantly reduced. Triptolide also inhibits the colony formation of breast cell lines MCF-7 and BT-20, stomach cancer cell lines MKN-45, MKN-7, and KATO-III, and promyelocytic leukemia cell line HL-60 (Wei & Adachi, 1991), implying that wilforol A may have anticancer activity against a broad range of cancers due to its structure similarity to celastrol and triptolide.

Several mechanisms have been proposed with regard to the inhibitory effect of these *T. wilfordii* compounds. For example, celastrol and triptolide may inhibit leukemia cell proliferation by inducing apoptosis and downregulating NF-κB activity and miR-16-1 (Chan et al., 2001; Meng et al., 2011). In cervical cancer cells caspase-dependent, mitochondria-mediated apoptosis results in loss of cell viability (Kim et al., 2010) and in head and neck cancer gasdermin E-mediated pyroptosis is induced after suppressing mitochondrial hexokinase-II (Cai et al., 2021). They not only directly induce apoptosis in cancer cells but also enhance apoptosis induced by tumor necrosis factor and downregulate the expression of inhibitors of apoptosis proteins (IAPs), such as IAP1 and IAP2 (Lee et al., 1999). Similarly, apoptosis was observed in our experiments in both cell lines after the cells were exposed to wilforol A and increased as wilforol A concentration increases. Furthermore, exposure to caspase inhibitor Z-VAD-fmk reduced apoptosis induced by wilforol A as previously reported (Arita et al., 2000; Yang et al., 2003), indicating that apoptosis is likely one of the pathways leading to the inhibition of cell proliferation. Analysis showed that the pro-apoptotic proteins such as p53, Bax and cleaved caspase 3 were upregulated while the anti-apoptotic protein Bcl-2 was downregulated after wilforol A treatment. Also, these regulations are concentration-dependent and have similar trends in both cell lines, suggesting that similar apoptosis mechanisms are motivated after wilforol A treatment. Apoptosis is a very complex process in which the activation of caspase family genes plays an important role (Christgen et al., 2020). Caspase 9 is a key protease in the endogenous apoptotic pathway at the top of caspase-cascade system that leads to the activation of caspase 3 to generate cleaved caspase 3, apoptosis and cell death (Nagata, 2018). How-

ever, since the apoptotic cells at the highest wilforol A concentration is about 40%, which is much less than the percentages of inviable cells determined by WST-8 assays, which were over 90%. The difference in cell death rate could be attributed to other causes of cell death, such as necrosis, pyroptosis and autophagy. In mice, celastrol acts as a nuclear receptor subfamily 4 group A member 1 (NR4A1) agonist and may induce autophagy in a Nur77-dependent manner (Hu *et al.*, 2017). However, our assessment showed that both autophagic and necrotic cells were not changed after exposure to wilforol A, suggesting that there might be other pathways of cell death that are involved in the wilforol A-induced cell injury, which needs to be identified to better understand the mechanisms underlying the anticancer activity of wilforol A (D'Arcy, 2019).

To further elucidate the mechanisms underlying the anticancer activity, we profiled the expression of proteins in the PI3K/AKT pathway, which is one of the most important signaling pathways that are crucial to many aspects of cell growth and survival (Porta *et al.*, 2014) and is often activated in various human cancers (Aoki & Fujishita, 2017), including gliomas (Li *et al.*, 2016). Akt may be activated to p-Akt by PI3K to promote or suppress a number of downstream molecules such as Bad, caspases, NF-κB, mTOR and eNOS to play a leading role in regulating tumor development (Xia & Xu, 2015). In addition, Akt can also activate nuclear transcriptional factors NF-κB to promote the expression of anti-apoptosis genes, such as c-Yaps and Bcl-2 that improve the survival and suppress apoptosis of tumor cells (Feng *et al.*, 2018). Furthermore, potentiated Akt and p-Akt have protective effect against cardiomyopathy (Zeng *et al.*, 2017). Our results showed that PI3K, Akt and p-Akt (phosphorylated at Ser473 or Thr308) are all downregulated in a concentration-dependent manner after the two cell lines were treated with wilforol A, although the downregulation of Akt is lower as compared to the other proteins and is not strictly concentration-dependent in A172 cells, suggesting that wilforol A might impact apoptosis in glioma cells through the PI3K/AKT signaling pathway. The reduction of total Akt might be attributed to reduced cell viability, which leads to lower metabolic activity. Furthermore, U118 MG overexpressing Akt1 was found less sensitive to wilforol A. This is consistent with previous finding that Akt overexpression decreases the chemosensitivity of gastric cancer cells to cisplatin (Zhang *et al.*, 2013), confirming that PI3K/AKT pathway is likely involved in wilforol A-induced cell death. However, a number of pathways and mechanisms might be involved in the control of viability. For instance, silencing FAM19A5 in the FAM19A5/S1PR1 signaling pathway significantly reduces the viability of mantle cell lymphoma (Wang, 2021), indirubin suppresses the viability of ovarian cancer cell through the STAT3 signaling pathway (Chen *et al.*, 2018a) and rhein induces cell death in hepaRG cells through the upregulation of proteins in the apoptotic pathways (You *et al.*, 2018). It is therefore essential to profile more signaling pathways to gain comprehensive understanding of wilforol A-induced cell death.

Although our data show that wilforol A suppresses the growth of glioma cells and induces apoptosis, it is unclear whether wilforol A exerts its biological activity from outside or inside of the cells, and if from inside of the cells, how the molecule enters the cells. Exposure of glioma cells to wilforol A generated increased ROS production, suggesting that it is likely that wilforol A exerts its biological activity from inside of the cells, because

mitochondria are major sites for ROS synthesis (Lucia *et al.*, 1997). However, more studies investigating cell membrane integrity, membrane potential changes and permeability are needed to understand the site of action of wilforol A. NR4A1 is mentioned as a target for wilforol A (https://pubchem.ncbi.nlm.nih.gov/compound/Wilforol-A#section=Biological-Test-Results). However, it is unclear whether the binding of wilforol A to NR4A1 results in the inhibition of cell growth. Previously, ectopic expression of NR4A1 was shown to enhance tumorigenesis by breast cancer cells (Guo *et al.*, 2021) and it may be possible that the binding of wilforol A to NR4A1 may deactivate NR4A1, resulting in reduced tumorigenesis. Furthermore, *T. wilfordii* is known to cause various adverse effects leading to leukopenia, gastrointestinal reactions, menstrual disorders and liver dysfunction when administered as crude extracts (Zhang *et al.*, 2016). However, whether purified wilforol A has adverse effects is largely unknown, and more studies are needed to further define the safety profiles and efficacy of this compound in *in vitro* and *in vivo* models.

Taken together, our experimental data have demonstrated that wilforol A has antiproliferative activity against glioma cells. It deactivates the PI3K/Akt signal transduction pathways, leading to reduced p-Akt expression and upregulated expression of pro-apoptosis genes, which might be responsible for increased apoptosis, and subsequently reduced proliferation of glioma cells.

Objective: To investigate the effects of resveratrol on multiple organ injury and energy metabolism and its possible mechanism in preeclampsia model. **Methods**: A total of 45 clean-grade female adults Sprague Dawley (SD) rats (weight 270–320 g) were randomly divided into three groups: a control group, preeclampsia group (PE), and Preeclampsia with resveratrol treatment group (RE). Preeclampsia was induced in rats by administering 200 mg/kg/day L-NAME. Expression levels of TNF-α and IL-6 in the lungs and kidney tissues were analysed by ELISA, while the activity of superoxide dismutase (SOD) and malondialdehyde (MDA) was determined by biochemical assays. The levels of lactic acid and pyruvate were detected using biochemical assays, while the epinephrine level in the kidney and heart tissues was determined by the ELISA method. Reverse transcription polymerase chain reaction and the western blotting were used to detect the expression of pyruvate dehydrogenase kinase 4 (PDK4) in the myocardial tissues. **Results**: We found that resveratrol treatment inhibited the levels of IL-6, TNF-α, and MDA in the lungs and kidney tissues, while the SOD activity was increased. Treatment with resveratrol reduced the levels of lactic acid, pyruvate, and epinephrine in the kidney and heart tissues. Furthermore, resveratrol treatment significantly increases the expression of PDK4 myocardial tissues in RE group compared to PE group. **Conclusion**: Resveratrol may inhibit the release of tissue inflammatory factors, regulate the body's energy metabolism, and ultimately protect tissue damage caused during Preeclampsia.

Key words: preeclampsia, multiple organ injury, resveratrol, inflammatory factors, proteinuria

INTRODUCTION

Pregnancy is associated with many complications like polycystic ovarian syndrome (PCOS), Dysmenorrhea and Preeclampsia. Among them, Preeclampsia is a very fatal and multifactorial disorder and is strongly associated with other entities such as hypertension and proteinuria that can occur within 20 weeks of gestation (Ding *et al.*, 2017). According to the World Health Organization (WHO), only 10% of pregnant women suffer from preeclampsia but the mortality rate associated with the disease can be as high as involving one-seventh of the affected women (Say *et al.*, 2014). The pathogenesis of preeclampsia associated with pregnancy is due to limited perfusion of the placenta causing hypoxia and subsequently apoptosis. The affected placenta in turn causes an increased oxidative stress, leading to the release of the various inflammatory mediators and anti-angiogenic proteins (Roberts & Escudero, 2012). The increased blood pressure demands the need for application of anti-hypertensive drugs, namely Labetalol, Nifedipine and Hydralazine. Compared to other drugs, Nifedepine is safer due to less side effects related to the maternal or fetal development (including control of arterial pressure and maintenance of urine output) (Zuo *et al.*, 2021; Childress & Katz, 1994). Antihypertensive drugs are effective, but some adjuncts can provide additional effects. There are expectations from adjuncts to modify the destructive processes in the body. Among the adjuncts, resveratrol (potent inhibitor of the nuclear factor kappa B-NF-κB) could prove to be an adjunct to current therapy of preeclampsia. It was found that RE has the capacity to lower the blood pressure along with several other beneficial effects related to promotion of healing and modulation of inflammatory mechanisms (Novakovic *et al.*, 2022).

The origin of resveratrol is purely natural as it is found exclusively in selected products such as red wine, grapes, peanuts, and in limited types of plants. In 1939, RE was extracted for the first time from Veratrumgrandiflorum and was later, found in dried roots of *Polygonum cuspidatum*. Initially, resveratrol was utilized for the treatment of injuries but later used for to manage various cardiovascular diseases (Novakovic *et al.*, 2022). Resveratrol was initially used to treat injuries but later was also utilized for the management of the cardiovascular diseases (Novakovic *et al.*, 2022). Resveratrol has the capability to repress the p38-Mitogen-Activated Protein Kinase (MAPK)/NF-κB pathway and produce several Reactive Oxygen Species (ROS) such as anti-angiogenic molecule (FMS-like tyrosine kinase 1 and sFlt-1) through which, it

mediates anti-inflammatory and anti-oxidative stress activities (Zuo *et al.*, 2021; Novakovic *et al.*, 2022).

The evidence present in the past literature shows that resveratrol can also suppress various factors such as Transforming growth factor (TGF-β), Matrix metalloproteinases (MMP), Cyclic oxygenase (COX-2), Tumour necrosis factor (TNF-α), Interleukins (IL-1β and IL-6), and Intercellular Cell Adhesion Molecule (ICAM-1). The effects of resveratrol can be broadly classified into two major mechanisms. The first one is the p50/p65 mechanism that controls the signaling cascade IKKBα/I ϰBα and activator protein-1 complex of MAPK/ERK/p38/c-Jun N-terminal kinase (JNK) (Wang *et al.*, 2017). Second mechanism is the inhibition of the p65 subunit translocation but it is based on the experimental model of hepatocarcinogenesis. Basically, resveratrol leads to decrease in two processes namely – phosphorylation (both IϰB and normal) and acetylation (Chavez *et al.*, 2008). Further reduction of IϰB phosphorylation leads to variation in p65 protein levels, causing resveratrol-induced apoptosis. Resveratrol also mediate mi-RNAs by suppressing miR-21 expression and inhibition of the NF-ϰB.

Studies have shown some beneficial effects of resveratrol in complicated pregnancies associated with gestational diabetes, malnutrition/obesity, any teratogen exposure or placental insufficiency) (Zielinsky & Busato, 2013). It resulted in improvement of sub-optimal fetal development. Even in the treatment of polycystic ovarian syndrome, this product is providing synergistic effects with metformin through *via* SIRT1 and AMPK activation (Pan *et al.*, 2016). It is probably the inherent properties of RE (including the anti-inflammatory and anticancerous capability) which enable it to be a treatment modality for endometriosis. It was found that resveratrol has the potential to discourage the process of invasion, adhesion, and angiogenesis of endometria-related lesions, thereby, slowing the process of inflammation and oxidative stress (Vian *et al.*, 2018). Even with the involvement of eutopic endometrial stromal cells, resveratrol could definitely, cause several valuable effects by altering the gene expression and inhibiting the insulin-like growth factor (IGF-1) and hepatocyte growth factor (HGF) (Taguchi *et al.*, 2016).

The inhibitory effects of resveratrol can prove to be a useful tool for the management of cancers and chronic diseases. Like in diabetes mellitus type 1, resveratrol has been shown to attenuate testicular apoptosis while in terms of respiratory diseases, there is inhibition of LPS-induced inhibition on SIRT1 expression (Novakovic *et al.*, 2022; Pan *et al.*, 2016). In addition to them, there is repression of activation effects of LPS on MAPKs and NF-ϰB activation also. Due to the inhibition of inflammatory responses leading to a complete perfusion, the healing of kidney is also promoted. Colorectal cancer is another example associated with induction of apoptosis and resveratrol provides suppression of NF-ϰB activation and finally relief to the devastating condition (Chavez *et al.*, 2008). Similarly for Thyroid and breast cancer, resveratrol shows marked improvement by inhibiting the NF-ϰB/p65 signaling in which levels of IL-6 and Cyclooxygenase (COX-20) are also affected. Lastly, it induces pancreatic apoptosis so it is also proven to be helpful in prevention of pancreatic cancer.

The NF-ϰB plays a mighty part during the treatment of preeclampsia by exhibiting the inflammatory factors. The benefits of resveratrol along with proven clinical studies are useful in managing many clinical problems. These can range from chronic diseases like Diabetes mellitus, Respiratory diseases, Hypertension, Reproduc-

tive problems and lastly, various types of cancers. It has both modulatory and attenuated effects. No doubt we have a variety of medications for all of the above mentioned critical conditions, yet the beneficial effects of resveratrol cannot be matched easily. Hence, resveratrol can be assumed to be a good adjunct for the prevention of complications and therapies of the human diseases including preeclampsia. The present study aims to explore the possible role of resveratrol in inhibiting multiple organ injury in preeclampsia rat model.

MATERIAL AND METHODS

Animal preparation and grouping

A total of 45 healthy female adults Sprague Dawley (SD) rats (weight 270–320 g and aged 2–3 months) and were provided by the Experimental Animal Center of the Shanghai Jiao Tong University (China). The animals were maintained in fully ventilated rooms with free access to pellet diet and fresh water. The photoperiod used for keeping animals was 12 h day and 12 h night cycle. Standard institutional ethical guidelines were followed in performing various experimental procedures on the rats. The rats were divided into three groups: the control group (n=15), Preeclampsia group (PE) (n=15), and Preeclampsia with Resveratrol treatment (RE) group (n=15). The animals received humane care in compliance with the principles of laboratory animal care.

Induction of the animal model

To induce preeclampsia, nitric oxide synthase (NOS) inhibitor namely N(gamma)-nitro-L-arginine methyl ester (L-NAME) (obtained from Sigma-Aldrich) at the dose of 200 mg/kg/day was administered to the rats. Resveratrol, dissolved in distilled water were given to rats at the doses of 20 mg/kg/day orally by oral gavage for 4 weeks. Systolic blood pressure (SBP) was monitored continuously through the experimental period by using a blood pressure recorder using tail-cuff method. The protein level in urine (proteinuria) was measured by the Coomassie blue method.

After completion of experimental periods, rats were sacrificed using pentobarbital sodium anesthesia. The livers, kidneys and hearts were collected rapidly and prepared for mRNA and protein extraction.

TNF-α, IL-6, MDA, and SOD detection

In accordance with the instructions on the operating kits, enzyme-linked immunoassay (ELISA) (SOLARBIO, China) was used to detect TNF-α and IL-6 in the kidney and myocardial tissues, the xanthine oxidase method (Sun *et al.*, 1988) was used to detect the content and activity of SOD, and the thiobarbiturates method (Draper *et al.*, 1993) was used to determine the MDA content. The SOD and MDA content in the lung and kidney tissues were calculated according to the formula and Coomassie Brilliant Blue detect protein content.

Detection of lactic acid, pyruvate, and epinephrine levels

In accordance with the instructions on the operating kits, biochemical methods were used to detect lactic acid and pyruvate levels, and ELISA was used to detect epinephrine levels in the heart and kidney tissues.

Reverse transcription polymerase chain reaction (RT-PCR)

RNA from tissues were obtained using TRIzol method and then reversed to cDNA with RT Kit. Quantitative PCR was carried out using SYBRGreen (Takara) with appropriate primers designed by Primer 5.0 according to the conditions, including an initial step of 10 minute in 95°C, and then 40 cycles of amplification, which includes 10 s in 95°C, 20 s in 55°C and 25 s in 72°C. Quantification was determined by $2^{-\Delta\Delta CT}$ (Livak & Schmittgen, 2001). The internal control used was GAPDH.

Western blot

The tissue was treated with RIPA lysis buffer for the isolation of total cellular proteins. Following, the protein concentrations were determined with Bradford method. From each sample, 45 µg of proteins were loaded and run on SDS-PAGE gels which were processed for blotting to PVDF membranes followed by exposure to primary and secondary antibodies and finally the protein bands of interest were visualized with the help of efficient chemilumniscence reagent. Primary antibodies were directed against PDK4. The GAPDH gene was used as internal control. Primary antibody treatment was followed by secondary antibody treatment overnight at 4ºC. Finally, enhanced chemiluminescence (ECL) reagent was used to detect the protein signals.

Statistical analysis

Values presented in the study are the mean of three biological replicates ± S.D., calculated from atleast three experimental replicas. ANOVA, Student's t-test and Duncan's test were used to estimate the significance of the statistical difference between two/among many data points. The at $p<0.05$ was considered as statistically significant difference.

RESULTS

Resveratrol Ameliorated Hypertension and Proteinuria in Preeclampsia group (PRE)

The control group (saline) exhibited stable SBP throughout experimental period. However, in the PRE rats, we observed significantly increased SBP. Interestingly, in (RE) group, a reverse effect was observed compared to the PE group.

Furthermore, the PRE group exhibited enhanced proteinuria, a clinical marker of renal malfunction) associated with PRE compared to control group. Interestingly, in (RE) group, a reverse effect on proteinuria was observed compared to the PE group.

TNF-α and IL-6 expression level

The expression of the inflammatory factor TNF-α in the kidney and myocardial tissues was lower in the control group than in the other two groups. The TNF-α expression in the kidney and myocardial tissues in the (PE) group increased significantly and was significantly lower in the (RE) group than in the LPS group ($P<0.05$). The concentration of IL-6 was higher in the (PE) than in the control group ($P<0.05$), but the administration of Resveratrol downregulated IL-6 production ($P<0.05$; see Fig. 1).

Figure 1. The expression of TNF-α and IL-6 in the lung and kidney tissues of rats.
*$P<0.05$ for comparison with the corresponding tissue of the control group, and #$P<0.05$ for comparison with the corresponding tissue of the preeclampsia group.

Figure 2. Malondialdehyde and superoxide dismutase levels in the lung and kidney tissues of rats.
*$P<0.05$ for comparison with the corresponding tissue of the control group, and #$P<0.05$ for comparison with the corresponding tissue of the preeclampsia group.

MDA and SOD levels

When compared with the control group, the MDA level was higher ($P<0.05$), and the SOD level was significantly lower in the (PE) group ($P<0.05$). When compared with the (PE) group, the MDA level was significantly lower ($P<0.05$), and the SOD level was higher in the (RE) group ($P>0.05$) (see Fig. 2).

Lactic acid, pyruvate, and epinephrine expression in the heart and kidney tissues

In order to study the effect of Resveratrol on organ metabolic damage induced by preeclampsia, the lactic acid, pyruvate, and epinephrine levels were measured in the heart and kidney tissues.

Lactic acid expression: The lactic acid level in the PE group was significantly higher than the control group ($P<0.05$), but there was no significant difference in this level between the RE group and the control group.

Pyruvate expression: The pyruvate level in the PE group was significantly higher than the control group

Figure 3. Lactic acid, pyruvate, and epinephrine expression in the heart and kidney tissues of rats.
[*]$P<0.05$ for comparison with the corresponding tissue of the control group, and [#]$P<0.05$ for comparison with the corresponding tissue of the preeclampsia group.

Figure 4. Pyruvate dehydrogenase kinase 4 expression in the myocardial tissue of rats.
[*]$P<0.05$ for comparison with the corresponding tissue of the control group, and [#]$P<0.05$ for comparison with the corresponding tissue of the preeclampsia group.

($P<0.05$), but administration of Resveratrol downregulated the pyruvate level ($P<0.05$).

Epinephrine expression: The epinephrine level in the PE group was significantly higher than the control group ($P<0.05$), but administration of Resveratrol downregulated the pyruvate level ($P<0.05$; see Fig. 3).

PDK4 expression in the heart tissue

The mRNA and protein expression levels of PDK4 were highest in the PE group compared to control. It was significantly lowered in the RE group than in the PE group ($P<0.05$; see Fig. 4).

DISCUSSION

In the present study, the effects of Resveratrol on inflammatory cytokines and the energy metabolism disorder were evaluated in a preeclampsia rat model. We observed that Resveratrol had protective effects, as evidenced by the suppression of the expression and release of inflammatory cytokines and the regulation of energy metabolic indicators in preeclampsia rats.

Systemic inflammation plays a key role in the occurrence and development of multiple organ injury (Menden *et al.*, 2015). Endotoxin activates macrophages and monocytes, leading to an inflammatory cascade in which large quantities of inflammatory mediators, such as interleukins and TNF-α, are produced and released. Inflammatory mediators cause damage to alveolar epithelial cells, pulmonary capillary epithelial cells, and renal endothelial cells, leading to the progression of injury. Several cytokines have been implicated in the pathogenesis of preeclampsia (Conrad & Benyo, 1997). TNF-α is an important initiating factor that mediates endotoxic shock, systemic inflammatory response syndrome, and organ injury (Susantitaphong *et al.*, 2013). TNF-α damages lysosomes; causes enzymes to leak; promotes the migration of leukocytes to the site of inflammation; induces endothelial cells and macrophages to synthesize and release IL-1, IL-6, IL-8, superoxide, and lysosome; and promotes inflammation, the metabolism of arachidonic acid, the production of lipid mediators, and the formation of microthrombosis, which lead to lung and kidney damage. IL-6 is also an important inflammatory factor that is secreted in large quantities in the lungs and blood of patients with multiple organ injury. IL-6 levels in patients with multiple organ injury are significantly higher than in healthy people and can reflect the degree of lung tissue damage. IL-6 participates in the differentiation and infiltration of macrophages, which can induce the production of adhesion molecules by activating the expression of complement and C-reactive protein, vascular endothelial cells, and lymphocytes and participate in the acute phase response of lung and kidney injury (Hattar *et al.*, 2001). Therefore, inhibiting the production of cytokines is an effective means of treating inflammatory diseases. This study showed that during preeclampsia, a significant increase in the levels of TNF-α and IL-6 in lung and kidney tissues, and Resveratrol can reduce multiple organ dysfunction caused by preeclampsia by reducing the levels of the pro-inflammatory factors TNF-α and IL-6.

At the onset and during the development of preeclampsia, redox damage caused by oxygen free radicals is one of the important causes of multiple organ dysfunction (Gupte & Wagh, 2014). In preeclampsia, many oxygen free radicals attack the polyunsaturated fatty acids in the biofilm, triggering lipid peroxidation and forming a large quantity of the lipid peroxidation product MDA. MDA is lipid peroxide and a marker of oxidative stress and antioxidant status. MDA levels can reflect the severity of the attack of oxygen free radicals on the body. SOD is a natural scavenger of oxygen free radicals in organisms and can scavenge superoxide anions and free radicals to protect cells from damage. SOD levels can indirectly reflect the body's ability to scavenge oxygen free radicals, and maintains body's oxidation and antioxidant balance. The combined detection of SOD and MDA can accurately reflect the oxidative stress state and represent the degree of tissue damage.

This study found that when compared with the control group, MDA levels in the lung and kidney tissues of the Preeclampsia group (PR) group were significantly higher and SOD levels were significantly lower, suggesting that Preeclampsia caused oxidative stress damage to these tissues. Resveratrol can increase SOD levels and reduce MDA levels, suggesting that Resveratrol can reduce the production of oxygen free radicals, improve the body's antioxidant capacity, and inhibit the oxidative stress damage caused by Preeclampsia.

Hyperlactic acidemia is considered to be a sign of oxygen debt, systemic hypoxia, and anaerobic metabolism. Elevated lactic acid levels represent an energy metabolism disorder, and decreased levels of lactic acid signify

an improvement in tissue hypoxia and energy metabolism (Husain *et al.*, 2003). Pyruvate is the direct and sole precursor of lactic acid, the end product of glycolysis, and the starter of the tricarboxylic acid cycle. Elevated pyruvate levels may be a consequence of reduced oxygen delivery (ischemic hypoxia) and reflect mitochondrial dysfunction (Hajjej *et al.*, 2017). Both lactic acid and pyruvate are the products of glucose metabolism and abnormalities can reflect a disorder in energy metabolism.

Myocardial dysfunction is a common complication of Preeclampsia (Melchiorre *et al.*, 2012). PDK4 is a key enzyme that regulates the pyruvate dehydrogenase complex (PDC). In some cases, the overexpression of PDK4 can lead to PDC inactivation, mitochondrial dysfunction, and negative health consequences (Jeon *et al.*, 2021). Energy metabolism disorder is one of the important causes of myocardial damage in Preeclampsia (Hu *et al.*, 2022). This study found that when compared with the control group, the lactic acid and pyruvate levels and the PDK4 gene and protein expression in the myocardial tissue were significantly higher in the Preeclampsia group, which suggests that Preeclampsia leads to increased anaerobic glycolysis in the heart and kidney tissues, causes glucose metabolism disorders, and results in the accumulation of lactic acid and pyruvate, which aggravate heart and kidney dysfunction. The results demonstrated that Resveratrol downregulated the excessive expression of the PDK4 and reduced the content of lactic acid and pyruvate in the heart and kidney tissues. Therefore, Resveratrol can reduce heart and kidney dysfunction induced by preeclampsia by regulating energy metabolism.

In the present study, we deduced that Resveratrol could decrease the exaggerated inflammatory response during preeclampsia conditions. Therefore, Resveratrol may be advantageous as a potential therapeutic agent for patients with preeclampsia.

CONCLUSIONS

In summary, Resveratrol can protect against multiple organ injury caused by preeclampsia by reducing the expression of anti-inflammatory cytokines and through the anti-oxidative stress pathway. Resveratrol can also inhibit the body's stress response, improve energy metabolism, and protect the heart tissue from preeclampsia. Therefore, Resveratrol is worthy of further investigation as a potential intervention strategy for preeclampsia in preeclampsia. Further studies are required to elucidate the precise mechanism of its protective action.

Introduction: Liver transplantation (LTx) is the only successful treatment for end-stage liver disease. The results of liver transplantation depend not only on graft survival but may be also affected by superimposed cardiovascular morbidities. The aim of this retrospective study was to assess the prevalence of lipid disorders as one of the important cardiovascular risk factors in patients before and after successful LTx. **Material and Methods:** One hundred eleven patients who underwent liver transplantation because of liver cirrhosis and survived at least 2 years with functioning graft between November 2005 and May 2014 were included in this retrospective analysis. The mean age of the patients at the time of liver transplantation was 49.7±12.2 years. The prevalence of dyslipidemia was assessed before and two years after liver transplantation. This was analyzed in relation to the etiology of liver disease, including alcohol toxicity, viral or autoimmune diseases. **Results:** The prevalence of hypertriglyceridemia before and after LTx was 13.5% and 40.5%, respectively ($P<0.001$). Similarly, hypercholesterolemia was noted in 17.1% and 51.4% respectively ($P<0.001$). The annual incidence of hypertriglyceridemia and hypercholesterolemia during the first two years after LTx was 16.2% and 20.7%, respectively. The prevalence of hypertriglyceridemia (18.5% *vs* 66.7%, $P<0.001$) and hypercholesterolemia (29.6% *vs* 70.0%, $P=0.002$) was significantly lower in patients with the autoimmune cause of liver cirrhosis in comparison to patients with the alcoholic liver disease. **Conclusions:** The prevalence of dyslipidemia is increased after liver transplantation. The prevalence of dyslipidemia may be related to the cause of liver injury before LTx.

Keywords: dyslipidemia, hypertriglyceridemia, hypercholesterolemia, cardiovascular risk factors, liver transplantation

INTRODUCTION

Liver transplantation is the only successful method for the treatment of end-stage liver disease. In the last decade in Poland, about 300 patients underwent liver transplantation every year (Poltransplant, 2022). The most common indications for liver transplantation in our population included end-stage liver disease caused by infectious hepatitis, autoimmune or alcoholic liver disease.

Despite decreasing the risk of early graft failure, due to improving surgical techniques and immunosuppressive therapy, in the last three decades, long-time survival in liver transplant recipients has not substantially improved (Rana *et al.*, 2019). Therefore currently transplant community focus has shifted to maximizing long-term survival after transplantation. The results of liver transplantation not only depend on graft survival but may be affected by superimposed cardiovascular morbidities. It has been shown that cardiovascular diseases are one of the most frequent causes of premature death in patients after liver transplantation (Berenguer *et al.*, 2002; Watt *et al.*, 2010). Current immunosuppressive drugs are very effective in preventing acute rejection of transplanted organs. However, it is well-recognized that some of these drugs, like tacrolimus or steroids, result in increased rates of hypertension, diabetes, and dyslipidemia (Gojowy *et al.*, 2016). Watt *et al.*, in long-term follow-up of liver transplant recipients, have shown that some well-known cardiovascular risk factors like hypertension or diabetes mellitus may be directly or indirectly involved in premature death in patients who survive one year after liver transplantation (Watt *et al.*, 2010). According to this observation, routine screening of cardiovascular risk factors seems to be an essential component of comprehensive post-transplant care for these patients. Population studies in Poland have shown that cardiovascular risk factors are common and hypercholesterolemia is present in 61.1-64.3% of the Polish adult population (Zdrojewski *et al.*, 2013; Stepniak *et al.*, 2016; Niklas *et al.*, 2018; Rutkowski *et al.*, 2020).

The current paper presents the results of a retrospective study which aimed to assess the prevalence of lipid disorders before and after successful liver transplantation.

MATERIAL AND METHODS

This retrospective, single-center study involved 111 patients (47 female, 64 male) aged 49.7±12.2 years who underwent liver transplantation because of liver cirrhosis in years 2005 to 2014 in the Department of General, Vascular and Transplant Surgery of the Medical University of Silesia in Katowice, Poland and who survived with functioning transplanted liver for at least 24 months. Patients who died or had liver re-transplantation before 24 months of observation were not included in the analysis. All transplantations were performed using cadaveric organs. After transplantation, patients were followed up in the Transplantation Outpatient Clinic of the Department of Nephrology, Transplantation and Internal Medicine Medical University of Silesia in Katowice, Poland. The median MELD score at the time of qualifica-

tion for liver transplantation was 14.0 (9.0;19.1). A retrospective analysis of the patients' medical history was performed.

In all patients, serum concentrations of total cholesterol and triglycerides, as well as doses and concentrations of immunosuppressive drugs were analyzed. Hypertriglyceridemia was diagnosed when triglycerides serum concentration was ≥1.7 mmol/L (150 mg/dL) or triglycerides-lowering treatment (i.e. one of the fibrates) was used. In such patients triglycerides serum concentration ≥1.7 mmol/L (150 mg/dL) was documented before initiation of this therapy. Hypercholesterolemia was defined as a total serum cholesterol concentration was ≥5.0 mmol/L (190 mg/dL) or cholesterol-lowering pharmacological treatment was used (i.e. one of statins or fibrates). In such patients, serum cholesterol concentration ≥5.0 mmol/L (190 mg/dL) was documented before initiation of this therapy. Because of the retrospective character of the current study due to the lack of data, the analysis of serum cholesterol fractions was not possible. Prevalence of lipid disorders was assessed a short time before liver transplantation (up to 6 months before the procedure) and two years after transplantation. Moreover, the annual incidence of these abnormalities during the first two years after liver transplantation was analyzed.

Etiology of liver disease

Thirty-seven patients had viral hepatitis as a cause of liver failure (among them, 28 patients suffered from hepatitis C, and 9 from hepatitis B infection); alcoholic liver disease was a cause of liver failure in 30 patients; autoimmune diseases in 27 patients (among them primary sclerosing cholangitis – 11 patients, autoimmune hepatitis – 9 patients, primary biliary cirrhosis – 5 patients, autoimmune hepatitis and primary sclerosing cholangitis overlapping syndrome – 2 patients) and others (17 cases).

Immunosuppressive treatment

Two years after liver transplantation, 90% of studied patients were treated with calcineurin inhibitors. Ninety-one patients (82% of all studied patients) received tacrolimus, and 9 patients (8% of all studied patients) received cyclosporine A. Eleven patients (10% of the studied patients) were treated with everolimus. Prednisone was used in 102 patients (92% of the studied patients), mainly in the dose of 5–15 mg/day. Thirty-seven patients (33% of the studied patients) were treated with mycophenolates. In three patients within 24 months after liver transplantation, the acute rejection of the transplanted liver was diagnosed only by clinical manifestation and treated with a high dose of intravenous methylprednisolone. None of these patients had a biopsy of the transplanted liver. In another two patients, it was necessary to transiently increase the prednisone dose to 60 mg/day in the early period after liver transplantation.

Statistical analysis

Statistical analysis was done using the Statistica 13.3 software (StatSoft). The Shapiro-Wilk test was used to determine the normality of distribution. Mann-Whitney U, chi-square tests, and Spearman's rank correlation were used in this study. The level of statistical significance is α=0.05. Results were presented as a mean and standard deviation for the parametric distribution of variables and as a median with an interquartile range for the non-parametric distribution of variables.

Ethics

Because of the retrospective character of the study, ethics committee consent was not required.

RESULTS

Hypertriglyceridemia before liver transplantation was found in 13.5% of patients. The prevalence of hypertriglyceridemia two years after liver transplantation was significantly higher – 40.5% (36.2% in females, 43.8% in males) ($P<0.001$). The annual incidence of new-onset hypertriglyceridemia in the first two years after liver transplantation was 16.2%. It has been shown a significant positive correlation between serum triglycerides concentration and the age of liver transplant recipients ($R=0.27$, $P=0.003$). Serum total cholesterol concentration was elevated above the normal range in 17% of patients before liver transplantation. After liver transplantation in 57 (51.4%) patients (51.0% of females, 51.6% of males) hypercholesterolemia was found ($P<0.001$) (Table 1). The annual incidence of new-onset hypercholesterolemia in the first two years after liver transplantation was 20.7%. It has been shown a correlation between serum total cholesterol concentration and the age of liver transplant recipients ($R=0.25$, $P=0.008$).

There was no significant correlation between MELD score before LTx and serum triglycerides and total cholesterol serum concentration before and 24 months after LTx. There were also no significant differences in MELD score before LTx between patients with and without diagnosis of any type of dyslipidemias before and 24 months after LTx.

Before LTx, none of the patients were treated with lipid-lowering therapy. Only 7 patients were treated with lipid-lowering therapy two years after LTx (3 received statins, 3 received fibrates, and one patient was treated with both drugs from the above-mentioned group of agents). Patients were not treated with other lipid-lowering drugs (i.e. ezetimibe). Hypercholesterolemia was diagnosed in three patients with normal serum total cholesterol concentration at the time of examination (i.e. 2 years after LTx) treated with lipid-lowering therapy (1 with statin and 2 with fibrates). Hypertriglyceridemia was diagnosed in one patient with normal triglycerides serum concentration at the time of examination (i.e. 2 years after LTx) treated with fenofibrate.

Immunosuppressive drugs and lipid disorders

Our study showed no significant differences in the prevalence of hypertriglyceridemia in patients treated with tacrolimus, cyclosporine A, and everolimus (40%, 33%, and 55%, respectively). There was a significant difference in the prevalence of hypercholesterolemia in patients treated with everolimus, tacrolimus and cyclosporine (91%, 45%, and 66%, respectively, $P=0.01$; everolimus vs. tacrolimus $P=0.002$). Prevalence of hypercholesterolemia and hypertriglyceridemia in patients treated and not treated with mycophenolates was 46% vs. 54% and 35% vs. 43%, respectively (differences in the above-mentioned prevalence were not significant).

There were no significant correlations between serum total cholesterol as well as triglycerides concentration and blood tacrolimus concentration (Figs 1 and 2),

Figure 1. Tacrolimus blood concentration and triglycerides serum concentration 24 months after liver transplantation.

Figure 2. Tacrolimus blood concentration and total cholesterol serum concentration 24 months after liver transplantation.

as well as mycophenolate and prednisone dose in liver transplant recipients.

Etiology of liver failure and lipid disorders

In an additional analysis, patients were divided into three groups - alcohol, viral and autoimmune diseases. Patients with the autoimmune disease were characterized by a significantly lower prevalence of hypercholesterolemia than patients with alcoholic disease of the native liver (29.6% *vs.* 70.0%, $P=0.002$). There was also a significantly higher prevalence of hypertriglyceridemia in patients with alcoholic liver disease than in patients with an autoimmune background (66.6% *vs.* 18.5%, $P<0.001$). The annual incidence of new-onset hypertriglyceridemia (9.3%, 13.5%, 30.0%; $P=0.001$; autoimmune *vs.* alcohol – $P=0.001$, viral *vs.* alcohol $P=0.006$) and new-onset hypercholesterolemia (13.0%, 20.3%, 28.3%; $P=0.06$; autoimmune *vs.* alcohol – $P=0.01$), were in autoimmune, viral and alcoholic liver disease, respectively (Table 2).

There was a correlation between triglycerides serum concentration and body weight as well as triglycerides serum concentration and BMI in 24 months after liver transplantation ($R=0.34$, $P<0.001$ and $R=0.32$, $P<0.001$, respectively). There was also a correlation between gain of body mass as well as gain of BMI before and 24

months after liver transplantation and triglycerides serum concentration 24 months after LTx ($R=0.22$, $P=0.02$ and $R=0.20$, $P=0.03$, respectively). There was also a trend of correlation between total cholesterol serum concentration and body weight ($R=0.19$, $P=0.05$) and a correlation between total cholesterol serum concentration and BMI in 24 months after liver transplantation ($R=0.20$, $P=0.03$). There was also a trend of correlation between gain of body mass as well as gain of BMI before and 24 months after liver transplantation and total cholesterol serum concentration 24 months after LTx ($R=0.16$, $P=0.09$ and $R=0.17$, $P=0.08$, respectively). Patients with hypertriglyceridemia had higher BMI in comparison with patients without that disorder (28.1 ± 5.4 *vs* 26.2 ± 4.1 kg/m^2; $P=0.03$). There was no significant difference in BMI in patients with and without hypercholesterolemia (27.6 ± 5.0 *vs* 26.3 ± 4.5 kg/m^2).

DISCUSSION

The prevalence of lipid disorders increased over a 2-year survey of patients undergoing liver transplantation at our facility. According to available data prevalence of dyslipidemia in liver transplant recipients varies widely among studies, and it is present in 14–71% of patients

Table 1. Prevalence of lipid disorders before and after liver transplantation

	Before liver transplantation			After liver transplantation		
	All (n=111)	Male (n=64)	Female (n=47)	All (n=111)	Male (n=64)	Female (n=47)
Hypercholesterolemia	19 (17%)	7 (11%)	12 (25%)	55 (51%)*	33 (52%)	24 (51%)
Hypertriglyceridemia	15 (14%)	6 (9%)	9 (19%)	45 (41%)*	28 (44%)	17 (36%)

*$P<0.001$ *vs* before liver transplantation

Table 2. Lipid disorders prevalence and etiology of liver cirrhosis

Cardiovascular risk factor (24 months after LTx)	Autoimmune (n=27)	Viral (n=37)	Alcoholic (n=30)	P-value
Hypercholesterolemia	8 (30%)	20 (54%)	21 (70%)	$P=0.05$* $P=0.02$+ NS^x
Hypertriglyceridemia	5 (19%)	15 (41%)	20 (67%)	NS* $P<0.001$+ $P=0.03$^{x}

*autoimmune *vs.* viral; +autoimmune *vs.* alcoholic; ^{x}viral *vs.* alcoholic

(Clart *et al.*, 1996; Gisbert *et al.*, 1997; Kallwitz *et al.*, 2012; Niklas *et al.*, 2018). In the current study, 51.4% of patients presented hypercholesterolemia two years after liver transplantation. It is less than in the general adult Polish population (results of NATPOL 2011 61.1% and WOBASZ II – 64.3% studies) (Zdrojewski *et al.*, 2013; Rutkowski *et al.*, 2020). An opposite tendency is in the case of hypertriglyceridemia. In patients after liver transplantation hypertriglyceridemia is present in 40.5%. It is more frequent than in the general adult Polish population (21% – results of NATPOL 2011 study) (Zdrojewski *et al.*, 2013). Results of previous studies suggest that hypertriglyceridemia is even more common during the first year after liver transplantation than in long-term observation (Clark *et al.*, 1997, Gisbert *et al.*, 1997). An important risk factor for developing hypertriglyceridemia after LTx is kidney dysfunction and greater body weight gain after LTx (Gispert *et al.*, 1997). The prevalence of studied lipid abnormalities was significantly lower before liver transplantation – hypercholesterolemia 17.1% *vs.* 51.4% and hypertriglyceridemia 13.5% *vs.* 40.5%. This might be influenced by malnutrition in patients with end-stage liver disease qualified for liver transplantation. An observational study of 165 liver transplant recipients showed that living liver donation was related to a better lipid profile (lower triglycerides and higher HDL serum concentrations) two years after transplantation (Chu *et al.*, 2017). In the current study, all transplanted livers were received from cadavers.

Dyslipidemia and immunosuppressive drugs

Dyslipidemia is a well-known complication associated with using steroids, tacrolimus, or everolimus.

Steroid therapy is a well-known risk factor for developing lipid disorders (Fatourou *et al.*, 2019). Some observational studies suggest that withdrawal of steroids in the long term after liver transplantation may decrease serum cholesterol concentration (Punch *et al.*, 1995; Stegall *et al.*, 1997; Trouillot *et al.*, 1999; Everson *et al.*, 1999).

The effect of immunosuppressive therapy with calcineurin inhibitors (cyclosporine A or tacrolimus) may also induce lipid abnormalities (Clart *et al.*, 1996; Stegall *et al.*, 1997; Fatourou *et al.*, 2019). Results of previous studies suggest that treatment with both calcineurin inhibitors predisposes to hyperglyceridemia. It has been shown that combined cyclosporine A and sirolimus therapy increase the risk of hypertriglyceridemia in liver transplant recipients (Trotter *et al.* 2001). Canzanello *et al.* suggest that the risk of hypertriglyceridemia in patients treated with cyclosporine A is higher than in patients treated with tacrolimus [Canzanell *et al.* 1997]. Another study by Dehghani *et al.* presents opposite findings (Dehghani *et al.*, 2007). In the observational study of 116 Spanish liver transplant recipients, Fernandez-Miranda *et al.* have shown a slight association between cyclosporine A and hypercholesterolemia in patients after LTx (odds ratio: 1.02; 95% CI: 1.00–1.03; *P*=0.01) (Fernandez-Miranda *et al.*, 2002). Because of the low number of patients treated with cyclosporine A in the current study, such an analysis was impossible to perform. Orlando *et al.*, in the interventional study of 42 liver transplant recipients with chronic toxicity of calcineurin inhibitors have shown that conversion of calcineurin inhibitors for mycophenolate leads to serum total cholesterol and triglycerides concentration reduction (Orlando *et al.*, 2007).

It has been shown that treatment with mTOR inhibitors (everolimus or sirolimus) is associated with developing hypercholesterolemia in renal transplant recipients

(Groth *et al.*, 1999). Randomized trials have shown that immunosuppressive conversion from calcineurin inhibitors to mTOR inhibitors in a short time after liver transplantation increases total cholesterol and LDL-cholesterol concentration (Masetti *et al.*, 2010; Fischer *et al.*, 2012, De Simone *et al.*, 2012; Teperman *et al.*, 2013). Only one of these trials (with modification for everolimus and low tacrolimus dose regimen) has shown an additional increase in serum triglyceride concentration and an increase in HDL-cholesterol concentration (De Simone *et al.*, 2012). Interestingly, the previously cited study has shown a hypertriglyceridemic effect of mTOR inhibitor on liver transplant recipients only in combination with cyclosporine A (Trotter *et al.*, 2001). Also, in patients long time after liver transplantation, the conversion from calcineurin inhibitor regimen to mTOR inhibitor increases the rate of hypercholesterolemia (Shenoy *et al.*, 2007; De Simeone *et al.*, 2009; Abdelmalek *et al.*, 2012). The current study's results align with the above data – the prevalence of hypercholesterolemia in patients treated with everolimus is higher.

A case-control analysis of 13 liver transplant recipients who withdrew all immunosuppressive drugs long-term after liver transplantation showed lower LDL-cholesterol concentration in patients within immunosuppressive therapy than in 22 patients who stayed with immunosuppressive treatment (Duizendstra *et al.*, 2019).

García-Pajares and others (Garcia-Pajares *et al.*, 2016) in an observational study of 204 Spanish liver transplant recipients have shown that hypertriglyceridemia in the first year after liver transplantation is an important risk factor for the development of metabolic syndrome in the next 5 years.

The current study also analyzed the impact of liver cirrhosis's etiology on dyslipidemia's prevalence. In patients with an autoimmune background of liver cirrhosis, the prevalence of hypertriglyceridemia and hypercholesterolemia was lower. This may be due to a younger age at liver failure diagnosis and a generally healthier lifestyle. Patients with an alcohol abuse history seem less likely to be on a healthy diet and their physical activity is presumably lower. This leads to an increased risk of diabetes mellitus and atherosclerosis.

In the current study, it has been shown that the prevalence of dyslipidemia increases after liver transplantation in comparison to the pre-transplant results. Moreover, hypertriglyceridemia is more frequent in a liver transplant recipient than in the general adult Polish population. Dyslipidemia is a risk factor for cardiovascular diseases, which are currently the most common causes of death in these patients (Watt *et al.*, 2010; Rana *et al.*, 2019). Available data suggest that the consequence of the increased occurrence of cardiovascular risk factors is overall survival reduction after liver transplantation (Watt *et al.*, 2010).

Treatment with hypolipidemic drugs

Patients qualified for liver transplantation mostly had end-stage liver disease, where statins were contraindicated, therefore in most patients with dyslipidemias,only diet was recommended. In the past usage of hypolipidemic drugs in our center was limited. The safety and effectivity of statins after liver transplantation in previous years have not been well established. Nowadays there are some data suggesting the advantages of statin therapy for cardiovascular outcome and decreased risk of hepatocellular cancer recurrence after liver transplantation and us-

age of statins after LTx is more common (Becchetti *et al.*, 2022; Kim *et al.*, 2023).

Limitations

The presented study has some limitations because the retrospective nature of the study does not allow for establishinga cause-and-effect relationship between the etiology of liver failure and the incidence of dyslipidemia.

CONCLUSIONS

Our study has documented that the prevalence of dyslipidemia might increase after liver transplantation. Further research will be needed to assess if these changes result in associated cardiovascular mortality or morbidity. As these risk factors may be associated with cardiovascular disease that may limit survival, formalized efforts should be made to modify these risk factors and improve the long-term survival of patients undergoing liver transplantation. The incidence of lipid disorders in patients after LTx is related to the etiology of liver cirrhosis before liver transplantation.

Circular RNA AGFG1 motivates breast cancer cell proliferation, invasion, migration, and glycolysis by controlling microRNA-653-5p/14-3-3 protein epsilon

Liang Chen[1#], JinXian Qian[1✉], Ying Shen[3✉] and Xiang Yu[2#]

[1]Department of Breast Surgery, The First Affiliated Hospital of Kunming Medical University, Kunming City, Yunnan Province, 650032, China; [2]Emergency Trauma Surgery, First People's Hospital of Yunnan Province, Kunming City, Yunnan Province, 650034, China; [3]Department of General Surgery, Yunnan New Kunhua Hospital, Anning City, Yunnan Province, 650301, China

A recent Pairwise meta-analysis confirmed that circular RNA AGFG1 (circAGFG1) is abnormally highly expressed in breast cancer (BC) and may be associated with death risk. The purpose of this study was to elucidate the biological role of circAGFG1 in BC and to explore its potential downstream molecular mechanisms. CircAGFG1, miR-653-5p and YWHAE expression in BC tissues and cells were analyzed by RT-qPCR or western blot. Gene expression was regulated by transfection of plasmids or oligonucleotides and the biological behaviors of BC cells were analyzed by a series of assays. The ring structure of circAGFG1 was analyzed by RNase R and actinomycin D treatment. Dual luciferase reporter assay and RNA-pull down were used to verify the targeting relationship of circAGFG1 and downstream factors. A nude mouse xenograft experiment was performed to verify the effect of circAGFG1 on cancer cells *in vivo*. The results showed that circAGFG1 and YWHAE were highly expressed in BC while miR-653-5p was lowly expressed. Both circAGFG1 and YWHAE had a targeting relationship with miR-653-5p. Knockdown of circAGFG1 inhibited BC cell proliferation, invasion, migration, and glycolysis. The inhibitory effect of circAGFG1 knockdown on BC was reversed by silencing miR-653-5p. The inhibitory effect of overexpression of miR-653-5p on malignant behaviors of BC cells was reversed by overexpression of YWHAE. Knockdown of circAGFG1 inhibited tumor growth *in vivo*. Taken together, these data suggest that circAGFG1 acts as a sponge for miR-653-5p to mediate YWHAE expression to promote the malignant behaviors of BC.

Keywords: Circular RNA AGFG1, MicroRNA-653-5p,YWHAE, Target binding, MDA-MB-231 cells

INTRODUCTION

Breast cancer (BC) is a malignant tumor in the mammary gland epithelial tissue, which seriously threatens the survival and health of women worldwide (Wang *et al.*, 2021). Surgery, endocrine therapy, chemotherapy, radiotherapy and targeted therapy are applicable for BC treatment to reduce the mortality rate (Li *et al.*, 2021). However, due to high recurrence and easy metastasis, patients' prognosis is still poor, and the mortality rate is still high (Xie *et al.*, 2021). Hence, an in-depth study of the latent molecular mechanisms of BC is crucial to provide new and effective therapeutic targets.

Circular RNAs (circRNAs) are a cluster of closed circular RNAs (Li *et al.*, 2019). A study has shown that circRNAs are available to control gene expression and the biological behavior of cancer cells (Wu *et al.*, 2019). Meanwhile, multiple circRNAs have been revealed to take part in regulating BC progression (Zhang *et al.*, 2021; Qi *et al.*, 2021; Cui *et al.*, 2021). CircAGFG1 is a novel circRNA that has been confirmed to be elevated in BC and may be implicated in the diagnosis and prognosis of BC (Ma *et al.*, 2021). However, it is unclear whether circAGFG1 affects the biological behavior of BC cells.

circRNAs can perform as competing endogenous RNAs (ceRNAs) for microRNAs (miRNAs) to control downstream targets (Chu *et al.*, 2021). In the light of the ceRNA theory, it predicted a miRNA (miR-653-5p) associated with circAGFG1. Recently, miR-653-5p has been tested to involve diversified cancers, such as non-small cell lung cancer (Han *et al.*, 2019) and gastric cancer (Li *et al.*, 2021). However, it is necessary to further elucidate other downstream target genes regulated by miR-653-5p in BC.

YWHAE, also known as 14-3-3ε, is a member of the YWHA protein family (Wu *et al.*, 2021). YWHAE which is extensively expressed in most cancers is a transcription factor [(Li *et al.*, 2021). Previous studies have shown that YWHAE is elevated in BC and can motivate the proliferation, metastasis and chemotherapy of BC cells, and may become a latent therapeutic target for BC (Leal *et al.*, 2016; Cimino *et al.*, 2008; Park *et al.*, 2019).

This study hypothesized that circAGFG1 might indirectly regulate YWHAE expression by adsorbing miR-653-5p to participate in BC cell biological behaviors. Our aim was to explore the biological function of circAGFG1 in BC and to elucidate its downstream underlying mechanisms.

MATERIALS AND METHODS

Clinical tissue specimens

From January 2018 to January 2020, BC tissues and adjacent normal tissues (2–5 cm from the tumor) of 60 patients (aged 47.5±11.4 years) who underwent tumor resection at The First Affiliated Hospital of Kunming Medical University were harvested. All tissues were stored at –80°C. Approval of this study was obtained from the Ethics Committee of The First Affiliated Hos-

pital of Kunming Medical University and written informed consent was collected from all participants.

Cell culture and transfection

Normal human breast cells (MCF-10A) and human BC cell lines (MDA-MB-231, MCF-7, SK-BR-3 and MDA-MB-157) were bought from ATCC (VA, USA). The cells were cultivated in Roswell Park Memorial Institute-1640 (31800, Solarbio, China) containing 10% fetal bovine serum at 37°C, and 5% CO_2. MDA-MB-231 cells were chosen as an auxiliary study object because they had the greatest difference in expression (Yang *et al.*, 2019).

Specific short hairpin RNAs against circAGFG1, miR-653-5p mimic/inhibitor, and corresponding NCs were gained from Genepharma (Shanghai, China). Lentivirus-negative vector, YWHAE and circAGFG1 lentiviral over-expression vectors were purchased from GeneCopoeia. MDA-MB-231 and MDA-MB-157 cells were transferred to a 6-well plate (1×10^5 cells/mL) and cultured for 24 h. Cell transfection was conducted using Lipofectamine® 2000 (Invitrogen, USA) (Gong *et al.*, 2021). 48 h after transfection, the transfection efficiency was evaluated by reverse transcription-quantitative polymerase chain reaction (RT-qPCR) and Western blot.

Ribonuclease R (RNase R) and actinomycin D

To test RNase R resistance, total RNA (2 µg) from MDA-MB-231 cells was collected and incubated with 3 U/µg RNase-R (07250, Epicentre Technologies, USA) at 37°C for 30 min. Actinomycin D experiment: MDA-MB-231 cells were treated with 2 mg/mL actinomycin D (129,935, Millipore, USA) to block transcription. Then, cellular RNA was obtained to measure circAGFG1 and AGFG1 expression by RT-qPCR.

Subcellular localization analysis

Cytoplasmic and nuclear RNAs of MDA-MB-231 cells were isolated using the PARIS Kit (Invitrogen). Then, circAGFG1 in cytoplasmic RNA and nuclear RNA was checked by RT-qPCR. U6 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were applied as nuclear and cytoplasmic controls, respectively.

RT-qPCR

Total RNA was extracted from BC tissues and cells using Trizol reagent (Invitrogen) PrimeScript RT reagent kit (Takara, Tokyo, Japan) and miRNA First Strand Synthesis kit (Takara, Japan) were employed for reverse transcription of circRNA/mRNA and miRNA, respectively. RT-qPCR was performed with SYBR Green kit (Thermo Fisher Scientific, MA, USA) and Mx3005P QPCR system (Agilent Technologies, Santa Clara, CA, USA). U6 and GAPDH were employed as internal controls for miRNA and mRNA/circRNA, respectively (Ma *et al.*, 2021). The primer sequences were manifested in Table 1. The relative expression of genes was analyzed by $2^{-\Delta\Delta Ct}$.

Western blot

Total protein from cells and tissues was extracted with 500 µL radio-immunoprecipitation assay lysis buffer (Beyotime). An equal amount of protein (20 µg) was separated by 8% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (Solarbio) and transferred to a polyvinylidene fluoride membrane (Invitrogen). After be-

ing blocked with 5% skim milk, the membrane was incubated with primary antibodies YWHAB (8312, Cell Signaling Technology, 1:1000), glucose transporter type1 (GLUT1; ab652, 1:1000), matrix metalloproteinase-9 (MMP9; ab38898, 1:1000), B cell lymphoma 2-associated X (Bax; ab32503, 1: 1000, all Abcam), and GAPDH (60004-1-Ig, 1:1000, Proteintech) overnight at 4°C. Horseradish peroxidase-conjugated goat anti-rabbit secondary antibody immunoglobulin G (1:1000, ab181236, Abcam) was added for incubation for 2 h. The signals were visualized by an enhanced chemiluminescence kit (34080, Thermo Fisher Scientific) and analyzed by ImageJ software. Three biological replicates of the experiment were performed.

Cell Counting Kit -8 (CCK-8)

MDA-MB-231 and MDA-MB-157 cells after transfection were seeded in 96-well plates (1×10^4 cells/well). At designated time points (0, 24, 48 h), 10 µL CCK-8 reagent (Dojindo, Kumamoto, Japan) was added to each well. Optical density values at 450 nm were recorded after 2 h on a microplate reader (PerkinElmer, USA).

Colony formation assay

MDA-MB-231 and MDA-MB-157 cells after transfection were seeded in 6-well plates for 14 d, fixed in 4% paraformaldehyde (Beyotime), stained with 0.1% crystal violet (Beyotime) for 2 h, and counted.

Flow cytometry

Apoptosis rates of transfected MDA-MB-231 and MDA-MB-157 cells were analyzed by Annexin V-Fluorescein isothiocyanate (FITC) propidium iodide (PI) apoptosis kit (BD Biosciences). Briefly, cells were resuspended in 1 × binding buffer (500 µl) and mixed with 5 µl Annexin V-FITC and 5 µl PI in the dark for 15 min. Finally, the percentage of apoptotic cells was evaluated by a flow cytometer (FACS Calibur).

Transwell migration and invasion analysis

MDA-MB-231 and MDA-MB-157 cells were placed in a serum-free medium at a density of 5×10^4 cells/well, and the medium containing 10% fetal bovine serum (Invitrogen) was added to the bottom chamber. Then after 24 h, cells were fixed with methanol for 30 min, stained with 0.1% crystal violet, and viewed in an inverted mi-

croscope (Tycom, Switzerland, magnification ×100). For invasion assays, cells (1×10⁶ cells/well) were placed in the upper chamber (Costar) coated with a matrix (BD Bioscience) (Wan *et al.*, 2021).

Glycolysis test

MDA-MB-231 and MDA-MB-157 cells (1×10⁵ cells/well) after transfection were seeded in 12-well plates. After 48 h of transfection, glucose consumption, and lactate production, the ADP/ATP ratio were tested using a glucose detection kit (Sigma-Aldrich), a lactate detection kit (BioVision, Milpitas, CA, USA), and a carrier sensor ADP/ATP ratio detection kit (BioVision), respectively (Xie *et al.*, 2021).

The luciferase activity assay

MDA-MB-231 cells were plated on 6-well plates and then co-transfected with the luciferase reporters pRL-TK-CircAGFG1/YWHAE-WT 3-UTR or pRL-TK-CircAGFG1/YWHAE-MUT 3-UTR (Promega), and miR-653-5p mimic or mimic-NC using Lipofectamine®2000 (Invitrogen). After 48-h incubation, luciferase activity was measured using a dual luciferase reporter gene kit (Promega) (Wu *et al.*, 2021).

RNA-pull down assay

Biotin-labeled miR-653-5p (Bio-miR-653-5p) probe and control probe (Bio-NC) were gained from Ribo-Bio. After transfection with Bio-NC or Bio-miR-653-5p, MDA-MB-231 cells were lysed after 48 h and incubated with Dynabeads M-280 Streptavidin (Invitrogen) at 4°C for 2 h. The RNA complexes on the beads were washed and the enrichment of circAGFG1 and YWHAE was tested by RT-qPCR.

In vivo tumor growth assay

Twelve BALB/c male nude mice (5 weeks old, body weight of 15–20 g) were purchased from Vital River

Figure 1. CircAGFG1 is elevated in BC

(Beijing, China). MDA-MB-231 cells (5×10⁶ cells/mouse) with or without stable knockdown of circAGFG1 were injected subcutaneously into each mouse (6 per group). Tumor volume was calculated in the light of the formula 0.5×length×width² and measured every 3 d. After 23 d, the mice were euthanized. Tumor tissues were excised for further analysis. This study was permitted by the Animal Research Committee of The First Affiliated Hospital of Kunming Medical University (Ding *et al.*, 2021).

Immunohistochemistry (IHC) analysis

After being fixed in 10% formalin (Beyotime), the tumor tissues were embedded in paraffin and dissected. Primary antibodies Ki67 (ab15580, 1:5000, Abcam, Cambridge, UK) and MMP9 (ab76003, 1:1000, Abcam) were

incubated at 4°C overnight, followed by the secondary antibody (ab205718, 1:5000, Abcam) overnight. After treatment with 3,3'-diaminobenzidine staining (Sangon Biotech, Shanghai, China), the sections were counterstained with hematoxylin (Beyotime) and examined with a fluorescence microscope (Leica, Wetzlar, Germany).

Statistical analysis

All experiments in this study were biologically replicated at least three times. SPSS 21.0 (SPSS, Inc, Chicago, IL, USA) statistical software was applied for analysis of the data. After the Kolmogorov-Smirnov test, the data were normally distributed and expressed as mean ± standard deviation (S.D.). The two-group comparison was done by t-test, while the multiple-group comparison was performed by one-way analysis of variance (ANOVA) and Fisher's least significant difference t-test (LSD-t). The chi-square test was used

to analyze the correlation between circAGFG1 and the clinicopathological data of patients and Kaplan-Meier analysis to examine the relationship between circAGFG1 and patients' survival P<0.05 was considered statistically significant.

RESULTS

CircAGFG1 is elevated in BC

Firstly, the circAGFG1 expression pattern in BC was detected by RT-qPCR. CircAGFG1 expression was higher in BC tissues compared with normal tissues (Fig. 1A). The link between circAGFG1 and clinicopathological characteristics of BC patients was then analyzed. The elevation of circAGFG1 was associated with tumor-node-metastasis stage, tumor size, lymph

node metastasis and distant metastasis, but not with age (Table 2). Kaplan-Meier survival analysis clarified that the elevation of circAGFG1 was associated with worse overall survival (Fig. 1B).

CircAGFG1 expression was higher in all BC cell lines (MDA-MB-231, MCF-7, SK-BR-3, and MDA-MB-157) than in normal cells (MCF-10A) (Fig. 1C). Among them, MDA-MB-231 cells and MDA-MB-157 cells with the highest CircAGFG1 expression were selected for follow-up experiments. The circular structure of circAGFG1 was confirmed by RNase R and actinomycin D experiments, and it came out that circAGFG1 was resistant to RNase R digestion and was more stable than linear AGFG1 mRNA, and actinomycin D did not affect the stability of circAGFG1 (Fig. 1D, E). Furthermore, subcellular localization analysis clarified that circAGFG1 was majorly distributed in the cytoplasm of MDA-MB-231 cells (Fig. 1F).

The above data suggest circAGFG1 is stably elevated in BC and may take part in BC progression.

Repressing circAGFG1 restrains MDA-MB-231 cell biological behaviors and glycolysis

To figure out circAGFG1's biological function in BC, circAGFG1 was silenced in MDA-MB-231 and MDA-MB-157 cells. CircAGFG1 knockdown efficiency was shown in Fig. 2A. CCK-8 and colony formation experiments showed that the knockdown of circAGFG1 inhibited the proliferation ability of BC cells (Fig. 2B, C). Flow cytometry showed that the knockdown of circAGFG1 promoted apoptosis in cells (Fig. 2D). Transwell experiments demonstrated that the knockdown of circAGFG1 increased the migratory and invasive abili-

Figure 5. YWHAE is a functional target of miR-653-5p in BC cells

(**D–E**) mRNA expression of YWHAE in BC tissues and adjacent normal tissues detected by RT-qPCR and western blot. (**F–G**) YWHAE expression in four BC cell lines (MDA-MB-231, MCF-7, SK-BR-3 and MDA-MB-157) and a normal breast cell line (MCF-10A) detected by RT-qPCR and western blot. (**H–I**) The correlation among YWHAE, miR-653-5p, and circAGFG1 evaluated by Pearson correlation analysis. (**J**) Western blot detection of YWHAE expression after transfection of sh-CircAGFG1 or miR-653-5p mimic. Measurement data were clarified as mean ± S.D. (N=3); *$P<0.05$.

ties of cells (Fig. 2E). Most fast-growing malignant cells have active glycolysis and gain more energy through glycolysis (Zhang *et al.*, 2022). Next, the effect of circAGFG1 on glycolysis was explored. It was examined that knockdown of circAGFG1 inhibited cellular glucose consumption, lactate production and ATP/ADP ratio (Fig. 2F-H). Western blot detected that knockdown of circAGFG1 suppressed the protein expression of MMP9 and GLUT1 and promoted the protein expression of Bax (Fig. 2I). The above data indicated that knockdown of circAGFG1 refrains BC cell biological functions and glycolysis.

CircAGFG1 performs as a sponge for miR-653-5p

circAGFG1 can target miRNAs to regulate BC progression (Qi *et al.*, 2015), so a bioinformatics website

Figure 6. Elevation of miR-653-5p restrains BC cell effect via targeting YWHAE
miR-653-5p mimic and YWHAE overexpression vector were co-transfected into MDA-MB-231 and MDA-MB-157 cells. (**A–B**) RT-qPCR and Western blot examination of YWHAE in MDA-MB-231 cells. (**C–D**) Cell proliferation activity was detected by the CCK-8 method and colony formation assay. (**E**) Cell apoptosis rate tested by flow cytometry. (https://starbase.sysu.edu.cn) was utilized to predict the target miRNAs of circAGFG1. In Fig. 3A, miR-653-5p had a targeted binding site for circAGFG1. miR-653-5p mimic elevated miR-653-5p expression in MDA-MB-231 cells (Fig. 3B). Dual luciferase reporter gene test results showed that miR-653-5p mimic restrained the luciferase activity of circAGFG1-WT, but not that of circAGFG1-MUT (Fig. 3C). RNA-pull down assay found that miR-653-5p could specifically combine with circAGFG1 (Fig. 3D). Meanwhile, miR-653-5p expression was reduced in BC tissues and cells (Fig. 3E, F). Clinical correlation analysis found that miR-653-5p was negatively linked with circAGFG1 expression (Fig. 3G). RT-qPCR found that depression of circAGFG1 enhanced miR-653-5p expression in MDA-MB-231 cells (Fig. 3H).

All in all, miR-653-5p is regulated by circAGFG1.

Repression of miR-653-5p reverses the effects of silencing circAGFG1 on BC cells

To further study the role of CircAGFG1 in regulating the expression of miR-653-5p in BC, rescue experiments were executed. The promotion of miR-653-5p by sh-CircAGFG1 was reversed by miR-653-5p inhibitor (Fig. 4A). Colony formation and CCK-8 experiments showed that miR-653-5p inhibitor eliminated the inhibition of sh-circAGFG1 on cell proliferation (Fig. 4B, C). Flow cytometry showed that the proapoptotic effect of sh-circAGFG1 was reversed by miR-653-5p inhibitor (Fig. 4D). Transwell assay showed that sh-circAGFG1 inhibited cell invasion and migration, while miR-653-5p inhibitor prevented this change (Fig. 4E). Detection of glycolysis-related indicators showed that sh-circAGFG1 reduced glucose consumption, lactate production, and ATP/ADP ratio, but this phenomenon was reversed by miR-653-5p inhibitor (Fig. 4F–H). In addition, sh-cir-

cAGFG1 inhibited MMP9 and GLUT1 expression and promoted Bax expression, while miR-653-5p inhibitor blocked these protein changes (Fig. 4I).

The above data suggest that circAGFG1 affects BC cell progression *via* targeting miR-653-5p.

YWHAE is a functional target of miR-653-5p in BC cells

Bioinformatics analysis on https://starbase.sysu.edu.cn found the multiple complementary binding sites in miR-653-5p and YWHAE (Fig. 5A). It turned out that miR-653-5p mimic effectively suppressed the luciferase activity of YWHAE-WT 3'UTR (Fig. 5B). Verified by RNA-pull down assay, YWHAE could specifically combine with miR-653-5p (Fig. 5C). The elevation of YWHAE expression was discovered in BC tissues and cells (Fig. 5D-G). Clinical correlation analysis found that YWHAE expression was positively linked with circAGFG1 expression and negatively associated with miR-653-5p expression (Fig. 5H, I). Furthermore, in MDA-MB-231 cells, down-regulation of circAGFG1 or enhancement of miR-653-5p reduced YWHAE expression (Fig. 5J).

The above data indicate that YWHAE is the downstream gene of miR-653-5p.

Elevation of miR-653-5p depresses BC cell effects *via* targeting YWHAE

For further investigating the link between miR-653-5p and YWHAE, a functional rescue experiment was performed. YWHAE expression was significantly increased after transfection of the YWHAE overexpression vector, and the inhibitory effect of miR-653-5p mimic on YWHAE was reversed by the YWHAE overexpression vector (Fig. 6A, B). CCK-8 and colony formation experiments showed that the inhibitory effect of overexpression of miR-653-5p on cell proliferation was reversed by overexpression of YWHAE (Fig. 6C, D). In addition, the promoting effect of overexpression of miR-653-5p on apoptosis was reversed by overexpression of YWHAE (Fig.

6E). Transwell experiments showed that overexpression of miR-653-5p inhibited cell invasion and migration, but overexpression of YWHAE prevented this phenomenon (Fig. 6F). Commercial kit results showed that the inhibitory effects of overexpression of miR-653-5p on cellular glucose consumption, lactate production, and ATP/ADP ratio were reversed by overexpression of YWHAE (Fig. 6G–I). Western blot showed that overexpression of miR-653-5p inhibited the expression of MMP9, GLUT1 and promoted the expression of Bax, and overexpression of YWHAE reversed the changes of these proteins (Fig. 6J).

The above data suggest that miR-653-5p affects BC cell progression by targeting YWHAE.

CircAGFG1 knockdown restrains tumor growth *in vivo*

To determine whether circAGFG1 silencing restrained tumor growth *in vivo*, sh-NC or sh-CircAGFG1-transfected MDA-MB-231 cells were implanted into nude mice. sh-CircAGFG1 reduced the tumor volume and weight of mice (Fig. 7A, B). Meanwhile, circAGFG1 knockdown suppressed circAGFG1 and YWHAE expression in tumor tissues, while elevated miR-653-5p expression (Fig. 7C, D). IHC analysis illustrated that repression of circAGFG1 repressed Ki67 and MMP9 expression in tumor tissues (Fig. 7E). All in all, it is suggested that circAGFG1 knockdown restrains BC tumor growth *in vivo*.

DISCUSSION

BC is an extremely familiar cancer worldwide and a momentous cause of death in women. Its high morbidity, high recurrence rate and unpleasing prognosis are the main reasons of patient death. Hence, in-depth studies of the molecular mechanisms of BC are urgently needed to confirm effective targets for BC therapy. With the in-depth research on regulatory mechanism in cancer, the study direction has gradually shifted from coding RNA to ncRNAs. BC development is complexly controlled by diversified ncRNAs, including circRNAs, and miRNAs (Liu et al., 2021). In the research, it was discovered for the first time that circAGFG1 combined with miR-653-5p, which targeted YWHAE, thereby facilitating MDA-MB-231 cell biological behaviors and glycolysis *in vitro* and accelerating tumor growth *in vivo*.

CircAGFG1 has been confirmed to be elevated in BC and may be implicated in BC patients' diagnosis and prognosis. A study has shown that circRNAs are more stable in tissues and exosomes compared with traditional linear RNAs (He et al., 2021). Likewise, in the research, circAGFG1 expression was elevated in BC, was not easily degraded by RNase R and was abundantly exhibited in the cytoplasm. In addition, this study also found that circAGFG1 elevation was associated with poor pathological features and prognosis of BC patients. CircAGFG1 expression is enhanced in various cancers like esophageal cancer (Fu et al., 2021), cervical cancer, and triple-negative BC (Zhang et al., 2021), and repressing its expression can restrain the malignant progression of cancer. In the research, the knockdown of circAGFG1 restrained BC cell biological behaviors and glycolysis, and depressed tumor growth *in vivo*. This suggests that circAGFG1 may offer a therapeutic target for BC. It has been reported that cells can secrete circRNAs through exosomes to regulate tumor growth and metastasis. As exampled, in BC, has_circ_0000615 is packaged by exosomes and transported into the circulating blood (Mashouri et al., 2019). Therefore, subsequent studies need to detect BC cell exosomes to detect the role of circAGFG1.

CircRNAs perform as ceRNAs to interact miRNAs. Through bioinformatics analysis, it was found that CircAGFG1 can sponge various miRNAs. Among these miRNAs, miR-653-5p was selected as circAGFG1's target in the research. Elevation of miR-653-5p refrains the proliferation and migration of melanoma (Liu et al., 2020), together with the proliferation of cervical cancer cells (Wu et al., 2020). MiR-653-5p's functions in BC have been initially clarified, and this miRNA is lowly expressed in BC and has anti-tumor effects. In the research, miR-653-5p expression was inhibited in BC. Furthermore, miR-653-5p inhibitor could partially suppress the effects of circAGFG1 silencing on BC cells.

YWHAE acts as a transcription factor to activate or depress the transcription of target genes. For example, targeting YWHAE to activate apoptotic signaling can suppress cutaneous squamous cell carcinoma (Holmes et al., 2021). Previous studies have shown that YWHAE is elevated in BC and motivates the metastasis and chemotherapy of BC cells, and may become a latent therapeutic target for BC. However, the mechanism by which the circAGFG1/miR-653-5p/YWHAE axis affects BC has not been investigated. In the research, it was also found that YWHAE expression was elevated in BC. In addition, it was originally discovered that YWHAE was a downstream gene of miR-653-5p. Meanwhile, YWHAE can integrate multiple signaling pathways by interacting with different proteins in cancer progression (Ou et al., 2021). In addition, YWHAE-NUTM2 has been reported to deregulate both v-raf-leukemia viral oncogene 1/v-Raf murine sarcoma viral oncogene homolog B and Hippo pathways, resulting in elevation of cyclin D1, which accelerates the progression of high-grade endometrial stromal sarcoma. Therefore, it was speculated that YWHAE might interact with NUTM2 protein to integrate signaling pathways, and then participate in the progression of BC, which needs to be further explored in follow-up studies.

Notably, circAGFG1 can affect MMP9, GLUT1, and Bax expression in BC cells by targeting and regulating the miR-653-5p/YWHAE axis. MMP9 can degrade matrix proteins, destroy extracellular matrix, and promote tumor cell invasion and metastasis (Augoff et al., 2022). In addition, high GLUT1 expression is associated with metabolic reprogramming of tumor cells, including increased glucose uptake, lactic acid production, and acidified microenvironment (Pezzuto et al., 2020). Bax activation can increase the permeability of the mitochondrial outer membrane and release apoptosis signaling molecules such as cytochrome C in mitochondria, thus inducing apoptosis (Edlich et al., 2018). In this study, we speculate that circAGFG1's function in promoting BC cell invasion and migration is significantly related to the increased expression of MMP9. In addition, circAGFG1 can increase the glycolytic capacity of BC cells by promoting GLUT1 expression, which will provide powerful energy for the proliferation and metastasis of BC cells. The inhibitory effect of circAGFG1 on Bax may reduce the permeability of the mitochondrial membrane of BC cells, thereby preventing the release of apoptosis signaling molecules, which will help to reduce the apoptosis rate of cancer cells.

However, this study is limited in that the effect of circAGFG1 in multiple models of each BC subtype requires further investigation. In addition, the mechanism of YWHAE regulating BC remains to be further explored. Future multicenter trials are required to illustrate circAGFG1's function in BC.

CONCLUSION

Taken together, this study demonstrates that circAG-FG1 targeted regulation of YWHAE expression *via* acting as a sponge of miR-653-5p, thereby promoting BC progression. CircAGFG1/miR-653-5p/YWHAE axis may offer as a latent therapeutic target for BC.

Downregulation of circular RNA 00091761 protects against heart failure after myocardial infarction *via* microRNA-335-3p/ ASCL4 axis

Qian Wei[1#], Mengni Jiang[2#], Bin Tang[1], Lanlan You[1] and Lin Zhao[1✉]

[1]Department of Ultrasonics Medicine, Chengdu Medical College, Clinical Medical College and The First Affiliated Hospital of Chengdu Medical College, Sichuan 610500 China; [2]Department of Cardiovascular Medicine, Chengdu Medical College, Clinical Medical College and The First Affiliated Hospital of Chengdu Medical College, Sichuan 610500 China

Our research tended to explore the biological roles and expression status of circ_00091761 in HF after MI. The hypoxia reoxygenation (H/R) injured H9c2 cells model was constructed to simulate HF after MI. The expression of circ_0091761 was examined in H/R injured H9c2 cells by qRT-PCR. Then, the effect of circ_0091761 expression on the proliferation of H/R injured H9c2 cells was evaluated by CCK-8 along with TUNEL assay. Secretion of lactate dehydrogenase (LDH), reactive oxygen species (ROS), Fe^{2+}, glutathione (GSH), and malondialdehyde (MDA) was measured to evaluate cell ferroptosis of H/R injured H9c2 cells, along with protein levels of glutathione peroxidase 4 (GPX4), solute carrier family 7 member 11 (SLC7A11), and transferrin receptor protein (TFRC). Luciferase reporter as well as RNA pulldown assays revealed the binding relationship between miR-335-3p and circ_0091761 or ASCL4. Circ_0091761 was upregulated in H/R injured H9c2 cells. Knockdown of circ_0091761 promoted cell proliferation and suppressed ferroptosis of H/R injured H9c2 cells. Interestingly, circ_0091761 sponges miR-335-3p to upregulate acyl-CoA synthetase long-chain family member 4 (ACSL4) expression. miR-335-3p inhibitor attenuated the effects of circ_0091761 knockdown on cell proliferation and ferroptosis in H/R injured H9c2 cells. Additionally, upregulated ACSL4 abrogated elevated miR-335-3p-induced effects on H/R injured H9c2 cells. Circ_0091761 inhibited cell proliferation and accelerated ferroptosis of H/R injured H9c2 cells by sponging miR-335-3p to upregulated TFRC axis. Therefore, Inhibition of circ_0091761 may protect against HF after MI.

INTRODUCTION

Heart failure (HF) is an acute decompensation of cardiac function under various causes. The etiology and inducement of HF are complex and diverse. The necrosis of myocardial cells caused by acute ischemia and hypoxia of the coronary artery during myocardial infarction (MI) is the main cause of HF and also one of the common causes of acute decompensation of HF (Bahit *et al.*, 2018; Orrem *et al.*, 2018). HF after MI seriously endangers the life and health of patients. Early accurate judgment will greatly benefit the treatment and prognosis of the disease.

In recent years, a new type of programmed death, named ferroptosis, is found to play an essential role in diverse disorders (Xie *et al.*, 2016). Because of the dysfunction of oxidative metabolism of the cell membrane phospholipids, biofilm polyunsaturated fatty acids (PU-FAs) lipid peroxidation occurs reduced glutathione (GSH) in cells will not be able to return the excess of harmful lipid hydroperoxide as harmless fatty alcohols, free iron ion mediated Fenton reaction catalyzed the accumulation of lipid free radicals within the cell leads to cell ferroptosis (Cao & Dixon, 2016). Accumulated evidence demonstrates that ferroptosis participates in HF after MI (Hu *et al.*, 2021). However, the specific mechanism needs to be further researched to clarify.

Circular RNAs (circRNAs) are a class of non-coding RNAs (ncRNAs) which can regulate the expression of several key genes by combining with microRNAs (miR-NAs) or other molecules (Meng *et al.*, 2017; Ashwal-Fluss *et al.*, 2014; Zhang *et al.*, 2017). Most circRNAs show miRNA binding capabilities, and are identified as miRNA sponges and enhance downstream gene expression by sponging miRNA (Li *et al.*, 2019). Recently, researchers found the significance of circRNAs in regulating cell functions and disease processes (Meng *et al.*, 2017; Ashwal-Fluss *et al.*, 2014; Zhang *et al.*, 2017). Furthermore, growing evidence shows that circRNA has the potential to become a promising biomarker for diagnosis and therapeutic targets of HF after MI (Devaux *et al.*, 2017; Altesha *et al.*, 2019). For instance, through the ceRNA mechanism, the circHipk3 accelerates cardiac regeneration after MI via the miR-133a-CTGF axis (Si *et al.*, 2020).

CircRNA_0001654, circRNA_0091761, circR-NA_0405624, and circRNA_0406698 have been identified to be obviously upregulated in MI (Zhao *et al.*, 2020)., and circRNA_0091761 expressions were demonstrated to be the most significant difference in H/R injured H9c2 cells.

Therefore, this study aimed to further explore the specific mechanism of circRNA_0091761 in HF after MI *in vitro*.

MATERIALS AND METHODS

Materials

H9c2 rat cardiomyoblast cell line (American Type Culture Collection, USA). Primary antibodies and internal reference protein (Abcam Company, USA): anti-GPX4 (ab125066, 1: 1000), anti-SLC7A11 (ab175186, 1: 3000), and anti-TFR1 (ab214039, 1: 1000). anti-GAPDH (ab8245,1: 1000). HRP labeled anti-rabbit secondary antibody (Beyotime Biotech, China). Plasmids for cell transfection (Gibco, USA): si-circ_0091761 1#, si-circ_0091761 2#, miR-335-3p mimic, miR-335-3p inhibitor, oe-ACL4, and their negative controls. Polybrene and purinomycin (Sigma, USA). Lipofectamine 3000 and the reverse transcription kit (Invitrogen, USA). Fetal bovine serum (FBS; Biological Industries, USA). PrimeScript™ RT-PCR Kit (Vazyme Biotech, China). TRIzol reagent (Invitrogen, USA), Nanodrop 2000 spectrophotometer (Mettler Toledo, China). RIPA lysate (Beyotime, China). Primer sequences for circ_0091761, miR-335-3p, and all mRNAs were designed by RiboBio (Guangzhou, China). RNase R treatment (Genesee, Guangzhou, China). miRNeasy Mini Kit (QIAGEN, Dusseldorf, Germany). Actinomycin D (Merk, USA). SuperScript First-Strand Synthesis Kit (Invitrogen, USA). LDH Cytotoxicity Assay Kit (Beyotime, China). Spectrophotometer (Thermo Fisher, USA). Oxidation-sensitive fluorescent probe DCFH-DA (Sigma, USA). Iron Assay Kit (ab83366, Abcam, USA). Glutathione Assay Kit (CS0260; Sigma, USA). Malondialdehyde Kit (ab118970, Abcam, USA). Cell counting kit 8 (CCK-8; Beyotime, China). TUNEL detection kit (ab66110, Abcam, USA). Microscope (Nikon, Japan). BCA kit (Sigma, USA). PVDF membranes (Bio-Rad, USA). Dual-Luciferase Reporter Assay kit (K801-200; BioVision Tech, San Francisco, USA). Pierce™ Magnetic RNA-Protein Pull-Down Kit (Thermo Fisher, Waltham, MA, USA).

Cell culture

H9c2 cells were cultured using a DMEM medium containing 10% FBS and 1% penicillin/streptomycin, and placed in an incubator (5% CO_2, 37°C). Then, the hypoxia-reoxygenation (H/R) injured H9c2 cells model was conducted to mimic HF after MI. H9c2 cells were incubated in a hypoxic environment (95% N_2 and 5% CO_2) at 37°C for 3 h. Then, DMEM free of FBS was added to H9c2 cells in a standard incubator for 4 h.

qRT-PCR

qRT-PCR was performed to measure the mRNA levels of circRNA_0001654, circRNA_0091761, circRNA_0405624, circRNA_0406698, miR-335-3p, and ACSL4. Firstly, TRIzol was used to isolate RNA of H/R injured H9c2 cells, and RNA concentration was analyzed using a spectrophotometer. M-MLV was used to synthesize cDNA through reverse transcription. qRT-PCR was conducted with the PrimeScript™ RT-PCR Kit. GAPDH and U6 were used as reference genes. Relative gene expression was calculated through the $2^{-\Delta\Delta Ct}$ method.

Stability detection of circular RNA

RNase R treatment is mainly used for circRNA identification and stability detection (Xiao MS & Wilusz JE, 2019). 5 μg total RNA extracted from H/R injured H9c2 cells were digested by RNase R enzyme. The circRNA_0091761 and the linear type mRNA levels were detected by qRT-PCR with 2 μg/mL actinomycin D for 0, 4, 8, 12, and 24 h.

Detection of lactate dehydrogenase (LDH) activity

H9c2 cells were seeded in 96-well plates and cultured in a medium containing LDH reagent for 0.5 h to measure LDH release according to the LDH kit procedure, which was provided by Nanjing Jiangcheng Bioengineering Institute (Nanjing, China).

Detection of reactive oxygen species (ROS) activity

H9c2 cells were treated with DCFH-DA (10 μmol/L) for 0.5 h at 37°C. Then, the fluorescence intensity of each group was detected under a fluorescence microscope (488 nm excitation wavelength, 525 nm emission wavelength).

Detection of Fe^{2+} content

After H9c2 cells were lysed, the Fe^{2+} level of cells in each group was detected according to the procedure of the Fe^{2+} detection kit, which was provided by Nanjing Jiangcheng Bioengineering Institute (Nanjing, China).

Detection of glutathione (GSH)content

After H9c2 cells were lysed, the GSH level of cells in each group was detected according to the procedure of the GSH Assay Kit, which was provided by Nanjing Jiangcheng Bioengineering Institute (Nanjing, China).

Detection of malondialdehyde (MDA)

After H9c2 cells were lysed, the MDA level of cells in each group was detected according to the procedure of the MDA Kit, which was provided by Nanjing Jiangcheng Bioengineering Institute (Nanjing, China).

Cell viability assay

Cell counting kit 8 (Beyotime, Shanghai, China) has been used to evaluate the cell viability of $H9C_2$ cells of each group. Cells were collected and seeded into a 96-well plate after successful transfection. Afterwards, cell viability was detected using a microplate under the absorbance of 450 nm after a supplement of CCK-8 reagents.

TUNEL assay

H9c2 cell death was measured by a TUNEL detection kit according to the instructions of the manual (Beyotime). The H/R injured H9c2 cells were observed under a microscope.

Western blotting assay

Ferroptosis-related proteins including glutathione peroxidase 4 (GPX4), solute carrier family 7 member 11 (SLC7A11), and transferrin receptor protein (TFRC) were measured in H9c2 cells of each group. Total protein was extracted from the H9c2 cells by RIPA buffer, and determined with the BCA kit. Subsequently, proteins were isolated with 12% SDS-PAGE gel and were moved onto PVDF membranes. Then the membranes were blocked with 5% defatted milk for 2 h and then incubated with primary antibodies overnight at 4°C. Immune complexes were then incubated with secondary antibody. Finally, the ECL chemiluminescence method was used to detect the expression of each protein. All experiments were repeated three times.

Dual-luciferase reporter assay

According to the reported methods, circR-NA_0091761 as well as ACSL4 recombinant pyratinase reporter plasmids containing the binding sequence of miR-335-3p and regroup plasmids containing the abrupt change of binding sequence were constructed. H9c2 cells (1×10^5/well) seeded in a 12-well plate were transfected with 1.5 μg recombinant luciferase reporter plasmid, 100 nmol/L miR-335-3p mimic and 10 ng PRL-TK (internal reference plasmid) for 24 h, the intensity of firefly luciferin and renal luciferin were measured.

RNA pull-down assay

500 μg streptavidin magnetic beads combined with a 200 pmol biotin labeled miR-335-3p mimic were added to the RNA extracted from the H9c2 cells. The complexes were gently mixed at room temperature and incubated for 30 min. After eluting buffer was added, the pulled RNA complex was then collected. The circRNA_0091761 and ASCL4 level was quantitatively analyzed by qRT-PCR.

Statistical analysis

Data were analyzed with GraphPad Prism version 8.3 and presented as mean ± SD. Student's t-test (two groups), as well as one-way ANOVA (multiple groups), were applied for difference analysis. A P value less than 0.05 was deemed statistically significant.

RESULTS

Circ_0091761 is highly expressed in H/R injured H9c2 cells

Expression of 4 circRNAs which have been identified to be highly expressed in MI was detected in H/R injured H9c2 cells, among which circ_0091761 was obviously highly expressed (Fig. 1A). The results of RNase R treatment indicated that the expression level of the linear group was substantially lower than that in circ_0091761 group (Fig. 1B). Meanwhile, circ_0091761 showed more stable mRNA expression compared with a linear group (Fig. 1C). The level of GSH in H/R injured and RSL3 treated H9c2 cells was notably decreased and increased in Ferrostatin-1 group; however, LDH, ROS, Fe^{2+}, as well as MDA levels were notably elevated by H/R injury and RSL3 and reduced by Ferrostatin-1 (Fig. 1D–I).

Inhibition of circ_0091761 promotes cell viability and inhibited ferroptosis of H/R injured H9c2 cells.

The expression of circ_0091761 was decreased after small interference RNA was transfected into H/R injured H9c2 cells. Circ_0091761 declined more significantly in group si-circ_0091761 1#, which was used in subsequent experiments (Fig. 2A). Knockdown of circ_0091761 notably improved cell viability (Fig. 2B), and suppressed

cell death (Fig. 2H). Simultaneously, LDH, ROS, Fe^{2+}, and MDA concentrations were declined while secretion of GSH was induced after circ_0091761 was silenced (Fig. 2C–G). Furthermore, ferroptosis-related proteins were detected. H/R injury decreased the GPX4 as well as SLC7A11 expression and increased the expression of TFR1, which were reversed by si- circ_0091761 significantly (Fig. 2I).

Circ_0091761 can bind with miR-335-3p

Potential interactions between circRNAs and miRNAs were evaluated using a Circular RNA Interactome on-line database (https://circinteractome.irp.nia.nih.gov/), and miR-335-3p was expected to bind with circ_0091761 (Fig. 3A). The luciferase activity reporter results demonstrated that luciferase-labeled miR-335-3p mimic and wild-type circ_0091761 co-transfection groups were decreased compared to that of the NC mimic (Fig. 3B). Furthermore, circ_0091761 was primarily enriched in the biotin-miR-335-3p group analyzed by RNA pull-down assay (Fig. 3C). Inhibition of circ_0091761 upregulated the expression of miR-335-3p (Fig. 3D). Furthermore, miR-335-3p was lowly expressed in H/R injured H9c2 cells (Fig. 3E).

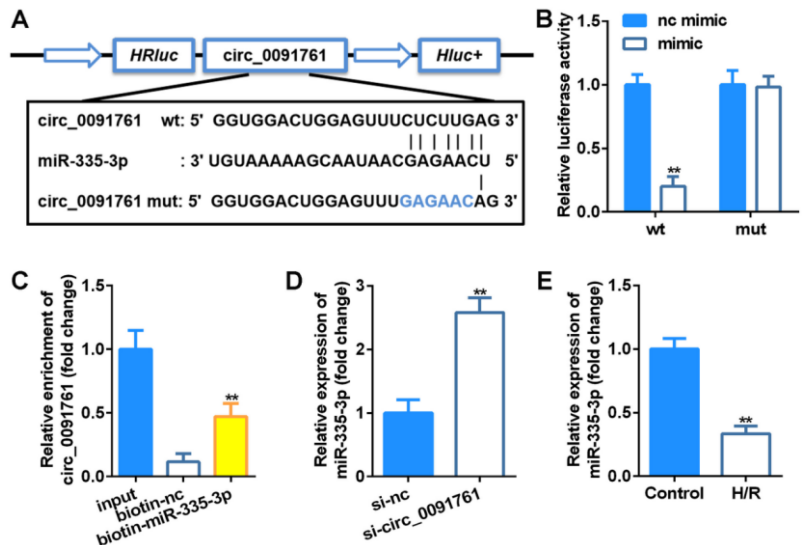
Suppression of miR-335-3p reverses the effects of circ_0091761 on cell viability and ferroptosis in H/R injured H9c2 cells

miR-335-3p expression was downregulated by miR-335-3p inhibitor and upregulated by miR-335-3p mimic, suggesting that H/R injured H9c2 cells were successfully transfected (Fig. 4A). miR-335-3p inhibitor obviously switched the effects of si-circ_0091761 on cell proliferation (Fig. 4B) as well as cell death (Fig. 4H). Furthermore, inhibited miR-335-3p alleviated the effects of downregulated circ_0091761 on the secretion of LDH, ROS, Fe^{2+}, MDA, and GSH (Fig. 4C-G) and the expression levels of GPX4, SLC7A11, and TFR1 proteins (Fig. 4I).

miR-335-3p directly targets ACSL4

TargetScan7.2 online database algorithm (http://www.targetscan.org/mmu_72/) was used to predict potential downstream targets of miR-335-3p and we identified ACSL4 as the potential candidate (Fig. 5A). Luciferase activity, as well as RNA pull-down assays further confirmed the binding relationship between miR-335-3p and ACSL4 (Fig. 5B and 5C). Furthermore, ASCL4 expression was negatively regulated by miR-335-3p (Fig. 5D).

Figure 5. miR-335-3p directly targeted ACSL4.
(**A**) Bioinformatics predicted the binding sites between miR-335-3p and ASCL4. (**B**) Dual-luciferase reporter assay was conducted to confirm the association between ASCL4 and miR-335-3p, $^{**}p<0.01$. (**C**) RNA pull-down assay revealed the enrichment of ASCL4 on biotin-miR-335-3p, $^{**}p<0.01$, compared with the biotin-NC group. (**D–E**) qRT-PCR analysis for the expression of ASCL4, $^{**}p<0.01$.

Figure 6. Overexpression of ACSL4 inhibited the effects of upregulated miR-335-3p.
(**A**) ACSL4 expression levels were detected by qRT-PCR in H9c2 cells after transfection, $^{**}p<0.01$. (**B**) CCK-8 assay was applied for cell viability detection, $^{**}p<0.01$, compared with the control group; $^{#}p<0.05$, compared with the H/R+ mimic+ OE-NC group. (**C–G**) Levels of LDH, ROS, Fe^{2+}, GSH, and MDA in H/R injured H9c2 cells after transfection, $^{**}p<0.01$, compared with the control group; $^{#}p<0.05$, $^{##}p<0.01$, compared with the H/R+ mimic+ OE-NC group. (**H**) Images and quantized bar chart of TUNEL stained cells, $^{**}p<0.01$, compared with the control group; $^{#}p<0.05$, compared with the H/R+ mimic+ OE-NC group. (**I**) Expression of GPX4, SLC7A11, and TFR1 proteins detected by western blotting.


Besides, ACSL4 was remarkably highly expressed in H/R injured H9c2 cells (Fig. 5E).

Overexpression of ACSL4 inhibits the effects of upregulated miR-335-3p

As indicated in Fig. 6A, ACSL4 was significantly highly expressed after transfection. Compared with miR-335-3p-overexpressing cells, co-transfection with miR-335-3p and ACSL4 vectors significantly suppressed cell viability (Fig. 6B) and facilitated ferroptosis (Fig. 6C–I).

DISCUSSION

HF is a common complication of MI. MI combined with HF is a clinically acute severe disease with high mortality. There is clinical value in identifying markers that can be obtained early and interpreted easily. Our study suggested that inhibition of circ_0091761 protected HF after MI by upheaving miR-335-3p to inhibit ACSL4 *in vitro*.

Accumulating studies have shown that ferroptosis plays a crucial role in the progression of cardiac dysfunction after MI (Park TJ *et al.*, 2019). In the mouse MI model, GPX4 is downregulated and heme oxygenase 1 (Hmox1) is upregulated in myocardial cells to degrade heme and release free iron, leading to mitochondrial dysfunction and ferroptosis. In addition, inhibition of GPX4 transcription in isolated H9c2 cells and neonatal mouse ventricular myocytes resulted in the accumulation of lipid hydroperoxides leading to cell ferroptosis (Park *et al.*, 2019, Li *et al.*, 2019; Fang *et al.*, 2019). These results suggest that ferroptosis is an important pathophysiological change of cardiac function injury after MI. What's more, ferroptosis participates in the occurrence and development of HF (Fang *et al.*, 2020; Vegter *et al.*, 2016). Inhibiting ferroptosis can reduce cardiomyocyte hypertrophy, improve ventricular dilation, and enhance the function of myocardial dilation and contraction (Fang *et al.*, 2020). In vitro cardiomyocytes pretreated with isoproterenol could inhibit the expression of GPX4 and ferritin heavy chain 1, increase the lipid hydroperoxide, and lead to ferroptosis in cardiomyocytes (Park *et al.*, 2019; Fang *et al.*, 2020). Antagonizing ferroptosis can effectively slow down the process of HF (Fang *et al.*, 2019; Friedmann *et al.*, 2014; Li *et al.*, 2020). Ferroptosis inhibitor can effectively inhibit the increase of free iron and lipid peroxidation in cardiomyocytes and reduce ferroptosis induced by isoproterenol (Fang *et al.*, 2019; Zou *et al.*, 2020).

Previous studies have shown that the Fenton reaction of ferrous iron in a labile iron pool (LIP) can produce a large number of ROS (Sui *et al.*, 2018). When the production of ROS exceeds the compensatory limit of GSH/GPX4, PUFAs containing arachidonic acid and adrenal acid are easily peroxidized and accumulated by ROS, leading to ferroptosis in cells (Yang *et al.*, 2016). In other words, GSH/GPX4 can inhibit lipid peroxidation in the cell membrane, thus inhibiting ferroptosis in cells. However, a large amount of studies have discovered new pathways that inhibit cell iron death during GSH/GPX4 inactivation. It was found that the N-terminus of Ferrastatin-1 was mystoacylated to promote the recruitment of coenzyme Q10 to the cell membrane, reducing it to a reduced coenzyme, and inhibiting ferroptosis in cells (Bersuker *et al.*, 2019). The antagonistic effect of FSP1 on ferroptosis was independent of GSH/GPX4 (Doll *et al.*, 2019). In addition, the metabolites of guanosine triphosphate hydrolase 1 (GCH-1), tetrahydrobiopterin and dihydrobiopterin (BH4/BH2), can selectively inhibit

the peroxidation of membrane polyunsaturated fatty acids containing two acyl-tail, and GCH1 can promote the production of coenzyme Q10 and inhibit cell ferroptosis in collaboration with FSP1 (Kraft *et al.*, 2020). These studies also found a range of genes that suppress lipid peroxidation in the absence of GPX4, providing new directions for future research. At present, the research on the regulation factors of iron death is still insufficient and needs further exploration.

Circ_0091761 is a newfound circRNA with a sliced length of 709bp, located on the X chromosome. Zhao *et al* collected blood samples of coronary arteries of MI patients as well as healthy controls, the intersection results of multiple bioinformatics analysis data showed that 4 dysregulated circRNAs (circRNA_0001654, circRNA_0091761, circRNA_0405624, and circRNA_0406698) may be associated with the regulation of MI process (Zhao *et al.*, 2020). In the present research, our data suggested that circRNA_0091761 was the highest expressed circRNA identified in H/R injured H9c2 cells, and was further elevated by ferroptosis inducer RSL3 whereas downregulated by ferroptosis inhibitor Ferrastatin-1, suggesting that upregulation of circ_0091761 may be associated with ferroptosis in H/R injured H9c2 cells. Subsequently, inhibition of circ_0091761 promoted cell viability and suppressed ferroptosis of H/R injured H9c2 cells, demonstrating that circ_0091761 may protect against HF after MI by suppressing ferroptosis *in vitro*, which was in line with previous studies (Fang *et al.*, 2020).

Recently, various studies have reported that miRNAs play essential roles in cardiovascular diseases (Vegter *et al.*, 2016). For instance, the downregulation of miR-221-3p and miR-222-3p promoted myocardial fibrosis of HF (Verjans *et al.*, 2018). In MI studies, miRNA-21 treatment of cardiomyocytes and endothelial cells significantly suppressed apoptosis and significantly improved cardiac function (Song *et al.*, 2019). In this study, we hypothesized that circRNA_0091761 might bind certain miRNAs to regulate HF after MI. Our data indicated that miR-335-3p has a specific binding effect with circRNA_0091761. Further functional experiments confirmed that miR-335-3p inhibitor could effectively reduce the proliferation promotion and ferroptosis inhibition effects of suppressed circrNA_0091761 on H/R injured H9c2 cells. All results confirmed that circRNA_0091761 can regulate the expression of related genes by binding miR-335-3p and play a role in inhibiting ferroptosis and thus HF progression.

ACSL4 drives ferroptosis by oxidizing cell membrane phospholipids, whichhave been recognized to be a typical marker of ferroptosis (Doll *et al.*, 2017; Song *et al.*, 2019). The ectonucleotide pyrophosphatase-phosphodiesterase 2 (ENPP2)/ lysophosphatidic acid (LPA) protected myocardial cells from erastin induced ferroptosis by regulating the expression of GPX4, ACSL4 and Nrf2 (Bai *et al.*, 2018). Our finding demonstrated that ACSL4 was a downstream gene of miR-335-3p, and overexpression ACSL4 obviously revealed miR-335-3p mimicked induced effects on cell viability as well as ferroptosis. Thence, on the basis of these findings, we concluded that circ_0091761 promoted ferroptosis in H/R injured H9c2 cells via binding with miR-335-3p to upregulate ACSL4.

CONCLUSION

The findings of the present study indicated that circ_0091761 functioned as a ceRNA to regulate ACSL4 expression by sponging miR-335-3p to regulate HF after the MI process *in vitro*. Therefore, inhibition of

circ_0091761 may be a potential target for protection against HF after MI.

Review

The role of USP1 deubiquitinase in the pathogenesis and therapy of cancer

Svitlana Antonenko[1]✉, Michael Zavelevich[2] and Gennady Telegeev[1]

[1]Department of Molecular Genetics, Institute of Molecular Biology and Genetics, National Academy of Sciences of Ukraine, Kyiv, Ukraine; [2]Department of Oncohematology, RE Kavetsky Institute of Experimental Pathology, Oncology and Radiobiology, National Academy of Sciences of Ukraine, Kyiv, Ukraine

Ubiquitin-specific protease 1 (USP1) is an important deubiquitinating enzyme (DUB) involved in the maintenance of genome integrity, cell cycle, and cell homeostasis. USP1 overexpression is a characteristic feature of various cancers, correlating with a poor prognosis. The review summarizes the recent knowledge in understanding the role of deubiquitinase USP1 in the stabilization of oncoproteins and tumor suppressors, as a critical event in cancer development and progression. The putative mechanisms of USP1 involvement in some prevalent human cancers are discussed. The numerous data demonstrate that inhibition of USP1 suppresses the proliferation and viability of malignant cells, sensitizes them to radiation and increases their sensitivity to various chemotherapeutic agents, which opens up new opportunities for combined therapy of malignant neoplasms.

INTRODUCTION

Deubiquitinating enzymes (DUB) are proteases that regulate ubiquitin dynamics by selectively cleaving mono- or polyubiquitin from protein substrates (Henning *et al.*, 2021; Caba *et al.*, 2022). The deubiquitination is crucial for maintaining the stability of target proteins, and in the absence of proteolytic load on proteasome it affects the activity of substrates, cellular localization, interactions with other proteins, activation or silencing of gene expression, and the functioning of signaling pathways (Snyder *et al.*, 2021; Tu *et al.* 2022; Estavoyer *et al.*, 2022 Trulsson *et al.*, 2022). More than 500 protease genes have been identified in the human genome, about 100 of which belong to DUBs (Bonacci & Emanuele, 2021). Based on the homology of the active site, DUBs

are classified into six families: ubiquitin-specific proteases (USPs), ubiquitin carboxy-terminal hydrolases (UCHs), ovarian tumor proteases (OTUs), the Machado–Joseph disease proteases (MJDs), motif-interacting with ubiquitin-containing novel DUB family (MINDYs) and JAB1/PAB1/MPN (JAMMs). The first five families (USPs, UCHs, OTUs, MJDs, MINDYs) are cysteine proteases, while the JAMMs family belongs to metalloproteases (Mullard *et al.*, 2021; Lei *et al.*, 2021a; Caba *et al.*, 2022). The largest family among DUBs is USPs. Members of the USPs family have a conserved structural organization consisting of three subdomains, namely the "thumb" and "palm" with a catalytic site between them and the "fingers" that provide interaction with ubiquitin on substrates (Fraile *et al.*, 2012; Snyder *et al.*, 2021). Sometimes USPs have additional domains, such as ubiquitin-binding zinc finger domain, ubiquitin-interacting motifs and ubiquitin-associated, etc. (Du *et al.*, 2019; Yang *et al.*, 2019).

The physiological role of DUB is to ensure the homeostasis of critical cell functions, including genome stability, gene expression, cell cycle progression, proliferation, stem cell differentiation, chromosome segregation, growth factor signaling, redox regulation, endocytosis, apoptosis, etc. Deregulation of functional activity and expression of DUB correlates with neurodegenerative and immune diseases, development and progression of cancer (Jerabkova *et al.*, 2020; Wang *et al.*, 2022; Tu *et al.*, 2022; Liu *et al.*, 2022). The growing interest in DUBs as markers of oncogenic transformation and new therapeutic targets for cancer treatment seems to be justified.

The most studied DUB to date is ubiquitin-specific protease 1 (USP1). Quite often, DUB expression is altered in many cancers (Poondla *et al.*, 2019; Lai *et al.*, 2020). Hyperexpression of USP1 is observed in glioma, osteosarcoma, leukemia, hepatocellular carcinoma, gastric cancer, breast cancer, ovarian cancer, prostate cancer, colorectal cancer, etc., being associated with low patient survival and malignant neoplasm progression (Williams *et al.*, 2011; Xu *et al.*, 2019; Ma *et al.*, 2019b; Kuang *et al.*, 2021; Liao *et al.*, 2021a; Liang *et al.*, 2022; Li *et al.*, 2021; Chen *et al.*, 2022).

Recently, many breakthroughs have been made in elucidating the role of USP1 as an important regulator of basic cellular processes including metabolism, proliferation, and apoptosis. Ensuring the balance between ubiquitination and deubiquitination, USP1 is critical for maintaining the integrity of signaling networks, the proper performance of functions controlled in a spatio-temporal mode, and the homeostasis of the cell as a whole. The impairment of this balance could be important for tumorigenesis and cancer progression (Cui *et al.*, 2020; Meng *et al.*, 2022; Sun *et al.*, 2022). USP 1

could be a valuable diagnostic marker in various types of cancer. USP1 is directly involved in tumorigenesis by regulating the stability of oncoproteins or tumor suppressors (Sonego *et al.*, 2019; Coleman *et al.*, 2022; Song *et al.*, 2022). Finally, USP1 ability to modulate the level of oncoproteins accumulating in cancer cells makes it an attractive therapeutic target for cancer treatment.

THE STRUCTURE AND FUNCTION OF USP1

USP1 belongs to the most numerous and diverse USPs of the DUB family (Cruz *et al.*, 2021). The protein was first identified in 1998 as part of the Human Genome project by a group of scientists from Japan (Fujiwara *et al.*, 1998). The USP1 gene is localized to the p31.3-p32.1 band of chromosome 1. The USP1 protein consists of 785 amino acid residues with a predicted molecular weight of 88.2 kDa. In the structure of USP1, there is a typical DUB conserved USP domain, which consists of a N-terminal Cys box motif with a C90 catalytic residue and a C-terminal His box motif with H593 and D751 catalytic residues. (Fig. 1A). It is believed that these three amino acids form the so-called catalytic triad, which actually forms the catalytic core of DUB (Yu *et al.*, 2017; Woo *et al.*, 2022). The catalytic domain of the USP1 protein is one of the largest in the USPs family due to additional insertions (Bishop *et al.*, 2016). The first additional insert L1 (within 227-433 amino acid residues) located between box 2 and 3 is able to enhance USP1

activity due to natural affinity to DNA and allosteric activation after binding of UAF1 (Dharadhar *et al.*, 2021). Within L1 there are phosphorylation sites, including the most studied S313, nuclear localization signals (NLSs) and a degradation motif (degron). A second additional L2 insert (between amino acid residues 602-744) is located between boxes 5 and 6 and includes an autocleavage site (G670-G671). The third smallest L3 insert is located between 465-483 amino acid residues. It is believed that L1 and L3 insertions together are able to cause autoinhibition that could be reversed by binding to UAF1 cofactor. Co-deletion of L1 and L3 leads to hyperactivation of USP1, while deletion of the L2 or L3 insert does not affect its enzymatic activity (Dharadhar *et al.*, 2021).

The database "Catalog of somatic mutations in cancer" (COSMIC) contains information on dozens of mutations in USP1 (Fig. 1B), among which 51% are missense substitutions, 12% are synonymous substitutions, slightly more than 7% are frameshift deletions, and 4% are nonsense substitutions. It is known that mutation of any of the C90, H593 or D751 amino acid residues significantly reduces the catalytic activity of the USP1 protein. While the functional effect of the vast majority of mutations has not been fully elucidated, about forty different mutations have been detected in various types of cancer.

For the first time, as a critical regulator of genome integrity, USP1 was described in Fanconi anemia, where its functions are realized by FANCD2 deubiquitination (Nijman *et al.*, 2005). It is believed that USP1 in complex with the cofactor UAF1 moves along the replication fork

(A)

Colour	Mutation type	Number of samples (%)
	Nonsense substitution	14 (4.50%)

and deubiquitinates its partner proteins (Lim *et al.*, 2018; Dharadhar *et al.*, 2021). DNA-dependent metalloprotease Spartan can cause USP1 molecule to be removed from DNA acting selectively only on catalytically active forms of USP1, while minimally affecting mutants with changes in the autocleavage domain. This defines a new role of USP1 autocleavage in its increased retention on DNA. Spartan does not specifically act on protease sequences, cleaving substrates mainly in unstructured regions near lysine, arginine, and serine residues (Coleman *et al.*, 2022). The preferential association of Spartan with ubiquitin-modified proliferating cell nuclear antigen (PCNA) protects against PCNA deubiquitylation by USP1 and facilitates the access of polymerase responsible for a translesion DNA synthesis to the replication fork (Juhasz *et al.*, 2012). These facts highlight the role of USP1 autocleavage regulation as one of the components maintaining the steady function of DNA replication machinery and genome integrity (Coleman *et al.*, 2022).

It is also known that USP1 participates in the regulation of centrosome duplication, therefore, a violation of its activity causes the formation of an abnormal mitotic spindle, amplification of centrosomes, incorrect segregation of chromosomes, which leads to aneuploidy, instability of the genome, thus creating prerequisites for oncogenic transformation of cells (Jung *et al.*, 2016; Twest *et al.*, 2017). Today, a wide range of USP1 cellular substrates is known, the dynamic balance between the activity of DAB and ubiquitin E3 ligase underlies the modulation of protein degradation and localization, the formation of protein-protein interactions, gene expression, activation and deactivation of signaling pathways, ensures homeostasis and the performance of critical cell functions, such as metabolism, proliferation and cell differentiation, autophagy, apoptosis.

USP1/UAF1 PROTEIN COMPLEX

The catalytic activity of USP1 is dramatically increased in complex with the USP1 cofactor-associated protein 1 (UAF1), also known as protein 48, or WDR48 (Yu *et al.*,

Figure 2. Localization of USP1 and the mechanism of its interaction with the UAF1 cofactor.
A – schematic representation of the location of motifs in the USP1 protein, which determine its localization and interaction with the UAF1 cofactor, B – domain organization of the UAF1 cofactor, a representation of the motifs responsible for the interaction with USP1, C – USP1 is a nuclear protein that colocalizes with the Bcr-Abl oncoprotein in CML cells. In cells treated with ML323 inhibitor, which acts on the protein complex USP1/UAF1, USP1 is localized exclusively in the cytoplasm, which indicates that only its activated form enters the nucleus in a complex with a protein cofactor.

2017; Arkinson et al., 2018). The UAF1 protein contains eight WD40 repeats, seven of which have a β-propeller structure, the eighth repeat belongs to the so-called auxiliary domain. WD40 repeats are localized to the N-terminal domain of UAF1, which binds to USP1 and other substrate proteins, including USP12 and USP46. Deletion of 2–4 repeats of WD40 disrupts the formation of the USP1/UAF1 protein complex, and deletion of the 8th repeat and the adjoining region causes impairment of function of the UAF1 cofactor itself, which is believed to be a consequence of disruption of its tertiary structure. At the C-terminus of UAF1, a SUMO-like domain is located with two subdomains. Deletions in the proximal part of the C-domain do not affect the formation of the USP1/UAF1 protein complex (Yang et al., 2011; Goncalves et al., 2017; Rennie et al., 2022). Villamil et al. suggested that USP1 is activated by the UAF1 cofactor via modulation of the conformation of the active site of DAB, while changes due to remodeling of the ubiquitin-binding site are unlikely (Villamil et al., 2012). The altered UAF1 expression has critical consequences; in particular, UAF1 deficiency causes the death of mice in the embryonic period (Arkinson et al., 2018). The formation of a protein complex involves joint subcellular localization of partner proteins, however, USP1 belongs to nuclear proteins, while UAF1 is localized mainly in the cytoplasm. It is assumed that the USP1/UAF1 complex is formed in the cytoplasm and subsequently imported into the nucleus due to the NLS region of the USP1 protein (Yu et al., 2017). There are contradictory data regarding the mechanisms of formation of the USP1/UAF1 protein complex. Villamil and others (Villamil et al., 2012) showed that the site between 235-408 amino acid residues on the USP1 protein is responsible for cofactor binding. On the other hand, García-Santisteban and others indicated that USP1 binds to its cofactor due to the site within 420–520 amino acid residues (Fig. 2A, B) (García-Santisteban et al., 2013; Yu et al., 2017). Currently, it is not completely clear, which of two USP1 sites is responsible for binding to UAF1 or whether both sites are involved under different physiological conditions.

PHOSPHORYLATION OF USP1

Phosphorylation is an important post-translational modification that can stabilize proteins, increase or decrease their abundance in the cell, influence their activity, localization, interaction with other protein substrates (Wang et al., 2021). Extensive phosphoproteomic studies found that the activity of the vast majority of human USPs is regulated by phosphorylation (Villamil et al., 2012). Phosphorylation at the Ser313 site may be one of the ways of regulating the level of USP1 during the cell cycle, preventing its degradation during mitosis. (Cotto-Rios et al., 2011). Villamil and others (Villamil et al., 2012) showed that phosphorylation of USP1 at the Ser313 site is one of the conditions for the formation of the USP1/UAF1 protein complex, while protein phosphatase treatment can lead to its inactivation. Nevertheless, Olazabal-Herrero and others (Olazabal-Herrero et al., 2015) found that the mutant USP1, which is not phosphorylated at the Ser313 site, is also able to interact with UAF1. In addition, the formation of the USP1/UAF1 protein complex does not depend on the two other known sites, Ser42 and Ser67 (Villamil et al., 2012). Phosphorylation of USP1 at S42 and S331 is a prerequisite for Snail interaction and deubiquitination, which promotes platinum resistance and metastatic pro-

gression in ovarian cancer. In turn, under the influence of phosphatases, the level of interaction between Snail/USP1 proteins decreases (Sonego et al., 2019). Phosphorylated forms of USP1 at tyrosine sites were detected in Bcr-Abl-positive chronic myeloid leukemia cells. USP1 is believed to be phosphorylated by interaction with the oncoprotein Bcr-Abl, which has uncontrolled tyrosine kinase activity, leading to deregulation of downstream signaling pathways and disease progression (Antonenko & Telegeev, 2020).

Taking into account the role of phosphorylation in USP1 activation, one may suggest that the inhibition of protein kinases that phosphorylate USP1 may impair its functional activity. In fact, we have observed that in CML cells treated with imatinib, the level of colocalization of USP1 and Bcr-Abl is significantly reduced, while part of the USP1 protein remains in the cytoplasm, which may indicate a lack of deubiquitinase activity (Antonenko S., unpublished data). It has been also shown that tyrosine kinase inhibitors reduce the expression of USP47 in CML cells, which can be potentially relevant to other USPs, including USP1 (Lei et al., 2021b).

SUBCELLULAR LOCALIZATION OF USP1

Subcellular localization is a key for the realization of enzymatic activity by any protein, as it ensures the execution of a whole complex of intricately connected pathways and processes within and between different compartments (Garapati et al., 2020). A change in subcellular localization can affect the catalytic activity of a protein, disrupt its physiological functions, protein-protein interactions, downstream signaling pathways, which creates prerequisites for the development of inflammatory and neurodegenerative diseases, malignant neoplasms (Wang & Wang, 2021; Garapati et al., 2021). USP1 belongs to nuclear proteins. Three NLS sites in USP1 are responsible for its nuclear transport. The first sequence, which is between 14–37 amino acid residues, has a weak NLS and ensures uniform distribution of USP1 in the nucleus and cytoplasm. The second region of the NLS, located within 266–287 amino acid residues, ensures almost complete movement to the nucleus, the third region of the NLS within the range of 298–321 amino acid residues, provides a clear, but less marked relocation. In the physiological context, the two NLS signals (266–287), (298–321) are the main motifs of USP1 nuclear-cytoplasmic localization, while the third motif does not have a critical role. It is believed that USP1 and UAF1 form a complex in the cytoplasm, which subsequently translocates to the nucleus thanks to defined NLS (266–287), (298–321) motifs (Garcia-Santisteban, et al., 2012). The nuclear export signal (NES), located within amino acid residues 141-159 of USP1, may mediate the interaction with the export receptor CRM1, although the ultimate physiological significance of this sequence has not been established yet (Fig. 2A) (García-Santisteban et al., 2013). We have demonstrated that in CML cells treated with ML323 inhibitor USP1 remains in cytoplasm suggesting that only the activated form of DUB in a complex with the UAF1 cofactor can enter the nucleus (Fig. 2C) (Antonenko & Telegeev, 2020).

DEGRADATION OF USP1

USP1 level in cells is regulated by its proteasomal degradation. The degradation motif (degron) ensures APC/CCdh1-dependent degradation of USP1 in the G1 phase

of the cell cycle (García-Santisteban et al., 2013). Calpain (CAPNS1) stabilizes USP1 by activating Cdk5, which in turn inhibits cdh1 and consequent USP1 proteolysis. It is believed that the region of interaction with CAPNS1 is located at the N-terminus of the USP1 protein; mutations in this region, in particular the Leu-to-Gly substitution in amino acid 12, dramatically destabilize the DUB (Cataldo et al., 2013). During mitosis, proteolytic degradation of the USP1 protein can be regulated by phosphorylation of the Ser313 site, which leads to the masking of the degradation motif and impairment of proteolysis. The USP1 level is significantly reduced in cells exposed to genotoxic agents (in particular, such as UV) due to autocleavage at the Gly670-Gly671 internal motif (Cotto-Rios et al., 2011). The autocleavage of USP1 leads to the formation of two protein fragments, namely the amino-terminal USP1NT or N-terminal fragment (residues 1–671) and the shorter carboxyl-terminal USP1CT or C-terminal fragment (residues 672–785), which are subsequently subjected to proteasomal degradation (Piatkov et al., 2012). It is believed that USP1 fragments may retain their enzymatic activity because they continue to form complexes with the UAF1 cofactor until their complete destruction. Destruction of the N-terminal fragment occurs at the expense of the C-terminal degron, which is recognized and eliminated by DesCEND pathway with recognition of unusual C-termini by the ubiquitin ligase CRL2. The smaller C-terminal fragment is destroyed by the Arg/N-terminal rule pathway through deamidation of its destabilizing N-terminal Gln24 residue (Piatkov et al., 2012; Coleman et al., 2022).

Four missense mutations G667A, L669P, K673T, A676T are known within the USP1 autocleavage site. Only the L669P mutation reduces protein cleavage, due to conformational changes of the protein impairing access to the cleavage site. USP1 autocleavage shows that the balance of USP1 autocleavage can be disrupted by a cancer-associated mutation (Olazabal-Herrero et al., 2015). USP1 activity is reversibly inactivated in response to stress and the accumulation of reactive oxygen species (ROS) in the cell due to the oxidation of the catalytic cysteine (Cotto-Rios et al., 2012). The mechanism of DUB inactivation involves disruption of isopeptide cleavage but without affecting affinity to ubiquitin (Lee et al., 2013). Disruption of USP1 enzymatic activity as a result of ROS bursts causes accumulation of Ub-PCNA during S-phase, while the effect is negligible during G0 or G1. The accumulation of Ub-PCNA is also observed under the influence of UV irradiation, which leads to the destruction of USP1 (Cotto-Rios et al., 2012; Coleman et al., 2022).

USP1 IN THE DEVELOPMENT AND PROGRESSION OF CANCER

Since ubiquitination and deubiquitination are suggested to be essential regulators of basic cell functions, the impairment of the coordination in this network is inevitably associated with the characteristic features of cancer cells. In fact, a vast number of data demonstrate the altered expression of one or another DUBs in cancer. Currently, such data are available for more than 40 USPs including USP1, USP2, USP4, USP7, USP9X, USP10, USP11, USP12, USP13, USP14, USP15, USP19, USP22, USP26, USP29, USP33, USP39, USP42, USP44, USP46 and USP51. For example, USP2, USP3, USP4, USP7, USP10, USP29, and USP42 regulate the tumor suppressor protein p53. While USP7, USP10, USP29 and

USP42 stabilize the level of p53, USP2 and USP4, on the contrary, contribute to its proteosomal degradation due to the stabilization of E3 ligase. A number of DUBs (USP4, USP11, USP13, USP15, USP28, USP51) contribute to metastasis. For USP4, USP11, USP15, this is possible by altering the level of ubiquitination of the TGFβ receptor, which promotes TGFβ (transforming growth factor β) signaling and invasiveness of malignant cells. The functioning of DUBs is an essential component of cell cycle progression (USP1, USP2, USP3, USP7, USP17, USP22, USP39), DNA damage repair (USP1, USP3, USP4, USP7, USP9x, USP11, USP20, USP21, USP34, USP51), chromatin remodeling (USP7, USP11, USP16, USP21) (Pal et al., 2014; Gorrepati et al., 2018; Poondla et al., 2019; Cruz et al., 2021; Guo et al., 2022). The list of the DUBs whose expression is deregulated in cancer is continuously expanding.

USP1 is a prime example of DUBs modulating the expression level of oncoprotein. Such an aspect is of particular interest from the point of cancer pathogenesis and antitumor therapy.

An expanding number of findings suggest the important role of USP1 in pathogenesis of various cancers via diverse mechanisms. The dynamic balance between USP1 and ubiquitin E3 ligase underlying the modulation of the activity, degradation and localization of proteins contributes to maintaining homeostasis and controlling the critical functions in cell. Overexpression of USP1 facilitates the development of metastatic phenotype as well as chemo- and radioresistance of cancer cells. Besides the expression upregulation, the fact of mutations in DUB genes demonstrated in several human cancers provides further evidence in the support of the putative involvement of these enzymes in the development and progression of various malignancies.

The USP1 activity is important for controlling expression of several proteins related to oncogenesis and cancer progression. Among them are SIK2, MMP-2, GSK-3β, Bcl-2, Stat3, cyclin E1, Notch1, Wnt-1, and cyclin A1. Moreover, deubiquitination stabilizes the level of both oncoproteins and tumor growth suppressors such as EZH2, CHEK, TAZ, PHLPP1, Bcr-Abl, Aurora B, BCAT2, TBLR1, RPS16, c-Kit, KPNA2, KDM4A, ERα, SIX1, Snail, and ID1/ID2/ID3 impairing their intracellular balance (Table 1).

USP1 overexpression is characteristic of various types of cancer. According to GEPIA data from The Cancer Genome Atlas and the Genotype Tissue Expression databases, the highest level of USP1 expression is observed in cervical squamous cell carcinoma and endocervical adenocarcinoma, and it also significantly exceeds expression compared to normal tissue samples in breast invasive carcinoma, sarcoma, cholangiocarcinoma, colon adenocarcinoma, diffuse large B-cell lymphoma, esophageal carcinoma, glioblastoma multiforme, head and neck squamous cell carcinoma, brain lower grade glioma, rectum adenocarcinoma, thyroid carcinoma, etc. (Fig. 3). Changes in USP gene expression in cancer cells can be caused by various mechanisms, such as DNA repair defects, activation of signaling pathways, post-translational modifications, etc. A characteristic feature of increased USP1 expression for various types of cancer is a violation of cell homeostasis, proliferation, and apoptosis, which can be realized due to the stabilization of ID1, ID2, and ID3 proteins or FANCD2, as a key regulator of genome stability. siRNA knockdown or pharmacological inhibition of USP1 reduces proliferative activity and cell migration, promotes the onset of apoptosis and res-

Table 1. The putative role of USP1 in different forms of cancer.

Cancer	Known pathways affected	The role USP1 in the pathogenesis of the cancer	References
Glioma	PDGF-E2F-USP1-ID2 β-catenin-USP1-EZH2 USP1-CHEK1 USP1-ID1	Support for cell survival of the proneural subtype of glioblastoma. Promotion of tumorigenesis. Survival support. GSCs and resistance to treatment. Reduction of NgR1 promoting myelin-related infiltration	Rahme et al., 2016; Ma et al., 2019a; Lee et al., 2016; Lee et al., 2016
Osteosarcoma	USP1-ID1/ID2/ID3 USP1-TAZ	Suppression of osteoblast differentiation, increased proliferation, invasiveness, metastasis. Violation of the Hippo signaling pathway, increased proliferation and migration of malignant cells.	Williams et al., 2011 Yuan et al., 2022
Non-small cell lung carcinoma	USP1-PHLPP1-Akt	Disease progression. Unregulated proliferation of cancer cells.	Zhiqiang et al., 2012
B-cell acute lymphoblastic leukemia	USP1-ID1- AKT	Support for cell growth and viability. Disease progression. Suppression of cell apoptosis.	Kuang et al., 2021
T-cell acute lymphoblastic leukemia	USP1-Aurora B	Promotion of chemoresistance of T-ALL cells. Promotion of cell invasion. Inhibition of glucocorticoid receptor expression and apoptosis.	Gong et al., 2021
Multiple myeloma	USP1-ID-Notch-Sox2	Promotion of cell viability and resistance to bortezomib treatment. Enhances cell growth and inhibits apoptosis through the activation of caspase-3, caspase-8, and caspase-9.	Das et al., 2017
Chronic myeloid leukemia	USP1-Bcr-Abl	Stabilization of the Bcr-Abl oncoprotein level in cells as one of the conditions for disease progression.	Antonenko & Telegeev, 2020
Esophageal squamous cell carcinoma	D1/CDK4/CDK6	Maintenance of esophageal cancer cell viability and colony formation. Promotion of genetic stability of cells.	Sun et al., 2022
Stomach cancer	USP1-ID2	Promotes proliferation, metastasis, epithelial-mesenchymal transition of gastric cancer cells.	Li et al., 2021
Pancreatic ductal adenocarcinoma	USP1-BCAT2	Promotes cell proliferation, the formation of ductal clones in pancreatic adenocarcinoma cells.	Li et al., 2022b
Hepatocellular carcinoma	USP1-TBLR1 USP1-RPS16-Twist1/Snail USP1-c-Kit	Promotes the survival of circulating tumor cells, promotes metastasis. Supports cell proliferation and metastasis. Decreased overall patient survival. Resistance to treatment with lenvatinib.	Li et al., 2020 Liao et al., 2021b Chen et al., 2022
Breast cancer	USP1-KPNA2 USP1-ERα USP1-TAZ	Correlates with a poor prognosis for patients, promotes metastatic progression of breast cancer cells. Supports breast cancer cell proliferation and invasion via estrogen signaling. Promotes the proliferation and migration of malignant cells in triple-negative breast cancer.	Ma et al., 2019a Niu et al., 2020 Mussell et al., 2020
Prostate cancer	USP1-KDM4A-AR-c-Myc GRP75-USP1-SIX1	Promotes the proliferation and survival of prostate cancer cells. Supports the growth and proliferation of prostate cancer cells. Associated with a poor prognosis for patients. Promotes cell resistance to AR-targeted therapy.	Cui et al., 2020 Liao et al., 2021a, Liao et al., 2022
Colorectal cancer	Upregulation of Bcl-2, Mcl1, A1, D1, E1 cyclins and DNA-repair related substrates FANCD2 and ID1	Associated with short overall patient survival. Promotes the growth and survival of colorectal cancer cells, resistance to radio- and chemotherapy.	Xu et al., 2019
Ovarian cancer	ATM/ATR-USP1-Snail	Facilitates resistance to platinum treatment and promotes metastasis.	Sonego et al., 2019

toration of sensitivity to antitumor therapy (Das *et al.*, 2015; Gong *et al.*, 2021; Rennie *et al.*, 2022).

USP1-mediated stabilization of inhibitors of DNA binding and cell differentiation (ID proteins family) has been reported in many cancers (glioma, osteosarcoma, B-cell acute lymphoblastic leukemia, multiple myeloma, esophageal squamous cell carcinoma, gastric cancer, etc.). The disrupted functional activity of ID proteins is asso-

ciated with deregulation of cell proliferation, metastasis, and apoptosis impairment. Moreover, the inhibition of USP1 deubiquitination activity diminishes proliferation and colony-forming activity of cancer cells, decreases their metastatic ability and restores the sensitivity to anticancer drugs. The findings suggesting the putative role of USP1 targeting in future design of therapeutic modal-
Figure 3. USP1 expression in normal samples (grey box) and tumor samples (red box) from patients with cancer compiled by GEPIA data from The Cancer Genome Atlas and the Genotype Tissue Expression databases.
ACC – adrenocortical carcinoma, BLCA – bladder urothelial carcinoma, BRCA – breast invasive carcinoma, CESC – cervical squamous cell carcinoma and endocervical adenocarcinoma, CHOL – cholangiocarcinoma, COAD – colon adenocarcinoma, DLBC – diffuse large B-cell lymphoma, ESCA – esophageal carcinoma, GBM – glioblastoma multiforme, HNSC – head and neck squamous cell carcinoma, KICH – kidney chromophobe carcinoma, KIRC – renal clear cell carcinoma, KIRP – renal papillary cell carcinoma, LAML – acute myeloid leukemia, LGG – low grade glioma, LIHC – hepatocellular carcinoma, LUAD – lung adenocarcinoma, LUSC – lung squamous cell carcinoma, MESO – mesothelioma, OV – ovarian serous cystadenocarcinoma, PAAD – pancreatic adenocarcinoma, PCPG – pheochromocytoma and paraganglioma, PRAD – prostate adenocarcinoma, READ – rectal adenocarcinoma, SARC – sarcoma, SKCM – cutaneous melanoma, STAD – stomach adenocarcinoma, TGCT – testicular germ cell tumors, THCA – thyroid carcinoma, THYM – thymoma, UCEC – uterine corpus endometrial carcinoma, UCS – uterine carcinosarcoma, UVM – uveal melanoma

ities for cancer treatment are considered below for various forms of malignancies.

USP1 in glioma

The functioning of more than 20 ubiquitin-specific proteases, including USP1, is associated with the progression of glioma. USP1 expression is upregulated in glioma, in particular in glioblastoma stem-initiating cells (CD133[+] or CD15[+]) cells that are associated with clonogenic activity of malignant cells and radioresistance. The involvement of USP1 in glioma progression could be related to stabilization of ID1 and CHEK1 proteins, which promotes cell survival, while genetic or pharmacological inhibition of USP1 reduced tumor growth in experimental models and sensitized tumors to chemotherapeutic agents. The expression level of USP1 significantly increases upon inhibition of IRE-1α, the most evolutionarily conserved resident protein of the endoplasmic reticulum membrane. Thus, USP1 responds to endoplasmic reticulum stress and hypoxia, potentially contributing to the regulation of cell apoptosis and proliferation (Minchenko *et al.*, 2016). A critical factor in glioma progression and recurrence is the high infiltrative capacity of glioma stem cells caused by a decrease in the level of NgR1, negatively regulated through the USP1/ID1 signaling pathway. Pharmacological inhibition of USP1 with pimozide correlates with increased NgR1 expression and decreased infiltration capacity of glioma cells (Lee *et al.*, 2016; Liang *et al.*, 2022). USP1 expression in proneural glioblastoma cells is PDGF-dependent. PDGF upregulates the expression of E2F transcription factors that directly bind to and activate USP1, which in turn stabilizes the inhibitor of DNA binding 2 (ID2). Thus, activation of the PDGF–E2F–USP1–ID2 signaling pathway is crucial for glioma cell survival and may be considered as a valuable therapeutic strategy in proneural glioblastoma (Rahme *et al.*, 2016).

USP1 in osteosarcoma

IDs proteins are also involved in progression of osteosarcoma. In osteosarcoma cells, USP1 stabilizes IDs, particularly ID1, ID2, and ID3, through its deubiquitinating activity, and directly interacts with and deubiquitinates TAZ, leading to disruption of the Hippo signaling pathway. In fact, overexpression of USP1 was found in 26 out of 30 osteosarcoma samples as compared to normal bone tissues. Interestingly, USP1 stabilizes TAZ also in breast cancer, which promotes the proliferation and migration of malignant cells. Suppression of USP1 destabilizes ID proteins, disrupts osteoblast differentiation, negatively affects cell growth, colony formation, and metastasis (Williams *et al.*, 2011; Liu *et al.*, 2016; Mussell *et al.*, 2020; Yuan *et al.*, 2022).

USP1 in non-small cell lung carcinoma

In non-small cell lung carcinoma cells (NSCLC), USP1 forms a protein complex with the negative Akt regulator protein PHLPP1, deubiquitinates and stabilizes it. Knockdown of USP1 leads to rapid accumulation of ubiquitinated PHLPP1 and reduced its half-life, which is a trigger for Akt1 phosphorylation and disease progression. USP1 expression in non-small cell lung carcinoma cells is regulated by PXN and ITGB4. Current data on USP1 expression in lung cancer are somewhat controversial. Zhiqiang and others (Zhiqiang *et al.*, 2012) claim that the level of USP1 protein in non-small cell lung carcinoma is reduced, in particular in A549, H157, H2126, and H1770 cell lines, while its overexpression suppresses the growth of lung cancer cells and promotes cell death. Nevertheless, García-Santisteban and others (García-Santisteban *et al.*, 2012) demonstrated the higher USP1 mRNA levels in a panel of 20 NSCLC cell lines as well as in NSCLC tumor samples compared with normal tissue supporting the association of USP1 overexpression with NSCLC. At the same time, Chen and colleagues (Chen *et al.*, 2011) identified the USP1/UAF1

protein complex as a promising therapeutic target and talked about the feasibility of using the inhibitors, pimozide and GW7647, to reduce its activity. They found that USP1/UAF1 inhibitors sensitize cisplatin-resistant NSCLC cells to cisplatin. The therapeutic potential of using USP1/UAF1 protein complex inhibitors lies in their synergistic action with cisplatin reducing chemoresistance and inhibiting proliferation of NSCLC cells (Chen et al., 2011; Mohanty et al., 2020).

USP1 in B-cell acute lymphoblastic leukemia

In B-cell acute lymphoblastic leukemia (B-ALL), overexpression of USP1 promotes the progression of malignant disease through the ID1/AKT signaling pathway. Genetic and pharmacological inhibition of USP1 correlates with downregulation of ID1 and results in additional inactivation of the PI3K/AKT signaling pathway. In addition, inhibition of the deubiquitinating functions of USP1 by SJB3-019A induces G2/M cell cycle arrest in B-ALL cells (Kuang et al., 2021).

USP1 in T-cell acute lymphoblastic leukemia

In T-cell acute lymphoblastic leukemia (T-ALL), high expression of USP1 is associated with the development of chemoresistance and a poor prognosis for patients. USP1 contributes to the chemoresistance of T-ALL cells by interacting with and deubiquitinating Aurora B, a key cell cycle regulator that ensures correct chromosome segregation and normal mitosis, its dysfunction is associated with tumorigenesis in many types of cancer, including solid tumors and hematological malignancies (Du et al., 2021). USP1 overexpression in T-ALL cells is mediated by ALKBH5, a member of the well-conserved AlkB family of non-heme $Fe(II)/\alpha$-KG-dependent dioxygenases, which mediates the repair of N-alkylated nucleobases by oxidative demethylation and is involved in the regulation of proliferation, migration, and apoptosis. ALKBH5 reduces m6A levels and stabilizes USP1 mRNA transcript, whereas ALKBH5 inhibition significantly reduces USP1 and Aurora B levels. m6A (N6-methyladenosine) is a reversible and most common type of mRNA modification characteristic of many biological processes including tumorigenesis (Huo et al., 2021). Blocking USP1 restores sensitivity of T-ALL cells to dexamethasone in vitro and in vivo, by facilitating the expression of the glucocorticoid receptor, promotes cell apoptosis and suppresses cell invasion (Gong et al., 2021).

USP1 in multiple myeloma

In multiple myeloma patients, a high level of USP1 expression is an unfavorable prognostic factor associated with poor survival. Blocking the deubiquitinating activity of USP1 by SJB3-019A (a synthetic inhibitor that targets USP1 in an irreversible manner with high selectivity for other deubiquitinases) causes a series of important functional events, reducing the viability of myeloma cells, inhibiting their growth, triggering apoptosis through the activation of caspase-3, caspase-8, and caspase-9, and overcoming resistance to bortezomib, a first-in-class selective and reversible 26S proteasome inhibitor with antiproliferative and antitumor activity (Das et al., 2017; Robak et al., 2019).

USP1 in chronic myeloid leukemia

In chronic myeloid leukemia (CML) cells, USP1 interacts with the Bcr-Abl oncoprotein via its PH domain with the formation of the Bcr-Abl/USP1 nuclear complex. Bcr-Abl has constitutive tyrosine kinase activity and thus uncontrollably phosphorylates its protein partners, suggesting that oncoprotein interactions may deregulate USP1 activity by overactivating the enzyme. It was established that pharmacological inhibition of the USP1/UAF1 complex by ML323 causes a decrease in the Bcr-Abl level in CML cells. It is believed that USP1 deubiquitinates Bcr-Abl, preventing its proteolysis, and leading to the Bcr-Abl accumulation (Antonenko et al., 2016; Antonenko & Telegeev, 2020).

USP1 in esophageal squamous cell carcinoma

In esophageal squamous cell carcinoma cells, USP1 activity is associated with high levels of c-Myc, cyclin D1, CDK4, and CDK6 proteins, while pharmacological inhibition of USP1 by ML323 significantly affects the viability of malignant cells by blocking cell cycle traverse in G0/G1, interfering with the ability to form colonies and inducing apoptosis by p53-Noxa. Inhibition of the deubiquitinating activity of USP1 causes the accumulation of DNA damage and promotes the development of protective autophagy (Sun et al., 2022).

USP1 in stomach cancer

In gastric cancer cells, USP1 stabilizes ID2 expression by its deubiquitination. Overexpression of USP1 promotes metastasis and correlates with low survival rates, while knockdown of USP1 suppresses proliferation, migration, invasion, and epithelial-mesenchymal transition of gastric cancer cells (Li et al., 2021; Meng et al., 2022).

USP1 in pancreatic ductal adenocarcinoma

Pancreatic ductal adenocarcinoma (PDAC) is the most common neoplastic disease of the pancreas, for the development of which BCAT2-mediated branched-chain amino acid (BCAA) catabolism is critical. A key role of USP1 in PDAC development is its ability to regulate BCAT2 levels in cells through its deubiquitinating activity. In turn, the level of USP1 increases under the influence of BCAA through the GCN2-eIF2α signaling pathway. Inhibition of the deubiquitinating activity of USP1 reduces cell proliferation and pancreatic tumor growth in an orthotopic transplant in mice, suggesting USP1-BCAT2-BCAA signaling pathway as a potential target for PDAC therapy (Li et al., 2022b).

USP1 in hepatocellular carcinoma

USP1 overexpression together with the cofactor UAF1 is a poor prognostic factor for survival of hepatocellular carcinoma (HCC) patients. A high level of USP1 promotes metastasis and survival of circulating tumor cells (CTCs) due to deubiquitination and stabilization of transducin β-like 1 X-linked receptor 1 (TBLR1), which is a critical regulator of Wnt (Li et al., 2020). USP1 interacts with 37 ribosomal proteins (RPs), including RPS4X, RPS18, and RPS16, among which the USP1/RPS16 protein complex plays a key role in HCC progression. The binding of USP1 to RPS16 occurs at its C-terminal domain (401–785 aa). USP1 prevents proteasomal degradation of RPS16 by deubiquitination at the K48 site. The USP1-RPS16-Twist1/Snail signaling pathway is believed to be involved in cell proliferation and metastasis in HCC. In addition, USP1 stabilizes c-kit tyrosine kinase, which is upregulated or overexpressed in HCC. Inhibition of USP1 activity increases the sensitivity of HCC cells to lenvatinib treatment by regulating the ex-

pression of c-Kit, and also causes a decrease in the expression of PCNA, cyclin D1, cyclin E1, RPS16, Nanog, Sox2, c-Myc and is accompanied by decreased cancer stemness, including sphere formation ability. Lenvatinib is a multi-targeted tyrosine kinase inhibitor with angiogenic, antitumor, and immunomodulatory effects targeting VEGF receptors (VEGFR) and fibroblast growth factor (FGF) receptors (FGFR), platelet-derived growth factor receptor alpha (PDGFRα), KIT, and RET (Zhong *et al.*, 2021). Restoration of cell sensitivity to doxorubicin after USP1 inhibition is associated with ubiquitination of PCNA, which promotes its proteolysis. PCNA is an important factor in DNA replication and repair, chromatin remodeling, cell cycle regulation, and can be used as a marker of tumor aggressiveness (Zhao *et al.*, 2020; Liao *et al.*, 2021b; Chen *et al.*, 2022; Lu *et al.*, 2022).

USP1 in breast cancer

Elevated expression of USP1 in human breast cancer (BC) cells compared with normal breast tissue correlates with poor patient prognosis, promotes metastasis and disease progression through increased expression of a number of pro-metastatic genes, and stabilization of KPNA2 by its deubiquitination. KPNA2 is an important member of the karyopherin family, which plays a central role in nucleocytoplasmic transport and is overexpressed in malignant neoplasms. In addition, due to its deubiquitinating activity, USP1 regulates ERα and thus affects cell proliferation and invasion *via* estrogen signaling. In triple-negative BC, which is the most aggressive BC form, USP1 interacts with and deubiquitinates TAZ (WWTR1), which promotes the proliferation and migration of malignant cells. Inhibition of the USP1 functional activity causes a decrease in the level and inhibition of the activity of KPNA2, ERα, TAZ proteins, disrupts cell proliferation and migration, suppressing BC metastases and preventing the progression of the disease (Ma *et al.*, 2019a; Mussell *et al.*, 2020; Niu *et al.*, 2020).

USP1 in prostate cancer

Proliferation and survival of prostate cancer cells is regulated by the USP1/KDM4A/AR-c-Myc signaling pathway. A critical event in its activation is the increased expression of USP1, which regulates the stability of KDM4A through K48-linked deubiquitination. Inhibition of USP1 activity significantly reduces cell proliferation and enhances the response of cells to enzalutamide, a second-generation androgen receptor (AR) antagonist. However, the USP1/KDM4A/AR-c-Myc signaling pathway is not the only one involving USP1 in prostate cancer cells. USP1, through deubiquitination, stabilizes the embryonic development transcription factor SIX1 in USP1/SIX1 complex with GRP75 chaperone. High expression of SIX1is associated with a poor prognosis for prostate cancer patients. Blocking the activity of the GRP75-USP1-SIX1 protein complex using SNS-032 inhibits the growth and proliferation of prostate cancer cells, and also restores the sensitivity of cells to AR-targeted therapy (Cui *et al.*, 2020; Liao *et al.*, 2021a; Liao *et al.*, 2022)

USP1 in colorectal cancer

A high level of USP1 expression is associated with the proliferation and survival of colorectal cancer cells and promotes resistance to radio- and chemotherapy. The properties of USP1 are realized due to its effect on the expression of anti-apoptotic proteins Bcl-2, Mcl1, cyclins A1, D1, E1 and DNA-repair related substrates FANCD2

and ID1. Knockdown of USP1 causes cell arrest in the G2/M phase and induces colorectal cancer cell death. Pharmacological inhibition of USP1 using ML323 significantly increases the sensitivity of colorectal cancer cells to DNA-targeting chemotherapy drugs, enhancing in particular, the cytotoxic effect of doxorubicin, PARP inhibitor (Olaparib), topoisomerase I and II inhibitors, and DNA-binding agent etoposide (Xu *et al.*, 2019).

USP1 in ovarian cancer

Inhibition of USP1 opens new opportunities to overcome platinum resistance in ovarian cancer. A critical event in ovarian cancer initiation is the phosphorylation of USP1 by ATM and ATR, which triggers the interaction and deubiquitination of Snail. Stabilization of Snail by USP1 correlates with the development of platinum resistance and metastasis, while knockout or pharmacological inhibition of USP1 restores platinum sensitivity (Sonego *et al.*, 2019).

USP1 INHIBITORS

The first identified inhibitors of the USP1/UAF1 protein complex were pimozide and GW7647. Pimozide belongs to the approved antipsychotic drugs, but its pharmacological properties are not limited to the neuroleptic function and it demonstrates an antitumor effect in various types of cancer, including glioma, osteosarcoma, melanoma, myeloproliferative neoplasms, lung cancer, hepatocellular carcinoma, pancreatic cancer, breast cancer, colorectal cancer, prostate cancer, ovarian cancer, etc. (Dakir *et al.*, 2018; Kim *et al.*, 2020; Cui *et al.*, 2020; Ranjan *et al.*, 2020; Vlachos *et al.*, 2021; Li *et al.*, 2022a). The ability to suppress the USP1/UAF1 protein complex is one of the key mechanisms of the effect on malignant cells. Pimozide and GW7647 belong to reversible inhibitors and are characterized by moderate PubChem promiscuity with hit rates of 9.5% and 11.4%, respectively. Both inhibitors bind outside the active site of USP1, which is thought to disrupt the protein-protein interaction between USP1 and the cofactor UAF1. Despite good cellular inhibition of the USP1/UAF1 protein complex, pimozide and GW7647 are able to show activity against unrelated targets. (USP7 for pimozide and USP2, USP7, USP12/USP46 for GW7647) (Table 2). Laboratory studies, which included kidney and liver function tests, showed non-toxicity of intraperitoneal GW6471 at a dose of 20 mg/kg for mice (Chen *et al.*, 2011; Dexheimer *et al.*, 2014; Gonçalves *et al.*, 2019; LaPlante *et al.*, 2021; Morishita *et al.*, 2022; Orozco *et al.*, 2022; Ler *et al.*, 2022). Another known USP1 inhibitor is the compound SJB2-043, which causes downregulation of ID2 and ID3 proteins, growth inhibition and apoptosis, and blocks pancreatic β-cell apoptosis by inhibiting the DNA damage response (Mistry *et al.*, 2013; Gorrepati *et al.*, 2018; Chen *et al.*, 2021). Inhibitor C527 promotes dose-dependent degradation of ID1 in osteosarcoma cells. The mechanisms of action of inhibitors SJB2-043 and C527 have currently been studied *in vitro*. Compounds flupenthixol and trifluoperazine belong to the group of antipsychotic drugs, which are widely used in medical practice for the treatment of mental disorders, in particular schizophrenia, neuroses with anxiety and fear phenomena. Flupenthixol and trifluoperazine have sufficient selectivity for human DUB, however, the mechanisms of their inhibitory effect on USP1 are currently insufficiently studied. Rottlerin is an irreversible inhibitor of USP1/UAF1 with poor selectivity for other DUBs,

Table 2. Selectivity of inhibitors to different USPs.

Compound	USPs						References

in particular it is able to bind to USP2, USP7, USP8, USP46, etc. Rottlerin is well tolerated when administered orally or intraperitoneally to mice and does not cause side effects (Chen *et al.*, 2011; Lee *et al.*, 2016; Ma *et al.*, 2018; Xia *et al.*, 2019; Chen *et al.*, 2021). ML323, the potent nanomolecular inhibitor of USP1/UAF1 complex, has excellent selective ability. The mechanism of ML323 inhibitory effect consists in replacing part of the hydrophobic core of USP1, conformational changes of the secondary structure lead to rearrangements in the active center and inhibition of USP1 activity. ML323 belongs to reversible inhibitors, being 5-10-fold more active than C527 (Dexheimer *et al.*, 2014; Rennie *et al.*, 2022). ML323 has shown good antitumor activity in various cancers, including esophageal squamous cell carcinoma, pancreatic ductal adenocarcinoma, chronic myeloid leukemia, breast cancer, colorectal cancer, etc. ML323 reduces DNA repair, increases the sensitivity of cells to cisplatin in osteosarcoma and non-small cell lung cancer. It is promising to use ML323 in combination with compounds that damage DNA, in particular cisplatin, to enhance the cytotoxicity of anticancer drugs. ML323 has low cytotoxicity *in vitro*. In mice ML323 inhibited osteosarcoma progression in the absence of significant cytotoxicity. (Dexheimer *et al.*, 2014; Yu *et al.*, 2017; Song *et al.*, 2022). In 2021, there were reports of a new compound, KSQ-4279, capable of highly selectively inhibiting the activity of USP1 and leading to the accumulation of its monoubiquitinated substrate proteins. Under in vitro conditions, KSQ-4279 performed well in ovarian and triple-negative breast cancer xenograft models, causing dose-dependent inhibition of tumor growth and tumor regression in models insensitive to PARP inhibitors (Shenker *et al.*, 2021). To date, in the available literature there are no reports on the study of KSQ-4279 *in vivo*.

CONCLUSIONS

In malignant cells, there are mechanisms to suppress the degradation of oncoproteins, in which DUBs play a key role. The imbalance between ubiquitination and deubiquitination is a critical event contributing to the accumulation of oncoproteins in the cell and preventing their degradation. Plenty of current research focus on the identification of DUBs associated with different aspects of oncogenesis. Study of their cellular localization, interactions with target proteins and substrate specificity is of importance for developing selective inhibitors and implementing a new cancer treatment strategy. USP1 as an important member of the DUB family with a wide range of cellular substrates is involved in ensuring genetic stability and cell homeostasis. Deregulation of its expression and deubiquitinating activity is revealed in various malignant neoplasms. Recent studies suggest a non-genomic mechanism of protein stabilization mediated by USP1 activity allowing for controlling expression of target genes that play a key role in cancer development and progression. USP1 overexpression is a hallmark of a number of cancers including glioma, osteosarcoma, B-cell and T-cell acute lymphoblastic leukemia, hepatocellular carcinoma, gastric, breast, ovarian, prostate, and colorectal cancers, which correlates with poor survival and unfavorable prognosis. Further studies will help understand the relationship between USP1 expression profiles and cancer, opening up new possibilities for using USP1 as a tumor marker for early detection, staging, and individualized therapy of malignant neoplasms. Inhibition of USP1 in vitro sensitizes cancer cells to radiation and increases their sensitivity to various chemotherapeutic agents, so targeting the USP1/UAF1 complex may be of great benefit in overcoming resistance and widening the use of combination therapy for cancer. The key function of USP1 in the regulation of the substrate ubiquitination allows modulating the level of specific proteins including those contributing to the development of malignant neoplasms.

Despite tremendous progress achieved in the past decade in studying the roles of DUBs in cellular events resulting in malignant transformation, many important questions have not yet been clarified. The exact roles of

different DUBs vary in different forms of cancer and the specific substrates that are ubiquitinated. Moreover, their roles in different cells and tissues of varying histogenesis or different metabolic conditions may not be the same. One should also be aware that DUBs interact with an array of enzymes that sometimes act oppositely defining the fate of cancer cells. The increasing specificity of the substances disrupting or enhancing specific interactions of DUBs with their substrates could be promising in search of more efficient therapeutic strategies.

Although we have a long way to go before the translation of the experimental research into the clinical practice, undoubtedly, DUBs represent putative therapeutic targets for the development of a new strategy for cancer treatment by modulating the levels and the activities of oncoproteins in cancer cell.

Involvement of Rictor/mTORC2/Akt/GLUT4 pathway in the regulation of energy metabolism in the gastric smooth muscle of diabetic rats

Sun Yan[1#], Yu-Rong Zheng[2#], Zheng Jin[1], Mo-Han Zhang[1✉] and Xiang-Shu Cui[2✉]

[1]Yanbian University College of Medicine, Yanji 133000, Jilin, China; [2]Yanbian University School of Nursing, Yanji 133000, Jilin, China

Diabetes mellitus can be accompanied by a variety of complications. The purpose of the present study was to characterize the Rictor/mTOR complex 2 (mTORC2)/Akt/glucose transporter 4 (GLUT4) pathway and its effects on energy metabolism in the gastric smooth muscle of diabetic rats. Diabetes was induced in rats using streptozotocin and their phenotype was compared with untreated rats. The relationship between gastric motility and energy metabolism was analyzed by comparing the contraction and ATP metabolism of muscle strips. Western blotting was used to detect the expression of key proteins in the pathway. The diabetic rats demonstrated less frequent and less powerful gastric smooth muscle contractions. The concentrations of ADP, AMP, and ATP, and the energy charge in gastric smooth muscle changed in different periods of diabetes, and these changes were consistent with changes in mechanistic target of rapamycin (mTOR) protein content. The expression of the key intermediates in signal transduction in the Rictor/mTORC2/Akt/GLUT4 pathway also underwent significant changes. Rictor protein expression increased during the development of diabetes, but the activation of mTORC2 did not increase with the increase in Rictor expression. GLUT4 translocation is regulated by Akt and its expression change during the development of diabetes. These findings suggest that altered energy metabolism is present in gastric smooth muscle that is associated with changes in the Rictor/mTORC2/Akt/GLUT4 pathway. Rictor/mTORC2/Akt/GLUT4 pathway may be involved in the regulation of energy metabolism in the gastric smooth muscle of diabetic rats and the development of diabetic gastroparesis.

INTRODUCTION

Diabetic gastroparesis is a gastric motility disorder characterized by delayed gastric emptying. The underlying reduction in gastric motility is directly related to changes in energy metabolism in gastric smooth muscle cells. ATP is the universal energy currency in cells and is predominantly generated in mitochondria by the action of ATP synthase (Kimoloi, 2018), although glucose can also be metabolized *via* the glycolytic pathway in the cytoplasm to generate a small amount of ATP.

Extensive research over the past two decades has established a central role for mechanistic target of rapamycin (mTOR) in the regulation of many fundamental cell processes, from protein synthesis to autophagy, and deregulated mTOR signaling is implicated in the progression of cancer and diabetes, as well as in the aging process (Kleinert *et al.*, 2014). Since mTOR is a protein kinase related to energy metabolism and diabetes, the putative relationship between mTOR and diabetes should be further explored. mTOR is a serine/threonine protein kinase and a member of the phosphoinositide 3-kinase (PI3K)-related kinase (PIKK) family. It forms the catalytic subunit of two structurally and functionally distinct protein complexes: mTOR complex 1 (mTORC1) and complex 2 (mTORC2) (Kleinert *et al.*, 2014; Saxton & Sabatini, 2017). Each complex has its own unique roles but they also interact with each other. mTORC1 is a major regulator of protein synthesis and cell growth, and comprises three components: mTOR, regulatory protein associated with mTOR (Raptor), and mammalian lethal with Sec13 protein 8 (GβL; mLST8) (Kimoloi 2018; Hara *et al.*, 2002). Recently, it has been shown that mTORC1 senses glucose through more than one mechanism (Kimoloi 2018; Kleinert *et al.*, 2014; Zhang *et al.*, 2017), and it also responds to intracellular and environmental stresses that are incompatible with growth, such as low ATP concentration. A reduction in cellular energy during glucose deprivation activates the stress-responsive metabolic regulator AMP-activated protein kinase (AMPK), which inhibits mTORC1 both indirectly, through the phosphorylation and activation of tuberous sclerosis complex 2 (TSC2), and directly, through the phosphorylation of Raptor (Kimoloi, 2018; Hara *et al.*, 2002; Zhang *et al.*, 2017). Most studies have pointed out that mTORC1 is involved in energy metabolism, but mTORC2 is rarely studied.

Rictor is essential for the integrity and stability of the mTORC2 complex (Kimoloi, 2018; Knudsen *et al.*, 2020). Low Rictor expression leads to lower SIN1 expression and *vice versa* (Hara *et al.*, 2002; Knudsen *et al.*, 2020). Studies have found that the deletion of Rictor gene affects the body's absorption of glucose. Diabetes mellitus is the disorder of glucose absorption and utilization. This suggests that Rictor may play a role in diabetes pathogenesis. It has been reported that alterations to the mTORC1 signaling pathway in skeletal muscle directly affects whole-body energy homeostasis (Mukaida *et al.*, 2017). mTORC2 is also a major upstream kinase for the Akt Ser473 residue (Kleinert *et al.*, 2014; Mu-

kaida *et al.*, 2017). The activation of Akt promotes glucose transporter 4 (GLUT4) translocation to the plasma membrane, which leads to increases in glucose uptake, glucose metabolism, and ATP synthesis (Mukaida *et al.*, 2017; Cosimo *et al.*, 2019; Hasannejad *et al.*, 2019). At the same time, the interaction between mTORC1 and mTORC2 may also affect the energy metabolism of the body.

Glucose is an important source of energy for muscle contraction. Furthermore, normal glucose metabolism is essential for the maintenance of good health, and abnormal glucose metabolism can lead to serious health problems, such as diabetes. Increases in glucose uptake are due to translocation of glucose transporters from intracellular storage vesicles in adipocytes and skeletal muscle cells to the plasma membrane (Khan & Kamal, 2019). GLUT4 is the principal transporter of glucose in muscle and fat cells and has a key role in the control of cellular glucose metabolism and whole-body energy homeostasis, which are strongly linked to type 2 diabetes (Zhao *et al.*, 2019).

The purpose of the present study was to characterize the Rictor/mTORC2/Akt/GLUT4 pathway and its effects on energy metabolism in the gastric smooth muscle of diabetic rats.

MATERIALS AND METHODS

Animals

Forty 8-week-old Sprague-Dawley male rats, weighing 200 ± 20 g, were housed in single cages at 20–25°C, under a 12-h light/dark cycle, and had free access to food and water. All animal experimental procedures were approved by the Ethics Committee of Yanbian University College of Medicine.

Preparation of the animal model

A 0.5% solution of streptozotocin (STZ) (Cat No. S0130, SIGMA, USA) was prepared in 0.1 mmol/L citrate buffer (pH 4.0). 40 rats were fasted for 12 hours, after which 30 of them were randomly selected, weighed, and given a single intraperitoneal injection of STZ at 65 mg/kg to induce diabetes. The remaining 10 rats were intraperitoneally injected with the same dose of citrate buffer and comprised a normal control (NC) group. One week later, glucose levels were measured in blood taken from the tail vein, and rats with glucose concentration of ≥16.9 mmol/L were regarded as diabetic. One diabetic rat died following the STZ injection; therefore, one rat was randomly selected from the control group and injected with STZ. Thus, 30 diabetic rats and 9 normal rats were studied. The diabetic rats were randomly allocated to 4-week (DM4w), 6-week (DM6w), and 8-week (DM8w) endpoints (n=10 rats per group). The NC rats were allocated to three groups, with n=3 rats per group, and they were sacrificed at 4, 6, and 8 weeks.

Preparation of muscle strips and measurement of spontaneous muscular contraction

The rats were euthanized at the determined time points. For each individual, the entire stomach was dissected, had its contents removed, and its muscle tissue peeled off. Gastric antrum ring muscle strips were dissected and placed vertically in oxygen-saturated Krebs's buffer (NaCl 118 mmol/L, KCl 4.75 mmol/L, $CaCl_2$ 2.54 mmol/L, KH_2PO_4 1.2 mmol/L, $MgSO_4$ 1.2 mmol/L, $NaHCO_3$ 25 mmol/L, and glucose 10 mmol/L, Kermel, TianJing, China) and connected with a tension sensor and a RM-6240 multi-channel physiological signal recorder (SCCHENGYI, ChengDu, China). Before each experiment readout, a load of 1 g was applied to each muscle strip for 30 min. After the spontaneous contractions of the smooth muscle strips stabilized, the number of muscle contractions every 400 s was recorded as the frequency, and the height of the peaks was recorded as the amplitude of the muscle contractions. All experiments were repeated independently 8 times.

High-performance liquid chromatography (HPLC)

One hundred milligrams of fresh gastric antrum annular muscle were added at 10 g/mg/mL to 0.4 mol/L perchloric acid solution that had been pre-cooled to 4°C, and the muscle was homogenized in an ice-bath. The supernatant was obtained by centrifugation (10000 rpm, 10 min) and its pH was adjusted to 6.5. Twenty microliter samples in triplicates at 4°C and at dilutions of 200, 100, 50, 20, and 10 mg/L were then subjected to HPLC to measure the concentrations of ATP, AMP, and ADP. A C18 column (4.6 mm×150 mm, 5 m; Shimadzu, Japan), a column temperature of 25°C, and a mobile phase of 100 mmol/L phosphate buffer (12 mmol/L disodium phosphate and 88 mmol/L sodium dihydrogen phosphate, pH=6.5) and methanol (99:1 volume ratio) were used. The flow rate was 1.0 mL/min and the UV detection wavelength was 254 nm. The energy charge was calculated according to the following formula: energy charge= (ATP+1/2ADP)/(ATP+ADP+AMP) (Wilbring *et al.*, 2013). All experiments were repeated 8 times, independently.

Western blotting

Western blotting was used to detect protein levels of Akt, phospho-Akt Ser473, mTOR, phospho-mTOR Ser2481, and Rictor. The circular muscle of the gastric antrum was added to a precooled lysis buffer at 75–125 µl/g, homogenized, and incubated at 4°C for 30 min. The lysates were then centrifuged at 14000 rpm for 30 min, the supernatants were obtained, and their protein concentration was determined. Samples containing 60 µg protein were subjected to SDS-PAGE, then electrotransferred to PVDF membranes. The membranes were then incubated with anti-Akt (1:1000, Cat No. 9272, Cell Signaling Technology®, Inc., MA, USA), phospho-Akt (1:1000, Cat No. 4060, Cell Signaling Technology®, Inc., MA, USA), mTOR (1:1000, Cat No. 2792, Cell Signaling Technology®, Inc., MA, USA), phospho-mTOR Ser 2481 (1:500, SAB4301526, Sigma, MO, USA), Rictor (1:1,000, Cat No. 2974, Cell Signaling Technology®, Inc., MA, USA), or β-actin (1:500, A5316, Sigma, MO, USA) at 4°C overnight. After washing, the membranes were incubated with secondary antibody (1:1000, Cat No. 7055, Cell Signaling Technology®, Inc., MA, USA) solution, washed, and exposed to a chromogenic agent. The expression of the proteins of interest was calculated relative to β-actin levels (A5316, Sigma, MO, USA).

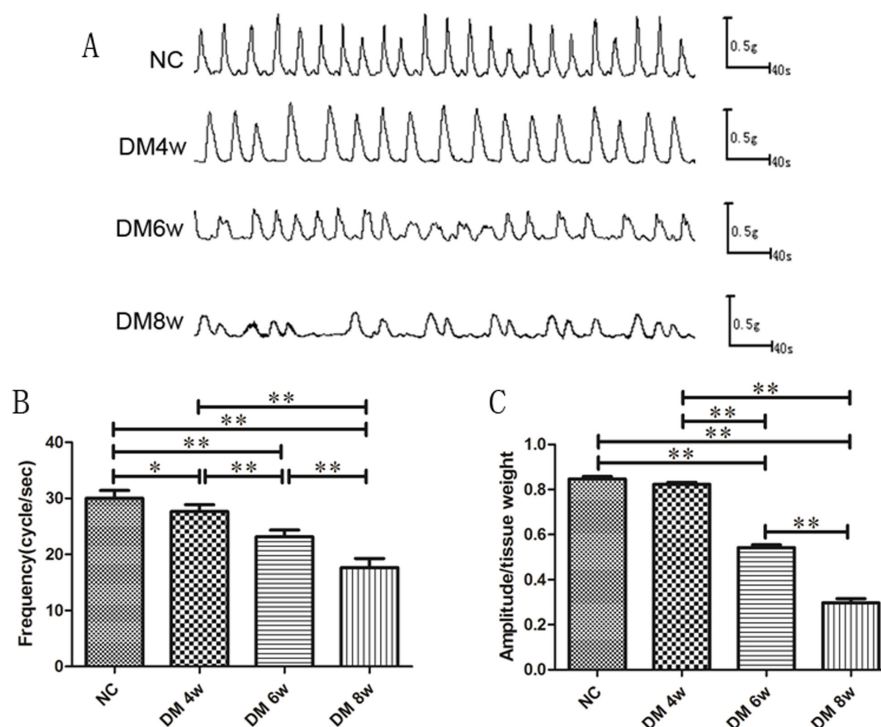
Western blotting was also used to measure the relative expression of GLUT4 protein (rabbit anti-GLUT4 antibody, Cat No. ab654, Abcam, Cambridge, UK) in gastric antrum teres muscle. The tissue was lysed as described above. The supernatant (containing cytoplasmic proteins) was added to the cell membrane lysate and the samples were mixed and centrifuged. Next, the supernatant (containing cell membrane proteins) was collected and its


Figure 1. Amplitude of spontaneous contractions in normal gastric smooth muscle and at each time point during the progression of diabetes mellitus.
(**A**) Gastric smooth muscle strip motility analysis; (**B**) The frequency of spontaneous contraction of gastric smooth muscle. (**C**) The amplitude of the contractions of the gastric smooth muscle. The data are displayed as mean ± S.D.; *$P<0.05$, **$P<0.01$.

protein concentration was determined. Samples containing 60 μg of protein were subjected to SDS-PAGE and electrotransfer, as described above. The membranes were incubated with the antibody against GLUT4 (1:1,000) at 4°C overnight, or with or β-actin at (temperature, time), a secondary antibody (1:1 000), and a chromogenic agent, and the expression of GLUT4 was calculated relative to that of β-actin. All experiments were repeated 8 times, independently.

Statistical analysis

Statistical analyses were performed with SPSS 19.0 software, and the figures were made with GraphPad Prism5 software (GraphPad Software, San Diego, CA). All experiments were repeated at least 8 times. The data are expressed as mean ± standard deviation (S.D.). Differences between groups were compared using t-test and two-way analysis of variance (ANOVA). $P<0.05$ was considered to indicate a significant difference, $P<0.01$ was considered to indicate a highly significant difference.

RESULTS

Contraction frequency and amplitude in gastric smooth muscle

We evaluated the rate and amplitude of the contraction of stomach muscle strips from diabetic and normal rats (Fig. 1A). The number of muscle contractions during 400 s was recorded as the frequency and the height of each registered peak was recorded as the amplitude of muscle contraction. The frequency of spontaneous contractions of gastric smooth muscle was lower in DM4w, DM6w, and DM8w groups compared to the NC

group ($P<0.05$ or $P<0.01$). This decrease in contraction frequency corresponded to the duration of diabetes: it was the lowest in the DM8w group ($P<0.01$ compared to DM6w, Fig. 1B). and both in the DM6w and DM8w groups displayed lower frequency than DM4w group (both $P<0.01$). The amplitude of the contractions of the gastric smooth muscle was decreased in the DM6w and DM8w groups compared to the NC group (both $P<0.01$), and compared to the DM4w group as well (both $P<0.01$). The amplitude of the contractions of the gastric smooth muscle was lower in the DM8w group than that in the DM6w group ($P<0.01$, Fig. 1C). Thus, the motility of rat gastric smooth muscle decreased with the progression of diabetes in the rats.

The concentrations of ATP, ADP, AMP and energy charge in gastric smooth muscle

ATP is the basic molecular unit of energy in the body; therefore, the amount of ATP present in a tissue and the rate of ATP synthesis (ADP/ATP) reflect overall energy metabolism in the tissue. We measured the concentrations of ATP, ADP, and AMP in the gastric smooth muscle of rats using HPLC (Fig. 2) and found that the concentration of ATP was not affected by diabetes ($P>0.05$). However, ADP concentration was decreased in the DM4w group ($P<0.01$), and increased in the DM6w and DM8w groups (both $P<0.01$) as compared to NC. It was also higher in the DM6w and DM8w groups than in the DM4w group (both $P<0.01$), and higher in the DM8w group than in the DM6w group ($P<0.01$, Fig. 2A). Therefore, a trend was observed for the ATP production (ADP/ATP ratio). The ADP/ATP ratio was the lowest in the DM4w group ($P<0.05$ compared to the NC) and the highest in the DM8w group ($P<0.01$ compared to the NC). The ADP/ATP ratio was higher

(**A**) ATP, ADP, and AMP concentrations in control and diabetic rats. (**B**) ADP/ATP ratio in control and diabetic rats. (**C**) The energy charge in control and diabetic rats. The data are displayed as mean ± S.D.; *$P<0.05$, **$P<0.01$.

Figure 3. Protein expression of the key proteins in the Rictor/mTORC2/Akt/GLUT4 pathway in control and diabetic rats.
(**A**) Western blot of the key proteins in the Rictor/mTORC2/Akt/GLUT4 pathway in the rat gastric smooth muscle; (**B**) mTOR expression in the rat gastric smooth muscle; (**C**) Rictor expression in the rat gastric smooth muscle; (**D**) p-mTOR Ser2481/ mTOR ratio; (**E**) p-Akt Ser473/ Akt ratio; (**F**) GLUT4 expression in the gastric smooth muscle of control and diabetic rats. The data are displayed as mean ± S.D.; *$P<0.05$, **$P<0.01$.

in the DM6w and DM8w than in DM4w (DM8w vs DM4w $P<0.01$, DM6w *vs* DM4w $P<0.01$,), and higher in DM8w than in DM6w ($P<0.01$, Fig. 2B). The energy charge of the gastric smooth muscle was increased in DM4w as compared to NC($P<0.05$). Conversely, the energy charge was decreased in the DM6w and DM8w-compared to DM4w ($P<0.05$, $P<0.01$), and was lower in DM8w than in DM6w ($P<0.05$, Fig. 2C). These results suggested that energy metabolism disorder was present in the gastric smooth muscle of diabetic rats, leading to the impairment of the energy supply to muscle and the development of diabetic gastroparesis.

Akt, phospho-Akt Ser473, mTOR, phospho-mTOR Ser2481, GLUT4, and Rictor protein expression in gastric smooth muscle

We used Western blotting to measure the expression of the key proteins in the Rictor/mTORC2/Akt/GLUT4 pathway the in gastric smooth muscle of rats in each group (Fig. 3A). mTOR expression in the gastric smooth muscle was decreased in the DM8w group compared to NC ($P<0.01$), DM4w ($P<0.05$), and DM6w ($P<0.05$) groups (Fig. 3B). Rictor is an important component of TORC2 but does not promote the phosphorylation of mTOR at Ser2481. Rictor expression in the gastric smooth muscle was increased in the DM6w and DM8w groups compared to the NC (both $P<0.01$), and DM4w groups (both $P<0.01$). also It was also higher in DM8w than in DM6w ($P<0.01$, Fig. 3C). The p-mTOR Ser[2481]/mTOR ratio was increased in the DM8w group compared to the NC ($P<0.01$), DM4w ($P<0.05$), and DM6w ($P<0.05$) groups (Fig. 3D). The p-Akt Ser[473]/Akt ratio was increased in both DM4w and DM8w compared to NC (both $P<0.01$). Also, the p-Akt Ser[473]/Akt ratio was lower both in DM6w and DM8w than in DM4w (both $P<0.01$), and lower in DM8w than in DM6w ($P<0.01$, Fig. 3 E). The gastric smooth muscle cell surface expression of GLUT4 was increased in both DM4w and DM6w groups compared to NC ($P<0.01$, $P<0.05$). It was also lower in both DM6w and DM8w than in DM4 (both $P<0.01$) and lower in DM8w than in DM6w ($P<0.05$, Fig. 3F). These results suggested that the Rictor/mTORC2/Akt/GLUT4 pathway is involved in the regulation of energy metabolism in the gastric smooth muscle, alters energy supply to muscle, which in turn participates in the development of diabetic gastroparesis.

DISCUSSION

ATP is the most direct source of body energy, and 90% of it is produced by mitochondria (Barros & Baeza-Lehnert, 2019; Marklund *et al.*, 2006; Korchazhkina *et al.*, 1999). There are two main ways to generate ATP in the body: in the anaerobic state, glucose undergoes glycolysis, during which each molecule of glucose is converted to pyruvate and two molecules of ATP are produced, whereas in the aerobic state, pyruvate is completely metabolized to generate 32 molecules of ATP per molecule of glucose. In the present study, we found that in the diabetic state, starting from the sixth week following the induction of diabetes, there was an obvious reduction in gastric motility, which corresponds to the development of diabetic gastroparesis. The ATP concentration in the muscle did not change significantly with the progression of diabetes, but we observed an upward trend for ADP and AMP and ATP generation (ADP/ATP ratio),and a downward trend for energy charge. Energy charge rep-

resents the number of high-energy phosphate groups in the total adenylate system (the total concentration of ATP+ADP+AMP), which reflects the energy status of the cell. The above results imply deterioration in the energy status of the tissue. This may reflect a reduction in the aerobic metabolism of glucose because of partial replacement by other pathways, mitochondrial damage, or other factors. Although the substrate in the muscle is sufficient to ensure the conversion of ADP, it cannot reverse the trend of reduced synthesis. The specific explanation for this requires further study.

Diabetic gastroparesis has previously been shown to develop 6 weeks after the induction of diabetes in rats and is accompanied by changes in mTOR pathway (Zhang *et al.*, 2017). mTOR is an atypical serine/threonine protein kinase that can integrate various extracellular signals, such as growth factors, nutrition, and energy status to regulate processes such as growth and the cell cycle. The mTOR complexes: mTORC1 and mTORC2 have different structures and functions, and different mTOR residues are phosphorylated in each complex (Saxton & Sabatini, 2017; Copp *et al.*, 2009; Gnocchi *et al.*, 2020). mTOR is activated by phosphorylation at multiple residues, including Ser2448 and Ser2481 (Saxton & Sabatini, 2017; Copp *et al.*, 2009; Vazquez-Martin *et al.*, 2012). Previous studies have shown that in mTORC1, mTOR is phosphorylated at Ser 2448, whereas in mTORC2, it is phosphorylated at Ser 2481 (Knudsen *et al.*, 2020; Copp *et al.*, 2009; Vazquez-Martin *et al.*, 2012). mTORC1 contains rapamycin-sensitive Raptor, MLST8 a proline-rich Akt substrate of 40 kDa, (PRAS40), and DEP domain of mTOR-interacting protein (DEP domain-containing mTOR-interacting protein, DEPTOR); whereas, mTORC2 contains Rictor and MLST8, neither of which is sensitive to rapamycin, and SAPK interacting protein 1 (SIN1) (Saxton & Sabatini, 2017). Thus, Raptor and Rictor are characteristic proteins of the mTORC1 and mTORC2, respectively. In the present study we found that Rictor protein expression increased with the progression of diabetes, but mTOR expression was decreased at 8 weeks of diabetes. The phosphorylation of mTOR-Ser[2481] requires intact mTORC2 (Knudsen *et al.*, 2020), as the autophosphorylation of Ser[2481] is proportional to the specific catalytic activity of mTORC2. By observing the changes in the p-mTOR Ser[2481]/mTOR ratio, we found that the phosphorylation of mTOR at Ser [2481] decreased prior to the development of gastroparesis, but increased after the onset of this complication, indicating that there are other factors that regulate the activation of mTORC2.

Rictor participates in glucose metabolism as an upstream effector of Akt, and when Rictor or mTORC2 is absent, glucose intolerance develops. While mTORC2 activates Akt, Akt can activate mTORC1 activity *via* Akt-(TSC1/2)-Ras homolog (RheB)-mTORC1, as was shown for brain tissue (Saxton & Sabatini, 2017). In another study, it was shown that the expression of Rictor in muscle cells is lower in a high-glucose environment and that the cells show lower insulin-induced glucose uptake, such that the glucose metabolism becomes disrupted (Mukaida *et al.*, 2017). A reduction in Rictor expression also affects GLUT4 translocation, resulting in a reduction in glucose transport and deleterious effects on overall glucose and energy metabolism (Mukaida *et al.*, 2017; Hasannejad *et al.*, 2019; Khan & Kamal, 2019; Zhao *et al.*, 2019). In this study, we found that the phosphorylation of Akt at Ser473 in the diabetic state gradually decreases, despite the increase in mTORC2 expression, which suggests that mTORC2 is not the dominant

regulator of Akt. GLUT4 translocation is mainly regulated by Akt, but Rictor is also required for this process. Although GLUT4 translocation is not mainly affected by mTORC2, there should be other ways to affect it.

GLUT4 translocation, and therefore glucose uptake by muscle cells, is promoted by Akt phosphorylation, but GLUT4 translocation decreases with the development of gastroparesis. In this study, the translocation of GLUT4 was found to be increased first and then decreased with disease progression. This result implies that in the diabetic state, glucose is taken up and used by cells also independently of insulin.

One of the limitations of this study is that we did not quantify the mRNA expression levels of the key proteins in the Rictor/mTORC2/Akt/GLUT4 pathway in the gastric smooth muscle of diabetic rats with RT-PCR.

CONCLUSIONS

Our findings documented that during the pathogenesis of diabetic gastroparesis, altered energy metabolism was present in the gastric smooth muscle of diabetic rats. is The change in energy metabolism was associated with the changes in protein expression and phosphorylation in the Rictor/mTORC2/Akt/Glut4 pathway, suggesting that this pathway may be involved in both the regulation of energy metabolism in the gastric smooth muscle of diabetic rats and in the development of diabetic gastroparesis.

Circular RNA-AnnexinA7 accelerates cisplatin resistance in non-small cell lung cancer *via* modulating microRNA-545-3p to mediate Cyclin D1

Jian Yao✉, Hai Yang Zhang, Shuang Gu, Jin Long Zou, Qiang Zhang and Ri Chu Qu

Department of Thoracic Surgery, Jilin Provincial People's Hospital, Changchun City, Jilin Province, 130021, China

Objective: To explore the mechanism of circular RNA (circRNA)-AnnexinA7 (ANXA7) in non-small cell lung cancer (NSCLC) cisplatin (DDP) resistance through microRNA (miR)-545-3p to target Cyclin D1 (CCND1). **Methods**: DDP-resistant and non-resistant NSCLC tissues and normal tissues were collected. DDP-resistant cells (A549/DDP and H460/DDP) were constructed. circ-ANXA7, miR-545-3p, CCND1, P-Glycoprotein, and glutathione S-transferase-π in tissues and cells were measured. Analysis of circ-ANXA7 ring structure was performed, as well as detection of circ-ANXA7 distribution in cells. Cell proliferation was detected by MTT and colony formation assay, apoptosis rate was detected by flow cytometry, and cell migration and invasion were evaluated by Transwell assay. The targeting relationship between circ-ANXA7, miR-545-3p and CCND1 was verified. Measurement of tumor volume and quality in mice was performed. **Results**: Circ-ANXA7 and CCND1 were elevated, while miR-545-3p was suppressed in DDP-resistant NSCLC tissues and cells. Circ-ANXA7 combined with miR-545-3p, which targeted CCND1 to expedite A549/DDP cell proliferation, migration, invasion, DDP resistance, but inhibited cell apoptosis. **Conclusion**: Circ-ANXA7 enhances DDP resistance in NSCLC *via* absorbing miR-545-3p to target CCND1 and might be a latent therapeutic target for NSCLC.

Keywords: Circular RNA-AnnexinA7, MicroRNA-545-3p, Cyclin D1, Target binding, A549/cisplatin cells

INTRODUCTION

Lung cancer (LC) is a malignant tumor with the uppermost morbidity and mortality in the world (Zhang *et al.*, 2021). Non-small cell lung cancer (NSCLC) is an extremely critical type of LC, taking up about 85% of LC cases (Xu *et al.*, 2020). Treatment strategies for NSCLC have improved recently, but the 5-year survival rate is still greatly reduced by about 10–15% (Xu *et al.*, 2021). Cisplatin (DDP) chemotherapy is a first-line anti-cancer chemotherapy agent in NSCLC. Nevertheless, patients treated with DDP for a long time develop DDP resistance (Wu *et al.*, 2020). As reported, around 63% of NSCLC patients have DDP resistance (Ye *et al.*, 2020). Consequently, lessening DDP resistance is the crux to ameliorating NSCLC patients' outcomes. This study was to comprehend latent mechanisms in NSCLC DDP resistance and identify latent biomarkers, offering brand-new insights into NSCLC therapy.

Circular RNAs (circRNAs), a non-coding RNA with closed continuous loops, have been testified to mediate primary or antitumor responses in different cancer treatments (Fan *et al.*, 2021). Notably, numerous circRNAs exert critical roles in multiple biological processes of NSCLC. For instance, circ_PIP5K1A (Feng *et al.*, 2021), circ-RNF121 (Liu *et al.*, 2022) and circ_0076305 (Wang *et al.*, 2021) have been reported to be implicated in the cancer progression and DDP resistance of NSCLC. Circ-AnnexinA7 (ANXA7), as a member of circRNA, has been reported to expedite lung adenocarcinoma progression (Wang, 2021). In the preliminary experiment, this circRNA was aberrantly modulated in DDP-resistant NSCLC tissues. Nevertheless, the latent impact of circ-ANXA7 on DDP resistance in NSCLC is unknown.

circRNA/miRNA/mRNA regulatory network has been adopted to elucidate circRNA's mechanism in multiple biological processes (Xu *et al.*, 2020). Bioinformatics predicted that miR-545-3p was the target of circ-ANXA7. Recently, miR-545-3p has been reported to participate in NSCLC progression. For instance, blocking circ_0014130 restrains resistance and malignant behaviors of NSCLC cells *via* modulating miR-545-3p (Du *et al.*, 2021). Circ_0072083 knockdown is involved in DPP-triggered NSCLC tumor inhibition through the miR-545-3p/CBLL1 axis (Li *et al.*, 2020). Nevertheless, it has not been reported that circ-ANXA7, as a competitive endogenous RNA, combined with miR-545-3p to participate in NSCLC DDP resistance.

Cyclin D1 (CCND1), a recognized cell cycle-associated protein, exerts a crucial action in cell cycle change (Meng *et al.*, 2021). CCND1 is a critical driver of malignant transformation and is frequently elevated in NSCLC, leading to the aberrant proliferation of NSCLC cells (Liu *et al.*, 2020). Notably, modulating CCND1 can alter DDP-resistant cell malignant phenotype (Ju *et al.*, 2020). In this study, it was hypothesized that circ-ANXA7 might participate in NSCLC DDP resistance *via* miR-545-3p to modulate CCND1.

In this study, 2 DDP-resistant NSCLC cell lines (A549/DDP and H460/DDP) were constructed, and

circ-ANXA7 was confirmed to modulate DDP-resistant NSCLC cell sensitivity and behavior. Additionally, this research further elucidated the action of circ-ANXA7/miR-545-3p/CCND1 axis in DDP resistance and cancerization of NSCLC.

MATERIALS AND METHODS

Clinical tissue specimen

90 tissue samples were obtained from the School of Medicine, University of Electronic Science and Technology of China, including 30 non-tumor tissue samples from patients with pulmonary laceration repair (control) and 60 NSCLC tissue samples from NSCLC patients with radical resection. Patients with progressive disease (PD) or postoperative recurrence less than 6 months were DDP-resistant, while patients without PD and postoperative recurrence over 12 months were non-resistant. All tissue samples were placed at –80°C. Authorization of the study was performed by the Ethics Committee of the School of Medicine, University of Electronic Science and Technology of China, and written informed consent was obtained from all participants.

Cell culture and transfection

NSCLC cell lines (A549 and H460) were purchased from American Tissue Culture Collection (Manassas, VA), and human bronchial epithelioid cells (HBE-1) were from Bena Culture Collection (Beijing, China). Cells were cultured in Roswell Park Memorial Institute-1640 medium (Hyclone, Logan, UT, USA) containing 10% fetal bovine serum, 100 U/ml penicillin and 100 mg/mL streptomycin (Gibco, Carlsbad, CA). DDP-resistant cells (A549/DDP and H460/DDP) were established and grown in a complete medium replenished with DDP (1 μg/mL, Sigma-Aldrich, St. Louis, MO) to maintain resistance. All cells were cultured in 5% CO_2 at 37°C (Pang *et al.,* 2020).

sh-circ-ANXA7, miR-545-3p mimic and inhibitor, as well as corresponding negative controls (sh-NC, mimic-NC, in-NC) were designed and generated (Ribo Biotech, Guangzhou, China). CCND1 overexpression plasmid was purchased from ORIGENE, with empty plasmid as NC. When cell confluence reached 70% to 80%, A549/DDP cells were plated into 6-well plates ($1×10^5$ cells/mL) and cultured for 24 h. Transfection of cells was performed using Lipofectamine 3000 (Invitrogen) (Hu *et al.,* 2021). Transfection concentrations of mimic and inhibitor were 50 nM and 20 nM, respectively, and 1 μg and 2500 ng for sh-circANXA7 and CCND1 overexpressed plasmid, respectively. After 48 h, the transfection efficiency was evaluated by reverse transcription quantitative polymerase chain reaction (RT-qPCR) or Western blot.

Ribonuclease R and actinomycin D assays

RNase R assay: total RNA (2 μg) from A549 cells was incubated with 3 U/μg RNase-R (07250, Epicentre Technologies, USA) at 37°C for 30 min. circ-ANXA7 and ANXA7 mRNA expressions were subsequently determined by RT-qPCR.

Actinomycin D test: Cells were cultured with or without 2 μg/ml actinomycin D (Sigma, USA) and harvested at different points in time. Circ-ANXA7 and ANXA7 mRNA was determined by RT-qPCR (Wu *et al.,* 2020).

Subcellular localization analysis

Cytoplasm RNA and nuclear RNA of cells were isolated using PARIS Kit (Invitrogen). Then, the examination of circ-ANXA7 in cytoplasm RNA and nuclear RNA was implemented by RT-qPCR. U6 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were nuclear and cytoplasmic controls, respectively.

RT-qPCR

Extraction of total RNA from NSCLC tissues and cells was done using Trizol reagent (Invitrogen). Reverse transcription of circRNA/mRNA and miRNA was performed with PrimeScript RT reagent Kit and miRNA First Strand Synthesis Kit (both Takara, Tokyo, Japan), respectively. RT-qPCR was performed with SYBR Green kit (Thermo Fisher Scientific, Waltham, MA, USA) and Mx3005P qPCR system (Agilent Technologies, Santa Clara, CA, USA). U6 and GAPDH were loading controls for miRNA and mRNA/circRNA, respectively. Primer sequences were presented in Table 1 (Song *et al.,* 2021).

Western blot

Extraction of total protein was done with 500 μL Radio-Immunoprecipitation assay lysis buffer (Beyotime, China). An equal amount of protein (20 μg) was separated by 8% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (Solarbio), electroblotted onto polyvinylidene fluoride membranes (Invitrogen), and blocked with 5% skimmed milk, followed by incubation with primary antibodies CCND1 (ab134175, Abcam, 1: 1000), anti-P-glycoprotein (P-gp) (ab170904, Abcam, 1:3,000), glutathione S-transferase π (GST-π) (ab233112, Abcam, 1:1,000) and GAPDH (1:7,500, ab8245) at 4°C overnight and horseradish peroxidase-conjugated goat anti-rabbit Immunoglobulin G (IgG) (1:1000, ab181236, Abcam) for 2 h. Visualization of the signal was performed with an enhanced chemiluminescence kit (34080, Thermo Fisher Scientific). Density analysis was performed with ImageJ software.

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay

A549/DDP cells ($5×10^3$/ well) were seeded into 96-well plates and cultured overnight. MTT reagent (beyotime) was added at different time points (0, 24, 48, 72 h) and incubated at 37°C for 4 h. Then, 150 μL Dimethyl Sulfoxide was added to each well and 10 min later, optical density at 490 nm was read with a microplate reader (PerkinElmer) (Zhu *et al.,* 2021).

Colony formation assay

A549/DDP cells ($5×10^3$/well) were seeded in 12-well plates and cultured for 14 d, during which a fresh complete medium was replaced every 3 days and the wells were washed twice with PBS. Then, colonies were fixed in paraformaldehyde (4%, Beyotime), dyed with 0.1% crystal violet (Beyotime) for 2 h, and washed with ddH_2O_3 times. The number of colonies was counted under an inverted microscope (Nikon).

Flow cytometry

A549/DDP cells ($1×10^5$ cells/well) after DDP treatment were incubated for 48 h. Cell apoptosis was analyzed by Annexin V-fluorescein isothiocyanate (FITC)/Propidium iodide (PI) assay kit (BestBio, Shanghai, China). In brief, cells were rinsed with cold phosphate-

buffered saline (PBS) and incubated with 5 μL Annexin V-FITC and 5 μL PI for 20 min. Ultimately, the assessment of cell apoptosis was implemented on a flow cytometer (FACS Calibur flow cytometer) (Wei *et al.*, 2021).

Transwell migration and invasion analysis

Transwell assay evaluated A549/DDP cell invasion and migration. For migration and invasion measurements, transwell chambers were used without or with Matrigel, respectively (Corning, USA). Cells were prepared at $2×10^6$ cells/mL, then 400 μL cell suspension was inoculated into the upper chamber containing serum-free medium, and 10% FBS was added to the lower chamber. After 24 h of culture, cells in the upper layer were removed with cotton swabs, while those in the lower layer were fixed with methanol for 30 min, stained with 0.1% crystal violet, and counted in five fields under a microscope (Swiss taikang, magnification ×100) (Guo *et al.*, 2022).

Luciferase activity assay

A549/DDP cells were plated on a 24-well plate. circ-ANXA7 or CCND1 3' untranslated region (UTR) (Promega) containing miR-545-3p wild-type (WT) or mutant-type (MUT) binding sites was inserted into the pmirG-LO vector (Promega, Madison, WI), and circ-ANXA7/CCND1-WT 3'UTR and circ-ANXA7/CCND1-MUT 3'UTR reporter genes were named. Co-transfection of the corresponding luciferase reporter gene with miR-545-3p mimic or miR-NC was done in A549/DDP cells. After 48 h of incubation, the determination of the luciferase activity was implemented with the luciferase reporter gene kit (Promega) (Guo *et al.*, 2022).

RNA immunoprecipitation (RIP) experiment

Anti-Ago2 (ab252812) and anti-IgG (ab109489) antibodies were utilized for detection. In short, cells were lysed with a lysis buffer and then incubated with protein-g magnetic beads-conjugated anti-Ago2 or IgG at 40°C for 6 h. Microbeads were later collected, and binding RNA was extracted to examine the enrichment of circ-ANXA7 and miR-545-3p (Zhang *et al.*, 2021).

In vivo tumor growth test

The tumor formation experiment was conducted in BALB/c male nude mice (n=24, 6 weeks old, weight of 18–20 g, Huafukang, Beijing, China). A549/DDP cells transfected with sh-Circ-ANXA7, or sh-NC ($1×10^7$) were injected subcutaneously into the back of mice. Mice were divided into four groups: sh-NC+PBS, sh-NC+DDP, sh-circ-ANXA7+PBS, and sh-circ-ANXA7+DDP groups. DDP (5 mg/kg) or PBS was injected to measure the tumor volume once a week. After 4 weeks, transplanted tumors from euthanized mice were weighed. Animal treatments were approved by the Animal Research Committee of the School of Medicine, University of Electronic Science and Technology of China (Shao *et al.*, 2021).

Statistical analysis

Statistical software SPSS 21.0 (SPSS, Inc, Chicago, IL, USA) was utilized to analyze data. Kolmogorov-Smirnov test checked the normal distribution of data, and the results were presented as mean ± standard deviation (S.D.). Two-group comparisons were performed using ttest. Comparisons among multiple groups were imple-

RESULTS

Circ-ANXA7 expression is modulated in DDP-resistant NSCLC tissues and cells

circ-ANXA7 levels in resistant and non-resistant NSCLC tissues and normal tissues were tested by RT-qPCR. Compared with non-resistant NSCLC tissues and normal tissues, circ-ANXA7 was elevated in DDP-resistant NSCLC tissues, clarifying that circ-ANXA7 was associated with DDP resistance in NSCLC (Fig. 1A). Subsequently, analysis of the clinicopathological characteristics was implemented. Table 2 elucidated no difference in age, tumor size, gender, and metastasis between DDP-resistant patients with non-resistant patients. Nevertheless, DDP resistant patients had high levels of circ-ANXA7, deep invasion, low rate of tumor metastasis, and poor differentiation.

Likewise, in normal cells (HBE-1), NSCLC cell lines (A549 and H460) and DDP-resistant NSCLC cells (A549/DDP and H460/DDP), it was observed that circ-ANXA7 was the highest in DDP-resistant cells (Fig. 1B).

RNase R analysis and Act D analysis confirmed the annular characteristics of circ-ANXA7, showing that circ-ANXA7 was available to resist RNase R detachment, and its stability was better than linear ANXA7 mRNA (Fig. 1C–D). Additionally, circ-ANXA7 was primarily distributed in NSCLC cell cytoplasm (Fig. 1E). Kaplan-Meier analysis revealed that high circ-ANXA7 was associated with unpleasing overall survival in DDP-resistant NSCLC patients, as presented in Fig. 1F.

To sum up, circ-ANXA7 was stable and elevated in DDP-resistant NSCLC and might be implicated in NSCLC DDP resistance.

Repressive circ-ANXA7 gene is available to suppress NSCLC's progression and strengthens DDP's sensitivity

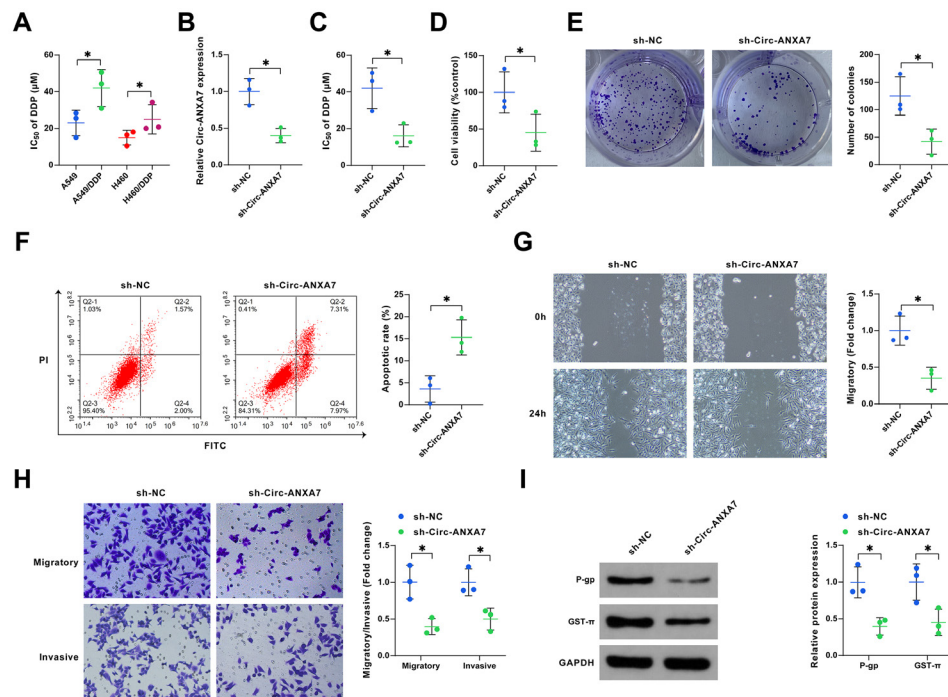
It was found that A549 cells had stronger DDP resistance (Fig. 2A) than H460 cells, and circANXA7 expression in A549 and A549/DDP cells was higher than that in H460 and H460/DDP cells (Fig. 1B), so A549/DDP cells were selected for subsequent studies. As presented in Fig. 2B, circ-ANXA7 was repressed in A549/DDP cells after transfection with sh-circ-ANXA7. Silence of circ-ANXA7 declined DDP IC_{50} (Fig. 2C). Cell proliferation and apoptosis were subsequently examined, and it was found that circ-ANXA7 gene knockout inhibited the viability of A549/DDP cells (Fig. 2D–E), while the apoptosis rate increased significantly (Fig. 2F). In addition, Transwell analysis confirmed that circ-ANXA7 silencing effectively blocked A549/DDP cell migration


Figure 2. Repression of circ-ANXA7 restrains NSCLC progression and strengthens DDP sensitivity

Data were expressed as mean ± S.D. (Number of samples=3). *$P<0.05$.

and invasion (Fig. 2G–H). Western blot analysis of drug resistance-associated proteins (P-gp and GST-π) was performed, elucidating that P-gp and GST-π in A549/DDP cells were lowered after suppressing circ-ANXA7, as presented in Fig. 2I.

In general, repressing circ-ANXA7 was available to suppress NSCLC progression and strengthened DDP sensitivity.

Circ-ANXA7 performs as a sponge for miR-545-3p

To explore the novel mechanism of circ-ANXA7 to modulate NSCLC, prediction of the target miRNA of circ-ANXA7 was performed on the bioinformatics website starBase. circ-ANXA7 and miR-545-3p had complementary fragments (Fig. 3A). MiR-545-3p in A549/DDP cells was elevated after transfecting miR-545-3p mimic (Fig. 3B). The interaction of miR-545-3p with circ-ANXA7 was verified. As presented in Fig. 3C, elevated miR-545-3p constrained the luciferase activity of circ-ANXA7-WT 3'UTR, but it did not repress that of the mutant construct. Circ-ANXA7 and miR-545-3p were abundant in Ago2 antibody-immunoprecipitated RNA complex, but not in IgG antibody-immunoprecipitated RNA complex (Fig. 3D). Additionally, miR-545-3p expression was downregulated in DDP-resistant NSCLC tissues and cells (Fig. 3E–F), and clinical correlation analysis found that miR-545-3p was negatively associated with circ-ANXA7 in DDP-resistant NSCLC tissues (Fig. 3G).

All in all, miR-545-3p could be modulated by circ-ANXA7.

Suppression of miR-545-3p turns around circ-ANXA7 knockdown's influence on NSCLC

To determine the functional regulation of circ-ANXA7 and miR-545-3p, sh-circ-ANXA7 and in-miR-

545-3p were constructed, and their efficacy was explicitly verified *in vitro*. It was discovered that silence of circ-ANXA7 elevated miR-545-3p (Fig. 4A). Subsequently, sh-circ-ANXA7 in combination with in-miR-545-3p or in-NC was transfected into A549/DDP cells. As presented in Fig. 4B, transfection with in-miR-545-3p declined miR-545-3p expression. MiR-545-3p expression was suppressed after sh-circ-ANXA7 was blocked by the miR-545-3p inhibitor. Additionally, it was observed that silence of circ-ANXA7 declined DDP IC$_{50}$, but this effect was suppressed by in-miR-545-3p (Fig. 4C). In the meantime, inhibition of cell viability and promotion of apoptosis by circ-ANXA7 knockdown could be partially reversed by in-miR-545-3p (Fig. 4D–F). Additionally, the introduction of in-miR-545-3p was available to eliminate silenced circ-ANXA7's suppression of cell invasion and migration (Fig. 4G–H). Reduction in circ-ANXA7 led to a decrease in resistance-associated proteins, and this inhibition could be mitigated by supplementation with in-miR-545-3p (Fig. 4I).

In short, circ-ANXA7 modulated NSCLC cell progression and DDP sensitivity *via* absorbing miR-545-3p.

MiR-545-3p immediately targets CCND1

As mentioned above, it was attempted to search for miR-545-3p's direct targets. As presented in Fig. 5A, star-Base predicted the common binding site of miR-545-3p and CCND1. In the meantime, miR-545-3p mimic was available to weaken the luciferase activity of CCND1-WT 3'UTR, while no distinct change was presented in the luciferase activity of CCND1-MUT 3'UTR (Fig. 5B). Additionally, circ-ANXA7 and miR-545-3p were abundant in Ago2 antibody immunoprecipitation but not in IgG antibody immunoprecipitation (Fig. 5C). Compared with non-resistant and normal tissues, CCND1 in DDP-

(**J**) Western blot examination of CCND1 after transfection with sh-circ-ANXA7 or miR-545-3p mimic. Data were expressed as mean ± S.D. (Number of samples =3). *$P<0.05$..

resistant tissues was elevated (Fig. 5D–E). Likewise, CCND1 was also elevated in DDP-resistant NSCLC cells (Fig. 5F–G). In clinical tissues characterized by drug resistance, CCND1 was positively correlated with circ-ANXA7 expression and negatively correlated with miR-545-3p expression (Fig. 5H-I). In A549/DDP cells, downregulation of circ-ANXA7 or overexpression of miR-545-3p decreased CCND1 expression (Fig. 5J).

In brief, CCND1 was miR-545-3p's downstream gene.

Circ-ANXA7 impacts NSCLC progression and DDP resistance via miR-545-3p/CCND1 axis

Functional tests were performed considering the association of miR-545-3p with circ-ANXA7 or CCND1. CCND1 overexpression plasmid strengthened CCND1 expression in A549/DDP cells (Fig. 6A–B). Then, to explain whether CCND1 mediates the effect of circ-ANXA7 on NSCLC progression and DDP resistance, A549/DDP cells were co-transfected with sh-circ-ANXA7 and CCND1 overexpression plasmid or empty plasmid. As presented in Fig. 6A–B, sh-circ-ANXA7 restrained CCND1 expression, which was reversed after co-transfection with the CCND1 overexpression plasmid. Additionally, the upregulation of CCND1 significantly restored the inhibitory effect of circ-ANXA7 silencing on DDP IC$_{50}$ and cell viability in A549/DDP cells in vitro (Fig. 6C–E). In the meantime, downregulation of circ-ANXA7 promoted apoptosis, which was eliminated by

CCND1 overexpression plasmid (Fig. 6F). Additionally, elevating CCND1 restrained sh-circ-ANXA7-mediated repression of A549/DDP cell migration and invasion (Fig. 6G–H). Additionally, silenced circ-ANXA7-induced suppression of P-gp and GST-π was turned around by overexpressing CCND1 (Fig. 6I).

In short, circ-ANXA7 modulated NSCLC progression and DDP resistance via miR-545-3p/CCND1 axis.

Loss of circ-ANXA7 reduces tumor growth *in vivo*

After sh-circ-ANXA7 or DDP treatment, tumor volume and weight were reduced, and sh-circ-ANXA7 and DDP treatment were provided with synergistic suppression (Fig. 7A–B). By examining circ-ANXA7 levels in xenografts, sh-Circ-ANXA7 did decrease circ-ANXA7 expression and promote miR-545-3p levels in excised tumors (Fig. 7C). Additionally, loss of circ-ANXA7 repressed CCND1 expression in excised tumors (Fig. 7D–E).

All in all, loss of circ-ANXA7 interacted with DDP therapy, thereby restraining tumor growth in xenograft tumor models.

DISCUSSION

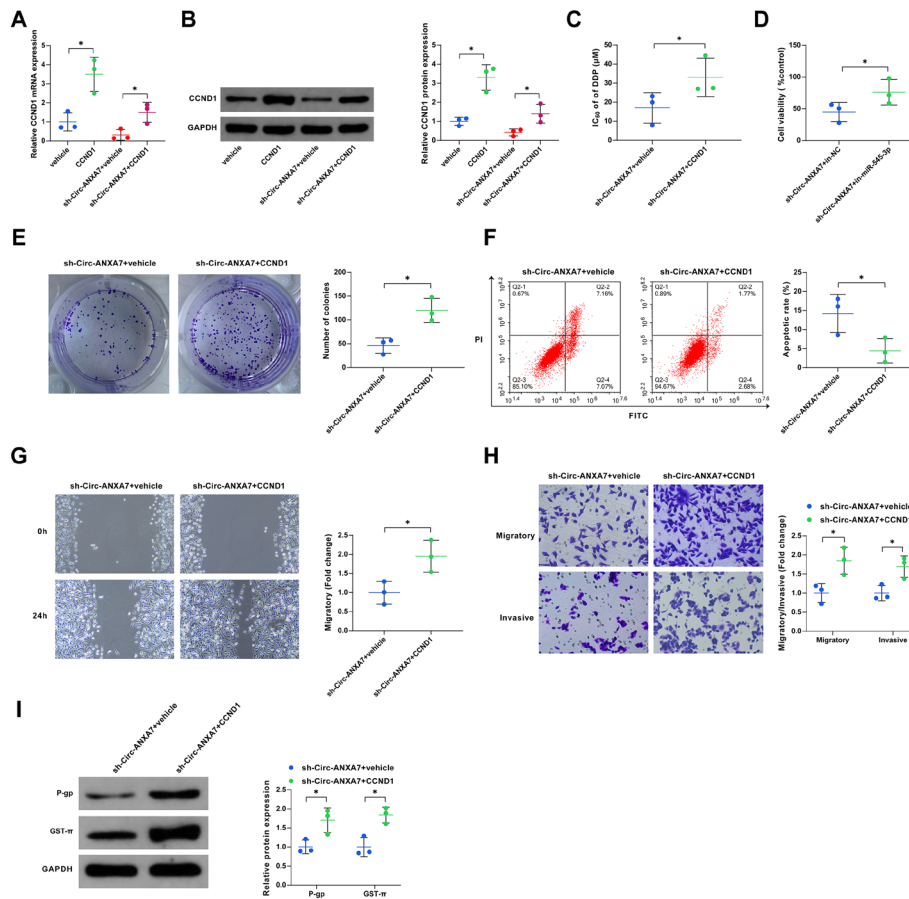
Globally, NSCLC is a deadly cancer with elevated morbidity and mortality (Cao *et al.*, 2021). DDP is the most frequently-adopted chemotherapy drug for the


Figure 6. Circ-ANXA7 impacts NSCLC progression and DDP resistance via miR-545-3p/CCND1 axis
(**A–B**) RT-qPCR and Western blot examination of CCND1 in A549/DDP cells; (**C**) MTT analysis of IC_{50} of DDP in A549/DDP cells; (**D–E**) MTT and colony formation assay detection of cell proliferative activity; (**F**) Flow cytometry test of cell apoptosis; (**G–H**) Transwell assay test of cell migration and invasion; (**I**) Western blot test of drug-resistance associated proteins (P-gp and GST-π). Data were expressed as mean ± S.D. (Number of samples =3). *$P<0.05$.

Figure 7. Loss of circ-ANXA7 lessens tumor growth in vivo
(**A**) Tumor volume changes of mice in each group; (**B**) Tumor weight of mice at 4th week; (**C**) Circ-ANXA7 and miR-545-3p in resected tumors; (**D–E**) CCND1 expression in resected tumors. Data were expressed as mean ± S.D. (Number of samples =3). *$P<0.05$.

treatment of NSCLC (Dong *et al.,* 2019). Nevertheless, DDP resistance severely limits its clinical efficacy (Hong *et al.,* 2020). Consequently, it was crucial to suppress DDP resistance for better treatment of NSCLC patients. It is reported that aberrant circRNA impacts NSCLC cancerization and chemotherapy resistance (Zhang *et al.,* 2021). In this study, it was first discovered that repres-

sion of circ-ANXA7 suppressed NSCLC progression and strengthened DDP sensitivity. Additionally, this study first verified the regulatory network of cir-ANXA7/miR-545-3p/CCND1.

Research has shown that the covalent closed structure of circRNAs makes them more stable in eukaryotes (Fu *et al.,* 2021). Likewise, the data displayed that circ-

ANXA7 after RNase R and Actinomycin D treatment was more stable than linear ANXA7. circRNAs exert critical roles in multiple biological processes of NSCLC (Liu et al., 2021). For instance, in DDP-resistant NSCLC tissues and cells, circ_PIP5K1A expression is augmented, while silencing circ_PIP5K1A is available to restrain cancer progression and strengthen DDP sensitivity (Feng et al., 2021). Additionally, silencing circ_0076305 ameliorates the DDP sensitivity of NSCLC (Wang et al., 2021). In other words, circRNAs modulate cancer progression and DDP resistance. This research focused on a novel circrNA (Circ-ANXA7) derived from host gene ANXA7 chr10 (75138745-75138766). Expression analysis displayed that circ-ANXA7 was elevated in DDP-resistant NSCLC tissues and cells, clarifying that circ-ANXA7 might participate in DDP resistance progression in NSCLC. As expected, it was discovered that circ-ANXA7 silencing inhibited the proliferative activity, migration, invasion, and DDP sensitivity of DDP resistant cells, but promoted apoptosis. Overall, the data have illustrated that circ-ANXA7 is a promoter of NSCLC progression and drug resistance. Nevertheless, circ-ANXA7 in patients' serum was not detected in this study. Notably, a recent report has clarified that exosomes-delivered hsa_circ_0014235 expedites DDP resistance and exacerbates NSCLC development *via* mediating miR-520a-5p/CDK4 pathway (Xu et al., 2020). Consequently, it was a necessity to further examine circ-ANXA7 in NSCLC clinical serum samples in subsequent studies, which might offer novel data support for circ-ANXA7 as a promoter of NSCLC resistance.

As reported, the regulatory function of circRNA is associated with the miRNA/mRNA signaling network (Feng et al., 2021). Notably, it is reported that circRNAs participate in various human cancers via effectively targeting miRNA to mediate gene (Liu et al., 2022). For instance, silencing circ_0007385 restrains malignant behavior and DDP resistance of NSCLC cells via miR-519d-3p/HMGB1 axis (Ye et al., 2020). Circ_0076305 modulates STAT3 and DDP resistance of NSCLC cells via absorbing miR-296-5p as a sponge (Dong et al., 2019). Consequently, miR-545-3p was discovered to have a targeted binding site with circ-ANXA7. Foregoing studies have elucidated that miR-545-3p is silenced in NSCLC and performs as a tumor suppressor gene, restraining NSCLC progression and strengthening DDP sensitivity (Du et al., 2021; Li, Liu, and Qin 2020). Likewise, in this study, it was discovered that miR-545-3p was silenced in DDP-resistant NSCLC tissues and cells and performed as a tumor suppressor gene. Additionally, it was first discovered that miR-545-3p was competitively adsorbed by circ-ANXA7, and upregulating miR-545-3p reversed the inhibitory effect of circ-ANXA7 loss on NSCLC progression and DDP resistance.

miRNAs are available to repress specific proteins after transcription via combining with the 3'UTR of target mRNA (Pang et al., 2020). Consequently, the target genes of miR-545-3p were predicted, and CCND1 among numerous mRNAs has drawn our attention due to its relationship with DDP resistance (Zuo et al., 2021). CCND1 performs as a carcinogen in NSCLC, promoting proliferation, migration, invasion, and drug resistance of NSCLC cells, and may become a potential therapeutic target for NSCLC (Huang et al., 2020; Cui et al., 2020; Liu et al., 2020). Nevertheless, the mechanism of circ-ANXA7/miR-545-3p/CCND1 axis in NSCLC DDP resistance has not been explored. In this research, it was testified that elevated CCND1 was presented in DDP-resistant NSCLC tissues and cells. Additionally, it was

first discovered that miR-545-3p was implicated in DDP resistance in NSCLC via targeting CCND1.

In brief, circ-ANXA7 accelerated DDP resistance in NSCLC via the miR-545-3p/CCND1 axis, which might offer brand-new insights into the treatment of DDP resistance in NSCLC. Nevertheless, the potential involvement of downstream pathways was not considered in this study. In addition, future multicenter and animal studies are needed to further elucidate the role of circ-ANXA7 in DDP resistance in NSCLC.

Effect of 6-hydroxydopamine increase the glutathione level in SH-SY5Y human neuroblastoma cells

Natalia Pieńkowska[1], Grzegorz Bartosz[2] and Izabela Sadowska-Bartosz[1]✉

[1]Laboratory of Analytical Biochemistry, Institute of Food Technology and Nutrition, College of Natural Sciences, University of Rzeszow, Rzeszów, Poland; [2]Department of Bioenergetics, Food Analysis and Microbiology, Institute of Food Technology and Nutrition, College of Natural Sciences, University of Rzeszów, Rzeszów, Poland

Treatment of human neuroblastoma SH-SY5Y cells with a catecholaminergic neurotoxin, 6-hydroxydopamine (6-OHDA) is an acknowledged *in vitro* experimental model of Parkinson disease (PD). A decrease in the glutathione content occurs in PD. Higher concentrations of 6-OHDA lowered the glutathione level in SH-SY5Y cells, nonetheless, we and other authors found a considerable increase in these cells' glutathione content after 24 h treatment with 60 µM 6-OHDA. A synthetic antioxidant, 4-aminotetramethylpiperidine-1-oxyl (4-AT) exerted a similar effect. The aim of the present study was to explain this surprising effect by monitoring the time course of changes in the levels of reduced (GSH) and oxidized glutathione (GSSG), total antioxidant activity (TAC) of human neuroblastoma cell SH-SY5Y extracts as well as the level of reactive oxygen species and activities of enzymes of glutathione metabolism after treatment of the cells with 60 µM 6-OHDA and/or 4-AT for 30 min – 24 h. A transient decrease in the level of GSH and TAC of cell extracts, increase in the level of GSSG, and decrease in the activities of glutathione peroxidase, glutathione reductase, glutathione *S*-transferase and γ-glutamyl-cysteine ligase activities were found followed by normalization or overshoot of the GSH level, TAC and enzyme activities. Increased activity of γ-glutamyl-cysteine ligase activity starting after 4-6 h was responsible for the elevation of the level of GSH and TAC in cells treated with 6-OHDA, 4-AT, and both compounds. The 6-OHDA-induced increase in the GSH content is a result of an overcompensatory response. The antioxidant 4-AT may be useful for the induction of an increase in the level of GSH in neural cells, without the negative effect of 6-OHDA.

Key words: Parkinson disease, 6-OHDA, 4-amino-TEMPO, glutathione, γ-glutamyl-cysteine ligase, oxidative stress

INTRODUCTION

Glutathione (GSH) is the most abundant intracellular antioxidant playing a crucial role in the maintenance of redox homeostasis in cells, including neurons (Aoyama, 2021). A decrease in the GSH content was observed in the substantia nigra of patients with Parkinson disease (PD) and attributed mainly to its reactions with dopamine and its degradation products (Smeyne & Smeyne, 2013; Bjørklund *et al.*, 2021).

The treatment of human neuroblastoma SH-SY5Y cells with 6-hydroxydopamine (6-OHDA) is an acknowledged cellular model of PD (Lopes *et al.*, 2010; Tsai *et al.*, 2020; Xicoy *et al.*, 2020; Pichla *et al.*, 2020; Elyasi *et al.*, 2021; Pichla *et al.*, 2021). 6-Hydroxydopamine induces oxidative stress in the neuroblastoma cells, as demonstrated by increased levels of reactive oxygen species (ROS), decreased activity of superoxide dismutase and catalase, decreased total antioxidant capacity (TAC) as well as increased total oxidant status and heightened levels of oxidative DNA damage, lipid peroxidation, and protein carbonylation (Pichla *et al.*, 2020; Cirmi *et al.*, 2021; Lee *et al.*, 2020; Rashidi *et al.*, 2021; Sun *et al.*, 2020; Ko *et al.*, 2019; Betharia *et al.*, 2019; Hara *et al.*, 2003a; Chen *et al.*, 2022; Ferak Okkay *et al.*, 2021; Ryu *et al.*, 2013; Zhang *et al.*, 2014). Although 6-OHDA is able to cause dopaminergic neurodegeneration in experimental models of PD by an oxidative stress-mediated process, the underlying molecular mechanism remains unclear. There are divergent data on the effect of 6-OHDA on the GSH level in the SH-SY5Y human neuroblastoma cell line. Sun and others (Sun *et al.*, 2020) observed about a 50% decrease in the GSH content after the treatment of SH-SY5Y cells with 80 µM 6-OHDA for 21 h. In turn, Urano and others (Urano *et al.*, 2018) found an about 50% decrease in the GSH content after 3 h treatment of the SH-SY5Y neuroblastoma cell line with 100 µM 6-OHDA. Ko and others (Ko *et al.*, 2019) reported an about 40% decrease in GSH content, while Jing and others (Jing *et al.*, 2016) a 30% decrease in GSH content after 24 h treatment of SH-SY5Y cells with 100 µM 6-OHDA. SH-SY5Y cells treated with 250 µM 6-OHDA for 24 h showed a decrease in the GSH content to about 60% (Cirmi *et al.*, 2021) and to about 20% of the control value (Rashidi *et al.*, 2021). Treatment with 500 µM 6-OHDA for 4 h decreased the GSH level by 40% in neuroblastoma cells (Barrachina *et al.*, 2003), whereas treatment with 600 µM 6-OHDA induced a progressive decrease of the GSH content in SH-SY5Y cells during 3 h incubation (Miyama, 2011).

In contrast, other authors reported increases in the GSH content after treatment of SH-SY5Ycells with lower concentrations of 6-OHDA. Betharia *et al.* (2019)

observed a 6-fold increase in total glutathione after 24-h SH-SY5Y cells treatment with 40 µM 6-OHDA. Tirmenstein and others (Tirmenstein *et al.*, 2005) found a 12-fold increase in the GSH concentration after 24 h treatment of SH-SY5Ycells with 50 µM 6-OHDA noting no change in the GSH: GSSG ratio. We observed no change and an about 2.6-fold increase in the GSH content after 1 h and 24 h treatment of SH-SY5Y human neuroblastoma cells with 65 µM 6-OHDA, respectively (Pichla *et al.*, 2020).

The level of glutathione seems to be critical for the survival of SH-SY5Y cells treated with 6-OHDA since a pretreatment with compounds increasing the level of glutathione ameliorated the toxicity of 6-OHDA to the cells. Pretreatment of SH-SY5Y cells with ³H-1,2-dithiole-3-thione (Jia *et al.*, 2008), *t*-butyl hydroquinone (Hara *et al.*, 2003b), dithiolethiones (Brown *et al.*, 2014, 2016) and 3,4-dihydroxybenzalacetone (Gunjima *et al.*, 2014) protected the cells against 6-OHDA toxicity; all these compounds increased the glutathione content of the cells. Buthionine sulfoximine, an inhibitor of glutathione synthesis, prevented this effect (Gunjima *et al.*, 2014, Brown *et al.*, 2016).

The increase in the GSH content of SH-SY5Y cells induced by lower concentrations of 6-OHDA is intriguing. We decided to study the kinetics of changes in the activities of glutathione metabolism enzymes and glutathione levels in order to understand the mechanism of alterations in the GSH level evoked by 60 µM 6-OHDA, a concentration causing 50% inhibition of cell proliferation and an over 2-fold increase in the GSH content, as found in our previous study (Pichla *et al.*, 2020). We observed previously the protection of SH-SY5Y cells by nitroxides and nitroxide-containing redox nanoparticles from oxidative stress so in this study, we checked also the effect of one of the previously employed nitroxides, 4-amino-(2,2,6,6-tetramethylpiperidine)-1-oxyl (4-aminoTEMPO, 4-AT), applied alone and in combination with 6-OHDA on the glutathione metabolism enzymes. The concentration of 4-AT of 75 µM was employed; this concentration offered significant (ca 50%) protection against 6-OHDA (Pichla *et al.*, 2020). Not differentiated cells were used, like in the previous study (Pichla *et al.*, 2020) and in most studies on the effects of 6-OHDA on the glutathione level in SH-SY5Y cells. We examined also the dynamics of changes in the TAC of SH-SY5Y cell extracts and in the level of ROS in the treated cells.

MATERIALS AND METHODS

Materials and equipment

Human neuroblast cell line from neural tissue SH-SY5Y (CRL-2266) was obtained from the American Cell Culture Collection. This cell line was derived from a metastatic bone tumor of a 4-year-old cancer patient.

Dulbecco's Modified Eagle Medium/Nutrient Mixture F-12 without phenol red (cat. no. 21041025), Dulbecco's Phosphate Buffered Saline (DPBS) (cat. no. 14040-117), and Geltrex™ LDEV-Free Reduced Growth Factor Basement Membrane Matrix (cat. no. A1413202) were purchased from Thermo Fisher Scientific (Waltham, MA, USA). Fetal Bovine Serum (cat. no. S1813), Penicillin-Streptomycin solution (cat. no. L0022), and Trypsin-EDTA solution (10×) (cat. no. X0930) were obtained from Biowest (Nuaillé, France). Dihydroethidium (DHE) (cat. no. 37291), 0.4% Trypan Blue solution (cat. no. T8154), 4-amino-TEMPO (4-AT; cat. no. 163945), *N*-

ethylmaleimide (NEM) (cat. no. E3876), dithiothreitol (DTT) (cat. no. D9760), trichloroacetic acid (TCA) (cat. no. T4885), diethylenetriaminepentaacetic acid (DTPA), ethylenediaminetetraacetic acid (EDTA) (cat. no. D1133), L-ascorbic acid (cat. no. A0278), dimethyl sulfoxide (DMSO) (cat. no. D2438), *o*-phtaldialdehyde (OPA) (cat. no. P1378), 6-hydroxydopamine hydrobromide (6-OHDA) (cat. no. 162957), Triton X-100 (cat. no. X-100), monosodium phosphate (cat nos. 567545), disodium phosphate (cat. no. 106580), 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) (cat. no. 10102946001), potassium persulfate (cat. no. 216224), (±)-6-hydroxy-2,5,7,8-tetramethylchromane-2-carboxylic acid (Trolox; cat. no. 238813), reduced glutathione (GSH) (cat. no. G4251), oxidized glutathione (GSSG) (cat. no. G4376), NADPH (cat. no. 10107824001), 1-chloro-2,4-dinitrobenzene (CDNB) (cat. no. 237329), the Folin-Ciocalteu reagent (cat. no. F9252), sodium carbonate (cat no. 223530), sodium hydroxide (cat. no. S5881), copper sulfate (cat. no. 209198), sodium tartrate (cat. no. 217255), bovine serum albumin (cat. no. A7030), and methanol (cat. no. 322415) were provided by Merck (Poznań, Poland). Hydrochloric acid was purchased from Chempur (Piekary Śląskie, Poland; cat. no. 115752837). Glutathione Peroxidase Assay Kit was obtained from BioAssay Systems, (Hayward, CA, USA; cat. no. EGPX-100). γ-Glutamylcysteine Ligase (GCL) Activity Assay Kit was from Solarbio Life Sciences (Beijing, China; cat. no. BC1210).

Cell culture T25 flasks (cat. no. 156367) were provided by Thermofisher Scientific (Waltham, MA, USA). Transparent 96-well Advanced TCTM culture plates (cat. no 655980), black 96-well flat bottom µClear® Advanced TCTM plates (cat. no. 655986), transparent 96-well plates (cat. no. 655101), black 96-well flat bottom plates (cat. no. 655209) and 24-well cell culture transparent plates (cat. no. 662160) were obtained from Greiner Bio-One (Kremsmünster, Austria). Other sterile cell culture materials were provided by Nerbe (Winsen, Germany) or Greiner Bio-One (Kremsmünster, Austria).

4-amino-TEMPO was dissolved in PBS, filtered through a 0.22 µm filter before each experiment, and diluted in the cell medium. 6-Hydroxydopamine hydrobromide was freshly prepared and stabilized with 0.01% L-ascorbic acid and filtered using a 0.22 µm syringe filter for each experiment. Distilled water was purified using a Milli-Q system (Millipore, Bedford, MA, USA). Fluorometric and absorptiometric measurements were performed in a Tecan Infinite 200 PRO multimode reader or a Spark multimode microplate reader (Tecan Group Ltd., Männedorf, Switzerland). Measurements were performed in nine repetitions (GSH and GSSG content) or in triplicate (ROS level, enzyme activities). Transmission light microscope observations were done in an inverted Olympus CKX53 microscope (OLYMPUS, Tokyo, Japan).

SH-SY5Y cell culture

SH-SY5Y cells were cultured in DMEM/F12 without phenol red (Dulbecco's Modified Eagle Medium Nutrient Mixture F-12), supplemented with 10% v/v heat-inactivated fetal bovine serum (hi-FBS) and 1% v/v penicillin/streptomycin solution. Cells were maintained at 37°C under 5% carbon dioxide and 95% humidity. The medium was changed twice a week, and the cells were passaged at about 80% confluence. For all studies, cells up to 14 passages were used. The morphology was examined under an inverted microscope with phase con-

trast Zeiss Primo Vert (Oberkochen, Germany).Cell viability was estimated by the Trypan Blue exclusion test. Cells were counted using a Thoma hemocytometer (Marienfeld Superior, Lauda-Königshofen, Germany).

Cell treatment

Cells were seeded into wells of transparent 96-well plates, previously covered with 1% Geltrex™ LDEV-Free Reduced Growth Factor Basement Membrane Matrix, according to the manufacturer's protocol, at an amount of 3.5×10^4 cells/well in 100 µL culture medium. After 48-hour incubation, the medium was gently removed and replaced with 100 µL/well of fresh culture medium or culture medium supplemented with adequate compounds: 60 µM 6-OHDA, 75 µM 4-AT, or both compounds together and placed in an incubator. Alternatively, when more cells were needed, 0.5×10^6 cells were grown in T-25 flasks for 48 h and added with proportionally higher volumes of the medium. After various times (30 min, 1 h, 2 h, 4 h, 6 h, 8 h, and 24 h) the plates were withdrawn and analyses were performed immediately.

Estimation of the content of reduced and oxidized glutathione (GSH and GSSG)

The content of GSH was assayed with OPA using a slightly modified method of Senft and others (Senft et al., 2000). Briefly, the medium was gently removed and cells were washed with 150 µL/well of phosphate-buffered saline (PBS). PBS was gently removed by aspiration. Subsequently, 60 µL/well of freshly prepared cold lysis buffer (RQB buffer: 20 mM HCl, 5% TCA, 5 mM DTPA, and 10 mM L-ascorbic acid was added; then, the plates were shaken at 900 rpm for 5 minutes, and centrifuged at 4,000 rpm (5 min, room temperature).

Cell lysates were transferred into two separate black 96-well plates ("+ NEM" and "– NEM") with a black bottom in a volume of 25 µL/well. Into the first plate, "+NEM", 4 µL/well of freshly prepared 7.5 mM NEM in ice-cold RQB buffer were added. Then, 40 µL/well of 1 M phosphate buffer, pH 7.0, was pipetted into both plates, which were shaken for 5 minutes at 900 rpm. Then, 160 µL/well of ice-cold 0.1 M phosphate buffer (pH 6.8) and 25 µL/well of newly prepared 0.5% OPA in methanol were added into "+NEM" and "–NEM" plates. Then, the plates were shaken at 900 rpm for 30 minutes. Fluorescence was measured with a TECAN Spark® multimode plate reader at 355/430 nm. GSH concentration was obtained by subtracting the fluorescence of the plate without NEM from the fluorescence of the NEM-containing plate and the GSH content was calculated, respectively, with reference to protein content in each well.

To determine the content of GSSG, 100 µL/well of the cell lysate was added to the "–DTT" and "+DTT" black 96-well plates followed by 4 µL/well of freshly prepared 7.5 mM NEM and 40 µL/well of 1 M phosphate buffer, pH 7.0. After 5-min shaking, 10 µL of 10 mM DTT was added to the "+DTT" plate, and the plates were incubated for 60 min at room temperature with shaking. Then, 80 µL/well of 0.2 M phosphate buffer (pH 6.8) and 25 µL/well of newly prepared 0.5% OPA were added and the procedure was run as above. The fluorescence of "–DTT" plate was subtracted from that of the "+DTT" plate and the GSSG content was calculated, respectively, with reference to protein content in each well.

Estimation of total antioxidant capacity

The cells (5×10^5) were seeded in T25 flasks and cultured for 48 h; after this time the flask contained about 10^6 cells. Then the cells were subjected to respective treatments and after 24 h, detached by trypsinization, centrifuged (1 000 rpm, 5 min) washed with PBS, centrifuged, and added with 500 µL of ice-cold 10 mM TCA to lyse the cells and prevent oxidation of cell constituents by acidification of the mixture, and frozen at –80°C. After thawing, the lysates were centrifuged (5 min, 13,000 rpm). The total antioxidant activity of the supernatants was assayed using a modified ABTS• decolorization assay (Kut et al., 2022). Briefly, stock ABTS• solution prepared by oxidation of ABTS solution with potassium persulfate was diluted so that absorbance of 200 µin a well of a 96-well plate at 734 nm was equal to 1. To this solution, 25 µL of the supernatants were added and a decrease of absorbance was measured after 1 min and after 30 min at room temperature and corrected for the ABTS• self-decomposition. Total antioxidant capacity was calculated using Trolox with reference to the protein content in each well.

Estimation of the level of reactive oxygen species (ROS)

Cells were seeded on black 96-well plates, cultured, and treated as described above. 100 µL/well of freshly prepared DHE working solution in PBS was added; the final concentration of DHE was 10 µM. The fluorescence was measured immediately at 37°C, at 405/570 nm for 30 min at 1 min intervals. The "area under the curve"(sum of the fluorescence values measured at successive times) was assumed as a measure of the level of ROS.

Estimation of glutathione peroxidase activity

The cells were grown in T25 flasks as above, and after 24 h of the treatments, were detached by trypsinization, centrifuged (1 000 rpm, 5 min) washed with PBS, centrifuged, and added with 500 µL of ice-cold 20 mM phosphate buffer, frozen and thawed. Glutathione peroxidase activity was determined in the cell lysates using the EnzyChrom Glutathione Peroxidase Assay Kit according to the manufacturer's instructions.

Estimation of glutathione reductase activity

Glutathione reductase was assayed by a modification of the method of Carlberg and Mannervik (1975). Aliquots (50 µL) of lysates prepared as above were pipetted to wells of a transparent 96-well plate, added with 110 µL of 0.1 M phosphate buffer, pH 7.6, 20 µL of 1 mM NADPH and 20 µL of 1 mM GSSG. Kinetics of absorbance decrease at 340 nm was measured in a plate reader at 37°C for 5 min. On the basis of the rate of absorbance decrease, the enzyme activity was calculated with respect to the protein content of a well.

Estimation of glutathione S-transferase activity

Glutathione S-transferase activity was assayed by a modification of the procedure proposed by Habig et al. (1974). Cell lysates (50 µL were pipetted to wells of a transparent 96-well plate and added with 130 µL of 0.1 M phosphate buffer, pH 6.5, 10 µL of 20 mM GSH, and 10 µL of 20 mM CDNB in ethanol. An increase in absorbance at 340 nm was monitored for 10 min at room temperature. On the basis of the rate of absorb-

ance increase, the enzyme activity was calculated with respect to the protein content of a well.

Estimation of γ-glutamyl-cysteine ligase activity

Gamma-glutamyl-cysteine ligase activity was assayed using the γ-Glutamylcysteine Ligase (GCL) Activity Assay Kit according to the manufacturer's instructions. The cells were grown in T25 flasks, subjected to the treatments, detached by trypsinization, and washed with PBS. They were lysed by sonication (3 min on ice) as recommended in the instruction.

Protein assay

Protein content was determined according to Lowry *et al.* (Lowry *et al.*, 1951) using bovine serum albumin as a standard.

Statistical analysis

The results are expressed as a percent of values obtained for control (not treated cells) cultured in parallel for the same time. The significance of differences between the control and treated cells was estimated using the Student's "*t*" test.

RESULTS

The time course of the contents of reduced and oxidized glutathione in SH-SY5Y cells treated with 6-OHDA, the nitroxide 4-AT, and both compounds together is shown in Fig. 1. After an initial decrease in the GSH content in cells subjected to all treatments after 30 min, the GSH content increased progressively with respect to control after all treatments. This increase reached statistical significance after 6, 8, and 24 h in cells treated with 6-OHDA, and after 2, 4, 6, 8, and 24 h in cells treated with 4-AT and treated with 6-OHDA and 4-AT. Changes at the "zero time" with respect to control observed in cells treated with 6-OHDA were apparently due to the fact that the minimal manipulation of the cells till complete stopping the reactions took at least a minute; during this time, the reagents applied could react with glutathione and other cell components.

There was an initial small increase in the GSSG content of the cells treated with 6-OHDA or 4-AT after 30

min. Then the GSSG level remained constant, except for a small decrease for 4-AT-treated cells after 8 hours.

Total antioxidant capacity of cell extracts measured by the reduction of the ABTS• radical after 1 min reflects mainly the content of "fast" (rapidly reacting) antioxidants while the measurement of the ABTS• reduction after 30 min reflects the content of the sum of "fast" and "slow" antioxidants ("summary" TAC). The values of TAC obtained after 1 min reduction by the cell extracts were about 67% of the values of TAC obtained after 30 min; this percentage was not affected by the treatments applied. Changes in TAC of cell extracts measured after both 1 min and 30 min were similar to those of the GSH content. There was an initial (for the 0 time) decrease in the content of "fast antioxidants" for cells treated with 4-AT and after 30 min for cells treated with 6-OHDA and a decrease of the "summary TAC" at the 0 time for all types of treatment, maintained after 30 min in cells treated with 6-OHDA. After 4, 6, 8, and 24 h the content of "fast" antioxidants increased over the control levels in cells treated with 6-OHDA, 4-AT, and both compounds, reaching the highest values after 24 h for cells treated with 6-OHDA and 6-OHDA plus 4-AT. Statistically significant elevation of the "summary TAC" was observed after 6, 8 and 24 h for all types of treatment (Fig. 2).

The level of ROS was elevated in cells treated with 6-OHDA over the entire experiment, after 30 min in cells treated with 4-AT, and at the 0 time and after 30 min and 1 h in cells treated with 6-OHDA and 4-AT simultaneously. Later on, the ROS level decreased in cells treated with 4-AT after 8 and 24 h, and in cells treated with 6-OHDA and 4-AT simultaneously after 24 h (Fig. 3).

The patterns of changes in the activities of glutathione peroxidase (GPx; EC 1.11.1.9) and glutathione reductase (GR; EC 1.6.4.2) were similar. Initially, the GPx activity was decreased in cells treated with 6-OHDA after 30 min, 1 h, and 2 h, and increased over the control level for cells treated with 6-OHDA and with 6-OHDA and 4-AT simultaneously after 8 h. GR activity decreased after 30 min for all types of treatment, and after 1 h in cells treated with 6-OHDA and 6-OHDA and 4-AT simultaneously. Later on, an increase in the GR activity was noted, peaking after 6 and 8 h for types of treatment. This increase was maintained after 8 h for cells

Figure 1. Time course of changes in the GSH and GSSG content of SH-SY5Y cells treated with 50 μM 6-OHDA, 75 μM 4-AT, and both compounds together.

treated with 6-OHDA and with 4-AT, coming back to control values after 24 h (Fig. 4).

The activities of glutathione *S*-transferase (GST; EC 2.5.1.18) and γ-glutamyl-cysteine ligase (GCL; EC 6.3.2.2) changed in a similar way though the amplitude of changes was greater for the latter enzyme. The activity of GST was decreased after 30 min in cells treated

with 6-OHDA, after 0.5 and 1 h for cells treated with 4-AT and after 30 min, 1 h and 2 h for cells treated with 6-OHDA and 4-AT simultaneously. Then its activity was significantly increased after 8 h in cells treated with 4-AT, and after 8 and 24 h in cells treated with 6-OHDA and 4-AT simultaneously. The activity of GCL was decreased after 0.5 h and elevated after 4, 6, 8 and 24 h in cells treated with 6-OHDA, decreased after 0.5 h, and increased after 2, 4, 8 and 24 h in cells treated with 4-AT, and increased after 6, 8 and 24 h in cells treated with 6-OHDA and 4-AT simultaneously (Fig. 5).

DISCUSSION

It was speculated that supplementation with N-acetyl-cysteine to restore the level of glutathione may inhibit the progression of PD (Aaseth *et al.*, 2018; Tardiolo *et al.*, 2018). The results of animal experiments are encouraging (Tardiolo *et al.*, 2018).

A decrease in the GSH level was observed in SH-SY5Y cells treated with relatively high concentrations of 6-OHDA as a cellular model of PD. Interestingly, cell treatment with lower concentrations of 6-OHDA induced a profound increase in the cellular GSH content (Tirmenstein *et al.*, 2005; Betharia *et al.*, 2019; Pichla *et al.*, 2020). Exact comparison of data of various authors

Figure 4. Time course of changes in the activities of glutathione peroxidase (GPx) and glutathione reductase (GR) in SH-SY5Y cells treated with 50 µM 6-OHDA, 75 µM 4-AT and both compounds together.
*$p \leq 0.05$ *vs.* control (not treated) cells (Student's "*t*" test); n=3.

Figure5. Time course of changes in the activities of glutathione *S*-transferase (GST) and γ-glutamyl-cysteine ligase (GCL) in SH-SY5Y cells treated with 50 µM 6-OHDA, 75 µM 4-AT and both compounds together.

may be not easy due to subtle differences in conditions. Inter alia, concentrations of the treating agents are usually reported while a description of exposure conditions in the mole per cell metric would be more relevant (Doskey *et al.*, 2015; Bartosz *et al.*, 2022). In any case, treatment with lower amounts of 6-OHDA induced an increase rather than a decrease in the glutathione content of SH-SY5Y cells. This phenomenon is intriguing as it may point to the ways of elevation of the glutathione content in neuronal cells subjected to oxidative stress.

Results of the present study strongly suggest that this increase in the GSH content is of adaptive nature and is preceded by a transient decrease in the GSH level in the cells shortly after the addition of 6-OHDA, 4-AT, and both compounds together. There was an initial small increase in the content of GSSG in cells treated with 6-OHDA and 4-AT alone and, with one exception, no significant changes afterward. The lack of significant changes in the GSSG level in SH-SY5Y cells challenged with a similar concentration of 6-OHDA after 4 h and 24 h was reported previously (Tirmenstein *et al.*, 2005).

The small increase in the GSSG content being a result of GSH oxidation after 30 min can contribute to but cannot account for the decrease in the GSH content occurring at this time as the GSSG constituted not more than 2% of the total glutathione content in SH-SY5Y cells. The main reason for the transient decrease in the content of GSH is most probably the formation of conjugates with products of 6-OHDA oxidation, especially *p*-quinone (Izumi *et al.*, 2005). Nitroxides are known to oxidize glutathione (Głebska *et al.*, 2003) the relatively low decrease in the GSH content and the relatively high increase of the GSSG content in cells treated with 4-AT are compatible with the assumption that in this case, GSH loss was mainly due to the GSH oxidation by 4-AT. 4-AT is a nitroxide, an antioxidant able to decompose superoxide radical anions in a pseudo-superoxide dismutase reaction and to react with other free radicals (Lewandowski & Gwozdzinski, 2017; Prescot & Bottle, 2017); reactions with free radicals can contribute to the GSH loss as well. It is therefore not surprising that the loss of the GSH content observed after 30 min in cells treated with 6-OHDA and 4-AT together is not higher than those observed for cells treated with any of these agents alone and the increase of the GSSG content observed after this time is even lower than that those found after the action of the single compounds. Changes in TAC of cell extracts generally coincided with those

observed for GSH content, in agreement with the view that thiols are the main determinants of cellular TAC.

The permanent elevation of the ROS level in cells treated with 6-OHDA evidences permanent oxidative stress induced by this compound, not counteracted efficiently by increased levels of GSH and TAC. The ROS level was not increased and even decreased by 4-AT at longer incubation times. The presence of 4-AT decreased the ROS level in cells treated with 6-OHDA, evidencing the antioxidant action of this compound.

Cell treatment with 6-OHDA, 4-AT, and both compounds together brought about transient decreases of activity of all enzymes of glutathione metabolism studied, starting at 30 min of incubation and followed by a recovery or even an overshoot several hours later. The loss of enzyme activity may be due to a non-covalent inhibition and (probably mostly) to the damage to enzymatic proteins by thiol oxidation (6-OHDA, 4-AT) and reactions of free radicals and products of 6-OHDA degradation.

Of particular importance are the changes in the GCL activity since it is the rate-limiting enzyme of glutathione biosynthesis. The decrease in GCL activity coincided with the loss of GSH level, apparently evidencing the inability of the enzyme to secure the normal level of GSH consumed at this stage of incubation. The activity of the enzyme was restored relatively quickly; later on, an overshoot took place lasting until 24 h and apparently was responsible for the elevation of GSH content over the control level. It was reported previously that exposure of SH-SY5Y cells to 6-OHDA results increased the expression of the Nrf-2-dependent genes coding for the GCL modifier and catalytic subunits (Tirmenstein *et al.*, 2005). Our results demonstrate that an increase in the activity of this enzyme indeed takes place under these conditions and leads to an overcompensatory increase in the GSH content.

An increase in the expression of increased genes coding for the GCL modifier and catalytic subunits was reported in SH-SY5Y cells treated with a similar concentration of 6-OHDA (Tirmenstein *et al.*, 2005). Genes coding for other enzymes studied (GPx , GR, and GST) are also under the control of the Nrf2 transcription factor (He *et al.*, 2020), which explains the common pattern of activation of all enzymes covered by this study. Semiquinones and quinones react with the Keap protein and activate Nrf2; such products of 6-OHDA metabolism are formed in the cells (Kang *et al.*, 2005).

4-amino-TEMPO increased the level of GSH and TAC, especially after 2-24 h (GSH content) and 4-24 h (TAC). Nitroxides can also activate Nrf2 (Greenwald *et al.*, 2014), which explains the similar pattern of enzyme activation by 6-OHDA and 4-AT. The common mechanism of Nrf2 activation may explain the lack of synergy or additivity of the response.

CONCLUSION

Elevation of the level of cellular GSH is apparently an adaptive reaction to oxidative stress imposed by 6-OHDA, occurring if the cell viability is not compromised too strongly and seems to be advantageous for the cells. Mounting of the Nrf2 response by 4-AT may be of potential therapeutic interest since in PD the level of GSH is decreased in substantia nigra and application of a nitroxide, which has beneficial antioxidant properties *per se*, might be an acceptable way in attempts to increase the level of this key cellular antioxidant.

NADPH oxidase 4 facilitates progression of chondrosarcoma *via* generation of reactive oxygen species

Zheng Jun✉, Wang Lei, Fang Ce, Ren Wen Tao, Meng Xiang Hui and Qing Ci Nan

Department of Orthopedics, Anhui Provincial Cancer Hospital, China

Nicotinamide adenine dinucleotide phosphate oxidase 4 (NOX4) is an enzyme that regulates reactive oxygen species (ROS) generation, and its function in the development of chondrosarcoma remains unclear. In the present study, we studied NOX4 expression in chondrosarcoma by immunochemical examination, and analyzed the role of NOX4 in viability and apoptosis of human chondrosarcoma cell line SW1353 using NOX4 siRNA or NOX4 inhibitor GKT137831. NOX4 level significantly increased in tumor compared to that in para-carcinoma sample. The levels of NOX4 were positively correlated with histological grade and Musculoskeletal Tumor Society stage of the patients. NOX4 level was significantly increased in SW1353 compared with that in chondrocytes CHON-001. Knockdown of NOX4 or inhibition of NOX4 by GKT137831 both decreased generation of ROS, and induced growth inhibition and apoptosis in SW1353, accompanied with the activation of caspases (caspase-3, caspase-8 and caspses-9), upregulation of Bax, cytochrome C(cyt-c), cleaved-PARP and down-regulation of Bcl-2. Moreover, NOX4 siRNA and GKT137831 decreased the expression of p-Akt, p-ERK and p-p65 in SW1353 cells. In an *in vivo* study, NOX4 shRNA transfected SW1353 have shown impaired growth ability compared to the SW1353 when they were injected into the nude mice. Meanwhile, GKT137831 induced growth inhibition and apoptosis in SW1353 xenograft animals, together with increased expression of Bax, cyt-c, cleaved-PARP, and decreased expression of Bcl-2, p-Akt, p-ERK and p-p65. NOX4 plays a positive role in the development of chondrosarcoma and could serve as a promising target against chondrosarcoma clinically.

INTRODUTCTION

Chondrosarcoma is a primary bone cancer with diverse morphological features and clinical behavior. Chondrosarcoma takes up about 20% of all primary malignant tumors of the bone and may occur at any age between 10 and 80 years old (MacDonald *et al.*, 2019). Although chondrosarcomas typically arise from cartilage or cartilaginous precursors within bone, they may occasionally develop within soft tissues throughout the body. At present, clinical treatment options (chemotherapy or radiation treatment) are labeled with poor response and unsatisfied effect, making a challenge to the management of chondrosarcomas (MacDonald *et al.*, 2019; Lee *et al.*, 2012; Gelderblom *et al.*, 2008). Due to absence of effective adjuvant therapy, mesenchymal malignancy has a poor prognosis.

Complicated biochemical processes involved in malignant tumor formation and development provide a lot of promising therapeutic targets and strategies. One of these strategies is to inhibit oxidative stress, as oxidative stress produced reactive oxygen species (ROS) is served as a stimulus for tumor angiogenesis (Klaunig, 2018; Ratliff *et al.*, 2016). Oxidative stress is the cellular state in which levels of ROS override antioxidant defense of the cell. ROS is an oxygen-based chemical intermediate with high reactivity. Under physiological condition, ROS level is tightly regulated through action of various scavenging and antioxidant systems to mediate the normal activity of cellular signaling pathways (Ratliff *et al.*, 2016). However, abnormally elevated ROS production that exceeds scavenging capacity of the antioxidant system has linked to pathobiology of many diseases. Many reports (Chen *et al.*, 2020; Chen *et al.*, 2020; Lee *et al.*, 2019) have supported that ROS play a positive role in the prevention of tumor programmed cell death and promotion of immortalization, metastasis, and other tumor features.

Nicotinamide adenine dinucleotide phosphate (NADPH) oxidase (NOX) produces superoxide anion and other ROS from molecular oxygen throughout the body. NOX transfers electrons from NADPH, they react with oxygen to form superoxide, which is usually rapidly converted to hydrogen peroxide (Ratliff *et al.*, 2016; Bedard & Krause, 2007). Therefore, NOX is a major component of oxidative stress system. At present, several members have been discovered and identified in the family of NOX, including NOX1, NOX2, NOX4, NOX5, etc. (Bedard & Krause, 2007). NOX4 is the sole NOX isoform present in human primary chondrocytes (Drevet *et al.*, 2018). Several reports confirmed the positive role of NOX4 in bone and cartilage homeostasis associated diseases (Drevet *et al.*, 2018; Wegner & Haudenschild, 2020). Moreover, NOX4 was involved in advanced glycation end-products-induced degradation of articular extracellular matrix (Lei *et al.*, 2019). However, NOX4's biological effect in the development of chondrosarcoma is still unclear. Therefore, the aim of the present study was to disclose NOX4's role in the development of chondrosarcoma, and meanwhile to evaluate effectiveness of targeted NOX4 in the prevention of chondrosarcoma.

MATERIAL AND METHODS

Clinical specimens

The present study was approved by the Ethics Committee of Anhui provincial Cancer Hospital and conducted along with the ethical standards of the Helsinki Declaration of 1975, as revised in the year 2000. A total of 40 patients with conventional chondrosarcoma were recruited into current study between 2019 and 2020 at Anhui provincial Cancer Hospital. Informed consents were obtained from all enrolled patients. None of the enrolled patients received radiotherapy or chemotherapy prior to surgery. A total of 80 samples (cancer and adjacent normal tissues) were obtained. Specimens were frozen in liquid nitrogen after resection and stored at -80°C until use.

Cells lines and culture

Human cancer cell lines

Human chondrosarcoma cell line SW1353 and chondrocytes cell line CHON-001 were obtained from the American Type Culture Collection (Manassas, VA, USA). All cells were conventionally maintained in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% fetal bovine serum, 100 U/ml penicillin and 100 μg/ml streptomycin, and routinely cultured in a humidified incubator at 37°C supplemented with 5% CO_2.

Transfection of cells

siRNAs against NOX4 and control siRNA were purchased from Gene Pharma (Shanghai, China). SW1353 cells were transfected with siRNAs using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's instruction. Briefly, the special NOX4 siRNA (40 nM) or non-binding control siRNA (40 nM) was transfected into SW1353 cells and cultured for 12h. After 12 h, the transfection medium was removed and 2 ml DMEM without FBS was added to recover cell growth for 24 h. The NOX4 siRNA sequences were sence 5'-CCAUGUGCCGAACACUCUUTT-3' and antisence 5'-AAGAGUGUUCGGCACAUGGTT-3' (Genepharma, Shanghai, China). Moreover, for stable transfection of shRNA *in vivo*, pGIPZ-lentiviral shRNA vectors targeting NOX4 gene and control vector were purchased from Open Biosystems (Thermo Fisher Scientific, Inc. Waltham, MA, USA), pGIPZ cloning vector contains a puromycin-resistant gene. Briefly, the nucleotide sequences were as follows: shNox4, 5'-GCATG-GTGGTGGTGCTATTCC-3'; and shNC, 5'-TTCTC-CGAACGTGTCACGT-3'. To generate lentiviral particles, HEK-293-T cells were transiently transfected with 4 mg pLKO.1 lentiviral vector (Sigma) containing shNOX4 or sh nontargeting control (Sigma) plus 4 mg of pCMVDR8.91 and 1.0 mg of pMD.2G plasmids using transfection reagent Lipofectamine 2000. SW1353 cells were transduced with lentiviral particles plus 0.4 mg/mL polybrene (Sigma) and infected overnight, and the selection of transfected cells was done by adding 0.75 mg/mL puromycin (Sigma).

Cell Viability Assay

Cell viability was analyzed using MTT assay. Briefly, 5×10^3 cells of SW1353 were seeded into 96-well plates and incubated with 1 μM cisplatin (Sigma Aldrich, St. Louis, MO, USA), 5 μM N-Acetyl-L-cysteine (NAC, Sigma Aldrich, St. Louis, MO, USA) and 1 μM GKT137831 (Med Chem Express, Shanghai, China) for 96 h. At the end of culture, DMSO was added to dissolve the formazan crystals. Absorbance was detected at a wavelength of 570 nm by a microplate reader (BioTek, Winooski, VT, USA). Percentages of cell viability (%) were determined by comparing with the untreated control.

Apoptosis assay

Cells (5×10^4/well) were treated with NOX4 siRNA for 48 h. Quantitative assessment of apoptotic cells was assessed by Annexin V/PI dual dying, as reported previously (Chen *et al.*, 2020). Briefly, at the end of the study, the cells were centrifuged at 1500 rpm for 5 min, washed twice with PBS, and resuspended in 0.5 mL binding buffer containing 1 μg/mL propidium iodide (PI) and 0.025 μg/mL annexin V-FITC (BD Biosciences, CA, USA). Finally, apoptotic cells were analyzed by using FACScan and the CellQuest program (Becton Dickinson, Lincoln Park, NJ, USA).

Measurement of caspases activities

Cells were seeded on 6-well plates (5×10^5 cells/well) and treated with 1μM GKT137831 for 48h or transfected by siRNA NOX4 for 48h. Caspase-3, caspase-8, and caspase-9 activities were measured using commercial colorimetric assay kits (Beyotime, Haimen, China) according to the protocol provided by the manufacturer.

Measurement of intracellular ROS

Intracellular levels of ROS were determined using the fluorescent probe 2',7'-Dichlorodihydrofluorescein diacetate (DCFH-DA) (Santa Cruz Biotechnology, Santa Cruz, CA, USA). The cells were treated with NOX4 siRNA for 48 h, and then were centrifuged, suspended in PBS, and loaded with 20 μM DCFH-DA at 37°C for 30 min. Fluorescence intensity of the formed DCF was analyzed by flow cytometry (Beckman Coulter, Fullerton, CA, USA). Similarly, ROS levels in the grown tumor were measured as described previously, based on the oxidation of DCFH-DA. ROS formation was quantified from a DCF standard curve, and data are expressed as pmol DCF formed/min/mg protein.

Western blot analysis

Western blotting analysis was performed to semi-quantitatively measure targeted proteins. In brief, the cellular or tissue lysates were prepared, and protein concentrations were determined using a bicinchoninic acid assay kit (Thermo Fisher Scientific, Inc., Waltham, MA, USA). Cell lysates were separated by 10% SDS-PAGE and transferred to polyvinylidene fluoride membranes. Blots were blocked with 4% BSA for 1 h at room temperature and then incubated with antibodies against NOX4 (1:1000, Abcam, Cambridge, MA, USA), Bax (1:1000, Abcam, Cambridge, MA, USA), Bcl-2 (1:1000, Abcam, Cambridge, MA, USA), cytochrome c (cyt-c, 1:1000, Abcam, Cambridge, MA, USA), cleaved poly ADP-ribose polymerase (PARP, 1:1000, Abcam, Cambridge, MA, USA), phosphorylated Akt (p-Akt, 1:1000, Abcam, Cambridge, MA, USA), Akt (Akt, 1:1500, Abcam, Cambridge, MA, USA), p-ERK (1:1000, Abcam, Cambridge, MA, USA), ERK (1:1500, Abcam, Cambridge, MA, USA), p-p65 (1:1000, Abcam, Cambridge, MA, USA), and p65 (1:1000, Abcam, Cambridge, MA, USA). After being washed three times, the blots were incubated with peroxidase-conjugated secondary antibody for 1 h at

room temperature, and finally, the bands were visualized by enhanced chemiluminescence gel imaging system, and semi-quantitatively analyzed by Image J software.

In vivo tumor xenograft study

The present animal study was approved by animals' care and use of ethics committee of Anhui provincial Cancer Hospital and carried out in accordance with the U.K. Animals (Scientific Procedures) Act, 1986 and associated guidelines. Male BALB/c nude mice (6 weeks old) were purchased from the Beijing Vital River Laboratory Animal Technology Co., Ltd. (Beijing, China). Animals were housed in a temperature-controlled room with a 12 h light/12 h dark cycle and provided with autoclaved chow and water *ad libitum*. SW1353 cells or shRNA transfected SW1353 cells (5×10^6 cells in 100μl) were injected subcutaneously into the flanks of nude mice, and tumors were allowed to develop for 14 days until they reached a size of approximately 100 mm³. Animals were divided into control group, cisplatin group (5 mg/kg, intragastric administration), GKT137831 group (50 mg/kg, intragastric administration), shRNA control group and NOX4 shRNA group. The mice were treated with vehicle or medicine for 14 days. The volume of implanted tumor of mice was measured twice a week with a caliper, using the formula (width²×length)/2. At the end of the study, all mice were killed, and the tumors were surgically excised, weighed and stored for further use.

Immunohistochemistry detection

Immunohistochemical (IHC) staining of tissue sections were performed using the manufacturer's standard protocols (Beyotime, Haimen, China). Briefly, sections were deparaffinized, and hydrated in a graded alcohol series. The protein reacted with antibody of NOX4 overnight at 4°C. Finally, the slides were incubated for 5 min with chromogen 3,3'-diaminobenzidine tetrahydrochloride. The level of NOX4 was analyzed by a pathologist according to the positive staining area.

Statistical analysis

The data are represented as the mean ± standard deviation. Statistical analysis between groups was performed using one-way analysis of variance and Dunnett's

Figure 1. Representative images of NOX4 immunohistochemical staining of patients with conventional chondrosarcoma.
Numerous positive cytoplasmic NOX4 staining was observed in the tumor samples, but not in the para-carcinoma samples. Results are expressed as the mean ± S.D. **$P<0.01$ compared with tumor samples.

tests (SPSS15.0, SPSS Inc., Chicago, IL, USA). Differences were considered statistically significant at $P<0.05$.

RESULTS

NOX4 overexpressed in chondrosarcoma

As shown in Table 1 and Fig. 1, 40 pairs of chondrosarcoma specimens were collected, and NOX4 expression in the tumor sites was detected and compared with that in para-carcinoma sites *via* IHC assay. The data in Fig. 1 has shown that NOX4 expression was significantly increased in the tumor tissue compared with those in the para-carcinoma ($P<0.01$). NOX4 was lightly expressed in the cytoplasm and nuclei of para-carcinoma sample, however, high staining was observed in the cytoplasm and nuclei of most tumor samples. We analyzed clinicopathologic parameters of the patients and then divided them into two groups based on the NOX4 expression. The result is summarized in Table 1. Briefly, it was interesting to find that NOX4 levels were correlated with histological grade and MSTS stage in patients.

NOX4 mediated viability and apoptosis of chondrosarcoma cell line SW1353

Expression of NOX4 was measured in chondrosarcoma cell line SW1353 and chondrocytes cell line CHON-001. Figure 2A has shown that NOX4 expression was significantly higher in SW1353 than in CHON-001 cells. We used antioxidants NAC and NOX4 specific inhibitor GKT137831 to verify the effect of NOX4 on cell viability. The data in Fig. 2B has shown that SW1353 vi-

Figure 3. Depletion and inhibition of NOX4 mediates activation of Caspases and expression of apoptotic related proteins.
(**A**) SW1353 were treated with 1 μM GKT137831 or transfected by NOX4 siRNA for 48 h, and expression of apoptotic related proteins was evaluated by western blotting analysis; (**B**) caspases activities were measured by commercial kits. Results are expressed as the mean ± S.D. **P<0.01 compared with control group; #P<0.05, ##P<0.01 compared with siRNA control group.

Figure 4. Depletion and inhibition of NOX4 decrease the expression of pro-survival proteins.
SW1353 was treated with 1 μM GKT137831 or transfected by NOX4 siRNA for 48 h. Pro-survival protein p-Akt, Akt, p-ERK, ERK (**A**), p-p65 and p65 (**B**) were evaluated by western blotting analysis. Results are expressed as the mean ± S.D. **$P<0.01$ compared with control group; ##$P<0.01$ compared with siRNA control group.

ability was inhibited by GKT137831 as well as NAC in a time-dependent manner. To further disclose bio-function and effect of NOX4 on cells viability, NOX4 knock-down cell model was developed in SW1353, and changes in the expression of NOX4 and ROS generation were verified by western blotting and flow cytometry analysis (Fig. 2C–2D, $P<0.01$). As seen in Fig. 2E–2F, cell viability and apoptotic death in the NOX4 depletion group was significantly attenuated and enhanced, respectively, compared with the control group ($P<0.01$).

Blocked or silenced NOX4 activated apoptotic related pathway in SW1353

ROS mediates activation of apoptotic related proteins (Bedard & Krause, 2007). Therefore, we measured the change in the expression of cyt-c and Bcl-2 family proteins. As shown in Fig. 3A, NOX4 knockdown by NOX4 siRNA or functional inhibition by GKT137831 greatly increased cytosolic cyt-c, Bax and cleaved-PARP compared with that in the control group. On the other hand, treatment of the cells with GKT137831 or siRNA NOX4 decreased level of Bcl-2 ($P<0.01$). Moreover, we have observed NOX4 siRNA and GKT137831 greatly increased activity of caspases family members (caspase-3, caspase-8 and caspase-9) as well.

Blocked or silenced NOX4 inhibited activation of pro-survival proteins in SW1353

Pro-survival protein Akt, ERK and NF-ϰB are mediated by ROS as well (Coso *et al.*, 2012). Therefore, we further measured the change in expression of p-Akt, Akt, p-ERK, ERK, p-p65 and p65 by western blot analysis. As shown in Fig. 4A, the group that received NOX4 siRNA or GKT137831 showed decreased ratios of p-Akt/Akt and p-ERK/ERK compared with control group ($P<0.01$). Moreover, as can be seen from the results present in Fig. 4B, p-p65/p65 was markedly decreased in cells that received NOX4 siRNA or GKT137831 ($P<0.01$). Therefore, it is suggested that NOX4 mediated SW1353 apoptosis may occur through the regulation of pro-survival proteins.

Blocked or silenced NOX4 effectively inhibited growth of chondrosarcoma in vivo

On the basis of NOX4 mediated pro-apoptotic effect *in vitro*, we further verified whether blocking or silencing NOX4 could possess an anti-chondrosarcoma action. As shown in Fig. 5A–B, in mice injected with NOX4 shRNA transfected cells, the tumor size and weight were significantly smaller than that of shRNA control group ($P<0.01$). Moreover, in the mice treated with GKT137831 or positive drug Cisplatin, the tumor size and weight were significantly smaller than that of control group as well ($P<0.01$). Further *ex vivo* analysis of tumors excised from mice was conducted (Fig. 5C–D), and we confirmed that NOX4 expression and ROS production were effectively reduced by treatment with NOX4 shRNA or GKT137831 ($P<0.01$). As seen in Fig. 6, increased expression of Cyt-c, Bax, cleaved-PARP and decreased level of Bcl-2 were shown in GKT137831/NOX4shRNA groups compared with control group ($P<0.01$). Moreover, we found that p-Akt/Akt, p-ERK/ERK and p-p65/p65 ratios in GKT137831/NOX4 shRNA groups were remarkably decreased compared with control group ($P<0.01$).

DISCUSSION

In recent years, more and more investigations focus on tumor prevention based on inhibiting oxidative stress (Klaunig, 2018). Recent investigations have implicated various NOX isoforms in pathological processes of malignant tumor. For instance, it has been reported that up-regulated NOX1 expression in gallbladder cancer associated fibroblasts predicts a poor prognosis (Wang *et al.*, 2019), and NOX2 expressed in endosomes promotes cell proliferation and prostate tumour development (Harrison *et al.*, 2018). However, little is known about the role of NOX in the development of chondrosarcoma. In previous studies (Drevet *et al.*, 2018; Wegner & Haudenschild, 2020; Lei *et al.*, 2019), it has been reported that among 7 NADPH oxidases expressed in humans, NOX4 is the sole isoform present in human primary chondro-

cytes. Moreover, NOX4 has been involved in the degradation of articular extracellular matrix. Therefore, we suspect that NOX4 plays an important biological effect in the development of chondrosarcoma.

In the present study, we collected clinical samples from chondrosarcoma patients who received surgical operation and found that the NOX4 expression significantly increased in tumor compared with those in paracarcinoma samples. To the best of our knowledge, this was the first time to semi-quantitatively analyze NOX4 in chondrosarcoma. Further study was conducted to

investigate the effect of NOX4 inhibitor on viability of SW1353. In previous studies, diphenylene iodonium (DPI) has been extensively used to inhibit activity of NOX4 because of its powerful inhibition (Yao *et al.*, 2017; Hwang *et al.*, 2020). However, several studies (Rand & Li, 1993; Castro *et al.*, 2009) found that DPI is a non-selective NOX4 inhibitor with mild inhibition on nitric oxide synthase and xanthine oxidase. GKT137831 is a specific inhibitor of NOX4 with high selectivity. Therefore, we used GKT137831 to treat SW1353. In the current study, GKT137831 induced an inhibitory ef-

fect on viability of SW1353 in a time-dependent manner and has shown a similar effect to that of positive medicine cisplatin. Additionally, to identify the potential role of NOX4 in the viability of chondrosarcoma cells, we transfected SW1353 with NOX4 siRNA and then validated transfection efficiency by western blotting and ROS generation. Our results revealed that prevention of NOX4 induced a significant increase in the proliferation inhibition and apoptosis of the cells. More importantly, animal studies demonstrated that NOX4 knockdown or function inhibition by GKT137831 significantly impaired growth of the tumor. In line with previous reports regarding the role of NOX4 in the development of malignant tumors (Tang *et al.*, 2018; Li *et al.*, 2014), NOX4 is a promising pharmacological target for chondrosarcoma prevention.

NOX4 generated ROS has a close relationship with intrinsic apoptosis pathway (Coso *et al.*, 2012). In brief, the status of intrinsic pathway is governed by interplay between pro- and anti-apoptosis members of the Bcl-2 family, including Bcl-2 and Bax. They keep cell death in check by restraining the pro-apoptotic protein Bax, which are the final arbiters of cell death. When activated, Bax triggers mitochondrial damage, allowing release of cyt-*c* and caspases activation (Franklin *et al.*, 2011; Jendrossek *et al.*, 2012). Here, we found that NOX4 knockdown by siNRA intervene, or function inhibited by GKT137831 significantly activate mitochondrial related apoptosis pathway, which was evidenced by increased expression of Bax, cyt-c, decreased level of Bcl-2, and activation of caspase-3, caspase-8 and caspase-9. In agreement with these observations, we noted similar results *in vivo* as well.

Some second messengers (such as protein kinases) and the third messenger are well known downstream of ROS. The first one is Akt, and it is a serine threonine kinase that mediates various biological functions, such as cell proliferation, survival, glucose metabolism, protein synthesis, genome stability, and inhibition of apoptosis in response to different growth factors and extracellular stimuli. Akt inactivates pro-apoptotic proteins (Bcl-2 antagonist of cell death and procaspase-9) to block apoptosis (Shariati & Meric-Bernstam, 2019; Downward, 2004). The second one is ERK. RAS-RAF-MEK-ERK pathway is the most well-studied of the mitogen-activated protein kinase cascades and is critical for cell proliferation, differentiation, and survival. Activation of receptor tyrosine kinases by growth factors and extracellular signals results in sequential activation of RAS, RAF, MEK, and finally ERK, which activates numerous transcription factors and facilitates oncogenesis in the case of aberrant pathway activation (Asati *et al.*, 2016; Barbosa *et al.*, 2021). The third one is NF-ϰB p65, and it is a ubiquitous transcription factor that mediates cytoplasmic/nuclear signaling pathway and regulates gene expression of various cytokines, cytokine receptors, which affected cell proliferation, differentiation, migration, and angiogenesis in tumor cells (Soleimani *et al.*, 2020). To disclose underlying mechanism involved in the NOX4 mediated apoptosis of chondrosarcoma cells, we focused on the effect of blocking NOX4 on activity of Akt, ERK as well as NF-ϰB. Here, we showed that NOX4 knockdown or functional inhibition both induced decreased levels of p-Akt, p-ERK and p-p65 *in vivo* and *in vitro*. These results, together with impaired tumorigenic capacity of NOX4-silenced SW1353 in mice, suggest that NOX4 acts as a growth promoter in chondrosarcoma.

CONCLUSIONS

Our results suggest that NOX4 mediates proliferation and apoptosis of chondrosarcoma cells. Moreover, inhibition of NOX4 induced tumor growth may be via activation of intrinsic apoptosis pathway and regulation of pro-survival factors Akt, ERK and NF-ϰB. NOX4 is a novel and promising target for the drug development against chondrosarcoma.

Gibinski University Clinical Center, Medical University of Silesia, Katowice, Poland, [2]Department of Biochemistry, Faculty of Medical Sciences in Zabrze, Medical University of Silesia, Zabrze, Poland, [3]Department of Ophthalmology, Faculty of Medical Sciences in Katowice, Medical University of Silesia, Katowice, Poland

Context: Oxidative stress is an important factor for vitreomacular interface disease development in a theoretical model.

Purpose: The aim of the study was to evaluate the correlation between oxidative stress in the human epiretinal membrane (ERM) and retinal morphological changes.

Material and methods: The study included patients scheduled for vitrectomy with epiretinal membrane removal. LogMAR best corrected visual acuity was assessed and optical coherence tomography was performed. Patients were divided into three groups: Type 1 – epiretinal membrane with premacular fibrosis; type 2 – epiretinal membrane with co-existing layer hole; and type 3 – ERM with co-existing full-thickness macular hole. During vitrectomy, epiretinal membranes were collected. Total oxidant status was determined by an automated colorimetric method in homogenates of epiretinal membrane.

Statistical analysis: The Mann-Whitney U test, Kruskal-Wallis test and Spearman linear correlation analysis were used. Statistical significance was set with a level of $\alpha = 0.05$.

Results: Twenty-one Caucasian women (60%) and 14 men (40%) were included in the study. The average age of participants was 74.7 years (95% CI: 71.13–75.45). The mean best corrected visual acuity LogMAR value in the group was 0.8 (95% CI: 0.9–0.7). The mean ratio of total oxidant status to protein level in the collected samples was 0.161 (95% CI: 0.08–0.23) μmol/mg of protein. No correlation was found between total oxidant status and the degree of morphological retinal changes.

Conclusion: The study found no significant correlation between the level of oxidative stress in epiretinal membrane and retinal morphological changes.

Introduction

Epiretinal membrane (ERM) is a disease occurring predominantly among patients over 50 years old. It may originate from disorders such as retinal tear, branch or central retinal vein occlusion, and diabetic retinopathy. However, it may also occur without a known reason, and then is termed idiopathic. Previously published data on ERM prevalence in ethnic and age groups vary in the range 2%–29% (Stevenson et al., 2016; Bu et al., 2014; Xiao et al., 2017).

Idiopathic ERM typically consists of a cellular part on the vitreous chamber side and a layer of extracellular matrix (Bu et al., 2014). The exact etiology of ERM is unknown. The cellular layer is mainly composed of retinal glial cells, which have probably migrated to its surface through microdamage of the internal limiting membrane, secondary to posterior vitreous detachment (PVD). Vitreous cortex hyalocytes are the second significant group of cells remaining on the internal limiting membrane (ILM) surface in the course of PVD. Moreover, the presence of macrophages and fibroblasts is found. Myofibroblasts are an important cellular ingredient, originating through the differentiation of glial cells or hyalocytes. They are responsible for formation of a significant part of the ERM extracellular matrix and in further stages for its contraction (Chen and Lee, 2008; Snead et al., 2004; Smiddy et al., 1989).

Another theory of ERM formation is the RPE cells migration through hidden breaks into the inner retina. However, there is currently no direct evidence to support this theory (Wang et al., 2015). Next possible theory suggests that other cell types, such as glial cells, may transform into RPE cells. These GFAP-positive cells could originate from hyalocytes or Müller cells (Bringmann and Wiedemann, 2009; Zhao et al., 2013).

Cellophane maculopathy is the early, asymptomatic stage of idiopathic ERM where the retinal architecture is not considerably affected. In advanced stages the growth and shrinkage of membranes result in retinal fold formation, its swelling, and retinoschisis, and can lead to the formation of holes. The condition is described as macular pucker or premacular fibrosis (Xiao et al., 2017). The coexistence of ERM and lamellar or full-thickness holes may be related to oxidative stress (Chen and Lee, 2008).

Metabolic processes allowing for the correct functioning of cells are largely based on oxidation reactions. They naturally result in the creation of the reactive oxygen species (ROS) which play a crucial role in numerous physiological processes such as the functioning of the immune system, cellular growth, proliferation, differentiation or apoptosis (Wert et al., 2018). An excess of ROS has a highly toxic impact on cells. Thus, its production is balanced predominantly by the activity of anti-oxidation mechanisms. The natural system designed to balance the toxic influence of free oxygen radicals is based on a system of a dozen enzymes. An excess of these reactive oxygen species may be reduced by two anti-oxidation systems, enzymatic and non-enzymatic (Wert et al., 2018; Beyazıldız et al., 2013; Erel, 2005; Altinisik et al., 2018).

Oxidative stress is an imbalance between reactive oxygen species production and their neutralization capabilities (Altinisik et al., 2018).

Rokicki et al. (2016) reported an important association between oxidative stress and glaucoma. Other studies have described the connection of oxidative stress with retinal diseases such as retinitis pigmentosa, retinal diabetes complications as well as retinal vessel diseases, e.g., central retinal vein occlusion (Erel, 2005; Martínez-Fernández de la Cámara et al., 2013; Guidry et al., 2003).

Retinal photoreceptor cells are a cellular population which is one of the most sensitive to oxidative stress in the body (Guidry et al., 2003). This particular vulnerability results from the fact that the retina is one of the most metabolically active human tissues additionally subjected to constant ultraviolet radiation exposure. As a result it produces particularly large amounts of ROS. Moreover, due to its structure and limited contact with the vascular system, the removal of free radicals is particularly ineffective. This is primarily related to the internal retinal layers where the maximization of tissue transparency takes place at the expense of vascularization. It is associated with the most intensive ROS production (Wert et al., 2018; Guidry et al., 2003). Internal layers of the retina are rich in extracellular free radicals, scavengers of vitreous cortex, and their damage may lead to the development of vitreomacular interface diseases (Kohno et al., 2009).

Total oxidant status (TOS) is one of the methods of describing the oxidative stress value, expressing the total oxidation activity of the tested material (Altinisik et al., 2018).

The objective of our research was to assess *in situ* oxidative stress in human tissues, in the direct vicinity of internal retinal layers. For the purposes of the study, it was hypothesized that the presence of lamellar and full-thickness holes is associated with greater oxidative stress than the presence of ERM itself.

Material and methods

The ethics committee of the Medical University of Silesia, Katowice (permission number: KNW/0022/KB1/85/III/18/19) approved the study protocol. The study adhered to the tenets of the Declaration of Helsinki for experiments involving human tissue samples. Written informed consent was obtained from all patients after explanation of the nature and possible consequences of the study.

Posterior vitrectomy with removal of ERM and ILM around the macula was performed in 35 eyes from 35 patients. The first collected structure during the surgery was directed for the examination, with its character determined based on interoperative dying of the retina internal limiting membrane at least twice with the MembraneBlue Dual DORC dye as ERM or ERM/ILM complex collected *en bloc*.

The criteria for inclusion in the study group were: age 65–80 years, white race, patient eligibility for ERM and/or ILM removal, informed consent to the procedure, and written consent to participate in the study.

The exclusion criteria were metabolic and inflammatory diseases in medical history, features of active inflammation measured by C-reactive protein (CRP) activity, and obesity above BMI 29.99.

Depending on the pre-surgery retinal morphology the cases were divided into three types. Type 1 – patients with diagnosed ERM presence with premacular fibrosis (PMF), type 2 – patients with ERM with co-existing lamellar hole, type 3 – patients with ERM with co-existing full-thickness macular hole.

For each patient LogMAR best corrected visual acuity (BCVA) was assessed. Optical coherence tomography (Cirrus HD-OCT 5000, Carl Zeiss Meditec, Dublin, CA) was performed to assess the morphology and describe central retina thickness parameters.

Analysis of Total Oxidant Status (TOS) was performed in ERM homogenate and was conducted using a PerkinElmer automated analyzer (PerkinElmer, Waltham, MA, United States) in according to Erel (2005). This method excludes the influence of solution dilution on the TOS value. The assay is based on the oxidation of ferrous ion to ferric ion in the presence of various oxidant species in acidic medium. The change in color of the ferric ion by xylenol orange is measured as a change in absorbance at 560 nm. The automated analyzer Perkin Elmer was calibrated with hydrogen peroxide. The TOS value was expressed in µmol/mg of protein.

Statistical data analysis was conducted using tools available in the Statistica v. 12.0 software. Quantitative variables are presented as the mean and 95% confidence interval. Statistical significance of differences in quantitative variables between two groups was estimated based on the Mann-Whitney U test and in the case of comparison of three groups the Kruskal-Wallis test. Spearman linear correlation analysis was used for the simple analysis of correlation between quantitative variables. The interpretation of results of simple statistical significance tests of differences and correlations was conducted with the adopted significance level $\alpha = 0.05$.

Results

The examined group consisted of 21 Caucasian women (60%) and 14 men (40%). The average age of participants in the whole group was 74.7 years (95% CI: 71.13–76.45). There were no statistically significant differences between the groups of men and women. Three groups were distinguished among the patients, based on the preoperative retinal morphology in OCT. Type 1 was represented by 18 people with a mean age of 74.11 (95% CI: 69.06–77.15); type 2 included 11 people, with a mean age of 75 (95% CI: 70.09–79.9); type 3 was represented by six people, with a mean age of 74.66 (95% CI: 66.99–82.34). Age differences among the groups were not statistically significant.

TABLE 1 Total oxidant status in groups.

Disease type	Parameter	Mean	95% CI
Type 1	TOS/protein [µmol/mg]	0.12	0.03–0.20
Type 2	TOS/protein [µmol/mg]	0.15	(−0.05) −0.37
Type 3	TOS/protein [µmol/mg]	0.28	0.09–0.47

The mean postoperative BCVA LogMAR value in the entire study group was 0.8 (95% CI: 0.9–0.7). For type 1 the mean BCVA was 0.8 (95% CI: 1.0–0.6), for type 2 the mean BCVA was 0.6 (95% CI: 0.9–0.5), for type 3 the mean BCVA was 1.4 (95% CI: 1.7–1.2). A statistically significant difference was found between types 3 and 2 ($p = 0.001$) and between types 3 and 1 ($p = 0.03$).

The average ratio of total TOS to protein level in the collected sample was 0.161 (95% CI: 0.08–0.23) µmol/mg protein. The analysis by group showed no statistically significant differences. The p-value for comparisons between the three groups was 0.3. The values of average TOS in relation to the amount of material collected, divided into groups, are presented in Table 1. There was no statistically significant relationship between the age of participants and the tested parameters ($p > 0.05$). The highest TOS value was in group 3 and was 0.28 µmol/mg protein. The mean TOS value in patients with ERM was 0.09 (95% CI: 0.03–0.15). However, the average TOS value in people with ERM/ILM was 0.17 (95% CI: 0.06–0.28). The p-value for the correlation between ERM and the ERM/ILM complex was 0.73.

The average value of central retinal thickness (CRT) in the entire group was 410.8 µm (95% CI: 373.74–447.85). When analyzing correlations with TOS parameters, protein concentration and age, no statistically significant correlations were observed. When divided into groups according to the type of disease, there was a statistically significant difference between the CRT value in patients with type 1 (460.22 µm) and type 3 disease (304.16 µm; $p = 0.012$). Detailed parameters in the groups are presented in Table 2.

Discussion

To the best of our knowledge this is the first study to assess the total oxidant status *in vivo* in internal retinal layers and in ERM directly associated with them. It is also the first study to determine the oxidative stress level in eyes with ERM depending on their morphology and degree of central retinal deformation estimated in the OCT examination.

The retinal membranes (pathological structure) and the internal limiting membrane (one of the layers of the retina) are the material closest to the nervous tissue of the eye that can be collected and evaluated *in vivo* in the immediate vicinity of the macula. The collection of the above membranes is part of the surgical procedure and the resulting limitation is a negligible

TABLE 2 Central retinal thickness.

Disease type	Central retinal thickness – CRT (μm)	95% CI
Type 1	460.22	415.20–505.23
Type 2	388.09	448.99–287.00
Type 3	304.16	192.86–415.47

amount of material that is obtained for testing. In our study we decided to assess the correlation between morphological changes of the retina and TOS. Previous studies demonstrated that in patients with ERM the mean central retinal thickness significantly corresponds with visual acuity. This constitutes an objective and repetitive parameter obtained in the OCT examination and is the basis of ERM severity grading systems (Stevenson et al., 2016).

We did not detect a significant relationship between the amount of oxidative stress, expressed by TOS *in situ*, and the thickness of the retina in the place where the material for testing was taken. We also found no statistically significant differences between TOS in the case of the co-occurrence of lamellar or full-thickness holes in the central retina. The determined TOS values do not show any dependence on the severity of morphological changes in the retina.

The myofibroblasts in the ERM cell layer are responsible for its tendency to contract, resulting in the formation of holes in the retina and/or its wrinkle and edema. They are derived from differentiated retinal glial cells and hyalocytes of the posterior hyaloid membrane (Kohno et al., 2009; Abrahan et al., 2009).

Abrahan et al. (2009) observed *in vitro* the effect of oxidative stress on the differentiation and proliferation of retinal microglia and Müller cells. In our *in vivo* model, we examined only one parameter of oxidative stress at the time of an already developed ERM and an advanced disease process known as macular wrinkle or PMF. The small amount of material obtained during the surgical procedure did not allow for the determination of a greater number of markers of oxidative stress with the biochemical methodology applied in this study.

The influence of oxidative stress on the function of the retina *in vivo* in an animal study was demonstrated by Berkowitz (Berkowitz et al., 2019). They found damage to the retinal light response in mice with pharmacologically induced oxidative stress, regressing with administration of antioxidants. Although the reduction of oxidative stress in the animal model led to the improvement of the functional retina, the available human studies did not confirm the effect of orally administered antioxidants on the improvement of retinal morphology parameters in optical coherent tomography (Garcia-Medina et al., 2015).

Available *in vivo* studies on humans refer to single oxidative stress marker assessment in patients with diabetic retinopathy. Collected samples of vitreous body or secondary ERM were compared with idiopathic ERM (Augustin et al., 1995; Lu et al., 2014).

When examining TOS, we did not find any relationship between the severity of changes in OCT and the state of oxidative stress in the retina. The advantage of our study is primarily the attempt to assess the state of oxidative stress *in situ*, which does not always correspond to the systemic state (Lavi et al., 2008; Davel et al., 2012). In our opinion, it gives a more precise picture of changes induced by oxidative stress in such specific oxygen conditions as the vitreoretinal region.

Study limitations

The main limitation of the study was the lack of measurement of TOS in both the ERM and the peripheral blood. However, due to the strong blood-retina barrier, oxidative stress in the eye may not reflect oxidative stress in the whole body.

The very strong point of this study is the measurement of oxidative stress *in vivo*, i.e., in the eye tissues, precisely in the ERM, and not using *in vitro* method. This pilot study included only 35 patients. A broader study is planned, including a larger group of patients, taking into account TOS parameters in both eye tissues and peripheral blood, and assessing their relationship.

Conclusion

The degree of epiretinal membrane does not directly depend on the state of oxidative stress.

Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Ethics statement

The studies involving humans were approved by The Medical University of Silesia ethics committee, Katowice

(permission number: KNW/0022/KB1/85/III/18/19). The studies were conducted in accordance with the local legislation and institutional requirements. The participants provided their written informed consent to participate in this study. Written informed consent was obtained from the individual(s) for the publication of any potentially identifiable images or data included in this article.

Osteosarcoma's genetic landscape painted by genes' mutations

Wiktoria Urban[1#], Dagmara Krzystańska[1#], Michał Piekarz[2#], Jerzy Nazar[2#] and Anna Jankowska[1✉]

[1]Department of Cell Biology, Poznan University of Medical Sciences, Poznań, Poland; [2]Department of Orthopaedics and Traumatology of Locomotor System, Heliodor Swiecicki Clinical Hospital in Poznan, Poznan University of Medical Sciences, Poznań, Poland

Purpose: Osteosarcoma (OS) is one of the most common primary bone tumors. Direct pathogenesis remains unknown, however, genes' mutations are proven to participate in the process. This study aimed to examine the most frequently mutated genes in OS to appoint candidates for the cancer markers. **Methods:** Using the COSMIC Catalogue twenty the most frequently mutated genes were selected leading to an up-to-date genetic OS landscape summary. The genes can be classified into four categories: suppressor genes (*TP53, RB1, NCOR1, SMAD2, NF1, TSC2, KMT2C*), proto-oncogenes (*GNAS, BRAF, MLLT3*), epigenetic and post-translational modification-related genes (*SMARCA4, ARID1A, ATRX, BCOR, H3F3A*) and cell growth and survival regulating genes (*EGFR, CAMTA1, LRP1B, PDE4DIP, MED12*). **Results and conclusions:** Their role in cancerogenesis was confirmed by the analysis of available articles published previously. The results of the study indicate that examination of selected genes' mutations might help to identify patients' predisposition to OS development, as well as monitor the disease progression, and establish prognosis. However, to fully understand the pathogenesis of OS further studies are required.

INTRODUCTION

Osteosarcoma (OS) is one of the most common primary bone tumors. It occurs intraosseous, mainly in the metaphyseal region of the long bones. OS is inflicting an accelerated osteoid matrix production, which is connected to being developed at sites where bone grows expeditiously. Current data prove that OS has two main peaks of incidence: in childhood and adolescence. OS is the third most common type of tumor affecting young people, with the highest incidents in the early twenties (Wu & Livingston, 2020; Sun *et al.*, 2020; Misaghi *et al.*, 2018; Czarnecka *et al.*, 2020).

Osteosarcoma is divided into several subtypes (Fig. 1). It can be categorized depending on the region of bone it affects (the surface and central part of the bone, and within the medulla). The staging scheme divides OS into two classes depending on the grade of the tumor (low or high), as well as the localization of the compartment (extra- or intra-compartmental). Additionally, it is classified considering the metastatic level of the tumor. The most common classification groups OS as osteoblastic, chondroblastic, fibroblastic, and small cell subtypes. Among mention above types of ostesarcoma, the most often diagnosed one is a high-grade tumor, occurring extra-cortically (Misaghi *et al.*, 2018).

Even though the exact mechanisms responsible for OS pathogenesis are not known, it is confirmed that genetics play a role in the tumor origin. The most common characteristic of OS includes genome disorganization, together with alterations of tumor suppressor and DNA repair, as well as changes in cell cycle aneuploids with chromosomal alterations (de Azevedo *et al.*, 2020).

**Classification of osteosarcoma subtypes**

Figure 1. The most common classification of osteosarcoma subtypes, depending on the predominant type of cells affected by OS.

It was proved that OS can be developed as a consequence of alteration in tumor suppressor genes, including *TP53* and *Rb1,* during hereditary disorders such as Li-Fraumeni cancer family syndrome and retinoblastoma (Porter *et al.*, 1992; Fletcher & Unni, 2002; Misaghi *et al.*, 2018; Sun *et al.*, 2020). However, also other genes, such as transcription factors, and tumor suppressor genes, including *CAMTA1*, or *KMT2C* might participate in osteosarcoma development (He *et al.*, 2021; Chen *et al.*, 2016; Chiappetta *et al.*, 2019).

Currently, there are no laboratory tests or specific biomarkers to diagnose osteosarcoma (Misaghi *et al.*, 2018). Even though there are some molecules expressed in OS that are proposed as their potential markers. The most promising one appears to be alkaline phosphatase (ALP), which increased serum level and seems to correlate positively with tumor volume (Limmahakhun *et al.*, 2011). Additionally, C-reactive protein (CRP), Cathepsin D, osteocalcin, SATB2, and aspartic endoprotease can help distinguish OS (Misaghi *et al.*, 2018; Czarnecka *et al.*, 2020; Agustina *et al.*, 2018; Machado *et al.*, 2016; Tallegas *et al.*, 2022).

In addition to proteins, microRNA expression also seems to be valuable in the diagnosis of osteosarcomas. Overexpression of miR-421 and miR-191 proves to be linked with proliferation, migration, and malignant character of the tumors. Their levels in the serum of OS patients were higher compared to samples from healthy volunteers (Czarnecka *et al.*, 2020).

Moreover, the presence of tumor-initiating cells (TICs) may help in OS diagnostics. TICs expressing markers of stem cell phenotype, such as NANOG or SOX4 were observed in both primary and metastatic tumor tissue (Yan *et al.*, 2016). These proteins, together with CD133+, which is a distinctive marker of TICs observed in osteosarcoma cell lines (Czarnecka *et al.*, 2020). It has been proved that the expression of CD133 in OS patients is related to distant metastasis and poor prognosis. making this a tumor marker (Xie *et al.*, 2018).

Finally, the prevalence of mesenchymal stem cells (MSCs) connected with OS progression is proposed to be the tumor marker. Changes in the expression of c-Myc, Rb, AP-1 or TWIST were shown to contribute to the transformation of MSCs into osteosarcoma tumor cells (Yang *et al.*, 2020). Most sarcomas characterize a permanent mesenchymal state. However, their phenotype can change by factors regulating epithelial-mesenchymal transition – EMT. These factors have been shown to be highly correlated with the invasiveness and higher risk of metastasis in malignant OS (Wu *et al.*, 2019; Yu, Yustein & Xu, 2021). An EMT-related genes' panel (including *LAMA3, LGALS1, SGCG, VEGFA, WNT5A, MATN3, ANPEP, FUCA1*, and *FLNA*) was used as a predictive marker in a multi-cohort study of OS. The panel proved to be a reliable tool for estimating the overall survival of OS patients. Moreover, it was proposed as a selection method for patients with metastases for personalized treatment (Yiqi *et al.*, 2020).

Even though numerous studies describe molecules, whose expression may characterize osteosarcomas, all pointed proteins and/or miRNA are not specific to OS. Thus, further studies are needed to establish biomarkers helping to diagnose and treat OS.

The present study aims to provide a comprehensive, up-to-date study of genes the most frequently mutated in osteosarcoma using the COSMIC Catalogue. Such genes would become candidates for OS markers.

COSMIC, the Catalogue Of Somatic Mutations In Cancer (https://cancer.sanger.ac.uk) is a database providing tools to explore somatic mutations and their correlation with human cancers. The catalogue is the collection of somatic mutations. The data used to build this catalogue derives strictly from the scientific literature. COSMIC additionally provides information about patients' genetic predispositions and environmental factors participating in the process of cancerogenesis (Tate *et al.*, 2019).

MATERIALS AND METHODS

To identify the most common somatic mutations occurring in osteosarcoma patients, the COSMIC Cancer Browser tool (https://cancer.sanger.ac.uk/cosmic/browse/tissue) was used. The catalogue provides information about 282 osteosarcoma samples (classified into 9 histological subtypes). The biological relevance of the 20 most frequently mutated genes pointed out by the COSMIC Cancer Browser was investigated by the analysis of publications available on PubMed (https://pubmed.ncbi.nlm.nih.gov/). To search for the publications, specific keywords, such as: selected genes' name, osteosarcoma, cancer, and mutation were used. For each gene research was divided into two keyword panels – first: selected genes' name, cancer, mutation; second: selected genes' name, osteosarcoma, mutation.

RESULTS AND DISCUSSION

Genes the most frequently mutated in OS

The analysis of the COSMIC Catalogue provided a list of genes in which somatic mutation may participate in osteosarcoma development. Out of 18,309 entries of genes, the top 20 genes, based on the frequency of their

Table 1. The frequency of gene mutation in OS samples in the COSMIC Catalogue

Gene	Number of OS samples available in COSMIC catalogue	Number of mutated samples and % of frequency
TP53	371	91 (25%)
RB1	285	22 (8%)
ATRX	212	16 (8%)
KMT2C	215	13 (6%)
LRP1B	136	8 (6%)
CAMTA1	134	7 (5%)
NCOR1	208	9 (4%)
MLLT3	134	6 (4%)
PDE4DIP	134	6 (4%)
GNAS	352	9 (3%)
SMARCA4	211	6 (3%)
ARID1A	210	6 (3%)
H3F3A	453	11 (2%)
EGFR	280	5 (2%)
BRAF	257	6 (2%)
SMAD2	243	5 (2%)
NF1	216	5 (2%)
MED12	210	5 (2%)
TSC2	210	5 (2%)
BCOR	209	5 (2%)

Figure 2. The top 20 most frequently mutated genes in OS according to COSMIC Catalogue

mutation were selected. They are shown in Table 1 and shown in Fig. 2.

All these genes are directly or indirectly involved in oncogenesis (Table 2). Seven out of these 20 genes – *TP53, RB1, NCOR1, SMAD2, NF1, TSC2, KMT2C* are

known to be tumor suppressor genes. Thus, their mutations lead to the expression of malfunctioning protein products and strictly correlate with tumourigenesis. The following three genes: *GNAS, BRAF,* and *MLLT3* are protooncogenes. Other genes – *SMARCA4, ARID1A,*

Table 2. Genes the most frequently mutated in osteosarcomas and their function

Gene	Function	References
TP53	tumor suppression	(Synoradzki *et al.*, 2021)
RB1	tumor suppression	(Li *et al.*, 2022)
ATRX	epigenetics and post-translational modifications	(He *et al.*, 2015)
KMT2C	tumor suppression	(Gala *et al.*, 2018; Lian *et al.*, 2022; Liu *et al.*, 2021)
LRP1B	cell growth, metabolism and survival	(Wang & Xiong, 2021)
CAMTA1	cell growth, metabolism and survival	(Lu *et al.*, 2018)
NCOR1	tumor suppression	(Tang *et al.*, 2020)
MLLT3	protooncogene	(Sun *et al.*, 2017)
PDE4DIP	cell growth, metabolism and survival	(Soejima *et al.*, 2001; Lehnart *et al.*, 2005)
GNAS	protooncogene	(Nomura *et al.*, 2014; Zauber, Marotta & Sabbath-Solitare, 2016; Patra *et al.*, 2018; Afolabi *et al.*, 2022)
SMARCA4	epigenetics and post-translational modifications	(Xu *et al.*, 2021; Jelinic *et al.*, 2014)
ARID1A	epigenetics and post-translational modifications	(Xu *et al.*, 2019)
H3F3A	post-translational modifications of histone H3.3	(Sturm *et al.*, 2012; Park *et al.*, 2016)
EGFR	cell growth, metabolism and survival	(Wang *et al.*, 2004)
BRAF	protooncogene	(Śmiech *et al.*, 2020)
SMAD2	tumor suppression	(Piek, Heldin & Ten Dijke, 1999; Pasche, 2001)
NF1	tumor suppression	(Trovó-Marqui & Tajara, 2006)
MED12	cell growth, metabolism and survival	(Ding *et al.*, 2008)
TSC2	tumor suppression	(Inoki *et al.*, 2002)
BCOR	epigenetics and post-translational modifications	(Huynh *et al.*, 2000)

ATRX, BCOR, and *H3F3A* are related to the epigenetic status of gene expression or posttranslational histone modifications. Finally, *EGFR, CAMTA1, LRP1B, PDE4DIP,* and *MED12* are associated with cell growth, metabolism, and survival.

Molecular basis of OS

Genome destabilization, aneuploids with chromosomal changes, dysregulation of cell cycle and tumor suppressor genes, as well as a lack of DNA repair are some of the most prevalent characteristics of OS (de Azevedo *et al.,* 2020). Epigenetic changes are also recognized as risk factors for OS (Sharma, Kelly & Jones, 2009). Still, the pathogenesis of OS is complex and poorly understood. Thus, the identification of additional genes involved in oncogenesis may lead to advances in understanding OS biology, as well as shortening the time needed to establish diagnosis and introduce proper treatment.

The results of the COSMIC Catalogue analysis allowed distinguishing 20 genes the most frequently mutated in cancer. All recognized genes (Table 2) are known to be key regulators of vital cellular processes such as DNA repair, cell proliferation and differentiation. Thus, their mutations might lead to cancer development.

The most frequently mutated genes and their possible role in OS biology

Among the genes examined during the analysis of the COSMIC Catalogue, the most frequently mutated gene in OS was *TP53.* Its mutation characterized 25% of samples available in the database. *TP53* encodes the P53 protein, which is an essential transcription factor with a tumor suppressor function. It stimulates several processes that result in cell cycle arrest, DNA repair, alterations in metabolism in response to cellular stress, apoptosis, and cell senescence. Moreover, it plays an important role in ontogenesis, myogenesis, and angiogenesis (Synoradzki *et al.,* 2021). Thus, mutated *TP53* appears to be essential for cancer development and its progression. Mutations in *TP53* are known to increase protein instability, which affects clinical characteristics of osteosarcoma, such as metastatic potential, tumor type, and grade as well as its aggressiveness. According to Chen *et al. TP53* mutations are a reliable predictive indicator for osteosarcoma patient survival (Chen *et al.,* 2016).

Another gene commonly mutated in OS is Retinoblastoma transcriptional corepressor 1 gene – *RB1.* Its mutations were observed in 8% of samples available in the COSMIC catalogue. Between 50% and 70% of osteosarcoma cases exhibit mutations in *RB1* (Wu & Livingston, 2020). *RB1* encodes retinoblastoma protein controlling the transition from the G1 to S phase. This makes it a crucial regulator of cell cycle progression. It is suggested that during OS oncogenesis, alterations of *RB1* may correlate with *TP53* inactivation (Wu & Livingston, 2020; Li *et al.,* 2022). Indeed, using mice models it was proved that deletion of *RB1* leads to osteosarcomas development. Osteoblast development and mineralization as well as an increase in the expression of osteogenic markers were positively impacted by the gene deletion (Li *et al.,* 2022).

Yet another gene mutated in 8% of OS is *ATRX* – alpha thalassemia/mental retardation syndrome X-linked. The gene encodes the protein that plays a role in chromatin remodeling and DNA repair. Loss of *ATRX* function has been linked to the accumulation of repetitive DNA sequences and alterations in the epigenetic regulation of the gene expression, which may contribute to the

development and progression of tumor (He *et al.,* 2015). Mutations in *ATRX* have been observed in a variety of cancer types (Haase *et al.,* 2018). In osteosarcoma, *ATRX* dysfunction was linked with chromosomal instability, which contributes the tumor development. The gene's mutations were also associated with poor prognosis and resistance to chemotherapy (Masliah-Planchon *et al.,* 2018). Thus, *ATRX* is pointed out as a promising biomarker of osteosarcoma.

6% of OS samples in the COSMIC catalogue manifested mutation of the *KTM2C* gene. KTM2C has been shown to act as a tumor suppressor. Its expression in OS has been shown to be downregulated, like in a variety of other human cancers, including breast and prostate cancer (Gala *et al.,* 2018; Lian *et al.,* 2022; Liu *et al.,* 2021). Loss of KTM2C expression is associated with poor prognosis and resistance to chemotherapy (Lian *et al.,* 2022; Liu *et al.,* 2021). What is more, KTM2C has been shown to regulate the other tumor suppressor genes, such as *TP53* and *p16INK4a.* By removing methyl groups from histones, KTM2C also activates the expression of oncogenes, such as *MYC* (Liu *et al.,* 2021; Lian *et al.,* 2022; Gala *et al.,* 2018). All these data demonstrate that the *KTM2C* gene can play an important role in OS development.

6% of available OS samples of the COSMIC catalogue were mutated in the *LRP1B* gene – Low Density Lipoprotein Receptor-Related Protein 1B that encodes cell surface receptor for LDL. *LRP1B* has been previously shown to play a role in tumor growth and progression. Additionally, it regulates angiogenesis in some of the cancer types, such as non-small cell lung cancer, renal cell cancer, and neuroglioma (Wang & Xiong, 2021). The gene overexpression observed in various cancers is linked to poor prognosis and decreased patient survival (Brown *et al.,* 2021; Príncipe *et al.,* 2021; Wang & Xiong, 2021). *LRP1B* is associated with the occurrence of osteosarcoma and its overexpression correlates with poor prognosis and decreased patient survival. Therefore the gene might be one relevant factor helping in OS diagnosis (Xu *et al.,* 2021).

A significant role in tumorigenesis and tumor progression is also played by the *CAMTA1* gene encoding a transcription factor – Calmodulin Binding Transcription Activator 1 (He *et al.,* 2021). The gene down-expression correlates with chemoresistance (Pan *et al.,* 2022). It has been shown that the expression of long noncoding RNA CAMTA1 (lncCAMTA1) in breast cancer affects cells viability and promotes their migratory state. Knock-down of lncCAMTA1 leads to cancer cell apoptosis (Lu *et al.,* 2018). *CAMTA1* mutations were observed in 5% of OS COSMIC samples. Even though there is a lack of information about the gene significance for osteosarcoma, still in Epithelioid hemangioendothelioma, that can arise from soft tissues and bones, CAMTA1 was proposed to be an immunohistochemical marker (Anderson & Jo, 2021).

Yet another gene shown to play a role in tumor development and its progression is *NCOR1* (Nuclear Receptor Corepressor 1) gene. COSMIC catalogue analysis showed that as many as 4% of OS samples showed *NCOR1* mutation. The gene encodes a corepressor involved in the regulation of gene expression (Tang *et al.,* 2020). *NCOR1* was observed to be frequently upregulated in breast cancer, and its high expression is associated with good prognosis and better patient survival (Noblejas-López *et al.,* 2018). Interestingly, in bladder cancer, *NCOR1* strongly correlated with immunogenicity, and its mutations were shown to cause activation of anti-tumor

immunity, as well as overexpression of immune-related genes (Lin *et al.*, 2021). According to Luo *et al.* *NCOR* is widely amplificated in osteosarcoma, as it might participate in tumor growth as a regulator of other gene transcription (Luo *et al.*, 2019).

Four percentage of OS samples of the COSMIC catalogue showed mutations of the *MLLT3* gene. MLLT3 protein is part of a super elongation complex (SEC), which is needed to increase the catalytic function of RNA polymerase II (Calvanese *et al.*, 2019). The knockout of the *MLLT3* gene can lead to decreased proliferation of osteosarcoma cell lines, associated with the JNK signaling pathway. Thus, *MLLT3* can be an oncogene candidate involved in osteosarcomas development (Sun *et al.*, 2017).

As much as 4% of samples deposited in the COSMIC catalogue were characterized by *PDE4DIP* gene mutations. Even though there is no information about the gene significance in osteosarcomas, still, PDE4DIP protein, also known as MMGL (myomegalin-like) protein is involved in several intracellular metabolic pathways, which may control OS biology (Soejima *et al.*, 2001; Lehnart *et al.*, 2005).

Three percentage of OS samples carried a mutation of *GNAS* (Guanine Nucleotide Binding Protein, Alpha Stimulating). The gene encodes a signaling molecule involved in many cellular processes involving cAMP signaling. It has been shown to play a role in tumorigenesis (Nomura *et al.*, 2014; Zauber, Marotta & Sabbath-Solitare, 2016; Patra *et al.*, 2018; Afolabi *et al.*, 2022). *GNAS* mutations were observed in various cancers, such as colon, pancreas, and gastrin adenocarcinoma as well as in fibrous dysplasia, which is known to have the potential to form malignancies such as osteosarcoma (Sugiura *et al.*, 2018).

Three percentage of samples deposited in the COSMIC catalogue manifested mutations of the *SMARCA4* gene. *SMARCA4* encodes the catalytic subunit of SWI/SNF complexes, which is associated with chromatin remodeling and making genes accessible for transcriptional factors. Unfortunately, there is a lack of information about the significance of gene alterations in osteosarcomas.

Also, the *ARID1A* gene product (AT-rich interactive domain-containing protein 1A) is a part of the SWI/SFI complex, associated with chromatin remodeling (Xu *et al.*, 2019). *ARID1A* mutations were observed in many cancers before (Jones *et al.*, 2010). Recent studies show that in osteosarcomas the expression of *ARID1A* is down-regulated compared to non-tumor tissues (Xu *et al.*, 2019). This can be correlated with the gene mutations measured in 3% of OS samples of the COSMIC catalogue.

Yet another mutated gene affecting the structure of chromatin and contributing to tumorigenesis is *H3F3A* (Sturm *et al.*, 2012; Park *et al.*, 2016). *H3F3A* overexpression has been shown to correlate with aggressive phenotype and chemoresistance leading to lower survival rates and relapse in lung cancer patients (Park *et al.*, 2016). COSMIC catalogue analysis showed that 2% of OS samples are mutated in *H3F3A*. This data finds approval in Koelsche *et al.* study showing hotspot mutations in *H3F3A* in six osteosarcoma cases analysed by the authors. Observed alternations were correlated with age and increased the incidence of osteosarcoma in patients over the age of 30 (Koelsche *et al.*, 2017).

Two percentage of the samples of the COSMIC catalogue were carrying mutations in the *BCOR* gene. BCOR protein is involved in the process of deacetylation of histones and when over-expressed inhibits BCL-6 tumor suppressor (Huynh *et al.*, 2000). Mutations in *BCOR* are associated with many types of cancer, such as clear cell sarcoma of the kidney, endometrial stromal sarcoma, or small round blue cell sarcomas (Astolfi *et al.*, 2019; Ueno-Yokohata *et al.*, 2015; Marinõ-Enriquez *et al.*, 2018; Sbaraglia *et al.*, 2020).

Among samples deposited in the COSMIC catalogue, approximately 2% carry mutations in the *MED12* gene. MED12 is part of a larger, multiprotein complex that mediates polymerase II RNA during the process of transcription (Ding *et al.*, 2008). *MED12* is associated with 70% of uterine leiomyomas and fibroepithelial tumors of the breast (Croce & Chibon, 2015; Lerwill *et al.*, 2022). As for now, only two clinical case reports described *MED12* mutations in osteosarcomas. Le and others (Le *et al.*, 2021) showed that the patient with *MED12*-mutated high-grade uterine sarcoma developed osteosarcoma with the same L36R missense mutation. Another team described *MED12* mutation in osteosarcoma which further led to the development of breast malignant phyllodes tumor (Tokoyoda *et al.*, 2018). More study is needed to assess the link between *MED12* mutations and the occurrence of osteosarcoma, especially since according to The Cancer Genome Atlas (TCGA) data, mutations in *MED12* can be biomarkers helping to select patients for the therapy with immune checkpoint inhibitors (ICIs) (Zhou *et al.*, 2022).

Two percentage of OS samples from the COSMIC catalogue displayed changes in the *EGFR* gene encoding receptor for the epidermal growth factor (EGFR). The receptor is known for its crucial role in the signaling pathway responsible for cell proliferation, differentiation, and/or survival (Wang *et al.*, 2004). Mutations of *EGFR* in a variety of malignancies are well documented. Most frequent is the gene's amplification leading to EGFR overexpression increasing cellular signaling (Sigismund, Avanzato & Lanzetti, 2018; Cheng *et al.*, 2021). The gene importance for OS has been already documented. Sheng-Lin and others (Sheng-Lin *et. al.*, ????) reported that high expression of EGFR together with HER-4 (human epidermal growth factor receptor 4) was associated with distant metastasis and the level of *EGFR* expression was proposed to be a potential prognostic biomarker of OS (Wang *et al.*, 2018).

Among OS samples deposited in the COSMIC catalogue, 2% manifested mutations of the *SMAD2* gene. This low number of samples can indicate that the gene mutations are not osteosarcoma specific. However, is worth mentioning that SMAD2, as a part of the TGF-beta superfamily, plays an important role in cell signaling, proliferation, and differentiation (Piek *et al.*, 1999) and may act as an oncosuppressor (Piek *et al.*, 1999; Pasche, 2001). Moreover, it has been shown that there are statistically significant changes in *SMAD2* expression in OS compared to healthy tissue. The correlation between alterations of Smad signaling, the high proliferation rate, and the invasive phenotype of osteosarcoma cells was observed in OS with Serine/threonine kinase 39 (STK39) knockdown (Won *et al.*, 2010; Yang *et al.*, 2013; Huang *et al.*, 2017).

Another gene selected during our study was the *NF1* gene. According to the data from the COSMIC catalogue 2% of OS samples were carrying the gene's mutations. The product of *NF1* is neurofibromin 1 – a cytoplasmic protein expressed in neurons, Schwann cells, and leukocytes. The protein is a part of the RAS/MAPK signaling pathway controlling cell proliferation (Huang *et al.*, 2017). It is suggested that NF1 can act also as an oncos-

uppressor. Although the *NF1* gene is associated mostly with neural malignancies, its mutations are observed in many cancers, e.g. lung cancers or melanomas (Trovó-Marqui & Tajara, 2006). Further studies are needed to prove *NF1* role in OS development.

An additional gene involved in the inhibition of cell proliferation is the tumor-suppressor gene *TSC2* (Inoki *et al.*, 2002). The gene's mutations were described in tuberous sclerosis complex (TSC) and non-small cell lung cancer. It was proved that patients with TSC1/TSC2 loss can benefit from target therapy including treatment with immune checkpoint blockade (ICB) (Huang *et al.*, 2022). Kuroda *et al.* reported a clinical case of a young patient with tuberous sclerosis complex (TSC) who developed osteosarcoma. Analysis of the tumor sample showed additional mutations in *TP53* as well as *TSC2* genes (Kuroda *et al.*, 2021). This observation is in agreement with COSMIC catalogue data showing that approximately 2% of OS samples were characterized by mutated *TSC2*.

Two percentage of OS samples were also characterized by mutated proto-oncogene *BRAF*. BRAF activates signaling pathways involved in the cell cycle, including proliferation, differentiation, and cell death. The gene mutations may result in malignancies development. In fact, dysregulation of gene expression was observed in several cancers, including melanoma, colorectal cancer, and non-small cell lung cancer (Śmiech *et al.*, 2020). Pignochino *et al.* reported that in 4 of 30 osteosarcoma patients analysed in their study, *BRAF* gene mutation was confirmed (Pignochino *et al.*, 2009).

CONCLUSIONS

COSMIC catalogue analysis allows to identify genes that are the most frequently mutated in osteosarcoma. Since 20 of the selected genes have previously been shown to be involved in cancerogenesis, thus their mutation might also play a role in OS development. However, to prove their clinical significance and the possibility of using them as OS biomarkers further studies are needed. The results of such a study would help to identify patient predisposition to OS development, follow cancer progression, and establish patients' treatment and prognosis.

MiRNA-19b-3p downregulates the endothelin B receptor in gastric cancer cells to prevent angiogenesis and proliferation

Xiaodong Hu✉, Hongbing Liu and Chaoyu Li

Department of General Surgery, Medical Centre Hospital of Qionglai City, Qionglai, Sichuan, 611530, China

MiR19b-3p acts as a tumor suppressor gene in various cancers, but its function in gastric cancer is unknown. This study investigated the role of miR19b-3p in angiogenesis and the proliferation of human gastric cancer cells targeting ET_BR expression. Cell proliferation in SGC-7901 cells, cell transfection, luciferase reporter assay, detection of endothelin B receptor mRNAs by RT-qPCR, and a Western blot assay were carried out. RT-qPCR expression analysis showed a prominent ($p<0.01$) downregulation of miR19b-3p in SGC-7901 cells, which was inversely correlated with a substantial increase ($p<0.01$) in the endothelin B receptor (ET_BR). However, overexpression of miR19b-3p in SGC-7901 cells with its mimic ($p<0.01$) resulted in the loss of cell viability in the MTT assay. This effect was reversed ($p<0.01$) by the inhibitor. Western blot analysis revealed that ET_BR was significantly ($p<0.01$) decreased by miR19b-3p overexpression compared with that of the negative control or its inhibitor. Based on bioinformatics tools and luciferase reporter assays, we found that miR19b-3p interacts with the 3'untranslated region (3'UTR) of ET_BR. Restoring miR19b-3p overexpression with its mimic led to downregulation of ET_BR in gastric cancer cells (SGC-7901), which significantly ($p<0.01$) decreased the expression of vascular endothelial growth factor A (VEGF-A). These findings were considerably reversed by miR19b-3p inhibitors ($p<0.01$). The results indicated that miR19b-3p exerts its molecular action by targeting ET_BR at the post-transcriptional level by regulating angiogenesis and proliferation by overexpressing miR19b-3p as a potential treatment target for gastric cancer.

Keywords: miRNA, gastric cancer, proliferation, angiogenesis, endothelial B receptor

INTRODUCTION

Cancer-related deaths from gastric cancer (GC) are among the fourth highest worldwide. The treatment strategies for GC depend on the stage of the disease. Early-stage GC can be treated with surgery, whereas advanced GC requires more aggressive treatments, such as chemotherapy and radiation therapy (Li *et al.*, 2019).

Combination treatment can be effective in treating nonmetastatic stomach cancer. Gastric cancer treatment includes perioperative or postoperative chemotherapy with radiation treatment. Early-stage gastric cancers are best treated with endoscopic resection. Fluoropyrimidines, platinum, taxanes, and irinotecan are active cytotoxic agents in gastric cancer. However, combination regimens are more effective and offer improved survival rates. Immunotherapy is an emerging treatment strategy for stomach cancers. A monoclonal antibody (ramucirumab) against VEGFR-2, either alone or along with paclitaxel, decreases the risk of gastric cancer (Joshi & Badgwell, 2021). Novel therapies are required to treat gastric cancer, which can be achieved by fully understanding its pathogenesis and associated molecular changes. Many disease states, including cancer, are associated with miRNA dysregulation and serve as significant markers for early diagnosis, prognosis, and treatment. Gastric cancer may be caused by dysfunctional miRNAs that disrupt the target genes of these miRNAs. This results in the downregulation and overexpression of tumor suppressor genes and oncogenes (Choi *et al.*, 2019).

miRNAs can regulate gene and miRNA expression in gastric cancer (Alessandrini *et al.*, 2018). These miRNAs (miR-143, miR-200, and miR-145) regulate cell movement and metastasis in gastric cancer by inhibiting Myo6 expression (Lei *et al.*, 2017a) and protein translation (N-cadherin) (Yuan *et al.*, 2014). According to previous studies, gastric cancer cells exhibit abnormal miRNA expression compared to surrounding normal cells (Li *et al.*, 2019). One of the earlier reports revealed that miRNAs have the potential to control or regulate several genes, and downregulation of miRNAs is correlated with the progression and development of gastric cancer (Zhu *et al.*, 2020). A recent study suggested that miR-19b-3p/NRP1 may play a role in inhibiting the GC progression (Wei *et al.*, 2020a). Another study reported that miR-19b-3p and miR-16-5p may be able to detect and predict the progression of gastric cancer (Zhang *et al.*, 2015a).

There is growing evidence that miRNAs, such as miR-125a, miR-1, miR-125b, miR-199, and miR155 modulate ET-1 expression through the 3' untranslated region (3'UTR) (Jacobs *et al.*, 2013). The small peptide endothelin-1 (ET-1) contains 21 amino acids and plays a variety of roles that affect various tissues, cells, and organs. However, the interaction between ET-1 and miRNAs in the gastric cancer is unfamiliar. Based on its own receptors, it has been established that it can exert a wide range of biological effects. Three endothelins (ET-1, ET-2, and ET-3), two G-protein-coupled receptors (ET_AR and ET_BR), and two endothelin-converting enzymes (ECE-1 and ECE-2) encompass the ET axis (Gu *et al.*, 2019). Different types of cancers, such as lung, prostate, colorectal, liver, breast and ovarian cancers includ-

ing melanoma, have been found to express ET-1 more frequently. There is some evidence that this may contribute to the proliferation, metastasis, angiogenesis, and suppressed apoptosis of cancer cells (Kalles *et al.*, 2019). The ET_AR receptor is primarily responsible for ET-1's ability to induce cell proliferation. A reduction in ET_BR expression has been implicated in the pathogenesis of various cancers, including those of the oesophagus, nasopharynx, prostate, and ovaries (Yin *et al.*, 2020). High levels of ET-1 have been detected in the plasma of patients with gastric cancer. This suggests that ET-1 can be used as a reliable indicator for predicting disease recurrence (Aliabadi *et al.*, 2022).

Currently, it is still unknown what biological function endothelin receptor B plays in gastric cancer and the mechanisms by which miR19b-3p regulates it. Our study was conducted to demonstrate that ET_BR plays a critical function in gastric cancer progression and to identify probable target sites for miR19b-3p and their cognate interactions within the 3'UTR of ET_BR employing a bioinformatics approach. We investigated the effects of miR19b-3p and its role in both the normal gastric epithelium and human gastric cancer cells targeting the endothelin B receptor (ET_BR) to prevent angiogenesis and proliferation. There is a possibility that this could lead to a new therapeutic approach and the identification of novel targets. Therefore, it is possible to use miRNAs as therapeutic targeting agents for various types of cancer.

MATERIALS AND METHODS

Cell culture

We obtained SGC-7901 (a human gastric cell line) and GES-1 (normal Gastric epithelial cell line) from the Chinese Academy of Sciences (Shanghai, China). RPMI-1640 was used to grow cells (Corning Life Sciences, Wujiang, China) added with 10% foetal bovine serum (FBS) (Corning Life Sciences, Wujiang, China) and 1% antibiotics such as streptomycin. The cells were allowed to grow in an incubator at room temperature with CO_2 (5%). For each line, the lowest passage number was between 3–5. A total of 1×10^5 cells were seeded in six wells of a six-well plate. The cells were then exposed to saturated humidity for 24 h. It is generally recommended that cells pass through when they reach 80–90% confluence. Immediately after the medium was removed, the cells were rinsed twice with phosphate-buffered saline (PBS), incubated for 2 min with 0.3% trypsin, and then resuspended in RPMI 1640 medium (5 ml) with 10% FBS before passing a second time. PlasmoTest™ (InvivoGen, USA) was used for colorimetric detection of mycoplasma contamination in cell cultures. Positive results indicate contamination of the cell culture. We did not detect mycoplasma contamination in cell cultures.

Cell transfection

A density of 2×10^5 cells/cm² was seeded in six-well plates once the cells reached 80% confluence. As previously reported (Xin *et al.*, 2019), miRNAs were transfected into the SGC-7901 cells. MiR19b-3p was evaluated by transfecting cells with miR19b-3p mimic (40 nM), miR19b-3p inhibitor (40 nM), mimic control (40 nM), or inhibitor control (40 nM) (Sangon, China) using Hi-PerFect transfection reagent from Qiagen (Hilden, Germany), according to the manufacturer's instructions. During the logarithmic growth phase, gastric cancer cells (SGC-7901) were transfected and divided into five groups: blank group (SGC-7901 cells without transfection), miR19b-3p-NC control group (SGC-7901 cells transfected with miR19b-3p mimic control), miR19b-3p mimic group (SGC-7901 cells transfected with miR19b-3p mimic), miR19b-3p inhibitor group (SGC-7901 cells transfected with miR19b-3p inhibitor), and miR19b-3p inhibitor control group (SGC-7901 cells transfected with miR19b-3p inhibitor control). Plasmid expression vectors encoding ET_BR and the accompanying empty vector (pGEM-T) controls were purchased from Origene (Rockville, MD, USA). For transfection of expression plasmids, 2.5 µg of empty vector or plasmid DNA was diluted with HiPerFect transfection reagent and added to cells grown in 6-well plates. Transfected cells were incubated for 24–72 h at room temperature, harvested for further assays with untreated cells, and used as blanks.

HiPerFect transfection solution (5 µL) was incubated at 37°C for 15 min in DMEM (300 µL) without serum. Five microliters of miR19b-3p mimic, miR19b-3p-NC, miR19b-3p inhibitor, or miR19b-3p-NC were placed in DMEM (250 µL) without serum. After incubation for 15 min, diluted miR19b-3p mimics, miR19b-3p mimic-NC, miR19b-3p inhibitor, and miR19b-3p inhibitor-NC were gently mixed with the diluted HiPerFect transfer reagent and incubated for another 20 min at 37°C. Phosphate-buffered saline (PBS) was used to wash the cells twice after removing the medium. Complexes (500 µL) were added to each well containing the cells and medium, and the plate was gently rocked to mix the solutions. To determine whether transgenes were expressed in cells, cells were incubated in a CO_2 incubator for 24 hours at 37°C.

Cell proliferation

The proliferation of transfected SGC-7901 cells with a miR19b-3p mimic, a miR19b-3p inhibitor, or their controls was studied using the MTT assay as previously described (Mu *et al.*, 2019). After transfection for 48 h, 1×10^5 cells were grown in 96 well plates and the assays were carried out in triplicate. MTT reagent (Thermo Fisher Scientific, Waltham, USA) at a concentration of 5 µg/ml was added to each well of 96 well plates containing cells (Thermo Fisher Scientific, Waltham, USA). After incubation for four hours, 150 µL DMSO was added after removing the MTT reagent. The optical density of each sample was determined at 490 nm after shaking each sample at room temperature using a microplate reader (Molecular Devices, USA). SGC-7901 cells were seeded in 96-well plates and incubated at room temperature with 5% CO_2 in a humidified atmosphere for two weeks to examine their morphology. After 48 h of transfection, cell morphology was observed. To measure the amount of absorbance, cells were seeded (2×10^5 cells per well) in a 96-well plate, and the proliferative rate of the cells was assessed. The general morphology and proliferative rate of SGC-7901 cells was observed every day with the aid of an inverted microscope (Olympus, Japan). Proliferation rates were calculated by determining the percentage change in the number of viable cells in relation to the period over which they were measured.

Assay for Luciferase reporter activity

We used Target Scan Human (http://www.targetscan.org/vert_72/), an online prediction tool for miRNA targets, to determine miR19b-3p binding targets in humans. Based on the predicted results, miR19b-3p may play a role in the regulation of ET_BR expression. Human tar-

get scanning indicated a potential binding site. RT-qPCR was used to amplify the 3'-UTR of the human ET_BR. The amplified human ET_BR sequence was cloned into a pGL3 control vector containing the XbaI site. The Q5 site-specific mutagenesis kit (Q5® Site-Directed Mutagenesis Kit; catalogue no: E0554S, NE Biolabs Inc., China) was used to generate the mutated binding site of miR19b-3p in the 3'-UTR of ET_BR following the manufacturer's protocol. Prediction validation was performed using a dual-luciferase assay (Promega, USA) and a microplate luminometer (BioTek, USA). Briefly, the ET_BR 3'-UTR with wild-type (ET_BR-wt) miR binding site or mutant-type (ET_BR/mut) miR binding site was first cloned into the pmir-GLO luciferase reporter vector. According to a previous study (L. Zhang *et al.*, 2018) prior to transfection, SGC-7901 cells were maintained in nutrient-enriched medium for 24 h in a 24-well plate. Using the HiPerFect-Transfection reagent, 0.5 µg of 3'-UTR-ET_BR with reporter vectors (1 ng/µL, WT or MUT type) and 0.5 µg miR19b-3p-mimic or control were transfected into SGC-7901 cells. To quantify the luciferase activity of the cells, host cells were isolated, washed, trypsinized for 48 h after transfection, and assayed as directed by the manufacturer using a dual luciferase assay.

Detection of endothelin B receptor mRNAs by RT-q PCR

Agilent Bioanalyzers (Agilent Technologies Co. Ltd., Beijing, China) using microfluidics to classify RNA samples based on RNA Integrity Numbers (RIN) ranging from 1 to 10. According to a study (Padhi *et al.*, 2018), a RIN of more than 8.0 indicates intact and high-quality RNA samples, a RIN between 5.0 and 8.0 indicates moderately degraded samples, and a RIN of less than 5.0 indicates degraded samples. To ensure reliable measurement of gene expression by RT-qPCR, it is generally recommended that RNA samples with a RIN value above 5.0.

As previously reported (Skovsted *et al.*, 2015), the total RNAs was extracted from normal and gastric cancer cells using TRIzol reagent. RNA extraction reagent was purchased from Dongsheng Biotech (Guangzhou, China). The extracted RNA was verified by agarose gel electrophoresis. Approximately five µg of RNA from both cell lines was reverse-transcribed using Moloney Murine leukemia virus reverse transcriptase (Sigma-Aldrich, Germany) and oligo (dT)18 primers in 20 µL reaction mixture. Then, the solution was made up to 50 µL with deionized water. For the PCR reaction, one µL of the solution was used as a substrate for PCR amplification. After 28 cycles, 25 µl of the solution was removed (91°C for 40 s, 57°C for 40 s, and 75°C for 50 s). Agarose gel electrophoresis was used to analyse approximately 10 µL of the solution containing the amplified products. PCR was carried out using pairs of primers specific for human GAPDH (5'-CATGTTCGTCATGGGGGTGAACCA-3' and 5'-AGTGATGGCATGGACTGTGGTCAT-3') and ET_BR (5'-ACTGGCCATTTGGAGCTGAGAT-3' and

5'-CTGCATGCCACTTTCTTCTCAA-3'). GAPDH was used as an endogenous control for the normalization of target gene expression. Inverse logarithms of ΔΔCt values were used to calculate the relative levels of miR19b-3p. Table 1 lists the information of the primer sequence.

Western blot assay and antibodies

RIPA lysis buffer was used to collect total protein from cells. We measured the protein concentration using a BCA protein assay kit. Protein separation of proteins (30 µg) was carried out using SDS-PAGE (Bio-Rad Laboratories Co., Ltd. Shanghai, China). A polyvinylidene fluoride membrane (PVDF) was then used to transfer the proteins. A 5–6% non-fat dry milk solution was used to occlude the membranes for one hour to prevent nonspecific binding. After blocking, antibodies such as anti-ET_BR (1:200) or anti-VEGF-A (1:3000) were transferred to the membranes and allowed for incubation for 10 hours at 4°C. Subsequently, HRP-conjugated secondary antibodies (1:2500) were applied to the membranes at 37°C for 1 hour. The protein bands on the membrane bound to antibodies were detected by a chemiluminescence system (GE LAS4000 Image, Quant, CA, USA). Protein expression was analysed using ImageQuant software. The bands were detected and photographed using a chemiluminescence analyser (Biotech Co., Ltd., Beijing). Densitometry was used to quantify protein bands using Quantity One software. The difference in loading between groups was corrected by dividing the volume per individual group by the volume of normalised β-actin for each group. The differences between each group and the control group were then determined by a normalisation procedure. The results were presented as percentages based on the control data (Sun *et al.*, 2022).

Statistical analyses

A minimum of three independent analyses of each experiment were performed to achieve the most accurate results. Data were analysed using GraphPad Prism (Version 9.0) using a student's *t*-test. In this study, we used the t-test to determine whether there was a significant difference between two groups. The values of the experimental and control groups were compared using one-way ANOVA. Tukey's multiple comparison test was used to compare the groups. We define statistical significance as a *p*-value <0.05.

RESULTS

miR19b-3p inhibits proliferation in SGC-7901 cells

Quantitative real-time PCR findings revealed that miR19b-3p expression in SGC-7901 cells was substantially ($p<0.01$) reduced compared to GES-1 cells (Fig. 1A). To examine the role of miR19b-3p in gastric cancer, the role of miR19b-3p in SGC-7901 cells was investigated by

Table 1. List of primers used in the study

| No	Primers	Sequences
1	miR19b-3p-mimic	forward: 5'-UGUGCAAAUCCAUGCAAAACUGA-3' and reverse, 5'-AGUUUUGCAUG GAUUUUGCA-CAUU-3'
2	miR19b-3p-mimic control	forward: 5'-UUCUCCGAACGUGUCACGUTT-3', and reverse, 5'-ACGUGACACGUUCGGAGAATT-3'
3	miR19b-3p-inhibitor	forward: 5'-UCAGUUUUGCAUGGAUUUGCACA-3' and reverse, 5'-ACGAGAAGGAUGGAUUGGGAU-3'

Figure 1. Downregulation of miR19b-3p in SGC-7901 cells.
(**A**) The miR19b-3p expression in normal gastric epithelial cells and gastric cancer cell line detected by RT-qPCR. (**B**) The miR19b-3p expression after transfection with negative control, blank, miR19b-3p mimic, and miR19b-3p inhibitor in SGC-7901 cells. *$p < 0.01$.

transfection with miR19b-3p-mimic, a miR19b-3p inhibitor or negative control in SGC7901 cells and transfection efficiency was measured by RT-qPCR. Figure 1B shows that miR19b-3p mimics markedly elevated miR19b-3p expression levels ($p < 0.01$) in SGC-7901 cells, while it decreased dramatically ($p < 0.01$) with the miR19b-3p inhibitor transfected into SGC -7101 cells.

The morphology of SGC-7901 cells treated with a miR19b-3p mimic or its inhibitor or NCs was examined under inverted microscopy (Fig. 2A–E). Cells in control groups (NCs) appeared round shaped and were densely packed. In the miR19b-3p mimic group, the cells showed a gradual rounding with significantly less densely

packed compared to those seen in the control groups. Furthermore, an increased number of floating cells in the miR19b-3p mimic-group indicated a decrease in cell viability. These findings indicated that SGC-7901 cells showed a significant decrease ($p < 0.01$) in their viability in the presence of a miR19b-3p mimic, but viability was significantly restored ($p < 0.01$) in response to miR19b-3p inhibitor. Cell proliferation analysis studied by the MTT assay showed the substantial ($p < 0.05$) inhibitory effects ($p < 0.05$) of miR19b-3p mimic on cell viability compared to negative controls, as shown in Fig. 2F.

The expression level of miR19b-3p was reversely correlated with the expression of the endothelin B receptor in SGC-7901 cells

To study the function of miR19b-3p in the angiogenesis of gastric cancer cells, the relationship between miR19b-3p and ET_BR was studied. The relationship between angiogenesis and endothelin receptor B is well documented. Endothelin-1 (ET-1) and its two receptors, endothelin receptor A (ET_AR) and ET_BR, are overexpressed in tumour cells. ET_BR has been reported to be a key regulator of tumour angiogenesis by being directly involved in VEGF-A expression. Changes in miR19b-3p expression levels and its effect on ET_BR expression were evaluated in SGC-7901 cells. We used Western blot to study ET_BR expression in SGC-7901 cells and GES-1cells. According to our findings, higher ET_BR levels were found in cancerous gastric cells compared to normal cells (Fig. 3A). Based on the results, it was evident that ET_BR was negatively correlated with miR19b-bp expression, as shown in Fig. 3B ($p < 0.01$). From these results, we hypothesise that miR19b-3p might negatively regulate ET_BR expression in gastric cancer cells.

ET_BR is one of the target genes for miR19b-3p

To identify putative targets for miR19b-3p, we used an online bioinformatics tool, Target Human Scan. Figure 4A shows that ET_BR is presumed to be the target

Figure 2. Transfection of miR19b-3p mimics decreases SGC-7901 cell proliferation.
(**A**) Observation of cell morphology under inverted microscope. The cells transfected with miR19b-3p mimic. (**B**) Cells transfected with miR19b-3p mimic negative control. (**C**) Cells transfected with miR19b-3p inhibitor. (**D**) Cells transfected with miR19b-3p inhibitor negative control. (**E**) Cells without transfection (blank). (**F**) Cell proliferation by MTT assay of various transfected groups at 24, 48 and 72 h. *$p < 0.01$.

The study aims to confirm the function of ET_BR in cancer angiogenesis, and we also studied the expression level of VEGF-A along with ET_BR. The results showed that the increase in ET_BR regulation is positively correlated with VEGF-A expression. When miR19b-3p expression increased, ET_BR and VEGF-A expression levels decreased (Fig. 6, $p<0.01$). The results showed that miR19b-3p played an active role in gastric cancer angiogenesis by regulating ET_BR expression, which is positively correlated with VEGF-A.

DISCUSSION

The miRNA has been shown to play a key role in tumour progression by regulating various genes after transcription. It is identified as a potential marker for cancer diagnosis and treatment (Blandino et al., 2014). miR19b-3p has been shown in the regulation of various cancers (Jin et al., 2018; Song et al., 2019). Down-regulation of miR19b-3p was previously reported in patients with gastric cancer at different stages (Zhang et al., 2015b). The precise role of miR19b-3p in gastric cancer and its angiogenesis remains unexplored.

The study findings showed that miR19b-3p could be involved in gastric carcinoma cells and healthy gastric epithelial cells. In this study, miR19b-3p was negatively regulated in SGC-7901 cells relative to GES-1 cells, which is consistent with previous reports (Wei et al., 2020b). Our findings showed that miR19b-3p mimic transfections reduced the proliferation of SGC-7901 cells, indicating the role of miR19b-3p as a tumour suppressor by inhibiting the progression of gastric cancer cells. Similar results from a study were reported, but using a different miRNA in gastric cancer through EMT (epithelial-mesenchymal transitions) regulation, showing that miR-423-5p overexpression suppressed gastric cancer cell invasion, colony formation, and proliferation through the Smad3 pathway (Li et al., 2022). Another showed that miR19b-3p negatively controlled the expression of NRP1 by targeting its 3'-UTR, thus suppressing gastric cancer cell growth, migration, and invasion (Zhang et al., 2018). Previous studies have established that miR19b-3p is capable of inhibiting breast cancer cell proliferation through PI3K/Akt signaling (Jin et al., 2018). Reduction in the accumulation of the non-small cell lung carcinoma (NSCLC) cell line A549 was observed when miR-19b was overexpressed (Li et al., 2015). However, some findings have also been reported to contradict the idea that miR19b-3p promotes proliferation of NSCLC cells (Baumgartner et al., 2018), colon cancer (Jiang et al., 2017), and pancreatic cancer (Song et al., 2019), which contrasts with our findings. The findings imply that miR-19b-3p plays a different role due to the untargeted effect of increased expression or cell-specific effects.

Our findings showed elevated expression of ET_BR in gastric cancer cells, SGC-7901. The similar results in the study were demonstrated the elevated levels of ET-1 and ET_BR expression in pancreatic adenocarcinoma relative to normal pancreatic samples (Cook et al., 2015). To investigate the interaction of miR19b-3p, we used bioinformatic analysis to look for miR19b-3p target genes. The results showed that miR19b-3p interacts with ET_BR at its 3'UTR binding site. The luciferase reporter assay confirmed ET_BR as the target gene for miR19b-3p in human gastric cancer cells. The role of ET-1 and its receptors, ET_AR and ET_BR, in cancer angiogenesis has been investigated and reviewed (Olender et al., 2016).

Tumour angiogenesis is directly promoted by ET-1 by inducing endothelial cell survival and proliferation and by upregulating ET_BR expression that causes the progression of breast cancer, and invasion and bone metastasis of triple negative breast cancer cells (Gu et al., 2019). Our findings revealed that increased expression of miR19b-3p is reversely correlated with a lower expression of ET_BR, resulting in decreased angiogenesis in gastric cancer cells. When miR-19b-3p expression was restored in SGC-7901 cells, it reduced ET_BR expression and angiogenesis. Similarly, to our findings, a recent study reported that up-regulation of miR-449a-5p, miR-19b-3p, miR-223-3p, miR-511-3p, and miR-130b-3p are likely involved in flow-stimulated angiogenesis in vivo through modulation of the expression of the mitochondrial membrane protein SYNJ2BP, oxygenation-associated genes (HIF1A, HMOX1), cytokines (e.g., IL1A, CXCL2) as well as the embryonic transcription factor FOXC1 (Henn et al., 2019).

The relationship between ET_BR expression and VEGF expression was studied by Western blotting. When miR19b-3p down-regulated ET_BR expression, VEGF expression was also reduced, leading to reduced angiogenesis in gastric cancer cells. The findings showed that angiogenesis indirectly reduced the up-regulation of VEGF by ET-1 through the down-regulation of ET_BR. Our findings are supported by the study results that demonstrate inhibited angiogenesis and permeability of blood vessels through the VEGF or VEGFR2 signalling pathway by antiangiogenic medicine (asiatic acid) significantly suppresses breast cancer growth and metastasis (Tian et al., 2021). In another study, it was found that miR-638 overexpression inhibited the processes of tumour angiogenesis in vitro and in vivo, suppressing angiogenesis and tumour growth of hepatocellular carcinoma by inhibiting VEGF signaling (Cheng et al., 2016). However, there are contrasting reports that ET_BR downregulation leads to upregulation of VEGF, causing an increase in angiogenesis in human melanoma cells (Carpenter et al., 2003; Lahav et al., 2004) and ET_BR mutant rats showed an increase in VEGF expression compared to wild-type (Li et al., 2012).

Regardless of the role of ET_BR in suppressing or repressing VEGF, our results showed that regulation of ET_BR expression plays a considerable role in controlling angiogenesis in human gastric cancer cells. In our investigation, we also tried to find whether miR19b-3p expression directly affects VEGF expression without ET_BR regulation, but there was no significant effect on VEGF expression. This shows that miR19b-3p is not directly involved in the regulation of VEGF expression.

The role of miRNAs in modulating endothelin expression by binding to a 3 untranslated region was previously reported (Lei et al., 2017b; Jacobs et al., 2013). Several research articles have been published on the possibility of using endothelin receptors as a new approach to cancer treatment (Tocci et al., 2019). However, how miRNAs interact and regulate endothelin-1 and its receptors must be clarified. Our findings suggest that miR19b-3p may be able to function as a tumour suppressor by regulation of ET_BR in human gastric cancer cells. Therefore, we propose that miR19b-3p could be used to inhibit the angiogenesis and proliferation of gastric cancer.

LIMITATIONS OF THE STUDY

Our functional experiments were conducted on a single SGC-7901 cell line. In our preliminary study, SGC-

7901 demonstrated greater proliferation ability using miR19b-5p than MKN-45 or AGS.

The *in vivo* expression of miR19b-3p and its regulation in gastric cancer remain unknown. More detailed *in vivo* studies on the role of miR19b-3p in gastric cancer should be explored.

There is a need for further studies exploring the effects of miR19b-3p on cell invasion, apoptosis and apoptotic proteins including cell cycle proteins.

CONCLUSIONS

According to our findings, reduced expression of miR19b-3p was found to be instrumental in the development and angiogenesis of cancerous cells in gastric tissues. However, overexpression of miR19b-3p could significantly inhibit ET_BR expression, leading to a reduction in angiogenesis and proliferation through the reduced expression of VEGF *in vitro*. Further studies on the role of gastric cancer will help develop potential therapies for gastric cancer.

Metabolic disorders and nutritional deficiencies in ASD children may be identified by the determination of urinary-modified compounds. In this study, levels of selected seven modified compounds: O-methylguanosine, 7-methylguanosine, 1-methyladenosine, 1-methylguanine, 7-methylguanine, 3-methyladenine, and 8-hydroxy-2`-deoxyguanosine in the group of 143 ASD children and 68 neurotypical controls were analyzed. An ancillary aim was to verify if the reported levels differed depending on the pathogenetic scoring of ASD (mild deficit, moderate deficit, severe deficit). Elevated O-methylguanosine and 7-methylguanosine levels and significantly lower levels of 3-methyladenine, 1-methylguanine, 1-methyladenosine, 7-methylguanine, and 8-hydroxy-'2'-deoxyguanosine were observed in ASD children compared to controls. O-methylguanosine levels were elevated in the mild and moderate groups, while the levels of 1-methylguanine, 1-methyladenosine, 7-methylguanine, and 8-hydroxy-'2'-deoxyguanosine in the same groups were lower than in neurotypical controls. The reported evidence shows that modified nucleosides/bases can play a potential role in the pathophysiology of ASD and that each nucleoside/base shows a unique pattern depending on the degree of the deficit.

Keywords: autism, methylation, modified nucleosides, bases

INTRODUCTION

Autism spectrum disorder (ASD) is a complex, pervasive developmental disorder with a neurological- etiopathogenetic basis, mainly occurring in childhood (Mughal & Saadabadi, 2020). It appears primarily as a qualitatively altered behaviour in social interaction, verbal and nonverbal communication. ASD covers a wide range of disorders, from mild to severe forms. "The Diagnostic and Statistical Manual of Mental Disorders, 5th Revision (DSM-5)" defines ASD as a neurodevelopmental disorder in which there are qualitative disorders in the field of social contacts, qualitative disorders in communication, which manifest themselves as stereotypical patterns of behaviour, interests, and life itself (American Psychiatric Association, 2013). ASD affects more than 1% (from 1 in 88 to 1 in 68) of children worldwide (male to female ratio of approximately 4:1) (Liu *et al.*, 2019). Generally, ASD is diagnosed based on assessing behavioural symptoms, including a questionnaire and a psychologist evaluation. Due to the early onset of symptoms (in the first two years of life) and their diversity, the diagnosis of ASD is difficult and often unreliable, especially at an earlier stage of development (Anwar *et al.*, 2018). Several studies indicate that there are metabolic disorders associated with ASD that can be assessed by identifying and determining characteristic biomarkers (Emanuele *et al.*, 2010; Kałużna-Czaplińska *et al.*, 2014; Żurawcz & Kałużna-Czaplińska, 2015; Kałużna-Czaplińska *et al.*, 2017; Kałużna-Czaplińska *et al.*, 2018; Adams *et al.*, 2019; Glinton & Elsea, 2019; Bitar *et al.*, 2020).

An accumulation of evidence suggests that environment-gene interactions may be critically important for the onset of ASD (Imamura *et al.*, 2020). The genetic endowment appears crucial to highlight both the etiopathogenesis and the development of ASD. However, different environmental impacts could play an important role in ASD onset and progress (Costa *et al.*, 2017; Ng *et al.*, 2017; Costa *et al.*, 2020; Ongono *et al.*, 2020; Radke *et al.*, 2020). Many pollutants are xenobiotics able to trigger the usual oxidative stress response of the individual. Under normal physiological conditions, the formation of free radicals and their neutralization is in a dynamic equilibrium. However, excessive production of reactive oxygen species and reduced antioxidant capacity, however, can lead to an imbalanced oxidative stress response, which

may contribute to the pathophysiology of ASD in predisposed individuals (Lambeth, 2007; Melnyk *et al.*, 2012; Ranjbar *et al.*, 2014; Kałużna-Czaplińska & Jóźwik-Pruska, 2016; Bobrowska-Korczak *et al.*, 2019; Osredkar *et al.*, 2019, Gątarek *et al.*, 2020). Nevertheless, excessive production of reactive oxygen species (ROS), particularly due to the imbalance between oxidants and antioxidants, can be toxic to neurons triggering DNA methylation (Wong *et al.*, 2019; Dreser, 2020; Sedley, 2020), which in turn means correlated damage to multiple further tissues (Ranjbar *et al.*, 2014). Several studies have suggested that redox imbalance and oxidative stress are integral parts of ASD pathophysiology (Bjørklund *et al.*, 2020). Early assessment and treatment of antioxidant status may result in a better prognosis as it could decrease the oxidative stress in the brain before it can induce more irreversible brain damage. However, the full comprehension of the role of ROS in ASD is still far to be elucidated. It was noted that oxidative stress can be attributable to the genotoxic effects of ROS, which can causebase modifications and genetic instability. Oxidative stress could induce an alteration in the methylation status of DNA/RNA, mainly by affecting the function and activity of the enzymes responsible for maintaining the epigenetic status, such as methyltransferases, histone methylase, and histone deacetylase. Additionally, it is worth underlining that children with autism have abnormal plasma levels of metabolites in pathways of folate-dependent methionine (transmethylation) and glutathione (transsulfuration) metabolism relative to unaffected age-matched control children (Melnyk *et al.*, 2012). Specifically, cellular methylation capacity expressed as the mean ratio of the methyl donor S-adenosylmethionine (SAM) to the methylation inhibitor, S-adenosylhomocysteine (SAM/SAH ratio), was significantly reduced in many children with autism. A decrease in the SAM/SAH ratio has been associated with the hypomethylation of DNA, RNA, proteins, phospholipids, and neurotransmitters with functional consequences in terms of gene expression, protein expression, membrane phospholipid composition, and dopamine synthesis, respectively. Based on the critical role of the redox and methylation status, it is, therefore, relevant to define biomarkers and show evidence of a functional impact on epigenetic regulation and antioxidant/detoxification capacity in children with autism. The development of tests based on ASD-specific biomarkers would certainly improve the diagnosis of ASD in children. Also, ASD-specific biomarkers may be used to evaluate treatment efficacy as a complement to current behavioral assessment (James *et al.*, 2004; Melnyk *et al.*, 2012). Recent studies show that the assessment of oxidative stress can be based on measurements of antioxidant enzymes and compounds, protein/DNA oxidation, and lipid peroxidation, such as important potential biomarkers of oxidative stress in ASD, e.g., methionine, cysteine, transferrin, 8-hydroxy-2'-deoxyguanosine, ceruloplasmin, 3-chlorotyrosine, 3-nitrotyrosine, F2-isoprostanes, and compounds in the glutathione system (Ranjbar *et al.*, 2014; Kałużna-Czaplińska *et al.*, 2017; Glinton & Elsea, 2019; Osredkar *et al.*, 2019). Measurements of reduced glutathione concentration, glutathione/glutathione disulfide ratio, or homocysteine thiolactone concentration provide information on whether patients are exposed to oxidative stress and whether their cellular antioxidant defense mechanisms work effectively (Kałużna-Czaplińska *et al.*, 2017; Gątarek *et al.*, 2020).

In the previous study (Bobrowska-Korczak *et al.*, 2019), the levels of 6 modified nucleosides/bases such as guanosine, adenosine, guanine, and adenine nucleotides

were studied. A group of 22 children with ASD and 20 neurotypical children participated in the study. The results showed significantly lower levels of 7-methylguanosine, 1-methyladenosine, 1-methylguanine, 7-methylguanine, and 3-methyladenine in the urine of children with ASD compared to neurotypical children. These preliminary results show that modified compounds suggest metabolic disorders and nutritional deficiencies in ASD children. The same nucleosides/bases in a larger group of 143 ASD children and 68 matched neurotypical controls were further analyzed to confirm these results. These 7 metabolites were selected as being considered the major physiological catabolites of human purines and pyrimidine metabolism in these subjects (Micheli *et al.*, 2011; Fumagalli *et al.*, 2017). The present study aims: (1) to determine the concentrations of O-methylguanosine, 7-methylguanosine, 1-methyladenosine, 1-methylguanine, 7-methylguanine, 8-hydroxy-2`-deoxyguanosine, and 3-methyladenine in the urine of children and adolescents with ASD in comparison to their neurotypical peers; (2) to check if the results of modified compounds differ depending on the level of autistic-mediated deficit (mild, moderate or severe). Due to the small size of the severe deficit group, these results were not further considered.

MATERIALS AND METHODS

Participants

The study group included 143 children. Sample size calculations, to reach the minimal significant sample size for two independent study groups, with anticipated incidence (endpoint) of 20% of subjects with ASD and impairments in the purine and pyrimidine metabolism, according to Gevi and coworkers (Gevi *et al.*, 2016), with statistic power=80% α=0.05, β=0.2 gave the minimal number of 68 patients, 34 individuals with ASD and 34 neuro-typical controls. In the recruited samples, the subjects' average age was 9.5 years in the range of 2.1-18.1 years. The control group included 68 neurotypical children without any acute or chronic illness, who were, on average, 8.3 years of age in the range of 2.5–20.8 years. Children in the study group were diagnosed with ASD by an expert paediatrician or a neuropsychiatrist in collaboration with a psychologist (Supplementary Material Table S1). The diagnosis was made using a multidisciplinary approach which combined a clinical evaluation with a psychological assessment. Children were grouped according to the criteria detailed and summarized by DSM-5 (American Psychiatric Association, 2013; Kuhn *et al.*, 2018). Additional behavioural ratings were based on a standardized classification of behaviour for children with ASD developed by the local educational authority for providing additional school support (Chawla *et al.*, 2002; Vovk-Ornik, 2015; Osredkar *et al.*, 2019). Ratings were given for two separate dimensions: a) the presence of deficits in social communication and social interaction, and b) the presence of deficits in behavioural flexibility and limited interests and activities. Each child in the ASD group received a rating on each of the two dimensions on a three-point rating scale (1: mild deficit; 2: moderate deficit; 3: severe deficit). Children in the control groups received a rating of 0 for both dimensions. Children with other additional diagnoses were excluded from the study. The children with ASD were not on a gluten-free, casein-free, or sugar-free diet.

The demographic characteristics of participating children and adolescents are given in Table 1. The study

Table 1. Demographic characteristics of autism spectrum disorder (ASD) and neurotypical control group.

	ASD	Control
N	143	68
Male	88%	60%
Median Age (in years)	9.5	8.3
Age range (in years)	2.1–18.1	2.5–20.8
Deficits in social communication		
Mild	47%	/
Moderate	47%	/
Severe	6%	/
Deficits in behavioural flexibility		
Mild	48%	/
Moderate	43%	/
Severe	9%	/

protocol was approved by the National Medical Ethics Committee (0120-201/2016-2 KME 78/03/16).

Analytical Methods

Second-morning urine specimens from all participants were collected. Urine samples were aliquoted immediately after collection and frozen at temperature of –80°C until they were analyzed. Before analysis, urine was thawed and centrifugated.

Modified nucleobases and nucleosides were determined using liquid chromatography coupled to mass spectrometry (LC-MS/MS) on Agilent 1260 Infinity (Agilent Technologies, Santa Clara, CA, US) coupled to QTRAP 4000 (AB Sciex, Framingham, MA, US). The method was validated and described previously (Raćkowska *et al.*, 2019). Briefly, MRM transitions, for O-methylguanosine, 1-methyladenosine, 7-methylguanosine, 7-methylguanine, 3-methyladenine, 1-methylguanine, and 8-hydroxy-2`-deoxyguanosine tubercidin (internal standard) were (m/z): 298->152 (collision energy, CE=17 V), 282->55 (CE=87 V), 298->166 (CE=19 V), 166->79 (CE=43 V), 150->123 (CE=31 V), 166->135 (CE=31 V) and 267->135 (CE=27 V), respectively. The curtain gas, ion source gas 1, ion source gas 2, and collision gas (all high-purity nitrogen) were set at 241 kPa, 207 kPa, 345 kPa, and "high" instrument units, respectively. The ion spray voltage and source temperature were fixed at 5500 V and 600°C, respectively. SeQuant® ZIC®-HILIC column (50 mm×2.1 mm; 5 μm) obtained from Merck (Darmstadt, Germany) was used for chromatography. The gradient of 20 mM ammonium acetate (eluent A) and acetonitrile with 0.2% formic acid (eluent B) presented as (%B) was as follows: 0 min, 95%; 1 min, 95%; 7 min, 50%; and 8 min, 50%. Second-morning urine was collected from all the participants, aliquoted, immediately frozen, and stored at -80°C till the analysis. On the day of the analysis, the sample was allowed to thaw. The centrifuged urine sample (5 min at 1000×*g*, 0.1 mL) was mixed with the tubercidin (0.1 mL, 1 μg/mL) and shaken for 3 min at high speed. Then, 0.6 mL of ice-cold acetonitrile was added, and the samples were vortexed for 3 min and centrifuged (5 min at 10 000×*g*). Five μL of supernatant was injected into LC-MS/MS.

The analysis was performed following the Guideline on bioanalytical method validation of European Medicines Agency guidelines in its work. Thus, together with the study samples we analyzed the blank sample (processed matrix sample without analyte and internal standard), zero sample (processed matrix with internal standard), and quality control samples (at low, medium, and high concentrations) at the level of at least 5% of the number of study samples.

The level of the modified nucleosides/bases in urine was standardized by conversion to the creatinine level.

Quantitative determination of creatinine concentration in urine was performed on a Roche Modular P analyzer (Roche Diagnostics GmbH, Mannheim, Germany).

Statistical Analysis

Statistical analysis was performed using Statistica 9.0 software (StatSoft, Poland STATISTICA, version 9.0, Quest Software, Aliso Viejo, CA, USA). The normal distribution of the data was tested using the Kolmogorov-Smirnov test. In the case of normal distribution and homogeneity of variance, a one-way ANOVA was used, while in the case of non-normal distribution, median values were calculated following the Mann-Whitney U non-parametric test. The results were considered statistically significant when $p<0.001$. Spearman's Rank Correlation Coefficient was used to verify if the results correlate to the disorder's severity.

RESULTS

Table 1 presents the demographic characteristics of autism spectrum disorder (ASD) and neurotypical control groups showing that the samples' statistical stratification is homogenously dispersed.

One of the study's major objectives was to examine the levels of O-methylguanosine, 7-methylguanosine, 1-methyladenosine, 1-methylguanine, 7-methylguanine, 8-hydroxy-2'-deoxyguanosine, and 3-methyladenine in the urine of children and adolescents with ASD in comparison to their neurotypical peers. The distribution of urine concentrations of a selected representative group of metabolites, referred to excreted creatinine as ng/mg and μg/mg, was not normal if one considers their own different ability in metabolizing nucleotides (intraindividual variability). Curves have skewness and kurtosis values that obliged researchers to use medians as a main comparative variable. Table 2 shows both mean ± standard deviation (S.D.) and median with CI95 of the indicated metabolites. The major observation is that only 2 of 5 measured guanine/guanosine metabolites were higher: O-methylguanosine and 7-methylguanosine in ASD patients compared with neurotypical controls. Children with ASD have about a 20–30% reduction in metabolite excretion, whereas they exhibit a very high 7-methylguanosine excretion (>65%), a modest higher O-methylguanosine excretion (13%), and a quite unchanged (+2%) level of 8-hydroxy-2'-deoxyguanosine (Table 2).

The values in Table 2 are compared according to their medians, but further comparisons conducted by removing the highest outliers (±S.D.) confirmed the observed differences in excreted metabolites between ASD subjects and neurotypical controls. Due to the fact that the Bonferroni correction was applied in the multiple comparison . To determine if any of the 7 correlations is statistically significant, the p-value must be $p≤0.007$. Therefore, we considered the p-value≤0.001 to be statistically significant. Due to the high variability in the levels of the determined compounds at this stage of the study, their usefulness as potential biomarkers in ASD cannot be clearly concluded.

Table 2. Statistical evaluations with corresponding *p*values of ASD and control group.

Name of the compound	ASD	Control		Delta %[1]	*p*[2]
All results are expressed as on mg creatinine	Mean ± S.D. Median (IC95)	Mean ± S.D. Median (IC95)		Delta %[1]	*p*[2]
O-methylguanosine [ng/mg]	913.98±1528.08 434.11 (661.38–1166.59)	494.36±651.34 384.49 (336.70–652.02)	↑	12.90	0.0745
3-methyladenine [ng/mg]	14.09±30.50 6.33 (8.84–19.34)	14.68±17.10 9.11 (10.47–18.88)	↓	30.52	0.0015
1-methylguanine [ng/mg]	460.04±617.12 299.75 (358.02–562.05)	450.25±300.60 421.71 (377.49–523.01)	↓	28.92	0.0084
1-methyladenosine [µg/mg]	48.87±62.58 30.87 (38.53–59.22)	52.99±25.73 45.33 (46.77–59.22)	↓	31.90	$<1.99\times10^{-5}$

7-methylguanosine [µg/mg]	136.67±241.70 51.96 (96.71–176.62)	75.40±104.57 44.30 (48.62–102.18)	↑	17.29	0.1035
8-hydroxy-2′-deoxyguanosine [ng/mg]	14.62±22.68 9.46 (10.57–18.67)	11.97±10.13 9.69 (9.48–14.46)	↓	2.37	0.3243

[1] calculated on medians; [2] *p*-values calculated by a Mann-Whitney U test.

The differences with the *p*-value≤0.001 were considered statistically significant. The Spearman's Rank Correlation Coefficient was used to verify if the results correlate to the age (Supplementary Materials Table S4 at https://ojs.ptbioch.edu.pl/index.php/abp/). Only O-methylguanosine concentrations (*p*<0.001) in the control group were significantly correlated with age. No correlations between the other metabolites and age were observed. Scatterplots illustrating the relationship between the age and the concentration of metabolites (A-G) in the urine of ASD patients (Fig. S4 at https://ojs.ptbioch.edu.pl/index.php/abp/) and controls (Fig. S5 at https://ojs.ptbioch.edu.pl/index.php/abp/) were added to the Supplementary Material (https://ojs.ptbioch.edu.pl/index.php/abp/). In the Supplementary Material, (https://ojs.ptbioch.edu.pl/index.php/abp/) plots were provided to illustrate the relationship between the male-female differences in the ASD and control groups. 7-panel (A-G), 4-group scatter plot (mild, moderate, severe, and control) for each of the 7 urinary purines was presented in Fig. S1 (https://ojs.ptbioch.edu.pl/index.php/abp/). The relationship between the gender and the concentration of metabolites in the urine of ASD patients and the concentration of metabolites in the control group were presented in Figs S2 and S3 (https://ojs.ptbioch.edu.pl/index.php/abp/), and also individual differences in the levels of compounds between the groups were found in Fig. S6 (https://ojs.ptbioch.edu.pl/index.php/abp/).

We encountered some significant differences again when examining the relationship between different levels of severity and excreted metabolites. Table 3 shows the proportion of children by group according to the level of deficit. Groups with mild (N=70) or moderate (N=61) impairment are comparable in terms of the number of individuals classified, while the group with severe disabil-

Table 3. The proportion of patients with a mild, moderate, and severe level of deficit.

	Mild	Moderate	Severe
N	70 (49.0%)	61 (42.6%)	12 (8.4%)
Male %	63 (90%)	54 (88.5%)	9 (75%)
Median age	9.4	9.7	9.9
Age range	4.5–18.1	2.1–17.5	6.1–13.9

ities (N=12) is small and thus presents a problem for us in interpreting the results. Due to the small size of the severe deficit group, only the results of the mild and moderate deficit groups were compared. Groups were comparable in age 9.4 (mild) and 9.7 (moderate), as well as the male to female ratio.

The next objective was to verify if the results correlated with the severity of the disorder. The results were checked as to whether metabolites differed depending on the deficit (mild, moderate, or severe). In Table 4, patients were divided into three groups depending on the level of deficit.

This table shows different excreted metabolites related to the level of deficit. As the group with a severe deficit is small, only the results of children from the mild and moderate groups were compared. These data need to be reappraised in the next research study. When comparing median values, taking into account the severity of the disorder (mild and moderate) compared to controls, it can be observed that the values for two compounds (O-methylguanosine and 7-methylguanosine) are similar for both the mild and moderate groups, while they are higher compared to the controls. For all other 5 compounds in the severity groups, the median values are similar but smaller compared to the control group. The Nonparametric Mann-Whitney U test was used to compare the concentration of compounds between the groups. The differences with a *p*-value lower than 0.001 were considered significant. Statistically significant differences between the mild and control groups for 1-methyladenosine (30.5 *vs* 43.51 µg/mg, $p=1.83\times10^{-5}$) and 7-methylguanine (38.41 *vs* 45.11 µg/mg, *p*=0.0009) were observed. For all other determined compounds, no statistically significant difference was found, with a p-value greater than 0.001. In the moderate group, a statistically significant difference in the case of 7-methylguanine (34.09 *vs* 45.11 µg/mg, *p*=0.0007) was found. It was not statistically significantly different between the mild and moderate groups with a *p*-value greater than 0.001, while statistically significant differences between the ASD and control groups for 1-methyladenosine ($p=1.99\times10^{-5}$) and 7-methylguanine (*p*=0.0002) were observed. All results are expressed on creatinine to eliminate the impact of fluid intake.

Table 4. The statistical distribution of excreted metabolites and severity level of deficit.

| Compound | ASD | | | | | | Control |
| | Mild | p | Moderate | p | *p | Severe | Median |
	Median (range)		Median (range)			Median (range)	(range)
O-methylguanosine [ng/mg]	444.51 (44.51–12586.37)	0.0605	432.62 (80.82–3450.42)	0.2376	0.5213	447.59 (14.26–5164.59)	369.90 (125.24–5336.67)
3-methyladenine [ng/mg]	6.66 (0.60–288.69)	0.0362	6.21 (0.39–75.42)	0.0015	0.3167	4.86 (0.38–44.94)	9.00 (1.76–90.40)
1-methylguanine [ng/mg]	304.04 (26.32–5830.77)	0.0148	272.64 (41.84–1588.26)	0.0317	0.8881	313.32 (14.18–1330.31)	417.39 (54.63–1501.42)
1-methyladenosine [µg/mg]	30.50 (2.07–454.16)	1.83×10^{-5}	31.82 (4.97–203.21)	0.0011	0.8917	42.12 (1.34–150.07)	43.51 (12.13–155.20)
7-methylguanine [µg/mg]	38.41 (3.84–568.44)	0.0009	34.09 (8.22–261.10)	0.0007	0.4287	44.30 (1.72–153.09)	45.11 (13.34–140.60)
7-methylguanosine [ng/mg]	59.67 (4.20–1798.71)	0.0454	44.36 (4.22–838.80)	0.5341	0.1593	92.95 (5.34–307.56)	40.43 (3.66–1798.71)
8-hydroxy-2'-deoxyguano-sine [ng/mg]	9.96 (0.85–68.23)	0.5086	8.16 (0.89–55.49)	0.1058	0.8662	15.29 (4.58–43.10)	9.56 (0.85–168.23)

*p Mann-Whitney U test p-value for the comparison of Mild and Moderate groups.

Finally, the Spearman's Rank Correlation Coefficient was used to verify if the results correlate to the severity of the disorder. The p-value≤0.001 was considered to be statistically significant. No correlations between the severity of the disorder and the levels of metabolite concentrations were observed (Supplementary Materials Table S2 at https://ojs.ptbioch.edu.pl/index.php/abp/). Nonparametric correlation analysis showed a strong and moderately positive correlation between the concentrations of metabolites determined in ASD urine (Supplementary Materials Table S3 at https://ojs.ptbioch.edu.pl/index.php/abp/).

To accurately demonstrate the biological variation among children with ASD, appropriate graphs are included in the supplementary material (Fig. S1–S6 at https://ojs.ptbioch.edu.pl/index.php/abp/).

Receiver operating characteristic (ROC) curves were used to characterize the diagnostic accuracy and evaluate the predictive accuracy. To obtain a final diagnostic score, ROC curves were generated using the MetaboAnalyst 5.0 (http://www.metaboanalyst.ca). ROC curve showed diagnostic values for 7 urinary purine results classified as mild, moderate, or severe severity of the disorder in ASD compared to controls. The area under the curve (AUC) was used to measure the overall degree of identification power. By combining the all metabolites, the AUC of the ROC curve reached 0.856 (95% CI 0.776 to 0.937) for mild severity of the disorder, 0.838 (95% CI 0.744 to 0.927) for moderate severity of the disorder, and 0.669 (95% CI 0.391 to 0.885) for severe severity of the disorder. The results of the AUC analysis stratified by severity of the disorder were shown in Fig. S7 at https://ojs.ptbioch.edu.pl/index.php/abp/.

DISCUSSION

The significant difference in excreted purines (adenine and guanine) with respect to control neurotypical subjects is a clear marker of impaired ASD metabolism (Gevi et al., 2016). The hypothesis based on folate defi-ciency in individuals with ASD suggests a possible explanation for our results. Folate depletion may reduce adenosine triphosphate (ATP) and then in S-adenosylmethionine (SAM) in neurons during a rapid cellular division. If a methylation defect arises, this might be a potential, etiopathogenetic, causative factor of ASD due to the consequent depletion in purine and, therefore, in SAM biosynthesis (Geryk et al., 2020). Whereas this could explain the reduction in adenine/adenosine metabolites in ASD patients, the increase in guanine/guanosine metabolites can be explained due to the increase in the ATP/GTP exchange to support the energetic demand, following ATP-SAM impairment.

In the current literature, elevated levels of modified nucleosides/bases are usually associated with ASD. The lack of conclusive evidence that ASD is only a genetic disorder suggests that epigenetic factors may impact ASD's susceptibility. Moreover, there is now compelling evidence that gene by environment interactions are important in the etiology of ASD (Gui et al., 2020; López-Tobón et al., 2020). However, there is a lack of knowledge of how environmental factors interact with genetic susceptibilities to confer individual risk for ASD. In normal and pathogenic brain development, a critical gene expression regulatory mechanism is DNA/RNA methylation. The pathogenesis of ASD leads to miscoded epigenetic mechanisms, cellular processes and functions, and altered expression of genes (Melnyk et al., 2012; Keil & Lein, 2016).

The results showed that in contrast to other urinary metabolites, lower concentrations of 3-methyladenine, 1-methylguanine, 1-methyladenosine, and 7-methylguanine in the urine of ASD were observed, confirming an abnormal purine metabolism in ASD children. Additionally, the concentration of the marker of oxidative stress, 8-hydroxy-'2'-deoxyguanosine, was also lower in ASD than in controls, although not at such an exceptional level as other markers. A more complete picture can be observed when children with ASD are rated into three groups: mild, moderate, and severe. A statistically

significant difference between mild and control groups for 1-methyladenosine ($p=1.83×10{-}5$) and 7-methylguanine ($p=0.0009$) was observed. A difference between mild and control groups in the level of 8-hydroxy-'2'-deoxyguanosine ($p=0.5086$) was observed, but it was not statistically significant again. In the moderate group, statistical differences in the case of only 7-methylguanine ($p=0.0007$) were found. Furthermore, other metabolites are not statistically different between the mild and moderate groups. However, the lack of statistical significance might result from the high variability in the metabolite's data distribution.

Moreover, the findings indicate that these compounds could play a potential role in the pathophysiology of ASD. Nutrient deficiencies may lead to hypomethylation, where the nutrients are the source of methyl donors. Significantly lower levels of urinary 7-methylguanosine, 1-methyladenosine, 1-methylguanine, 7-methylguanine, and 3-methyladenine were observed in the research on ASD children conducted by Bobrowska-Korczak and coworkers (Bobrowska-Korczak et al., 2019). Alteration of urinary metabolites is related to a purine metabolism disorder in ASD children (Bobrowska-Korczak et al., 2019). Nucleosides and deoxynucleosides are endogenous metabolites excreted from RNA turnover and DNA degradation, respectively (Patejko et al., 2018). Because the concentration of RNA nucleosides exceeds DNA nucleosides in the cell by about 10 to 1, most of the measured abnormalities are reported as coming from modified mRNA, rRNA, and tRNAs. 7-methylguanosine comes from mRNA. This suggests that capped mRNAs turn over more in ASD patients than in controls. 1-methyladenosine is most commonly found in tRNA and it also is an important regulator of mRNA efficiency. Studies have shown that the up-regulated genes modified by N-6-methyladenine are mainly related to neuron differentiation, neurogenesis, and cell proliferation (Zhou et al., 2020). N-6-methyladenine is the most abundant methylation modification of mRNA in eukaryotic cells, which affects every process of the RNA life cycle. Alteration in the purine metabolism was also observed in the research on ASD children conducted by Bitar and coworkers (Bitar et al., 2018). They found that 5-aminoimidazole-4-carboxamide, an intermediate metabolite in purine synthesis and guanine, was altered in ASD children's urine. Accumulation of aminoimidazole carboxamide and succinyladenosine in body fluids is caused by adenylosuccinase deficiency, an inborn error of purine metabolism. This is manifested by epilepsy, developmental delay, and ASD. The deficiency may cause neurological problems like developmental delay and intellectual disability in purine nucleoside phosphorylase, which is responsible for the metabolism of purine such as guanine (Markert, 1991; Zecavati & Spence, 2009; Bitar et al., 2018). Other researchers have also studied epigenetic changes in ASD (Goldani et al., 2014; Tang et al., 2017).

Several purine metabolism disorders are linked to ASD or behavioural features (Balasubramaniam et al., 2014). Adenylosuccinate lyase (ADSL) deficiency is also an alteration of purine (adenine) metabolism and is caused by mutations in the ADSL gene. The symptoms of this deficiency are various and include delayed development of mental and movement abilities, problems with communication and social interaction, psychomotor retardation, hypotonia, and seizures. However, it is still unclear whether this alteration of pathological mechanisms results directly from the deficiency of intermediates' purines or toxicity (Spiegel et al., 2006; Micheli et al., 2011).

Adenosine deaminase (ADA) is one of the essential enzymes in purine catabolism, which catalyzes adenosine deamination into inosine, thus having an important role in immunological responses. Examples of ADA neurological deficiency, include hearing loss, seizures, autism-like behavior, learning disability, and attention deficit (Bottini et al., 2001; Kelley & Andersson, 2014). Phosphoribosyl-pyrophosphate synthetase (PRPS) superactivity is a disorder with overproduction and accumulation of uric acid (2,6,8-trioxypurine) in blood and urine. The major manifestations of PRPS are hyperuricemia with gout, sensorineural hearing loss, mental retardation, and hypotonia. Hypoxanthine-guanine phosphoribosyl transferase (HPRT) deficiency is related to recycling the purine bases hypoxanthine and guanine to nucleotides. HPRT deficiency occurs as a full spectrum of residual enzyme activity, from mild to severe. Three major clinical features are connected with HPRT: hyperuricemia, neurologic manifestations, and behavioural disturbance (Kelley & Andersson, 2014). Nucleotidase-associated pervasive developmental disorder (NAPDD) is another kind of disorder in purine metabolism and is related to a ten-fold increase in purine and pyrimidine '5'nucleotidase activity (Page et al., 1997). There are numerous symptoms associated with this disorder. Among them are language delay, behavioural disorders, hyperactivity, attention deficit, aggressiveness, social maladjustment, epilepsy, coordination impairment, ataxic gait, and dexterity problems (Micheli et al., 2011). Some of these symptoms are characteristic of ASD (Abraham et al., 2019).

The research on epigenetic mechanisms connected with RNA/DNA molecules is still under-investigated. At present, there is no clear answer to whether methyl marks of RNA/DNA play any role in ASD (Abraham et al., 2019).

CONCLUSIONS

The results reported in the present study show that modified metabolites can play a potential role in the pathophysiology of ASD and that each compound shows a unique pattern that depends on the degree of deficit. These results showed that in contrast to other urinary metabolites, only 2 of 5 measured guanine/guanosine metabolites were higher: O-methylguanosine and 7-methylguanosine in ASD patients compared to neurotypical controls. Moreover, lower concentrations of 3-methyladenine, 1-methylguanine, 1-methyladenosine, and 7-methylguanine in the urine of ASD children were observed, indicating abnormal purine metabolism in ASD children.

Additionally, the concentration of the oxidative stress marker, 8-hydroxy-'2'-deoxyguanosine, was also lower in ASD compared to controls. A different picture is seen when we rate patients into mild and moderate deficits. A statistically significant difference between mild and control groups for 1-methyladenosine ($p=1.83×10^{-5}$) and 7-methylguanine ($p=0.0009$) was observed. The levels of 3-methyladenine, 1-methylguanine, 1-methyladenosine, and 7-methylguanine in the mild and moderate groups were lower than in the control group. These findings must be further confirmed in future studies.

Clinical efficacy of different androgen deprivation therapies for prostate cancer and evaluation based on dynamic-contrast enhanced magnetic resonance imaging

WenXiao Guo and MengZhu Li*

Department of Radiology, Wuhan Fourth Hospital, Wuhan, Hubei, China

Objective: To evaluate the clinical efficacy of different androgen deprivation therapies for prostate cancer (PCa) based on dynamic-contrast enhanced magnetic resonance imaging (DCE-MRI).

Methods: 104 patients with PCa were studied, all of whom were treated with androgen deprivation therapy. The patients were divided into a continuous group (continuous androgen deprivation therapy) and an intermittent group (intermittent androgen deprivation therapy) by random number table method, 52 cases/group. The therapeutic effect and DCE-MRI indices were compared and the relationship between DCE-MRI indices and clinical efficacy and the evaluation value of therapeutic efficacy were analyzed.

Results: The objective response rate (ORR) of the intermittent group was higher than that of the continuous group ($p < 0.05$), and there was no significant difference in disease control rate (DCR) between the two groups ($p > 0.05$). After treatment, volume transfer coefficient (K^{trans}), reverse transfer constant (K_{ep}), volume fraction (Ve), blood volume (BV), and blood flow (BF) in both groups were lowered, and those in the intermittent group were lower than the continuous group ($p < 0.05$). K^{trans}, K_{ep}, Ve, BF, and BV in the ORR group were lower than those in the non-ORR group ($p < 0.05$). K^{trans}, K_{ep}, Ve, BF, and BV were correlated with the therapeutic effect of PCa ($p < 0.05$). The AUC value of the combined detection of DCE-MRI indices in evaluating the therapeutic effect of PCa was greater than that of each index alone ($p < 0.05$).

Conclusion: Compared with continuous androgen deprivation therapy, intermittent androgen deprivation therapy has better clinical efficacy in the treatment of PCa, and DCE-MRI indices are related to the treatment efficacy of PCa and have an evaluation value.

Introduction

Prostate cancer (PCa) mainly refers to the pathological changes in the tissues around the prostate gland affected by various complex factors, resulting in the growth dysfunction or irregular growth of acinar cells and eventually inducing malignant tumors (Mori et al., 2022). Androgen deprivation therapy (ADT) is the main method to treat PCa, which can block androgens from testis and adrenal gland and has become the gold standard in the treatment of advanced PCa. However, total ADT can lead to adverse reactions in patients, such as hot flashes, gynecomastia, and osteoporosis, which significantly affect the quality of life of patients (Kishan et al., 2022). In recent years, intermittent androgen deprivation has become increasingly prominent in prolonging androgen resistance and reducing adverse reactions and has gradually attracted attention in the treatment of PCa (Denmeade et al., 2022). Currently, it is believed that the premise and basis of tumor formation are tumor neovascularization, which is an important index to evaluate tumor growth, metastasis, and malignancy degree, so the evaluation of tumor hemodynamics is extremely essential (Qu et al., 2021). Dynamic-contrast enhanced magnetic resonance imaging (DCE-MRI) calculates volume transfer coefficient (K^{trans}), reverse transfer constant (K_{ep}), and extracellular volume fraction (Ve) values through the pharmacokinetic model, which can reflect the changes of neovascularization density and blood perfusion in tumor tissues physiologically and pathologically before the changes of morphology and thereby provide quantitative data on the therapeutic effect of tumors at the molecular level (Ghoreifi et al., 2023). This study evaluated the clinical efficacy of different androgen deprivation therapies in the treatment of PCa from the perspective of DCE-MRI and provided references for the evaluation of therapeutic efficacy of this disease.

Materials and methods

Clinical data

104 patients with PCa from January 2020 to January 2023 were studied, all of whom were treated with ADT. The patients were divided into a continuous group (continuous ADT) and an intermittent group (intermittent ADT) by random number table method, 52 cases/group. Study procedures were reviewed and approved by the Ethics Committee of Wuhan Fourth Hospital (IRB number: 201912WH10; Registration number: ChiCTR1900075593; Date Granted: 2019-12), and all study subjects gave informed consent and signed written consent.

Inclusion criteria: (1) Patients confirmed as PCa by transrectal ultrasound-guided puncture and patients staged at T3~T4; ② Patients with expected survival greater than 6 months;

③ Patients with complete clinical data; ④ Patients with well tolerance to MRI.

Exclusion criteria: ① Patients with poor image quality; ② Patients with other prostate diseases; ③ Patients with other malignant tumor diseases; ④ Patients with a history of radiation therapy and endocrine therapy before enrollment; ⑤ Patients with a recent history of prostatic puncture (within 1 month before enrollment).

Treatment methods

Intermittent group received intermittent ADT, that is, anti-androgen combined with medical castration. All patients took 50 mg bicalutamide tablets orally once daily (CORDEN PHARMA GMBH, H20140720). Two weeks later, 3.6 mg goserelin acetate sustained-release depot (AstraZeneca UK Limited, J20100126) was injected subcutaneously into the lower abdomen. Serum rostate specific antigen (PSA), testosterone, and DCE-MRI were measured monthly during the treatment. Treatment was given every 4 weeks until PSA dropped to the lowest level (4 ng/mL), after which treatment was stopped at 3 months from PSA stabilization, entering the treatment intermission. Subsequently, serum PSA and blood testosterone levels were measured monthly, and DCE-MRI examinations were conducted to determine lesion expansion and the emergence of new metastatic lesions. If serum PSA rose again to more than 10 ng/mL or 50% of the initial diagnosis, the second cycle of treatment was required until serum PSA reduced to the lowest value. When intermittent therapy was completed, the treatment was stopped until new metastatic lesions appeared or primary lesions expanded. All patients were treated for 4–6 months and followed up for more than 6 months.

Serum PSA is a specific marker of PCa according to Prostate Cancer Diagnosis and Treatment Guidelines in 2014. PSA levels less than 4.0 ng/mL are considered normal, while PSA levels greater than 10 ng/mL are considered high-risk PCa. In this study, serum PSA and testosterone were monitored with regular follow-up, and Imaging examinations were performed to see if any new lesions had developed or if existing lesions had expanded. Medication can be stopped when serum PSA is less than 4.0 ng/mL and serum testosterone is less than 20.0 ng/dL.

The continuous group was given continuous ADT after bilateral testicle resection. Patients were given 50 mg bicalutamide orally, qd. Patients with hormone resistance received 250 mg flutamide (TASLY Diyi, H19990144) tid rather than bicalutamide tablets. Serum PSA, testosterone, and DCE-MRI examinations were monitored monthly (Yu et al., 2010; Mottet et al., 2012). Serum PSA levels must be reduced to 4 ng/mL, and serum testosterone to 20 ng/dL.

Resistance was defined as serum testosterone <50 ng/dL with a continuous PSA increase greater than 10 ng/mL 1 week apart.

DCE-MRI detection method

Siemens 1.5T MR Scanner was used for DCE-MRI examination with 8 channel array coil and Siemens Syngo.via equipment. The scanning sequence mainly included T_2WI, T_1WI, diffusion weighted imaging (DWI), and DCE-MRI. DCE-MRI sequence took FLASH 3D-VIBE, T_1WI axis position, layer thickness 3.5 mm, TR 4.2 ms, TE 1.58 ms, FOV 260 mm × 260 mm, NEX1, inverse angle 12°, voxel size 1.4 mm × 1.4 mm × 3.5 mm. Gd-diethylenetriamine pentaacetic acid (Gd-DTPA) and 20 mL normal saline were prepared according to the standard of 0.2 mmol/kg, and Gd-DTPA and 20 mL normal saline were simultaneously injected with a high-pressure syringe at 2.5 mL/s starting from the fourth stage. The scan was repeated for 36 stages, with a total scanning time of 4.1 min. 20 images were obtained in each stage, and a total of 720 original images were obtained. The original DCE-MRI images were transmitted to SiemensSyngo.via, Tissue 4d was specified as the workflow, and quantitative parameter values were obtained through motion correction, alignment, processing, and film reading. Alignment and motion correction were performed on 720 original images. In the processing program, The region of interest of the whole prostate was manually sketched through axial, coronal, and sagittal views, K^{trans}, K_{ep}, and Ve were quantified and measured twice to get an average value. The perfusion parameters blood volume (BV) and blood flow (BF) were calculated according to the first-pass effect of the drug. DCE-MRI were measured monthly during the treatment and follow-up in both the intermittent group and continuous group.

Clinical efficacy evaluation

Efficacy evaluation was conducted according to the RECIST criteria (Uemura et al., 2022). Complete response (CR): all target lesions disappeared completely except nodular diseases. These target nodules should be evaluated and reduced to normal size (short diameter <10 mm). Partial response (PR): The total diameter of all target lesions is ≥30% below baseline. Target nodules are measured by short diameter to calculate total diameter, whereas all other target lesions are measured by longest diameter. Progressive disease (PD): The minimum sum of the target lesion diameters was used as reference, and the relative increase in the diameter sum was at least 20% (if the baseline measurement was minimal, the baseline was used as reference); In addition, an absolute increase of at least 5 mm in the diameter sum must be satisfied (the presence of one or more new lesions is also considered disease progression). Stable disease (SD): The reduction of target lesions did not reach PR, and the increase did not reach PD, the minimum sum of diameters can be used as a reference. Objective response rate (ORR): the proportion of patients with a complete response or partial response to treatment. Disease control rate (DCR): the percentage of patients with advanced cancer whose therapeutic intervention has led to a complete response, partial response, or stable disease. The

comparison results are the data after the end of treatment compared with those before treatment, no data during follow-up were included.

Observation measures

(1) Clinical efficacy and DCE-MRI indicators. (2) DCE-MRI indices were compared after treatment, and the influence of DCE-MRI indices on the therapeutic effect of PCa was analyzed by logistic regression, and the evaluation value of DCE-MRI on the therapeutic effect of ADT was analyzed by operator characteristic (ROC) curve.

Statistical analysis

Statistical data were analyzed using SPSS 22.0 software, and differences in enumeration data (percentage) were compared using the χ^2 test. Measurement data were expressed by ($\bar{x} \pm s$) after normal test, and the differences were compared by t-test. DCE-MRI was evaluated for its efficacy in the treatment of PCa using logistic regression, and its effectiveness in ADT was evaluated using ROC curves. A statistically significant difference was indicated by $p < 0.05$.

Results

Clinical data

Clinical data from both groups were not significantly different. There was no significant difference in age, BMI, fasting blood glucose, blood lipid levels and PSA between the two groups. In addition, tumor related data, such as maximum tumor diameter, IPSS score and TNM staging, were not statistically significant ($p > 0.05$, Table 1).

Clinical effect

The ORR of the intermittent group was higher than that of the continuous group ($p < 0.05$). Although there was no significant difference in DCR between the two groups ($p > 0.05$, Table 2), compared with the continuous group, the DCR in the intermittent group still showed an upward trend.

DCE-MRI indices of patients with different therapeutic effects

As a result of treatment, K^{trans}, K_{ep}, Ve, BF, and BV decreased, and those decreased in the intermittent group significantly more

TABLE 1 Comparison of clinical data between the two groups.

Items	Continuous group ($n = 52$)	Intermittent group ($n = 52$)	χ^2/t	P
Age (years)	69.03 ± 5.37	70.15 ± 5.31	1.069	0.287
BMI (kg/m2)	22.74 ± 2.19	22.58 ± 1.97	0.392	0.696
FPG (mmol/L)	5.26 ± 1.03	5.19 ± 1.16	0.325	0.746
TG (mmol/L)	1.47 ± 0.28	1.51 ± 0.24	0.782	0.436
TC (mmol/L)	4.53 ± 0.81	4.60 ± 0.85	0.43	0.668
PSA (μg/L)	62.76 ± 3.56	63.01 ± 3.78	0.347	0.729
Maximum tumor diameter (cm)	7.95 ± 1.16	8.05 ± 1.24	0.425	0.672
IPSS score	24.15 ± 2.09	23.98 ± 2.76	0.354	0.724
TNM staging			0.158	0.691
T3	31	29		
T4	21	23

TABLE 2 Comparison of clinical efficacy between the two groups (n, %).

Groups	n	CR	PR	SD	PD	ORR	DCR
Continuous group	52	9	19	20	4	53.85	92.31
Intermittent group	52	13	25	11	3	73.08	94.23
χ^2						4.147	1.182
P						0.042	0.277

Notes: CR, complete response; PR, partial response; SD, standard deviation; PD, progressive disease; ORR, objective response rate; DCR, disease control rate.

than those in the continuous group ($p < 0.05$, Figure 1). These data show that the efficacy of intermittent ADT treatment is significantly higher than that of continuous ADT treatment group in terms of MRI performance. K^{trans}, K_{ep}, Ve, BF, and BV in the ORR group were lower than those in the non-ORR group ($p < 0.05$, Figure 2).

Comparison of DCE-MRI indices of the therapeutic effect of PCa in the two treatment

Logistic regression analysis showed that K^{trans}, K_{ep}, Ve, BF, and BV values were correlated with the therapeutic effect of PCa ($p < 0.05$, Table 3). These suggests that these DCE-MRI parameters can well predict the clinical treatment efficacy of PCa.

Evaluation value of DCE-MRI indices on the therapeutic effect of PCa

AUC value evaluated by the combined detection of K^{trans}, K_{ep}, Ve, BF, and BV was greater than that by each index alone ($p <$

0.05, Table 4; Figure 3). The combination of five items of DCE-MRI had the best predictive effect on PCa disease.

Discussion

PCa is a common malignant tumor of the male reproductive system. For patients with advanced PCa and those who cannot tolerate surgery, ADT is the most widely used therapeutic means at present (Cucchiara et al., 2019; Cipollari et al., 2022). ADT can inhibit the synthesis of vascular endothelial growth factor, induce endothelial cell apoptosis, inhibit the growth of androgen-dependent PCa tumors, and manage lymph node and bone metastasis (Al Salmi et al., 2020). At present, ADT is not only used for palliative treatment of advanced PCa but also adjuvant therapy before or after radical resection or radical radiotherapy to improve prognosis (Cereser et al., 2022). Continuous ADT can block androgens from testis and adrenal glands to the greatest extent, while intermittent ADT has become increasingly prominent in prolonging androgen resistance and reducing adverse reactions (Schaudinn et al., 2019; Carvajal et al., 2021). This study showed that the ORR of the intermittent

FIGURE 1
DCE-MRI indices (Compared with the group before treatment, *p < 0.05; Compared with the continuous group, #p < 0.05.).

group was higher than that of the continuous group, indicating that the clinical efficacy of intermittent ADT was better than that of continuous ADT. This was mainly because intermittent ADT could not prevent the transformation of androgen-dependent tumors into non-androgen-dependent tumors, but it could delay the transformation process and thus improve the therapeutic efficacy.

ADT is mainly recommended for symptomatic patients, patients with metastatic (M1) prostate cancer, or PSA dynamics characterized by rapid PSA rise or short PSA doubling time (less than 6 months). Intermittent ADT has been used as a method of monotherapy for ADT, which limits the incidence by periodically restoring serum testosterone levels. However, the clinical efficacy of intermittent ADT and continuous ADT is still controversial (Perera et al., 2020). The best method for ADT has not been clearly established. Traditionally, ADT is administered in a continuous manner, and the castration level of testosterone is ensured by repeated injections. This scheme usually continue to be used (Ravi and Choudhury, 2023). However, continuous use of GnRH analogues for ADT treatment can lead to considerable incidence of sexual

and endocrine dysfunction and poor quality of life (QOL) outcomes. These problems led to the proposed intermittent application of ADT. The existing data of patients with locally advanced or recurrent non metastatic prostate cancer suggest that intermittent ADT treatment does not significantly affect OS outcome. Studies have shown that intermittent treatment may be the most beneficial for men with locally advanced or recurrent non metastatic prostate cancer and low baseline risk (PSA ≤1 ng/mL) (Bianchi et al., 2021).

ADT-treated PCa progresses to castration-resistant PCa after remission (Zhang et al., 2020). Patients may develop castration-resistant PCa within 5 years of treatment. Therefore, monitoring the efficacy of PCa after treatment is particularly considerable (Christophe et al., 2020). PSA is an index for monitoring the efficacy of PCa after radical surgery or conservative treatment. Although post hoc analyses of contemporary ARPI trials suggest that the depth of the initial PSA response is associated with favorable long-term outcomes. However, it could not reflect the changes of tumor morphology and microcirculation characteristics. PSA levels cannot truly reflect the histological and biological changes of tumors after endocrine therapy or

radiation therapy, especially in cases with metastasis (Pesapane et al., 2020). ADT monitoring for PCa should therefore be applied with other indicators. Currently, it is believed that the growth and invasion of PCa depend on the tumor neovascularization. As the neovascularization wall fails to develop correctly, permeability increases, and blood is exchanged more rapidly between tumor and blood vessel, resulting in tumor invasion. MRI is the best imaging method

FIGURE 3
ROC curve of DCE-MRI to evaluate the therapeutic effect of PCa.

for PCa, among which DCE-MRI quantitative analysis has been proven to be useful for evaluating tumor hemodynamics. Based on the difference in microvascular characteristics of lesions with different properties, DCE-MRI technology uses the difference in the time and concentration of contrast agent to reach normal tissues and pathological tissues with different properties to form different intensification methods, which can evaluate blood perfusion status of different tissues, so as to achieve the purpose of lesion diagnosis (Tamada et al., 2021; Forster et al., 2022).

DCE-MRI, combined with corresponding pharmacokinetic models, can obtain parameters that reflect tissue perfusion and permeation characteristics and quantitatively analyze the physiological characteristics of pathological tissues, which can be applied not only to the clinical diagnosis but also to the evaluation of the efficacy of tumor radiotherapy and chemotherapy (Prendeville et al., 2018). The common penetration parameters of DCE-MRI are K^{trans}, Ve, and K_{ep}. K^{trans} refers to the volume transport constant of contrast agent diffused from plasma into extravascular extracellular space, reflecting the level of vascular permeability in tissues. K_{ep} is the rate constant at which contrast agent diffuses from interstitial space to reflow into blood vessels. Ve refers to the volume ratio of EES per unit tissue volume. The perfusion parameters of DCE-MRI to reflect the blood perfusion status include BF and BV. BF represents the BF velocity in the blood vessels of the interest area per unit time, and BV represents the BV, both of which mainly reflect blood perfusion and depend on the microvascular density in the tissue (Arnoldner et al., 2022; Chatterjee et al., 2022; Fan et al., 2022; Nakayama et al., 2022). This study showed that DCE-MRI indices were all decreased after ADT, and K^{trans}, K_{ep}, Ve, BF, and BV

in the ORR group were lower than those in the non-ORR group, suggesting that DCE-MRI indices may be used to evaluate the efficacy of ADT. This is mainly related to the reduction of PCa volume, gland atrophy, and fibrosis after ADT treatment (Lu et al., 2020). BF and BV of tumors after endocrine therapy are significantly reduced, and K^{trans} and K_{ep} are significantly reduced (Ikoma et al., 2020), which was consistent with the results of this study. ADT causes acinar atrophy, fibrosis, and basal cell hyperplasia in the prostate, resulting in a reduction in total glandular interstitial tissue and ultimately, total gland. In addition, after ADT, not only does vascular endothelial growth factor decrease with the decrease of androgen level, but also the BF of PCa tissues decreases, and cells show obvious apoptosis and necrosis, thus achieving anti-tumor angiogenesis, so K^{trans}, $K_{ep,}$ and Ve values are significantly reduced after endocrine therapy (Kim et al., 2021; Ueda et al., 2022). Further analysis found that K^{trans}, K_{ep}, Ve, BF, and BV were correlated with the therapeutic effect of PCa, and the AUC value of the combined detection of all indicators to evaluate the therapeutic effect of PCa was greater than 0.9, indicating that the DCE-MRI indices were correlated with the therapeutic effect of PCa.

In summary, As compared with continuous ADT, intermittent ADT improves PCa treatment outcomes, and DCE-MRI indicators are correlated with PCa treatment outcomes.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary material, further inquiries can be directed to the corresponding author.

Ethics statement

The studies involving humans were approved by the Ethics and Scientific Committees of Wuhan Fourth Hospital and performed in accordance with The Declaration of Helsinki. The studies were conducted in accordance with the local legislation and institutional requirements. The participants provided their written informed consent to participate in this study. Written informed consent was obtained from the individual(s) for the publication of any potentially identifiable images or data included in this article.

Author contributions

WG designed the research study. WG and ML performed the research. ML provided help and advice. WG and ML analyzed the data. WG wrote the manuscript. ML reviewed and edited the manuscript. All authors contributed to editorial changes in the manuscript. All authors contributed to the article and approved the submitted version.

Competitive binding of circCCDC6 to microRNA-128-3p activates TXNIP/NLRP3 pathway and promotes cerebral ischemia-reperfusion defects

ChongShu Wang[1], MingMing Dong[2], XiaoYi Zhang[3], XiaoYu Wang[4], Yan Zhao[2] and Yunpeng Cao[1]✉

[1]Department of Neurology, The Fourth People's Hospital of Shenyang, Shenyang City, Liaoning Province, 110001, China; [2]Department of Neurology, The Fourth People's Hospital of Shenyang, Shenyang City, Liaoning Province, 110031, China; [3]Department of Geriatric Medicine, The First Affiliated Hospital of China Medical University, Shenyang City, Liaoning Province, 110001, China; [4]Department of Neurology, Liaoyang Central Hospital, Liaoyang City, Liaoning Province, 111010, China

Objective: Circular RNAs (circRNAs) are enriched in the brain and involved in various central nervous system diseases. The potential role of circCCDC6 in cerebral ischemia-reperfusion defects was partly elucidated in the work. **Methods:** A middle cerebral artery occlusion/reperfusion (MCAO/R) rat model and an oxygen-glucose deprivation and re-oxygenation (OGD/R)-treated SH-SY5Y cell model were constructed. CircCCDC6 expression in the two models was examined, and circCCDC6-involved mechanisms in neuronal pyroptosis and inflammation were analyzed through loss- and gain-of-function assays. **Results:** MCAO/R rat brain tissues and OGD/R-treated SH-SY5Y cells exhibited upregulated circCCDC6. Silencing circCCDC6 attenuated neuronal pyroptosis and inflammation in the brain tissue of MCAO/R rats. Overexpressing circCCDC6 or inhibiting miR-128-3p stimulated OGD/R-induced pyroptosis and inflammation in SH-SY5Y cells, while upregulating miR-128-3p attenuated OGD/R injury. CircCCDC6 silencing-induced effects on SH-SY5Y cells were antagonized by TXNIP overexpression. **Conclusion:** Mechanistically, circCCDC6 mediates miR-128-3p and activates TXNIP/NLRP3, thereby promoting OGD/R-induced neuronal pyroptosis and inflammation. CircCDC6 may provide a new strategy for the treatment of MCAO/R.

INTRODUCTION

Ischemic stroke (IS) is a severe neurological response syndrome that leads to damage to neurovascular units, inflammation, and neuronal death (Zhu *et al.*, 2020). Reperfusion after cerebral ischemia often leads to a series of cellular and biochemical consequences, including the production of reactive oxygen species (ROS) and inflammatory cytokines, and brain cell damage, collectively referred to as cerebral ischemia-reperfusion (CIR) injury (Lim *et al.*, 2021), which are also key factors attributing to the poor prognosis of IS patients (Zuo *et al.*, 2018). It is unable to effectively protect the neurological function of IS patients despite great progress in the treatment options. Therefore, an urgent need for new therapeutic approaches is on the agenda to protect CIR-induced neurological deficits.

Pyroptosis is a special way of cell death, which is different from necrosis and apoptosis (Yu *et al.*, 2021). Pyroptosis plays an important role in CIR injury (Zhang *et al.*, 2022). Cerebral ischemia leads to the disruption of intracellular energy metabolism and oxidative stress, which activates the inflammatory response and intracellular inflammasome recombination (Zhang *et al.*, 2022). The inflammasome complex includes molecules such as ASC, NLRP3, and Caspase-1, which interact and activate the Caspase-1 enzyme. Activated Caspase-1 cleaves the precursor's IL-1β and IL-18, releasing active pro-inflammatory cytokines (Wang *et al.*, 2022; Luo *et al.*, 2022). These pro-inflammatory cytokines induce inflammation in CIR injury and promote the further development of pyroptosis.

Circular RNAs (circRNAs) are highly stable covalently closed endogenous non-coding RNAs that are specifically expressed in tissues and cells (Vo *et al.*, 2019). CircRNAs are enriched in multiple organs, especially the brain, and a large body of evidence indicates that circRNAs are involved in the physiological and pathological processes of the brain, including CIR (Yang *et al.*, 2018). In addition, circRNAs exert their biological functions as molecular decoys of microRNAs (miRNAs) (Zhang *et al.*, 2020). In a circRNA expression profile after transient focal ischemia, circCCDC6 is confirmed to be upregulated in the brain of a model of middle cerebral artery occlusion (MCAO) rats (Mehta *et al.*, 2017). However, its related mechanism in CIR awaits further investigation.

MiRNAs, a group of post-transcriptional regulators of gene expression (Brennan *et al.*, 2020) are involved in the regulation of various cellular activi-

ties (Saliminejad *et al.*, 2019). miRNAs are emerging regulators of neuronal survival during CIR injury (Liu *et al.*, 2020). For instance, promoting miR-34c-5p expression is able to suppress inflammation and apoptosis, thereby preventing CIR injury (Tu *et al.*, 2021). The anti-inflammatory and anti-apoptotic properties of miR-128-3p have been accepted previously. miR-128-3p overexpression could protect against chronic constrictive injury to suppress neuroinflammation (Zhang *et al.*, 2020) and could restrain sepsis-induced apoptosis and inflammation (Yang *et al.*, 2021). However, not much was known about miR-128-3p-involved mechanism in CIR injury.

Hence, the function of circCCDC6 in neurological deficits following CIR was probed through *in vivo* and *in vitro* experiments. Speculation was put up that circCCDC6 activates TXNIP/NLRP3 inflammasome pathway by miR-128-3p to exacerbate CIR.

MATERIALS AND METHODS

MCAO/R animal model

Sixty male Sprague-Dawley rats, with a body weight of 220-280 g (Hunan SJA Laboratory Animal Co., Ltd., Changsha, China) were housed in an environment of 24-26°C with an adequate supply of water and food. The MCAO/R model was established as previously described (Yan *et al.*, 2020). Briefly, after anesthetization with 5% (v/v) isoflurane at a flow rate of 2 L/min, a monofilament nylon suture was inserted into the right common carotid artery through an incision over the head, and passed through the internal carotid artery as possible. After blocking the common carotid artery for 1 h, the suture was slowly retracted for reperfusion. Monitored by Laser Doppler flowmetry, and blood flow falling below 30% of baseline flow suggested the success of MCAO. Restoration of cerebral blood flow to >80% of baseline indicated the success of reperfusion. For the sham group, the same procedure was performed without suture insertion. After 24 h of reperfusion, neurological function was evaluated. After that, the rats were euthanized by overdosed CO_2, and 10 successfully modeled rats were selected from each group, of which the brain tissue of 5 rats was used for histopathological analysis, and that of the remaining 5 rats was for RNA or protein extraction. The success rate of modeling was 80%, and some rats died during the experiment. Authorization of animal care and methods procedures was by the Animal Ethics Committee of Dalian Municipal Central Hospital.

Lentiviral vector injection

circ shRNA-GFP (shRNA-Con) lentivirus or circCCDC6 shRNA-GFP (shRNA-circ CCDC6) lentivirus (2 µl, 1×10^9 TU/ml) was microinjected into the left ventricle of the rat to knock down circ CCDC6 at the following coordinates: AP, −0.3 mm; lateral, 1.0 mm; and ventral, 2.2 mm. The lentiviral vector was injected 2 weeks before MACO/R surgery. All lentiviral vectors mentioned above were purchased from GenePharma.

Neurological function scoring

Neurological function was assessed 7 d after MACO/R surgery (Tatlisumak *et al.*, 1998). 0-no obvious defect, 1-failure to fully extend the left front paw when

stimulating tails, 2-circling to the left contralateral side when stimulating tails, 3-turning or walking left, 4-walking only when stimulating tails, 5-no response to stimuli, and unconsciousness.

Nissl staining

Brain tissues that were fixed with 4% paraformaldehyde were made into coronal fragments of 10 µm after routine paraffin embedding (Meng *et al.*, 2018). Each fragment was observed by light microscopy after staining with Nissl staining kit (Beyotime, Shanghai, China).

Immunofluorescence staining

After antigen retrieval through citrate buffer, brain slices were incubated with primary antibody GSDMD (20770-1-AP, Proteintech), followed by the addition of a secondary fluorescent antibody. Afterward, 4',6-diamidino-2-phenylindole-stained slices were observed under a fluorescence microscope (Olympus. Tokyo, Japan).

Transferase-mediated deoxyuridine triphosphate-biotin nick end labeling (TUNEL) staining

Pyroptosis was assessed using the TUNEL staining kit (Roche, Mannheim, Germany) following the protocols, and the percentage of pyroptotic cells was calculated.

Cell culture

Dulbecco's modified essential medium (DMEM, Gibco, Thermo Fisher Scientific) containing 10% fetal bovine serum (Gibco), 100 U/ml penicillin, and 100 µg/ml streptomycin was the culture system for SH-SY5Y cells (Cell Bank Type Culture Collection, Shanghai, China). For oxygen-glucose deprivation/reoxygenation (OGD/R) treatment, SH-SY5Y cells were cultured in glucose-free DMEM for 4 h in an anoxic environment (95% N_2 and 5% CO_2), and maintained in a normoxic environment with normal DMEM for 24 h (Xin *et al.*, 2017).

Cell transfection

Small interfering RNAs targeting circCCDC6 and TXNIP and negative controls (si-CCDC6, si-TXNIP, si-NC), pcDNA 3.1 overexpression vector and empty vector (pcDNA 3.1-circCCDC6, pcDNA 3.1-TXNIP, pcDNA 3.1) were purchased from Ribobio (Guangzhou, China), whereas miR-128-3p mimic/inhibitor and mimic/inhibitor NC were from Invitrogen (CA, USA). Transient transfection of SH-SY5Y cells was implemented by Lipofectamine 2000 (Invitrogen), followed by OGD/R treatment.

ELISA

Concentrations of IL-1β and IL-18 in cell supernatants or brain tissue homogenates were quantified using ELISA kits (Thermo Fisher Scientific).

Viability analysis

SH-SY5Y cells, along with MTT solution (20 µL/well, Sigma-Aldrich) were incubated for 4 h. Then, the original medium was replaced with dimethyl sulfoxide (150 µL/well), and absorbance was measured at 490 nm using a microplate reader (Bio-Rad, CA, USA).

Table 1. PCR primers

Note: circCCDC6, circular RNA CCDC6; miR-128-3p, microRNA-128-3p; GAPDH, glyceraldehyde-3-phosphate dehydrogenase

Colorimetry

Lactate dehydrogenase (LDH) release from cell supernatants was quantified colorimetrically to determine cytotoxicity using the kit (Clontech, CA, USA).

Flow cytometry

Using the FAM FLICATM Caspase-1 kit (AbD Serotec, Oxford, UK), pyroptosis of SH-SY5Y cells was tested. SH-SY5Y cells after trypsinization were made into cell suspension for staining with 5 μL caspase-1 FLICA and 5 μL propidium solution, followed by analysis on a flow cytometer (BD Company, NJ, USA). Data quan-

tification was done by FlowJo software (TreeStar, CA, USA).

Quantitative PCR

From brain tissues and cells, total RNA extracts were collected *via* Trizol reagent (Invitrogen), and made into first-strand cDNA through PrimeScript RT kit (Takara, Tokyo, Japan). On the ABI7500 system, PCR was conducted by the SYBR Green method. Primers for all genes (Table 1) were from GeneCreate (Wuhan, Hubei, China). Standard controls for mRNA and miRNA were glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and U6, respectively. Relative expression was calculated using the $2^{-\Delta\Delta Ct}$ method.

Immunoblotting

Total protein extracts were obtained using RIPA buffer (CST, USA), which was then quantified by BCA kit (Abbkine, USA) and separated on sodium dodecyl sulfate polyacrylamide gel electrophoresis. After that, proteins were covered with polyvinylidene fluoride membrane (Millipore, USA), followed by blockade with 5% nonfat milk and incubation with primary antibodies β-actin (sc-47778, Santa Cruz), IL-1β (12242, CST), IL-18 (10663-1-AP, Proteintech), cleaved caspase-1 (4199, CST), TXNIP (14715, CST), NLRP3 (15101, CST), ASC (sc-514414, Santa Cruz) and the horseradish peroxidase-conjugated secondary antibody (CST). Through visualization by an enhanced chemiluminescence kit (GE Healthcare), band plots were further analyzed using ImageJ.

Figure 1. Effects of injection of shRNA-circCCDC6 lentiviral vector on biochemical indexes and pathological tissue damage of MCAO/R rat brain.
circCCDC6 expression in brain tissue (**A**), neurological function score (**B**), Nissl-stained cerebral cortex (**C**), immunofluorescence staining of GSDMD (**D**), TUNEL-stained brain tissue (**E**), IL-1β and IL-18 contents in brain tissue (**F**), protein expressions of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 in brain tissue (**G**); data were reported as mean ± S.D. (C, n=10; rest, n=5).

Figure 2. Effect of transfection of pcDNA 3.1-circCCDC6 on the biological behavior and biochemical indexes of OGD/R-treated SH-SY5Y cells.
circCCDC6 expression (**A**), cell viability (**B**), toxicity (**C**), caspase-1 positive cells (**D**), IL-1β and IL-1β contents (**E**), protein expression of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 (**F**); data were reported as mean ± S.D. (N=3).

Dual-luciferase reporter assay

The putative binding site of circCCDC6 or TXNIP 3'UTR was amplified by PCR and cloned into a pmirGLO vector to generate pmirGLO-circCCDC6-WT and pmirGLO-TXNIP-3'UTR WT. Mutants of circCCDC6 or TXNIP 3'UTR were created based on QuickChange Lighting Multi Site-Directed Mutagenesis Kit (Agilent Technologies, CA, USA) to produce pmirGLO-circCDC6-Mut and pmirGLO-TXNIP-3'UTR-Mut. The generated reporter, in combination with mimic NC or miR-128-3p mimic was co-transfected into SH-SY5Y cells to determine luciferase activity 48 h later using a dual-luciferase reporter gene assay system (Promega, WI, USA).

Antibody enrichment analysis

RNA immunoprecipitation assay was performed using the Magna RNA-Binding Protein Immunoprecipitation Kit (Millipore). Cell lysates were incubated with RIP buffer containing magnetic beads conjugated to mouse IgG or human anti-Ago2 antibody. After digestion with proteinase K, the resulting immunoprecipitated RNA was purified and utilized for quantitative PCR.

Statistics

Data were presented as mean ± standard deviation (S.D.), and statistical analysis was performed using GraphPad Prism 9.0. Unpaired Student's t-test was utilized for bilateral comparison whereas one-way analysis of variance for multi-data comparison. $P<0.05$ was considered statistically significant.

RESULTS

Silencing circCCDC6 ameliorated MCAO/R-induced pyroptosis and inflammation

CircCCDC6 is abnormally expressed after MCAO/R injury. To examine the biological role of circCCDC6 in CIR-induced pyroptosis, we interfered with circCCDC6 expression in MCAO/R rats by injecting lentivirus. It was demonstrated that the promoted expression of circCCDC6 induced by MCAO/R treatment was suppressed after injection of shRNA-circCCDC6 (Fig. 1A). Assessment of neurological function presented that MCAO/R rats had severe nerve damage, which could be alleviated by knocking down circCCDC6 (Fig. 1B). Nissl staining further pictured that neurons in MCAO/R rats were swollen, vacuolated in the cytoplasm, and the number of Nissl bodies was reduced, and knockdown of circCDC6 alleviated these symptoms (Fig. 1C). During pyroptosis, GSDMD mediates the formation of membrane pores (Wang *et al*., 2020). Here, we performed immunofluorescence staining of GSDMD and ultimately report-

Figure 3. Binding relation of circCCDC6 and miR-128-3p.
Potential binding sites of miR-128-3p and circCCDC6 (**A**), miR-128-3p expression in *in vivo* and *in vitro* models (**B**), verification of targeting relationship between circCCDC6 and miR-128-3p (**C–D**), effects of low or overexpression of circCCDC6 on miR-128-3p expression in SH-SY5Y cells (**E**). data were reported as mean ± S.D. (N=3).

Figure 4. Effects of transfection of miR-128-3p mimic/inhibitor on the biological behavior and biochemical indexes of SH-SY5Y cells treated with OGD/R. miR-128-3p expression (**A**), cell viability (**B**), toxicity (**C**), caspase-1 positive cells (**D**), IL-1β and IL-1β contents (**E**), protein expression of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 (**F**); data were reported as mean ± S.D. (N=3).

Figure 5. Targeting relation between miR-128-3p and TXNIP. (N=3).

Figure 6. Effects of transfection of si-circCCDC6 and pcDNA 3.1-TXNIP on the biological behavior and biochemical indicators of OGD/R-treated SH-SY5Y cells.
miR-128-3p expression (**A**), TXNIP protein expression (**B**), viability (**C**), toxicity (**D**), caspase-1 positive cells (**E**), contents of IL-1β and IL-18 (**F**), protein expression of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 (**G**) in SH-SY5Y cells; data were reported as mean ± S.D. (N=3).

ed that MCAO/R treatment increased the fluorescence intensity of GSDMD, but this trend was restricted in response to knockdown of circCCDC6 (Fig. 1D). Additionally, there were an increased number of TUNEL-positive cells (Fig. 1E), promoted release of IL-1β and IL-18 (Fig. 1F), and elevated protein expression of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 (Fig. 1G) in the brain tissue of rats receiving MCAO/R surgery; the changes induced by MCAO/R were all reversed when circCCDC6 was knocked down (Fig. 1E). Clearly, silencing circCCDC6 ameliorated MCAO/R-induced pyroptosis and inflammation.

Overexpression of circCCDC6 aggravates OGD/R-induced neuronal pyroptosis and inflammation

Next, the molecular mechanism of circCCDC6 affecting neuronal pyroptosis and inflammation was explored through cellular experiments. It was checked that OGD/R treatment-induced elevation of circCCDC6 expression in neurons was further raised after transfection of pcDNA 3.1-circCCDC6 (Fig. 2A). Neuronal viability and toxicity were examined by MTT and colorimetry, respectively. The collected data displayed that after OGD/R treatment, neuronal viability was suppressed and LDH release was increased, and these changes were enhanced by overexpression of circCCDC6. Besides, it was further examined that OGD/R treatment induced the increase in the percentage of caspase-1 positive cells (Fig. 2D), contents of IL-1β and IL-18 (Fig. 2E), and protein expression of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 in neurons (Fig. 2F); moreover, circCCDC6 upregulation further facilitated all of these alternations. Evidently, overexpression of circCCDC6 aggravates OGD/R-induced neuronal pyroptosis and inflammation.

CircCCDC6 competitively binds miR-128-3p

Next, we explored the downstream effectors bound by circCCDC6. Through the bioinformatics website https://starbase.sysu.edu.cn/, we predicted 20 miRNAs with potential binding sites for circCCDC6, among which miR-128-3p was particularly focused. miR-128-3p and circCCDC6 had binding sites at chr10:61564232-61564251[-] (Fig. 3A). miR-128-3p has been reported to be down-regulated in spinal cord I/R injury, and its overexpression is capable of ameliorating neuroinflammation and apoptosis (Wang et al., 2020). Similar results were obtained in this study, with miR-128-3p down-regulated in both MACO/R rats and OGD/R neurons (Fig. 3B). Dual-luciferase reporter experiments showed that co-transfection of WT-circCCDC6 with miR-128-3p mimic reduced luciferase activity (Fig. 3C), and RIP experiment further supported that circCCDC6 and miR-128-3p were increased in the Ago2 group (Fig. 3D). Subsequently, we examined that knockdown or overexpression of circCCDC6 upregulated and downregulated miR-128-3p expression, respectively. To conclude, circCCDC6 competitively binds miR-128-3p.

MiR-128-3p is involved in the process of pyroptosis and inflammation of OGD/R-conditioned neurons

Subsequently, we explored the role of miR-128-3p in OGD/R-induced neuronal pyroptosis and inflammation. Transfection of miR-128-3p mimic and inhibitor upregulated and down-regulated miR-128-3p expression in SH-SY5Y cells, respectively (Fig. 4A). Responded to miR-128-3p upregulation, neuronal viability increased

and LDH release reduced, percentage of caspase-1 positive cells, contents of IL-1β and IL-18, and protein expressions of IL-1β, IL-18, cleaved caspase-1, ASC and NLRP3 decreased; while knockdown of miR-128-3p had completely opposite effects (Fig. 4B–F). Anyway, miR-128-3p is involved in the regulation of neuronal pyroptosis and inflammation.

A binding of miR-128-3p TXNIP 3′ UTR

TXNIP has been shown to be a pro-inflammatory factor in I/R injury (Jia et al., 2020), and activation of the TXNIP/NLRP3 inflammasome pathway is a key factor in pyroptosis (Kong et al., 2021). In both in vivo and in vitro models of CIR, TXNIP expression was found to be increased (Fig. 5A, B). Regarding miR-128-3p-mediated TXNIP expression change, quantitative PCR was performed to prove that transfection of miR-128-3p mimic or miR-128-3p inhibitor decreased and increased the protein level of TXNIP in neurons, respectively (Fig. 5C). Bioinformatics website searched for the complementary sequences of miR-128-3p and TXNIP 3'UTR (Fig. 5D), and their targeting relationships were subsequently by dual-luciferase reporter assays and RIP experiment (Fig. 5E, F). In short, a binding of miR-128-3p TXNIP 3′ UTR is ensured.

CircCCDC6 affects neuronal pyroptosis and inflammation by regulating the miR-128-3p/TXNIP/NLRP3 pathway

Finally, rescue experiments were implemented to identify the effect of the circCCDC6/miR-128-3p/TXNIP/NLRP3 axis on OGD/R-induced neuronal pyroptosis and inflammation. It was examined that knockdown of circCCDC6 promoted miR-128-3p expression, while overexpression of TXNIP had no effect on miR-128-3p expression (Fig. 6A); circCCDC6 knockdown-induced suppression of TXNIP protein expression was reversed by overexpressing TXNIP (Fig. 6B). Functionally, circCCDC6 silencing-mediated protection against pyroptosis and inflammation was prevented when TXNIP was upregulated (Fig. 6C-G). CircCCDC6 affects neuronal pyroptosis and inflammation by regulating the miR-128-3p/TXNIP/NLRP3 pathway.

DISCUSSION

The key to the treatment of IS is blood reperfusion, but this can cause I/R injury (Wen et al., 2019). Permanent damage to neurons with concomitant cell death happens in the hours following an IS (Zhang et al., 2020). Acute neuroprotective agents attract much attention, however, clinical outcomes are often unsatisfactory. A genome-wide RNA sequencing report on the subcortical structure of CIR-injured rats shows that the expression of nearly 400 circRNAs is significantly altered 24 hours after tMCAO (Filippenkov et al., 2021). This study reported a potential mechanism by which circCCDC6, regulates CIR injury-induced neurological deficits.

CircRNAs can interact with miRNAs, and their interaction is key in human diseases, including IS. For example, circTTC3 silencing could upregulate miR-372-3p, thereby suppressing CIR injury and neural stem cell apoptosis (Yang et al., 2021). Moreover, depletion of circ_008018 in MCAO/R mice could prevent CIR damage by targeting miR-99a (Yang et al., 2018). Also, in the model of MCAO/R, circHECTD1 knockdown induces neuroprotection against IS through binding to miR-133b

(Dai *et al.*, 2021). In this study, we found for the first time that circCCDC6 was upregulated in MCAO/R mouse model and OGD/R-treated neurons, and that circCCDC6 depletion alleviated MCAO/R-induced neuronal pyroptosis and inflammation, while overexpression circCCDC6 exacerbates OGD/R-induced neuronal pyroptosis and inflammation. Importantly, we investigated the possible miRNA sponge mechanism of circCCDC6 in CIR injury, paid great attention to the binding of circCCDC6 to miR-128-3p, and eventually confirmed that circCCDC6 may be involved in the pathogenesis of CIR injury by targeting miR-128-3p to promote neuronal pyroptosis and inflammation.

More attention is currently focused on the neuroinflammatory response triggered by I/R, and anti-inflammatory is likely to be a potential therapeutic strategy after IS (Wang *et al.*, 2020). miR-128-3p can exert anti-inflammatory effects by regulating gene expression and multiple signaling pathways. For example, overexpressing miR-128-3p could inhibit OA progression through PI3K/Akt/NF-κB pathway (Chen *et al.*, 2020), and restrain apoptosis and inflammation in LPS-induced sepsis by targeting TGFBR2. In both MACO/R rats and OGD/R neurons, we examined the downregulation of miR-128-3p and validated the protective actions of overexpressed miR-128-3p on increasing neuronal viability and reducing LDH release as well as inflammatory factors. Notably, MCAO/R treatment and OGD/R treatment promoted TXNIP and NLRP3 expression, while their expression could be regulated by circCCDC6 and miR-128-3p, suggesting that the role of circCCDC6 in CIR injury may be related to TXNIP/NLRP3 axis-mediated inflammation and pyroptosis.

TXNIP/NLRP3 signaling pathway is the key to pyroptosis and is activated in a variety of inflammatory diseases. It has been documented that (Chen *et al.*, 2021) in a rat model of myocardial I/R injury, the promoted expression of TXNIP reverses the inhibition of cardiomyocyte pyroptosis by overexpression of miR-200a-3p by promoting NLRP3 expression. (Yao *et al.*, 2022) have explained that cerebral ischemia leads to the accumulation of ROS, driving TXNIP overexpression and NLRP3 activation to induce pyroptosis. Furthermore, TXNIP/NLRP3 pathway has been shown to mediate pyroptosis by activating inflammatory factors such as IL-1β (Liu *et al.*, 2019). In CIR, we found increased expression of TXNIP and NLRP3 in animal and cell experiments, and confirmed that TXNIP was a downstream target of miR-128-3p, a result similar to the previous report (Liu *et al.*, 2021). Furthermore, rescue experiments obtained a conclusion that overexpression of TXNIP reversed the effects of silencing circCCDC6 on neuronal pyroptosis and inflammation.

However, there are some limitations as to the study design: 1, no detection of circCCDC6 expression in IS patients; 2. the correlation of circCCDC6 expression with clinicopathological features and whether it can be used as a diagnostic biomarker for IS has not yet been determined; 3. further systematic investigation of the relevant mechanism of circCCDC6 in MCAO-induced neurological deficits is required to further define the circRNA-miRNA gene network.

CONCLUSION

To sum up, circCCDC6 mediates neuronal pyroptosis and inflammation through the miR-128-3p/TXNIP/NLRP3 axis. This finding provides new insights into the mechanism by which circCCDC6 regulates CIR injury-induced neurological deficits and provides a potential target for CIR injury therapy.

Review

Pheochromocytoma and paraganglioma in children and adolescents

Teresa Stachowicz-Stencel✉, Natalia Pasikowska and Anna Synakiewicz

Department of Pediatrics, Hematology and Oncology, Medical University of Gdansk, Gdańsk, Poland

Pheochromocytoma (PPC) and paraganglioma (PGL) are the tumors that rarely occur in the pediatric population (PPGL). Both originate from chromaffin cells, pheochromocytoma is localized in the adrenal gland, whereas paragangliomas are regarded as the tumors present in other localizations, from head to the pelvis. The clinical image is characterized by the presence of the sustained hypertension, headaches, sweating, palpitations. The symptoms are caused by the catecholamine secretion or are related to tumor mass pressure on different organs. The catecholamines and their metabolites levels in urine collection or plasma are necessary for further evaluation of the diagnosis. In pediatric population the tumors occur in multiple familial syndromes such as Multiple Endocrine type 2, Neurofibromatosis type 1, Von Hippel-Lindau syndrome, Familial Paraganglioma syndrome are related to specific mutations (*SDHx, RET, VHL, NF1*) leading to the characteristic phenotype. The radiological and nuclear imaging are an important part of the examination. Although CT and MR are reported to have overall good sensitivity for the tumor detection, further analysis with nuclear imaging is recommended for the specified diagnosis. Right now 68GA-DOTATATE is regarded as the tracer of choice, leading to the complex evaluation of patients with different mutations and metastatic disease. The treatment of choice is the tumor excision. Also, lately new therapeutic approaches including genetically targeted therapies are under investigation for more complex treatment of tumors with underlying genetic cause or metastatic disease. Long term follow-up after treatment to avoid recurrence or to detect it in early stadium must be performed.

Keywords: children, malignant tumors, paraganglioma, pheochromocytoma, treatment, young adults

INTRODUCTION

Pheochromyctoma (PPC) and paragnaglioma (PGL) are rare tumors in the pediatric population. The prevalence is 0.2–0.5 per million of children, which constitutes only for 20% of its general incidence in the population (Ardicli *et al.*, 2021; Park *et al.*, 2021). They can occur at any age, however the mean age at diagnosis is reported to be 11 years old, with male predominance (Ross *et al.*, 2000; Havekes *et al.*, 2009). Pheochromocytoma and paraganglioma are the neuroendocrine tumors originating from chromaffin cells which form the adrenal medulla. Tumors located in the adrenal medulla are regarded as pheochromocytomas. The chromaffin cells can also be present extramedullary around sympathetic and parasympathetic ganglia, resulting in the formation of paragngliomas in various localizations of the body, from head to the pelvis (Park *et al.*, 2021; Ross *et al.*, 2000). Around 33% of tumors are located in the adrenal glands, and the rest are found in the other body regions (Pamporaki C *et al.* 2017). The tumors produce and most of them (70%) relsease catecholamines such as epinephrine and norepinephrine and their metabolites, metanephrines and normetanephrines. Head and neck paragangliomas are mostly biochemically silent, however they can produce dopamine (Shah MH *et al.*, 2021). The catecholamine production contributes to the symptoms and clinical image of the PPGL, leading to the occurrence of hypertension, excessive sweating, palpitations, headaches and abdomen pains (Eisenhofer *et al.*, 2022). Around 0.5–1.7% of pediatric hypertension is the implication of the PPGL (Ross *et al.*, 2000; Yen & Lodish, 2021; Barontini *et al.*, 2006). 50-80% of the tumors present in the pediatric population are showing the germline mutations in the known genes, including *VHL, RET, SDHx, MAX, NF1, HIF2* presenting the phenotype characteristic for various familial syndromes (Park *et al.*, 2021; Shah *et al.*, 2021; De Tersant *et al.*, 2020). Due to the high incidence of the mutations in pediatric PPGL population, the tumors tend to be more aggressive and metastatic, which should lead to the complex evaluation of diagnosis, treatment and lifetime surveillance (Shah *et al.*, 2021).

CLINICAL IMAGE

The clinical image of pheochromocytoma and paraganglioma depends predominantly on the catecholamine secretion. As the tumors present in the pediatric population are highly related to the germline mutations, leading to the metastatic, multifocal and aggressive disease, the majority of the pediatric patients – 90% show the symptoms of the illness (Kuo *et al.*, 2022). The most common symptom is the sustained hypertension, which, in rare and severe cases can lead to the encephalopathy, cardiomyopathy, hypertensive crisis and cardiac failure (Edmonds *et al.*, 2011; Armstrong *et al.*, 2008). The paroxysmal hypertension is less frequent in children comparing to adults (Kuo *et al.*, 2022; Jain *et al.*, 2020; Edmonds *et al.*, 2011; Ben-Skowronek & Kozaczuk, 2015). It is reported that there is no direct correlation between the catecholamine level and the severity of hypertension (Havekes *et al.*, 2009; Bravo & Tagle, 2003). The triad of

symptoms typical for the pediatric population includes: palpitations (53%), excessive sweating and headaches (39–95%) (Jain *et al.*, 2020; Kuo *et al.*, 2022). Other frequently and less commonly occurring symptoms of the tumor presence include the disturbances in vision, diarrhea, orthostatic hypotension, nausea, flushing, pallor, behavioral and psychiatric changes. The tumor can also be found incidentally in the radiological work-up or due to the mass-related symptoms e.g abdomen pain, back pain, loss of weight and constipation (Jain *et al.*, 2020; Edmonds *et al.*, 2011). Pheochromocytoma and Paraganglioma can be present in various familial syndrome including Von Hippel-Lindau syndrome, Multiple Endocrine Neoplasia type 2 syndrome, Neurofibromatosis type 1 syndrome and Familial Paraganglioma syndrome, so that once the syndrome is diagnosed or suspected, the patient should be under the specialistic care for tumor evaluation (Edmonds *et al.*, 2011; Fargette *et al.*, 2023). The VHL syndrome is characteristic for the occurrence of various tumors, in pediatric population especially PPGLs and hemangioblastomas which can remain silent until presence of serious symptoms as a result of a tumor mass pressure on organs (Rednam *et al.*, 2017; Ben-Skowronek & Kozaczuk, 2015). In neurofibromatosis, the clinical image develops with children's age and the most common features include cafe-au-lait spots, freckles of auxiliary and inguinal regions, plexiform neurofibromas and gliomas of optic nerves, pheochromocytoma occurs rarely, nonetheless the patients should be under observation (Edmonds *et al.*, 2011; Miller *et al.*, 2019). Familial Paraganglioma syndrome is the result of the *SDHx* pathogenic variants, according to Chetty *et al.* it is reported that patients with *SDHA* pathogenic variants do not develop paragangliomas (Chetty *et al.*, 2010), however Nölting and others proves that paragangliomas can be present in this pathogenic variant (Nolting S *et al.*, 2022; Bausch B *et al.*, 2014). In SDHB pathogenic variants the tumors are solitary, in various localizations including abdomen, pelvis, retroperitoneum; less common in mediastinum and head/neck, and they tend to metastasize. Up to 70% of patients with *SDHB* mutations can show metastases. Most commonly metastases can be found in bones, lymph nodes, liver and lungs (Kuo *et al.*, 2022). *SDHD* and *SDHC* pathogenic variants carriers show incidence in presence of tumors in the head and neck localization, but *SDHD* pathogenic variant carriers can show multiple tumor presence, whereas SDHC carriers solitary tumor (Chetty *et al.*, 2010). The patients with head and neck paragangliomas are mostly asymptomatic, while tumors in other localization show typical symptoms (Işik *et al.* 2006). Multiple Endocrine Neoplasia type 2 syndrome is divided in type 2A and type 2B. Type A is associated with C-cell hyperplasia or medullary thyroid cancer, phechromocytoma and hyperparathyroidism, while type B is associated with higher prevalence of C-cell hyperplasia or medullary thyroid cancer than type A, pheochromocytoma, mucosal neuromas and marfanoid habitus (Van Treijen *et al.*, 2022).

BIOCHEMICAL TESTING

As the pheochromocytomas and paragangliomas can secrete catecholamines and their metabolites eg. methanephrines and normethanephrines, the laboratory 24-hours urine or plasma collection need to be undertaken to evaluate the diagnosis. Before the beginning of the laboratory tests, the patient should be prepared for the sample taking, which means going off the drugs and di-

etary products that would impact the catecholamine production or that would influence the methods of its detection. The products that must be avoided are bananas, cheese, nuts, tomatoes, alcohol, disulfiram, metronidazole, paracetamol, amoxicillin, methenamine, urapidil, L-dopa and others (Corcuff *et al.*, 2017; Shah *et al.*, 2021). As well the stress should be avoided before the sample taking and the blood tests should be undertaken while patient is laying as it is reported that sitting position can alter the level of blood metanephrines (Lenders & Eisenhofer, 2017; Seamon & Yamaguchi, 2021). It is reported that measurements taken from the plasma samples show higher sensitivity than from the urine collection (Lenders & Eisenhofer, 2017). The results of plasma level metanephrines 2 times more than the upper normal limit is considered to result in PPGL diagnosis (Lenders & Eisenhofer, 2017, Eisenhofer *et al.*, 2023). Shah MH *et al.* consider the diagnosis while the metanephrines level is 3 times upper than the cut-off value (Shah *et al.* 2021). The *SDHB* pathogenic variant carriers can show lack of elevation of catecholamines, while increased level of 3-metoxythyramine can be useful to assess the metastatic disease (Lenders & Eisenhofer, 2017).

GENETICS

Owing to germline mutation in one of the subsequent susceptibility genes: *VHL, SDHx, RET,* and *NFI*, pediatric PPGLs are frequently found to possess a genetic cause. Genes encoding for pseudohypoxia in cluster 1 are organized to cluster 1A with TCA-cycle genes, along with the *SDHx* genes, and cluster 1B associated with hypoxia signaling, primarily *VHL* and *EPAS1*. Cluster 2 is where the other two crucial genetic causes of pediatric PPGL, RET and NFI associated with kinase signaling are located (Crona *et al.* 2017; Nolting *et al.*, 2022). Genetic abnormalities undermining PPGL are all inherited in autosomal dominant patterns, but with the risk of increased PPGL susceptibility in case of paternal inheritance as a result of pathogenic variants of *SDHD* (including *SDHAF2* and *MAX*). Nevertheless, identification of *SDHD* variants inherited from the mother is implicated for screening of the relatives and further generations. Although genealogical records of PPGL are often present in pediatric patients with PPGL, the lack of genealogical record should not restrain clinicians from referring for genetic counseling and testing, as the feasibility of de novo mutations must be contemplated. With no exception, genetic counseling and evaluation are encouraged in all patients with PPGL.

Succinate Dehydrogenase Subunit Defects (*SDHD*)

PPGLs were reported to harbor mutations in four subunits of *SDHD* and assembly factor gene *SDHAF2*. Mutations in *SDHB* on chromosome 1p36.13 were proved to be responsible for metastatic PPGL. In the study of King and others 71.9% patients who were younger than 20 years had a germline mutation in *SDHB* (King *et al*, 2011). The risk of a metastatic disease for *SDHB* carriers with PPGL is noted about 31–70% (Rijken *et al.*, 2018). Other authors reported that 70% children with PPGL had metastases at a median age of 16. *SDHC* on chromosome 1q23.3 and *SDHA* on chromosome 5p15.33 are less common in PPGLs with a percentage of 8.3 and 1.7, respectively (Benn *et al.*, 2018). Nonetheless, the metastatic risk is higher in *SDHA* in 30–60% but in *SDHC* it is very low (Nolting *et al.*, 2022; Bausch *et al.*, 2014). *SDHC* and *SDHD* are present in

head and neck PGLs (Read *et al.*, 2021). In accordance with the international guidelines for PPGLs in asymptomatic *SDHA, SDHB, SDHC* and paternally-inherited *SDHD* variants screening should be conducted (Amar *et al.*, 2021). Pediatric patients with *SDHB* carriers screening is worth doing at the age of 6–10 years old and at 10–15 years old in cases of other mutations. The tumor size plays an essential role in the prognosis. Patients with tumor's diameter less than 5 cm developed metastases within 7 years post the primary treatment, while patients with larger tumors show metastatic spread within 2 years. (Jochmanova *et al.*, 2020). It has been reported that mutations in *SDHD* on chromosome 11q23.1 show higher penetrance than in *SDHB* and autosomal dominant inheritance pattern is modified by maternal imprinting, hence the disease is frequently inherited from the paternal allele (Bayley *et al.*, 2020).

Von Hippel-Lindau Syndrome (VHL)

VHL syndrome is a consequence of pathogenic variants in *VHL* located on chromosome 3p25.3. Owing to the loss of tumor suppressor gene function that encoded for an E3 ubiquitin ligase decaying HIF-2a. *VHL*, a cluster 1B gene, is linked to noradrenergic biochemical phenotype. About 10-25% individuals with VHL develop PPC, with sympathetic and parasympathetic PGLs occurring less commonly, bearing metastatic risk of 5–8%. It has been proved that VHL is the cause of PGLs in children and it develops at the age of 11–12. Every fifth patients will possess *de novo* mutation. What is worth noticing is that the rate of *de novo* mutation has been found to be significantly higher in PPGL patients representing an overall rate of 60% and 50% for the pediatric group; the sample size was accredited by the researchers. (Cascon *et al.*, 2013; Rednam *et al.*, 2017). The earliest onset of PPGL occurs in patients between the age of 11–12 on average.

EPAS1 Gain-of-Function Syndrome

Pacak Zhuang syndrome (PZS) characterized by polycythemia, PPGL, and duodenal somatostatinoma is the noteworthy exception for the generally established rule of germline susceptibility; it was initially discerned in two female patients with congenital polycythemia and PGL in the adolescence. Post-zygotic somatic mutation in the gene encoding for the transcription factor HIF-2 ALFA (the *EPAS1* gene located on chromosome 2p21) can lead to PZS which is hardly ever related to germline inheritance (Zhuang *et al.*, 2012; Lorenzo *et al.*, 2013). PGLs were occurring repeatedly in all patients and almost 30% of them had metastatic disease, which was indicated in a study of 7 patients with PZS (Darr *et al.*, 2016). Hence, those cases are a profound driving factor in favor of somatic, as well as germline, genetic testing when patient tumor tissue is inaccessible. Not only may it provide information about the etiological factors, but also it may improve omnipresent understanding of related formidable clinical characteristics and risk of "multiplicity, recurrence, and malignancy".

Neurofibromatosis Type 1

The undermining factor of neurofibromatosis type 1 is mutation in the *NF1* gene that encodes for neurofibromin placed on chromosome 17q11.2. *NF1*, a tumor suppressor in cluster 2, inhibits the RAS-MAPK signaling pathway. National Institutes of Health established the clinical diagnostic criteria for NF1 (Gutmann *et al.*,

2017). Interestingly, up to 50% patients with NF 1 arise de novo, which is why the absence of a family history should not preclude NF1 from the differential diagnosis in the presence of suggestive clinical findings. Pheochromocytomas occur in patients with NF1 in 0.1 to 5.7%, yet in 3.3 to 13% on autopsy (Plouin *et al.*, 2001). Kepenekian and others (Kepenekian *et al.*, 2016) identified pheochromocytoma in 7.7% adult patients with NF1 presenting no symptoms. The adrenal disease presents most commonly unilaterally (in 78–84%), with bilateral disease reported in 9.6 to 16.6% of patients with pheochromocytoma (Al-Sharefi *et al.*, 2019). Metastatic PCC was mainly noted in adults in 11.5% (Jiang, *et al.*, 2020). Fortunately PPGL in children with NF1 is less frequent (1–3%) (Pamporaki *et al.*, 2017).

Multiple Endocrine Neoplasia Type 2 (MEN-2)

MEN-2A is associated with pheochromocytoma in 57% and other diseases such as medullary thyroid cancer or hyperparathyroidism. MEN-2B is only in 5% of MEN-2 and is linked to pheochromocytoma in 50% and aggressive medullary thyroid cancer, mucosal neuromas and a marfanoid habitus (Moriaitis *et al.*, 2014). The risk of metastases in pheochromocytoma is less than 5% (Nolting *et al.*, 2022).

RADIOLOGICAL AND NUCLEAR DIAGNOSTIC WORK UP

Computed Tomography (CT) and Magnetic Resonance

Although the computer tomography is an easily accessible diagnostic method, with no specific preparation needed before the examination and short time of the imaging test, it is not considered as the best diagnostic method for children's PPGL tumors detection, as it leads to the radiation absorption. In children, MR is preferred for the initial diagnostic pathway as it is a safer method. Both methods are good in imaging tumors, including incidentalomas and differentiating them between benign tumors like adenoma or PPGLs (Carrasquillo *et al.*, 2021). Adenomas on CT show the attenuation value of around 10 HU, while pheochromocytomas around 50–60 HU (Carrasquillo *et al.*, 2021; Fsrrugia *et al.* 2019). The MR examination is important, as it can show the vascularization of the big tumors which is necessary to be determined before further evaluation (Farrugia & Charalampopoulos, 2019). Nevertheless, Havekes *et al.* report that as much as MR sensitivity is high for tumor detection, its specificity for the PPGLs is not enough and further nuclear imaging is recommended (Havekes *et al.*, 2009).

Somatostatin receptor-based PET/CT

68GA-DOTATATE (68Ga-DOTA(0)-Tyr(3)-octreotate)

A radiotracer composed of hormone peptide and 68Ga positron emitter, targeting the somatostatin receptors. It has a 68-minutes half-life period and can accumulate in every tissue providing the entire body scan. It is used in PPGL/PCC detection due to the high level of somatostatin receptors expression in PCC/PPGL (Rees *et al.*, 2023; Jaiswal *et al.*, 2021).The substance can be easily administered to the patient as no preparation is needed before the examination (unless the anesthesia in pediatric population is necessary, then 6 hours prior to examination food/fluids uptake is forbidden) (Rees *et al.*, 2023). It is used in paraganglioma diagnostic work up in

adult population as it is reported that patients with sporadic and *SDHx*-related paraganglioma indicate higher number of lesions found by Ga-DOTATATE PET CT compared to F-FDG PET CT and CECT/MRI (Jaiswal et al., 2021; Jha et al., 2018). Jaiswal and others reported that it has a better sensitivity for both primary and metastatic lesions, as well as for VHL-associated lesions not detected by CECT in pediatric population (Jaiswal et al., 2021). Also it has a higher susceptability for head and neck paragangliomas, which are difficult to be found as they are not biochemically active (Carrasquillo et al., 2021; Yen & Lodish, 2021). 68GA-DOTATATE is a tracer of choice in any situation stated above (Janssen et al., 2016).

CU-DOTATATE

Another target for somatostatin receptors, with a higher half-life period and similar sensitivity to 68GA-DOTATATE, however not yet approved in the paediatric population (Rees et al., 2023; Yen & Lodish, 2021).

18FDG PET/CT (18fluorodeoxyglucose)

Before the diagnostic work up patient should not be given glucose or any fluid containing glucose intravenously for 6 hours prior to the examination, no food should be administered orally as it interferes with the radiotracer and can lead to false positive results (Rees et al., 2023). The F-FDG is better in detecting metastatic PCC/PGGL than MIBG, but has a lower sensitivity than 68GA-DOTATATE, for benign tumors its sensitivity is similar/lower than MIBG (Carrasquillo et al., 2021; Jaiswal et al., 2021). 18FDG PET/CT has a higher detection for the tumors with *SDHx* pathogenic variant comparing to the *SDHx* negative tumors, however still lower than 68GA-DOTATATE (Carrasquillo et al., 2021).

131/123 I-MIBG

A guanethidine analog, the compound is structurally similar to norepinephrine, binds with norepinephrine transporters and accumulates in adrenergic tissues (Carrasquillo et al., 2021; Rufini et al., 2008). Prior to the examination, the uptake of potassium iodate is mandatory for thyroid blockade, also interfering medications including anti-arrhtyhmics, beta-, adrenergic-, calcium-blockers, vasoconstrictors and others should be gone off before the diagnostic work up (Rees et al., 2023; Jacobson & Travin, 2015). The I-MIBG has a significantly high detection rate for non metastatic PPC/PPGL, the overall rate is higher for pheochromocytoma rather than paraganglioma. The detection of tumors with *SDHx* pathogenic variant is low, in general the rate of hereditary tumors discovery is low by I-MIBG (Carrasquillo et al., 2021).

F-DOPA (6-18F-fluoro-L-3,4-dihydroxyphenylalanine)

The amino acid radio tracer which was predominantly and historically used to diagnose parkinsonian's syndromes as it evaluates the dopamine synthesis (Carrasquillo et al., 2021; Darcourt et al., 2014). No preparation is needed before the tracer administration as no drugs have been claimed to disturb the radioimaging with F-DOPA (Carrasquillo et al., 2021). The tracer has a high detection rate for benign PCC/PGGL and metastatic pheochromocytoma, though sensitivity for metastatic paraganglioma is low, 68GA-DOTATATE outperforms F-DOPA in the general detection rate of PCC/PGGL(Carrasquillo et al., 2021). It is reported that

MYC-associated factor X (*MAX*) pheochromocytomas show high level of F-DOPA uptake and should be considered a tracer of choice in those particular cases (Taïeb et al., 2018).

TREATMENT

Before the surgery is performed the crucial role plays the cooperation of the endocrinologist, oncologist, surgeon, cardiologist and anasthesiologist. The surgical resection is the mainstay of the treatment of patient with diagnosed PPGL. The type of surgery (laparoscopy vs open access) depends on the indivudual assesment of patient including tumor loclization, age of the patient and clinical stage of the disease. Before the surgery is performed the patient needs the hypertension evaluation e.g normalizing blood pressure, heart rate and preventing patient from excess of catecholamine secretion. Two-three weeks before surgery antihypertensive drug such as non-selective (phenoxybenzamine) α-antagoist should be administered, if this treatment is insufficient the calcium antagonists can be used as the additional drugs. It is imporatant for the patient to be well hydrated. In case of tachycardia, after the α-blocker administration, the cardioselective β-blocker is recommended (Fang et al., 2020). The preparation for surgery in pediatric patients takes about longer as a result of lower starting dose of medications to avoid complications and increased sympathetic activity in children than in adults (Amrish et al., 2020). Laparoscopic excision is recommended, however the surgery type depends of the anasthesiological assesment before and during surgery. Open laparotomy is reserved for the patients with huge tumors orr difficult to approach paragangliomas. During surgeries there is a huge risk of hypertensive crisis, myocardial ischemia, stroke, etc. (Schutler et al., 1995). Previously the mortality risk was high, nowadays it is reduced to less than 2% (Ploutin et al., 2001).

It was proved that about 70–80% of patients with PPGL have a germline or somatic mutation, so genetic testing ought to be performed in each patient with that diagnosis to guide their management and improve their clinical outcome (Jiang et al., 2020; Ochmanova et al., 2018). According to the literature germline mutations are known in 30–35% of patients and somatic mutations were found in 50% of patients (Jhwar et al., 2022). While treating patients with PPGL, the metastatic disease is still a challenge and there is no way to completely cure the disease. It is documented that about 10% to 15% of all patients with pheochromocytoma and 35–40% with paraganglioma, develop metastases (Eisenhofer et al., 2012; Patel et al., 2020). Metastasizing depends on the type of the pathogenic variant. In patients with *SDHB* and *SDHA*-mutant PPGL, there is a high risk of metastases, about 75% (Bechmann et al., 2020; Crona et al., 2019). On the other hand, cluster 2 pathogenic variants disrupt the kinase signaling pathway and lead to their overactivation (*RET, BRAF, NF1, HRAS, MAX, NGFR*) and are associated with low metastatic risk of 3–10% (Bechmann et al., 2020, Kumar et al., 2021). Cluster 3 pathogenic variants affect the Wnt signaling pathway (*MAML3, CSDE 1*) and are rare but very aggressive with poor prognosis. Overall 5-year mortality rates is 37% but 10-year mortality rate is 29% (Alzofin et al., 2021; Nolting et al., 2022).

In this situation, novel therapeutic approaches are needed (Nolting et al., 2022; Nolting et al., 2019). Lately a lot of genetically guided therapies were investigated and used some molecular treatment in patients with met-

astic PPGls. (Wang *et al.*, 2022; Lee *et al.*, 2018; Mak *et al.*, 2019).

CONCLUSION

Pheochromocytoma and paraganglioma in pediatric patients are rare, but should always be considered with tumor mass detected or when typical symptoms such as hypertension, palpitations, sweating or headaches are happening. Genetic testing should be performed in every patient with this diagnosis, as it helps in the initial diagnostic pathway, targeted treatment, prognosis of the disease and follow up for early detection of recurrence of the disease. The main treatment is the radical excision of the tumor.

Patients with a hormonally active tumor are at risk of complications such as internal instabilities and pressure fluctuations. Long follow-up of a patient with PPGL is essential to avoid recurrence. It is important to monitor blood pressure and the level of catecholamines in the urine collection as well as radiological imaging tests in case of clinical symptoms or catecholamine increase. For patients with certain mutations (*SDHD* and *VHL*) where there is a risk of recurrence, there is a need for frequent and long-term monitoring.

Onco-nephrology is a new field of medicine which combines many aspects of kidney injury in cancer patients and cancers in patients with kidney disease. This connection takes many forms and includes drug-induced nephrotoxicity, electrolyte disorders, numerous paraneoplastic syndromes and an increased rate cancers in dialysis and transplanted patients. The appropriate laboratory assessment of the kidney function allows to optimize chemotherapy and thus minimizes the risk of complications. This article focuses on acute kidney injury (AKI), chronic kidney disease (CKD), various electrolyte and acid-base disorders, the most common cancers after kidney transplantation and the kidney disorders associated with HSCT (hematopoietic stem cell transplantation). The possibility of the application of novel cancer therapy, such as cancer immunotherapy and proton therapy in transplant recipients was also discussed.

Key words: onco-nephrology, cancer, kidney disease, transplantation, HCT, therapy

INTRODUCTION

There are complex relationships between kidneys and cancer. Many crucial points could be underlined by factors such as acute kidney injury and chronic kidney disease in a cancer patient, the renal effects of anticancer therapy, adverse effects of the tumor itself, management of patients after nephrectomy due to kidney cancer, cancer treatment on dialysis and after kidney transplantation (KT). Another very important issue is oncological treatment in other than kidney solid organ transplant recipients (SOTR) and in hematopoietic cell transplantation (HCT).

A multidisciplinary onco-nephrology team, including not only oncologist and nephrologist, but also other health professionals is crucial to providing care to the aforementioned groups of patients (Cosmai *et al.*, 2016). This was the reason for the creation of a new field of medicine – called onco-nephrology (Bączkowska *et al.*, 2019)

In this paper, we discussed acute and chronic kidney disease in SOTRs with cancer as well as nephrotoxicity associated with existing and novel cancer therapy. We also focused on the most common cancers in SOTRs such as skin cancer and urinary tract cancer. An additional part is dedicated to kidney disease in HCT recipients.

Adequate assessment of kidney function allows for selecting the optimal anticancer therapy in terms of the type of drug and its dose (Malyszko *et al.*, 2020a). Treatment efficacy and outcomes, as well as survival, could be affected by both the overestimation and underestimation of renal function.

Patients with impaired renal function are at a higher risk of developing adverse events and toxicities to an anti-cancer drug. The use of some drugs in patients with renal failure can lead more often to myelotoxicity, hepatotoxicity, and life-threatening electrolyte disorders (e.g., cisplatin, cyclophosphamide, vinblastine, and vincristine).

An equally important issue is the use of new groups of anticancer drugs in patients with kidney damage and kidney transplanted patients (Małyszko *et al.*, 2016; Sprangers *et al.*, 2021). In recent years, novel therapies, including immunotherapy with immune checkpoint inhibitors (ICIs) and proton therapy, have revolutionized cancer treatment and are becoming a new standard of care for many tumor types. Nephrological problems more and more often also affect patients undergoing stem cell transplantation (Kępska-Dzilińska *et al.*, 2022). Kidney damage/deterioration is often found in these patients due to the extension of the eligibility criteria for this procedure and its use in older patients and/or with additional chronic diseases. Kidney injury after high-dose chemotherapy might be due to the direct effect of cytotoxic agents or indirect complications caused by cytotoxic agents such as mucositis and diarrhea, infections, or veno-occlusive disease. On the other hand, HCT is increasingly used in patients with renal failure, including end-stage renal disease undergoing dialysis due to multiple myeloma. The different HCT protocols are required in patients with normal renal function, mild impaired renal function, and dialysis-dependent patients, which is discussed in this article.

Kidney transplantation is the best method of renal replacement therapy, it prolongs the patient's life by decades but the price is much higher than in the general population - the risk of cancer. Cancer is listed as the second, after cardiovascular diseases, cause of death in patients after KT and also causes death in many other SOTRs (Serkies *et al.*, 2022). Treatment of these patients is very complex due to immunosuppression and requires the cooperation of specialists in many fields depending on the transplanted organ and type of neoplastic disease. Skin cancers are the most common tumors in SOTRs. The most prevalent are squamous cell carcinoma (SCC), basal cell carcinoma (BCC), malignant melanoma (MM), and Merkel cell carcinoma (MCC) (Mittal & Colegio, 2017). Appropriate prophylaxis allows for a considerable reduction of the risk of skin cancer, while regular dermatological examination allows for a diagnosis in the early phase of the disease and improves the prognosis. The second most common are cancers of the urinary tract, including the transplanted kidney (Bellini *et al.*, 2022). As these neoplasms occur more often in older age, their detection is growing with time, with the number of recipients followed up. In the case of urinary tract cancers, surgery is recommended. The possibilities and limitations of urological management are presented in our article.

The presented paper summarizes the key information provided in lectures delivered during the 2nd Scientific and Training Conference "Nephro-oncology" in Gdańsk, Poland, on October 2–3, 2020. It is also updated using crucial management issues in nephrology relevant to patients with malignancy, published by KDIGO (Kidney Disease: Improving Global Outcomes) and the current status on malignancies in adult kidney transplant candidates and recipients published most recently in NDT (Porta *et al.*, 2020; Małyszko *et al.*, 2020a; Serkies *et al.*, 2022).

KIDNEY INJURY IN CANCER

Acute and chronic kidney disease definition and classification

The term Acute kidney disease (AKD) was introduced recently to incorporate both acute kidney diseases and disorders. The definition of AKD includes abnormalities of kidney function and/or structure with implications for health lasting ≤3 months. AKD may include AKI (acute kidney injury), but, more importantly, also other abnormalities in kidney function that are not as severe as AKI or that develop over a period of >7 days (Table 1) (Lameire *et al.*, 2021; Levey *et al.*, 2022). The cause(s) of AKD should be sought, and classification includes functional and structural parameters. Minimal dataset for evaluation: history and examination including; past medical history, drug history (in cancer patients particularly important), infectious diseases, full physical examination including blood pressure, assessment of volume, serum creatinine and eGFR (estimated glomerular filtration rate), urea and electrolytes, full blood count, urinary dipstick (qualitative albuminuria/proteinuria), and ultrasound. Management of AKD is currently based on empirical considerations.

Kidney function assessment in oncology

It has been learnt that renal function in patients with malignancy should be estimated to profile the survival risk, assess the appropriate dose of antineoplastic drugs and define the eligibility of these patients for clinical trials with novel therapies (Porta *et al.*, 2020). The problem of drug dosing in oncology was described in detail in two recent reviews (Sprangers *et al.*, 2021; Malyszko *et al.*, 2020a). Treatment efficacy and outcomes as well as survival could be affected by both overestimation and underestimation of renal function. Overestimation of renal function may result in overdose or inappropriate choice of anticancer drugs with their serious adverse

Table 1. Functional and structural criteria for kidney diseases and disorders.

	AKI	AKD	CKD
Duration	Within 7 days	≤3 months	>3months
Functional criteria	increase Scr by >50% within 7 days or increase SCr by >0,3mg/dL (26.5μmol/L) within 2 days or oliguria for ≥4 hours	AKI or GFR<60 mL/min/1.73m2 or decrease GFR by >35% vs baseline or increase SCr o >50% w vs baseline	GFR <60 ml/min/1.73m^2
And/or		And/or	And/or
Structural criteria	Not defined	Markers of kidney damage (albuminuria, hematuria, or pyuria are most common)	Markers of kidney damage (albuminuria is most common)

Abbreviations: AKD, acute kidney disease; AKI, acute kidney injury; CKD, chronic kidney disease; GFR, glomerular filtration rate; SCr, serum creatinine.

events. On the other hand, underestimation of renal function may cause underdosing or exclusion/withdrawal of an anticancer agent leading to worse outcomes/subsequent treatment failure. The majority of patients with malignancies are treated with several anticancer drugs with renal clearance. Therefore, patients with impaired renal function are at higher risk for developing adverse events and toxicities to these therapeutic protocols. Recently introduced immune checkpoint inhibitors (e.g., ipilimumab, nivolumab, and pembrolizumab) may cause acute interstitial nephritis and podocytopathy. Moreover, anti-VEGF (vascular endothelial growth factor) drugs may cause microvascular injury and DITMA (drug-induced thrombotic microangiopathy) or various glomerulopathies, in particular, minimal change disease and/or collapsing-like FSGS (focal segmental glomerulosclerosis). Therefore, in patients with malignancy, an accurate assessment of kidney function i.e. GFR is critical. To date, creatinine is a nearly ideal filtration marker, despite some limitations. Therefore, several formulae assessing GFR were introduced in healthy subjects as well as in patients with chronic kidney disease, however, the use of these formulae in cancer patients is not established. Sarcopenia is a common finding in patients with advanced malignancy prior therapy, in addition, it develops or worsens during anticancer therapy in the vast majority of patients. As creatinine is produced by muscles, in patients with reduced muscle mass creatinine-based formulae are not appropriate with potentially negative consequences. Recently, Janowitz and others performed an extensive study and showed that the BSA-adjusted CKD-EPI formula appeared to be the most accurate and least biased GFR estimate of those currently used in oncology patients when compared with ^{51}Cr-EDTA (Janowitz et al., 2017). Calculation of GFR based on the Janowitz formula is available online at http://tavarelab.cruk.cam.ac.uk/JanowitzWilliamsGFR/. It appears that the Janowitz formula is the best option for creatinine-based equations in cancer patients. In everyday clinical oncology practice, adjustment of drug dosage is generally based on eGFR. However, The US FDA promotes the usage of Cockcroft-Gault or the MDRD formulae for drug dosage prescriptions (Malyszko et al., 2020a). Despite the fact, that either Janowitz or CKD-EPI formula estimates GFR more precisely, the drug manufactures still refer drug dosage to other eGFR formulae. Therefore, we need to take into account these eGFR formulae when adjusting the drug dose. Kidney function, besides changes in glomerular filtration rate/serum creatinine, also encompasses tubular dysfunction and vascular disorders, more studies including urinalysis and imaging studies such as computed tomography, magnetic resonance imaging, etc are to be considered prior to taking therapeutic decisions (Malyszko et al., 2020a).

Evaluation of renal function in AKI is another challenge for nephro-oncologists, as AKI is common in cancer patients either due to malignancy or its therapy. It is of utmost importance as AKI represent a dynamic state with a fast fall in GFR whereas CKD is a relatively stable state and GFR formulae were developed in stable CKD patients. Therefore, in AKI, estimation of eGFR based on creatinine may lead to serious errors. Moreover, as kidney injury originates in tubules, significant tubulopathy may not result in significant rise in serum creatinine concentration and changes in creatinine/GFR represent relatively late changes. Taking into account these limitations, there is a search for serum and urinary markers. Several biomarkers such as neutrophil gelatinase–associated lipocalin, proinflammatory cytokines (interleukin-6 and interleukin-8), kidney injury molecule-1, netrin, semaphorin, etc and some others were assessed (Malyszko et al., 2020a). However, no data are available on their application in cancer patients. Serum uric acid might reflect a convenient and simple measure of kidney function. Recently, fasting urine osmolarity has been proposed as a simple measure of tubular function (Malyszko et al., 2020a). In the setting of known tubular damage, impaired urine concentration ability precedes a decline in GFR Thus, fasting urine osmolarity determination may be a simple and inexpensive tool to assess renal function and could be done at the bedside.

As kidney function assessment and the problem of the narrow therapeutic range of anticancer drugs is crucial, we should look for the appropriate methods used to assess renal function to avoid either underdosing or overdosing leading to failure/relapse or toxicity, respectively, both resulting in worse outcomes (Sprangers et al., 2021).

Acute kidney injury in patients with cancer

Acute kidney injury is diagnosed frequently in patients with cancer (Porta et al., 2020). The incidence of AKI differs from 12 to more than 20% of these patients. It is significantly higher in patients with multiple myeloma (up to 50%) and those who were treated with cisplatin (20-30%) or were admitted to the Intensive Care Unit (more than 50%) (Salahudeen et al., 2013). Up to 70% of all AKI develop during the first week after admission to the cancer centre. Many patient-specific (age, comorbidity especially diabetes mellitus, nephrotoxic chemotherapy, etc.) and cancer-related risk factors (neutropenia, sepsis, haematological cancers, hypercalcemia, tumour lysis syndrome, and many others) may increase the risk of AKI in patients with cancer (Rosner & Perazella, 2019). In the pathogenesis of AKI in patients with cancer several prerenal (extracellular fluid depletion, cardiac failure), intrarenal (glomerular or tubulointerstitial diseases, sepsis, thrombotic microangiopathy) or postrenal (obstructive uropathy) causes may play an important role. Many of these factors are present in patients with multiple myeloma; therefore, the incidence rate of AKI is high in these patients (Malyszko et al., 2020b). Chemotherapy plays a crucial role in the pathogenesis of AKI in cancer patients, which may affect each of the nephron segments (Malyszko et al., 2016). Mortality related to AKI in patients with cancer is high (25-30%) and up to 60% of these patients will develop end-stage kidney disease in the future, requiring renal replacement therapy (Salahudeen et al., 2013). Therefore all prophylactic maneuvers are very essential, including magnesium supplementation and the algorithms for the prevention of AKI after CT with contrast media frequently performed in patients with cancer (Cosmai et al., 2020).

Electrolyte disorders in cancer patients

Electrolyte disorders are very common conditions in cancer patients, and may significantly worsen the treatment outcome. Malignancy-specific electrolyte disorders can lead to life-threatening complications, particularly in patients with AKI. Hyponatremia, hypokalemia, hypomagnesemia, hypercalcemia and hyperphosphatemia can be disturbances directly related to the tumour or its treatment.

The Chinese population study revealed electrolytes and acid-base balance disturbances in 58% of 25,800 cancer patients (Li et al., 2020). This proportion is significantly higher than in other reported patient populations,

such as elderly people (22%) or patients admitted to the emergency units (14%).

Hyponatremia

Hyponatremia is the most common electrolyte disorder in patients with cancer. The prevalence of hyponatremia ranges from approximately 4% to as high as 44% (Berardi *et al.*, 2019). The most common disturbance directly related to malignancy is the inappropriate secretion of antidiuretic hormone (SIADH) from cancer cells (paraneoplastic syndrome). It is most commonly seen in small-cell lung cancer (SCLC) and head/neck cancer because as many as 10% to 15% of patients are hyponatremic from the beginning of the disease. Additionally, up to 70% of patients have significant elevations of plasma arginine vasopressin (AVP) (Rosner & Dalkin, 2014). The drugs most often associated with SIADH are cyclophosphamide, cisplatin, vinblastine, and vincristine (Verzicco *et al.*, 2020). For many patients with malignancy-related SIADH, the hyponatremia can be refractory to therapy. Another possible mechanism of hyponatremia in SCLC is the nonphysiological release of atrial natriuretic peptide (ANP) (Berardi *et al.*, 2019). Cisplatin can cause not only SIADH but also salt-losing nephropathy.

Hypokalemia

Hypokalemia is the second most common electrolyte disorder, with a prevalence of around 15% (Li *et al.*, 2020). The reasons for hypokalemia can be related to cancer and/or the used treatment. Cancer-specific causes include tumours that secrete ectopic adrenocorticotropin hormone (ACTH) such as SCLC, carcinoids, neuroendocrine tumours, or thyroid medullary carcinoma. These tumours cause the typical symptoms of hypercortisolemia and stimulate renal potassium wasting by activating the mineralocorticoid pathway. Another cancer-specific etiology for hypokalemia is possible in M4 and M5 subtypes of acute myeloid leukaemia (AML) (Milionis *et al.*, 1999). These malignancies increase serum lysozyme and lysozymuria, which leads to tubular injury (Mason *et al.*, 1975). Hypokalemia in these patients usually occurs together with other electrolyte and acid-base disorders (hyponatremia, hypokalemia, hypophosphatemia, hypomagnesemia and metabolic acidosis).

Chemotherapeutic agents (such as cisplatin, and ifosfamide) may induce serum potassium derangements mainly by changing renal tubular transport. Platinum-derived agents can also induce hypokalemia due to renal potassium wasting secondary to hypomagnesemia. In this case, potassium supplementation may fail until hypomagnesemia has been corrected. The incidence of cisplatin-related hypokalemia is around 27%. The treatment for hypokalemia often prevents the continuation of anticancer therapy with cisplatin, ifosfamide or/and cyclophosphamide.

Calcium and phosphate disturbances

The most common and relevant mineral disturbances in malignancies include hypercalcemia and hyperphosphatemia in the tumour lysis syndrome, and calcium and phosphate disturbances associated with the use of anticancer drugs and tumor-induced osteomalacia.

The tumour lysis syndrome is a consequence of the massive and acute lysis of the cancer cells caused either by chemotherapy or, rarely, due to their spontaneous rupture (Belay *et al.*, 2017). The lysis of the cancer cells leads to the release of large amounts of ions, including potassium and phosphate, that rapidly proliferating neoplastic cells are rich in. Tumour lysis syndrome is mainly diagnosed in hematologic malignancies and is uncommon in solid tumours. The release of phosphate leads to secondary hypocalcemia that may cause muscle cramps and seizures. The most important measures in managing patients with a high risk of tumour lysis syndrome include intensive hydration and monitoring of the serum levels of phosphate and calcium. Only the patients with the highest risk are administered allopurinol for prophylaxis and recombinant enzyme rasburicase for the treatment (Belay *et al.*, 2017).

Many drugs used for chemotherapy may cause mineral disturbances. The pathomechanism of these disturbances may vary from the tumour cell lysis, acute tubular necrosis with a secondary tubulopathy resulting in an impaired urine electrolyte excretion, a direct interference of the drug with the tubular transport of water and electrolytes, to thrombotic microangiopathy and thrombosis (Verzicco *et al.*, 2020).

The drugs that frequently cause mineral disturbances include cisplatin and carboplatin (hypocalcemia, hypophosphatemia and hypomagnesemia), ifosfamide and bendamustine (hypophosphatemia), sorafenib, nilotinib and erlotinib (hypocalcemia), cetuximab, panitumumab and 5-fluorouracil (hypocalcemia), and anthracyclines (hypophosphatemia) (Verzicco *et al.*, 2020).

The new promising class of antineoplastic drugs includes blockers of the fibroblast growth factor-23 receptor (FGFR). These drugs directly interfere with the mechanism of renal phosphate disposal and therefore hyperphosphatemia has been a major concern in clinical trials (Mahipal *et al.*, 2020).

Tumour-induced osteomalacia is a rare paraneoplastic syndrome caused by increased production of the fibroblast growth factor-23 by tumour cells (Florenzano *et al.*, 2021). It is mainly caused by slow-growing benign mesenchymal tumours and may manifest with muscle weakness, bone pain and bone fractures. The treatment of the condition includes the surgical removal of the tumour, phosphate and vitamin D supplementation.

Other consequences of oncological therapy

Hypertension

Several classes of antineoplastic drugs have hypertensinogenic properties (angiogenesis inhibitors, 17α-hydroxylase CYP17 inhibitor - abiraterone, aromatase inhibitors – anastrozole and letrozole and cisplatin derivatives) (Essa *et al.*, 2020). New onset hypertension or aggravation of pre-existing hypertension is predominantly found in patients treated with angiogenesis inhibitors like vascular endothelial growth factor (VEGF) inhibitors and tyrosine kinase inhibitors (Katsi *et al.*, 2019). Angiogenesis inhibitors exert their effect through inhibition of the VEGF signalling pathway. Inhibition of this pathway suppresses nitric oxide synthesis, leading to endothelial dysfunction and capillary rarefaction. VEGF signalling inhibitor-induced blood pressure increase appears to be mechanism-dependent on-target toxicity and has been suggested to be a positive biomarker of the clinical efficacy of these drugs. Results of several retrospective studies demonstrated that hypertension caused by angiogenesis inhibitors was associated with improved results of antineoplastic therapy (Liu *et al.*, 2019).

In the absence of controlled trials, hypertension in oncology patients should be managed by utilising the same treatment guidelines as for the general population (Tini *et al.*, 2019). The only specific recommendation is that

non-dihydropyridine calcium channel blockers, such as verapamil and diltiazem, should be avoided by patients treated with angiogenesis inhibitors. These antihypertensive drugs inhibit cytochrome P450 3A4, leading to the potentially high, toxic plasma concentration of angiogenesis inhibitors (Rizzoni *et al.*, 2017). It should be stressed that, in clinical practice, new onset hypertension or aggravation of pre-existing hypertension due to antineoplastic therapy, should be treated preferably by initiation or intensification of antihypertensive therapy, but not by reduction of dose or by ceasing therapy with antineoplastic agents.

Urinary tract infections

Urinary tract infections (UTIs) represent a severe complication in immunocompromised-neoplastic patients. Predisposing factors include urinary tract obstruction, catheterisation (i.e. with Foley catheter most often), percutaneous nephrostomy (PCN), hemorrhagic cystitis (after chemo- or radiotherapy), neutropenia, bone marrow transplantation, neoplasms (especially of the urinary tract) after transplantation, history of recurrent UTIs and/or kidney stones with prolonged antibiotics treatment, and autosomal dominant polycystic kidney disease (ADPKD). Enterococcus species are the leading cause of UTIs, especially in hospitalized patients, regardless of a cancer diagnosis. Despite the fact that their clinical manifestation is often mild, they can cause serious complications such as bacteraemia or endocarditis. Limited therapeutic options for UTIs due to the emergence of multidrug-resistant enterococci, particularly vancomycin-resistant *E. faecium* and *E. faecalis*, have become a global crisis over the last few years. It became a cause of higher patient mortality as well as increased worldwide healthcare costs (Giannakopoulos *et al.*, 2019). Currently, there is an overall lack of consensus about the optimal approach to catheter-associated urinary tract infections (CAUTIs). One of the strategies is an evidence-based, nurse-driven protocol for discontinuing indwelling urinary catheters (McCoy *et al.*, 2017). To reduce the high rate of recurrent infections and the potential delay of further chemotherapy, when the result of the antimicrobial susceptibility test is available and the patient is under compatible antimicrobial therapy, clinicians should proceed with an immediate Foley catheter or PCN replacement (PCN ideally within the first 4 days of the infection) (Szvalb *et al.*, 2019).

On the other hand, the link between recurrent UTIs and cancer development has been studied for many years, but the results are inconclusive so far. Several of them reported an association between chronic UTIs and prostate or bladder cancer (Giannakopoulos *et al.*; Anderson-Otunu & Akhtar, 2016). There are some prerogatives that ADPKD, besides ascending UTIs, cyst infections and haemorrhage, predispose to renal cell carcinoma, mainly in chronic dialysis patients.

Chronic kidney disease

According to registries and population studies, as many as 16–25% of cancer patients present with eGFR<60 ml/min (de Francisco *et al.*, 2019). Considering that every fifth cancer patient developed CKD, the mutual relationship between malignancy and CKD seems obvious. It was demonstrated that in the Chinese population 32.4% of patients with newly diagnosed cancer exhibited CKD. In addition, renal function was inversely related to all-cause mortality. Moreover, eGFR below 60 mL/min/1.73m² was an independent predictor of mor-

tality relative to eGFR ≥60 mL/min/1.73 m², and it was dependent upon the cancer site (Yang *et al.*, 2016)

On the one hand, CKD progression and accumulation of uremic toxins cause multiple quantitative and functional changes in the immune system, resulting in reduced malignancy surveillance and aberrant responses to cancer (Corredor *et al.*, 2020). On the other hand, cancer may induce CKD in numerous, largely unknown mechanisms. Circulating factors produced by the tumour cells may be suspected. For example, IL6 and TNF concentrations were reported to be significantly higher in cervical cancer patients than in the controls (Vitkauskaite *et al.*, 2020). Also, other tumours including lung cancer and renal cell carcinoma were found to produce excess amounts of IL6. Another factor derived from the tumour mass, and able to stimulate autoimmune reactions, is circulating free DNA (cfDNA). After release from cancer cells, the cfDNA circulates and can be detected in serum. Several types of cancer are currently diagnosed using specific cfDNA analysis. The potential of cfDNA to stimulate dendritic cells via toll-like receptor 9 could explain glomerular immune activation, inflammation and damage. Increased incidences of CKD, particularly, in the elderly, are of clinical importance and relevance. Many cancer drugs are cleared primarily by the kidneys as unchanged drugs or active metabolites. Therefore, any impairment in kidney function can potentially lead to alterations in pharmacokinetics, elevated blood levels of the drugs, and the increased toxicity discussed in the first parts of the paper (Janus *et al.*, 2010)

THE MOST OFTEN CANCERS IN SOLID ORGAN TRANSPLANT RECIPIENTS

Skin cancers

Skin cancers are the most common tumours in SOTRs. The most often are squamous cell carcinoma (SCC), basal cell carcinoma (BCC), malignant melanoma (MM) and Merkel cell carcinoma (MCC) (Euvrard *et al.*, 2003; Mittal & Colegio, 2017) Common risk factors include: chronic exposure to ultraviolet (UV) radiation, HPV infection, pretransplant skin cancer, older age at transplantation, white race, male sex and immunosuppression (being those with a higher risk azathioprine and cyclosporine) (Al-Adra *et al.*, 2022). The mean interval between transplantation and skin tumour diagnosis is 3 to 5 years (Euvrard *et al.*, 2003). Skin tumours in SOTRs are also more likely to be multiple and more aggressive with a higher risk of relapse, metastasis and death due to tumour progression.

The risk of developing BCC in patients after solid organ transplantation (SOT) is about 10 times higher than in the general population (GP). BCC is the most common skin cancer in the GP, while in SOTRs the SCC/BCC ratio changes in favour of SCC. BCC may develop at the site of precancerous conditions or previously unchanged skin. BCC occurs in younger patients than in the GP and grows more often multifocally and more extensively. The prognosis for early diagnosis and appropriate treatment of BCC is good, and the risk of recurrence is 5–10% (Euvrard *et al.*, 2003).

Squamous-cell carcinoma is the most common skin cancer in SOTRs, occurring 65 to 250 times as frequently as in the GP (Euvrard *et al.*, 2003; Mittal & Colegio, 2017). The majority of cancers arise from precancerous lesions including actinic keratosis, Bowen's disease, and Queyrat erythroplasia. Patients who develop their first

focus SCC have an over 60% risk of developing more SCC in the next 5 years. According to Lindelöf *et al.*, 25% of patients with a first SCC will have a second lesion within 13 months, and 50% will have a second lesion within 3.5 years (Lindelöf *et al.*, 2000). SCC develops in younger patients and has a rapid growth rate. In 50% of cases it develops multifocally, more often presents deep tissue invasion and metastasizes (8–12%) (Liddington *et al.*, 1989; Berg *et al.*, 2002). As in the GP, recipients with a fair skin phototype and high cumulative dose of UV radiation are associated with a higher risk of SCC. The main location of the SCC is the face, backs of the hands, forearms and mucous membranes, mainly the lower lip. Tumours appearing on the skin usually are asymptomatic, but 1/3 of patients experience tenderness, pain or itching. These symptoms constitute an unfavourable prognostic factor that may indicate a perineural invasion. The risk of metastases in the course of SCC in GP is 3.6% within 3 years, whereas for immunocompromised such as SOTRs the risk reaches 7%–12%. In SOTRs SCC may cause distant metastases. Patients who suffer from metastatic SCC have a bad prognosis (3-year survival is 56%, and 5-year survival is 34%) (Haug *et al.*, 2020; Imko-Walczuk *et al.*, 2015). SOTRs have a 2 to 8-fold increased risk of developing MM in the posttransplant period (Mittal & Colegio, 2017). Melanoma in SOTRs can arise in three principal scenarios; an existing MM prior to transplantation, an MM arising *de novo* after transplantation and MM derived from an organ donor (Imko-Walczuk *et al.*, 2009; Matin *et al.*, 2008). Melanoma results from the malignant transformation of melanocytes, representing the skin tumour with the highest mortality rate. This tumour has high immunogenicity and changes its behaviour in the field of immunosuppression. The incidence of MM in SOTRs is increased to a smaller degree as compared to SCC and BCC, although its potential morbidity and mortality have to be considered in post-transplant care. In candidates for SOT with MM in medical history, such factors as: tumour stage, disease control, and the period from diagnosis to transplantation are the most relevant factors to consider. In a study conducted by Penn and others the risk of MM recurrence in SOTRs was 19% which was similar to the GP subjects, whereas mortality was 30% (50% higher than in the GP) (Penn, 1996). Waiting time for transplantation depends on the MM stage and is as follows: MM in situ has 100% survival therefore no waiting time is required (Imko-Walczuk *et al.*, 2015); MM of <1 mm depth and without surface ulceration (stage I) have a good prognosis (85% 5-year survival), however, due to a risk of metastasis, the waiting time should be two years; MM with a 4-mm-depth, has a high potential of metastasis, and bad prognosis (5-year survival is 45–67%), it is, therefore, necessary to postpone SOT for 5 to 10 years (Penn, 1996; Imko-Walczuk *et al.*, 2015).

The risk of MM transmission from the donor through circulating cells localized in the graft is very high. To prevent this transmission, the donor's medical history and physical examination are essential, and the history of MM in a donor candidate is an absolute exclusion criterion for donating organs (Penn, 1996). Initial treatment of melanoma appearing in the posttransplant period does not differ from the standard approach in the GP. In addition to that, reduction or change of immunosuppression is suggested to be a reasonable and effective adjuvant strategy. A balance must be struck between a strength of immunosuppression that does not favour tumour spread and that, at the same time, avoids rejection of the transplanted organ. Therapeutic management is particularly challenging in advanced MM stages as the use of immune checkpoint inhibitors confers a high risk of organ rejection.

Merkel cell carcinoma (MCC) is a rare neuroendocrine neoplasm that typically appears in the elderly in sun-exposed areas. SOTRs have a 24-fold higher risk of MCC. This tumour presents at a younger age than in immunocompetent individuals (the mean age at diagnosis is 50 years) (Goedert, 2009). Most cases result from malignant transformation secondary to the Merkel cell polyomavirus infection, which may be relevant in SOTRs. It was confirmed that immunosuppression is an established risk factor for MCC (Hernandez *et al.*, 2022; Penn & First, 1999). Just as with other skin cancer, the highest incidence of MCC was observed in patients receiving a combined regimen of azathioprine and cyclosporine (Hernandez *et al.*, 2022). The key role of immunosuppressants on MCC development is also confirmed by the fact of temporary regression of the tumour upon reduction or withdrawal of the immunosuppressive treatment. MCC typically presents as a painless, rapidly expanding cutaneous nodule or plaque. Lesions are often erythematous or violaceous with a smooth and shiny appearance and generally arise on sun-exposed areas, notably the head and neck, and limbs (Euvrard *et al.*, 2003; Kanitakis Jean, 2009). SOTRs with MCC should be treated with similar modalities as patients without immunosuppression i.e. wide local excision, radical node dissection, radiation therapy, and chemotherapy. The prognosis is serious because 31% of patients develop tumour recurrence with a mean interval of 58 months after excision of the primary foci. Two-thirds of SOTRs MCC develop rapid lymphatic metastases to the regional lymph nodes and systemic metastases to the liver, bones, and lung with a high 1-, 3-, and 5-year mortality rate (20%, 51%, and 54%, respectively) (Greenberg & Zwald, 2011; Goedert, 2009; Lewis *et al.*, 2020).

In summary, it should be underlined that the risk of all skin cancers in SOTRs is much higher than in the GP. They appear at a younger age, the clinical course is much more serious, and they are more likely to relapse, metastasize and appear de novo in another location. Survival of patients is worse than in the GP.

Urinary tract cancers

The second most common cancers in SOTRs particularly in kidney transplant recipients are urinary tract cancers (Bellini *et al.*, 2022). They are common, and as these neoplasms occur more often in older age, their detection is growing with time, with the number of recipients followed-up (Karami *et al.*, 2016).

Renal cell carcinoma

The most frequent urological neoplasm encountered after kidney transplantation is renal cell carcinoma (RCC). It may appear in the native kidneys or the transplanted ones. It may arise de novo or be transmitted with the kidney graft and also recur after treatment of the recipient in the past (Porta *et al.*, 2020; Serkies *et al.*, 2022). The literature shows that the risk of RCC in the native kidneys of dialyzed patients due to end-stage kidney disease (ESKD) is increased by 10–15 times. The incidence grows with the dialysis time along with the development of acquired cystic kidney disease (ACKD). Some authors claim that transplantation, by improving kidney function may reduce ACKD and its oncological potential, but this effect is probably decreased by immunosuppression (Yanik *et al.*, 2016). Interestingly, the

longer the dialysis lasts the percentage of a less aggressive papillary RCC in relation to clear cell RCC grows. Nowadays, diseased kidneys are most often left in place after their failure, so the risk of RCC in them has to be addressed and they should be observed by at least an annual ultrasound (Dahle *et al.*, 2022). Nevertheless, the risk of cancer and mortality rate in patients with functioning kidneys or already on dialysis are similar. They are also better compared to the general population as RCC in ESKD tends to present lower malignant potential. It has been generally accepted that in the case of RCC in the native diseased kidneys total nephrectomy is the most appropriate strategy (Yanik *et al.*, 2016).

Noteworthy, nowadays according to Kidney Disease Improving Global Outcomes (KDIGO) in 2020, after radical removal of small <3 cm low-grade T1NOMO RCC the patient can be qualified for the KTx with no waiting period (Karami *et al.*, 2016).

Another issue is de novo cancers in the transplanted kidney. Overall, the risk of it stays within 0.2–0.7% with the observation of 5 years (Hevia *et al.*, 2019). It may be caused by a tumour transmission with unintentional kidney transplantation with an undetected small or even microscopic RCC or by the origination of the tumour in the kidney afterwards (Boissier *et al.*, 2018). It is difficult to distinguish these two scenarios with the time between KTx and diagnosis being the most logical parameter. Its incidence is lower with living donors, who are generally healthy, their kidneys are better examined, and the history of the donor and his family may be well-known, especially as we now are aware of a possible inherited RCC in 5–8%. The transmission may be higher if the donors are older than 50, which is currently accepted more freely because the RCC develop more frequently in older age (Boissier *et al.*, 2018). As far as the treatment of RCC in the graft is concerned, the European Urological Association recommends its surgical removal with the increasing role of the nephron-sparing approach as an alternative to graftectomy, which was the gold standard in the past. Tumours are usually discovered in the early stage without symptoms. The disease staging may be tricky due to the changed tissue layers after implantation (Rodríguez Faba *et al.*, 2018; Tillou *et al.*, 2012).

Nowadays, data shows that total nephrectomy should be restricted to high-grade, high-stage tumours or tumours in the irreversible dysfunctional kidney. It is also known that these high-risk RCCs have a poor prognosis, so many authors recommend biopsy before treatment method selection. Nephron-sparing procedures should be preferred if possible because they give a chance of up to 95% of 5 years survival time in $T_1N_0M_0$. On the other hand, graftectomy with a return to dialysis results in only 34% of 5-year survival, although the patient groups studied usually are different (Boissier *et al.*, 2018).

The nephron-sparing surgery which is limited to the tumour less than 4 cm may be challenging with more complications in about 20% of cases. The open approach is usually used, but recently robot-assisted laparoscopy has also been reported. In some series, a minimally invasive approach using Radio Frequency Ablation or Cryoablation is also described as promising in very small exophytic tumors (Dhakal *et al.*, 2017). The surgery should be used together with a modification of the immunosuppression regimen. In this case, the use of mammalian target of rapamycin (mTOR) inhibitors seems to be the most interesting drug, because of their anti- neoplastic properties(Boissier *et al.*, 2018).

There are interesting considerations about the origin of cancer occurring in the allograft kidney. We used to assume that it arises from the donor cell. Still, some reports suggest that a significant percentage (up to 40 %) may be of recipient origin proved by DNA analysis, with some having mixed DNA being a form of chimerism. Whether it has any clinical importance for example on the choice of immunosuppression, is not known yet (Dhakal *et al.*, 2017).

Having in mind that there is a global lack of kidney donors, there has appeared to be a little controversial concept of using kidneys removed for small, low-risk RCC as a possible so-called "restored" donor of kidneys. The tumour is biopsied and removed outside the body, then prepared and implanted. The published result shows more than 90% of 5-years graft survival and a low cancer recurrence rate of about 2% (Xiao *et al.*, 2013)

Prostate cancer

Generally, the significance of prostate cancer (PC) has been growing as the population of kidney recipients gets more extensive and older. The data about the increased incidence of PC after KTx are unclear, though recent studies suggest that it is higher. However, one has also to remember that any data about this group of patients must consider the estimated life expectancy independent of malignant disease before making any therapeutic decision (Sherer *et al.*, 2017).

Especially interesting is an issue of low-risk PC, which occurs very often and often is managed by active surveillance meaning repeated exams (DRE, PSA, MRI) and biopsies and postponing of the intervention until the proven progression. In the GP it leads to sparing of the treatment in a significant part of patients. Recent studies have shown that active surveillance can be possible also in KTx candidates, where we must assume that undetected small focuses of PC already exist. The same strategy is acceptable in patients on dialysis. The survival in both groups should not differ from the GP (Stöckle *et al.*, 2018).

The situation changes if a medium-risk or a high-risk PC is diagnosed. Then active treatment ought to be implemented with radical prostatectomy being the most popular solution, as it leads to the elimination of the cancer cells, with PSA becoming a perfect cancer marker to follow-up. In KTx candidates, the 2-year waiting time after renal surgery is recommended (Bratt *et al.*, 2020a; Bratt *et al.*, 2020b).

A urologist must regard anatomical relations between the graft and the prostate when the clinically significant PC is discovered after KT. The diagnosis usually is early because the patients are closely controlled. The staging is similar to that of the GP. Surgery can be challenging and this side's lymphadenectomy has very often been skipped. Nonetheless, the results are promising with a 14-years survival time reaching 65% (Carvalho *et al.*, 2017). Modern series recommend using the robot-assisted technique for this situation with a result similar to GP.

Radiation therapy is also a feasible option with some limitations in planning to avoid ureteral stricture or post-radiation nephritis. However, there are a few papers recommending brachytherapy as the better solution (Bratt *et al.*, 2020a).

Bladder cancer

The incidence of bladder cancer (BC) in KTx is reported to be 2–4 times higher than in the GP with the age of presentation being lower and the malignant po-

tential much higher. The non-urothelial histology is also found more often. The upper urinary tract of native kidneys is also involved more frequently. Some authors suggest the BK or HPV viral infection is responsible (Leon *et al.*, 2020). The diagnosis is usually made after hematuria. The medium time after KT is 4 to 5 years. The more aggressive course of the disease caused the waiting time for kidney candidates to be usually preserved with the only exception of very low-risk superficial tumours (Chadban *et al.*, 2020). The staging is based on imaging and transurethral resection with microscopic invasion analysis. The role of surgery is crucial. Superficial tumours in the bladder should be endoscopically resected with adjuvant intravesical chemotherapy. The BCG installation is viewed to be possible, but some authors underline a risk that immunosuppression can provoke Mycobacterium sepsis. In the case of upper tract involvement radical nephroureterectomy is recommended. When there is a high-risk bladder tumour most authors favour early cystectomy with some form of urinary diversion. It can be bowel neobladder of uretero-ileo-cutaneostomy according to Bricker. During surgery, the lymphadenectomy can be difficult as well as anastomosing of the short transplanted ureter to the bowel without kinking. The same problem exists when a kidney is transplanted into the patient with urinary diversion due to a previous cystectomy due to bladder cancer. Then, it can be solved by implanting the kidney upside down. The treatment results of superficial bladder tumours are similar between kidney recipients and the GP with more local recurrences in the former group.

Urothelial cancer in the native kidney upper tract has a worse prognosis than matched ESKD patients, underlining the role of immunosuppression (Chadban *et al.*, 2020). Data about the results of invasive bladder cancer treatment after KTx are limited, but generally high-risk urothelial cancers have a poor prognosis even with an aggressive protocol including early cystectomy and chemotherapy.

Penile Cancer and Testicular Neoplasm

These urological malignancies are so rare that there is no robust data about their association with KTx. Penile cancer occurs in 10 per 1 million a year and testicular neoplasms in 50 per 1mln per year. Both treatments after KTx should not differ from the GP, with the need to modify immunosuppression in more advanced cases. In both, chemotherapy plays an essential role, so the renal function is important. Results of both depend strongly also on lymphadenectomy so it is vital that surgically there may be some difficulties when dealing with the patient after KTx (Besarani & Cranston, 2007).

KIDNEY IN BONE MARROW TRANSPLANTATION

Bone marrow transplantation is a common name for hematopoietic cell transplantation (HCT) in which the most important for hematopoietic system recovery are stem cells present among the CD34+ cell population. The stem cell source might be autologous or allogeneic determining the type of HCT (autologous or allogeneic; auto-HCT, allo-HCT). These two types of transplantation have different spectra of complications. In fact, the synonym of auto-HCT is high-dose chemotherapy with the support of the hematopoietic cells; therefore, the complications including those related to kidneys are limited to high-dose chemo/radiotherapy administered as a conditioning regimen before cell infusion. In allo-

HCT, in addition to the conditioning regimen that might be myeloablative, reduced, or even non-myeloablative, two other important factors contribute to kidney injury: post-transplant immunosuppression and immune-related complications such as graft versus host disease (GvHD) or transplant-associated thrombotic microangiopathy (TA-TMA). Hence, the greatest risk of acute kidney injury (AKI) carries myeloablative allo-HCT (21–73%), followed by nonmyeloablative allo-HCT (29–56%), and then autologous HCT (10.4–19%) (Miyata *et al.*, 2022).

Chronic kidney disease is a risk factor for transplant-related complications. In the HCT-specific comorbidity index (HCT-CI) the presence either of serum creatinine concentration above 2 mg/dL (177 umol/L), being on dialysis or prior renal transplant increases 1-year non-relapse mortality (NRM) to 21% in allo-HCT and 3% in auto-HCT recipients, respectively. Chronic kidney disease present after HCT also indicates poor survival both after auto-HCT and allo-HCT. A recently published study on a large cohort of allo-HCT recipients showed the impact of different degrees of renal dysfunction on HCT outcomes using growing grades of renal dysfunction based on estimated glomerular filtration rate (eGFR) (<45; 45-59; 60–90; and >90 mL/min); Increased risk for NRM and the requirement for dialysis post-HCT were associated with an eGFR <60 mL/min (Gutiérrez-García *et al.*, 2020; Farhadfar *et al.*, 2021).

Kidney injury related to high-dose chemotherapy

Kidney injury after high-dose chemotherapy might be due to the direct effect of cytotoxic agents or indirect complications caused by cytotoxic agents such as mucositis and diarrhoea, infections or veno-occlusive disease. The most common cytotoxic agents used as a part of the conditioning regimen before auto- and allo-HCT are alkylating agents such as melphalan, cyclophosphamide, busulfan, carmustine, bendamustine; antimetabolites: fludarabine, and much less common cladribine and clofarabine and most recently bcl-2 inhibitors such as venetoclax. Most of the aforementioned agents do not induce nephrotoxicity directly despite some of them (e.g. busulfan, cyclophosphamide) being used in much higher doses compared to standard chemotherapy regimens. A few exceptions include bendamustine (used in the BeEAM protocol: bendamustine, etoposide, cytarabine, melphalan) that have been reported in three cases to induce nephrogenic diabetes insipidus (Desjardins *et al.*, 2022).

High-dose chemotherapy adjustment in patients with chronic kidney disease

HCT recipients suffering from CKD have a substantial risk of unintended overdosing or underdosing due to variable pharmacokinetics in this patient population. Overdosing may lead to multiorgan toxicity and/or graft failure whereas underdosing may result in graft rejection or inadequate disease control (Bodge *et al.*, 2014). Therefore, the dose adjustment of some agents used in the conditioning regimens in patients with CKD is recommended to avoid excessive toxicity, particularly to hematopoietic cells usually infused 24 hours after the end of the conditioning regimen.

The best example is melphalan commonly used as a single agent dosed on body surface area (BSA) at day-1 (200 mg/m^2) of the conditioning regimen before auto-HCT for patients with multiple myeloma (MM). Patients with CKD and eGFR <50 ml/min/1.73 m^2 or older than 70 years with additional co-morbidities or frailty

Table 2. The different auto-HCT protocols applied in patients with: a) normal renal function, b) impaired renal function and c) patients on haemodialysis.

Day	Autologous High-Dose Melphalan (HDM) transplant protocol		
	Normal Renal Function	Impaired Renal Function	Haemodialysis
-5			Admission
-4			Dialysis
-3		Admission	Melphalan 140 or 100 mg/m² a
-2	Admission	*Melphalan 140 or 100 mg/m²	Rest day: dialysis
-1	Melphalan 200 mg/m²	Rest day	Rest day
0 b	Cell return 24 hrs after Melphalan infusion	Cell return 48 hrs after Melphalan infusion	Cell return 72 hrs after Melphalan infusion
			Return units and dialysis Ensure 2 hrs gap if dialysis post-re-infusion c
+5	GCSF	GCSF	GCSF

Abbreviations: GCSF granulocyte colony-stimulating factor. [a]Patients on dialysis require a 72-hour (hr) gap after the Melphalan infusion and prior to stem cell infusion, whereas patients with renal impairment require a 48 hr gap. [b]The Melphalan dose can be further reduced to 100 mg/m², depending on the presence of co-existent comorbidities. [c] For patients on hemodialysis, a repeat dialysis session is scheduled after the return of the fourth stem cell unit, with a 2hr gap between the stem cell infusion and the dialysis.

usually receive a lower dose of melphalan of 100 or 140 mg/m². Recently, CKD was reported as an independent risk factor for AKI after HCT for MM, with a significantly higher mortality rate in this subgroup of patients (Andronesi *et al.*, 2019). Surprisingly some centers do not reduce melphalan dose in patients with moderate CKD since despite higher toxicity improved outcomes were reported in patients with moderate CKD receiving melphalan at a high dose of 200 mg/m² (Sweiss *et al.*, 2016). Of note, melphalan is not removed by dialysis (Bodge *et al.*, 2014).

However, recently published data on 370 MM patients who underwent the first auto-HCT without CKD or with mild, moderate, and severe CKD showed no significant difference in NRM, progression-free (PFS), or overall survival (OS) regardless of renal function. The results of this study indicate that auto-HCT is an effective and rather safe option for MM patients with CKD, including those on dialysis, allowing some of them to permanently discontinue dialysis. Specific protocols applied in this population are presented in Table 2.

The second most common agent used agent for HCT and the most common for allo-HCT is fludarabine (Flu). The dose of Flu is calculated using BSA. The drug is administered IV as a monophosphate prodrug (F-ara-AMP) that is converted to the circulating metabolite F-ara-A, which is mainly excreted by the kidney. Recently published data indicated a substantial variability (more than sixfold) in F-ara-A plasma exposure using standard BSA-based dosing. Extended but still retrospective analysis in 192 allo-HCT recipients showed that Flu exposure is a strong predictor of event-free survival (EFS) (events: relapse, NRM, and graft failure) with two-fold higher HR for EFS in overexposed patients. This translates to the lowest overall mortality in the optimally exposed group (31%), compared to the under- (43%) and over-exposed groups (64%). This increase in overall mortality was mainly caused by infections (over- and underexposure), multiorgan failure (overexposure), and GVHD (overexposure). Of note, overall GVHD (grade 2–4 or 3–4) incidence was similar among groups with different exposures (Langenhorst *et al.*, 2019). The data presented above suggest that the current dosing method based on BSA is not optimal and should include not only weight but also kidney function based on eGFR using the Cockcroft–Gault equation. Flu is adequately removed during dialysis, therefore, the dose should be adjusted after dialysis (van Besien *et al.*, 2012; Shadman *et al.*, 2017). Cyclophosphamide may increase myocardial toxicity in CKD patients. Pharmacokinetic studies have demonstrated decreased clearance with renal insufficiency, therefore dosage reduction in the setting of moderate to severe renal impairment should be considered. Cyclophosphamide is moderately dialyzable (20–50%); for dialysis-dependent patients, cyclophosphamide should be administered after hemodialysis (Bodge *et al.*, 2014). The cyclophosphamide doses should be reduced by 25–50% in patients with severe renal impairment (GFR <10 mL/min) and a supplemental dose after dialysis should be considered (Shadman *et al.*, 2017). Clofarabine should be avoided in adults >60 years with creatinine clearance <60 mL/min (NCCN AML guidelines), and a 50% dosage adjustment should be made for patients with eGFR 30 to 60 mL/min. Busulfan and thiotepa dosing does not require modification in patients with CKD (Bodge *et al.*, 2014).

Kidney injury in recipients of allogeneic HCT

Acute kidney injury is a common and important complication after allo-HCT since it increases the risk of both early and late NRM (Małyszko *et al.*, 2020a). The recently published meta-analysis based on reports from 1995–2019 indicates AKI occurrence in about half (55.1%) of allo-HCT recipients, with the most severe form (stage 3) in 8.3% of patients (Kanduri *et al.*, 2020). AKI leading to CKD increases mortality about three times at 1-year post-allo-HCT (HR: 3.54; *p*<0.001). In most allo-HCT recipients the development of AKI is multifactorial. Conditioning with total body irradiation (TBI) and using calcineurin inhibitors for GVHD prevention contribute to the risk of AKI development with a little lower likelihood of AKI induced by tacrolimus relative to cyclosporine (Malyszko *et al.*, 2020b). Other patient-related factors contributing to the risk of AKI after HCT include female sex, older age (>55 years), and comorbidities such as diabetes, hypertension, and pre-transplant CKD that are also associated with early mortality (Miyata *et al.*, 2022; Gutiérrez-García *et al.*, 2020). Additionally, other transplant-related complications such as veno-occlusive disease, also known as sinusoidal ob-

struction syndrome, cytomegalovirus reactivation, and bacterial infections (sepsis) increase the risk of AKI (Gutiérrez-García *et al.*, 2020). Finally, in allo-HCT recipients, acute GvHD and TA-TMA often induced by calcineurin inhibitors, especially tacrolimus, make the aetiology of AKI multifactorial and sometimes difficult to determine the leading cause. All attempts should be therefore made to decrease the risk of AKI development including a proper choice of conditioning regimen (myeloablative *versus* reduced intensity or non-myeloablative) regular blood levels measurement of calcineurin inhibitors and other nephrotoxic agents (such as vancomycin, and amikacin), proper hydration, careful dose adjustment for drug interactions – for example, reduction of 90% dose of calcineurin inhibitors in the case of concomitant anti-fungal treatment with voriconazole. Cases with hypertension, refractoriness to platelet transfusions, and increased lactate dehydrogenase activity should prompt suspicion of TA-TMA and a fast decision regarding the continuation of calcineurin inhibitors.

Hemodialyzed patient as a bone marrow transplant recipient

Almost all patients on dialysis are referred for HCT because of MM. Indeed, dialysis-dependent patients with MM should not be excluded from high-dose melphalan and auto-HCT since some of them may even recover renal function on top of other benefits related to auto-HCT. The shorter the hemodialysis period prior to transplantation, the higher the probability of renal function recovery in patients with MM. Improvement of kidney function following auto-HCT can also be observed later after transplants in patients with severe kidney failure. However, only a few cases have been reported so far who became dialysis-independent after a high-dose melphalan autograft (Waszczuk-Gajda *et al.*, 2018). Recent data suggest that auto-HCT can be performed safely in MM patients on dialysis using a specific adjustment to the routine protocol (Table 2). Prior experience including the experience of the Polish centers (24 cases) indicates higher toxicity in hemodialyzed patients compared to non-dialysis matched cases in the following endpoints: mucositis (88% *vs* 55%), infection (79% *vs* 51%), parenteral nutrition (50% *vs* 24%), diarrhea (71% *vs* 38%), prolonged duration of hospitalization (medians: 30 *vs* 21 days), the requirement for red blood cell transfusion (83% *vs* 36%) while no significant differences were found in post-transplant response (ORR; 75% *vs* 87%), 5-year PFS (36% *vs* 20%) and OS (39% *vs* 50%) (Waszczuk-Gajda *et al.*, 2018).

Research conducted by Chapchap and others indicates that HD was associated with decreased survival in allo-HSCT (Chapchap *et al.*, 2022) The HD group (34 HD cases versus 151 controls) had a higher mortality rate (HR:6.68; 95% CI: 4.1–10.9; $p<0.001$). At the Fred Hutchinson Cancer Research Center between 1997 and 2014, only six patients on hemodialysis received allo-HCT. Recently reported the largest group of patients on dialysis at the time of alloHCT (46 patients) had a 1-year probability of OS of 20%, and NRM of 67% (Farhadfar *et al.*, 2021).

The data on patients after kidney transplantation is very limited, and in most institutions, these patients are not referred for allogeneic HCT. Even in very big transplant centres, these patients are exceptional.

CKD in patients after HCT

In most auto-HCT recipients CKD after HCT results from precedent CKD before transplant. A minor-ity experience *de novo* CKD related to sepsis or drug toxicity. The need for hemodialysis after HCT increases late NRM. In allo-HCT recipients, renal dysfunction is a common complication. The cumulative incidence of CKD after allo-HCT varies from 13~60% in adult studies to as high as 62% in children (Chen *et al.*). Causes of CKD are multifactorial and usually overlapping. The result of an interesting paper in which 24 allo-HCT recipients underwent kidney biopsy for either proteinuria or deterioration of kidney function confirms the great diversity of putative causes of kidney damage. The most common pathological findings were GVHD (n=8), membranous nephropathy (MN, n=5), TA-TMA, (n=4), BK virus nephropathy (n=2), and single cases with ischemic nephropathy, chronic interstitial nephritis, minimal change disease (MCD), GVHD with TMA, MN with focal segmental glomerular sclerosis (FSGS), MCD with acute tubular injury, BK virus nephropathy combined with calcineurin inhibitor nephrotoxicity (Chen *et al.*, 2019). Clearly, a kidney biopsy with an expert histopathology examination might be necessary to establish the proper cause of kidney injury after all-HCT.

NOVEL CANCER THERAPY

The use of cancer immunotherapy and proton therapy in transplant recipients (IK)

The standard of care in different cancers includes surgery, chemo- and radiotherapy. In recent years, novel therapy, including immunotherapy with immune checkpoint inhibitors (ICIs) and proton therapy, has revolutionized cancer treatment and is becoming a new standard of care for many tumour types.

ICIs in transplant patients

Mechanism of ICIs action

Cancers can weaken the immune system, and the host's immune system does not destroy cancer cells. The so-called negative regulatory components participate in this phenomenon (Szychowska, 2021). ICIs are monoclonal antibodies capable of blocking negative signals for T-cell activation or T-cell effector activity and represent an essential therapeutic option in the case of many tumours, including melanoma, non-small cell lung cancer, kidney cancer, urothelial cells cancer, Hodgkin's lymphoma, oral, throat or larynx squamous cell carcinoma etc. It seems that about 44% of newly diagnosed cancer can be qualified for ICIs (Haslam & Prasad, 2019).

The anti-CTLA4 (cytotoxic T-lymphocyte-associated protein 4) monoclonal antibody (e.g., ipilimumab or tremelimumab) binds to the CTLA4 receptor and activates a T cell (Perazella & Shirali, 2020). AntiPD-1 (nivolumab, pembrolizumab, cemiplimab) and antiPD-L1 (atezolizumab, avelumab, durvalumab) antibodies act through the activation of programmed cell death-1 (PD-1) receptors on the T cell with its ligand PD-L1 or PD-L2 (Perazella & Shirali, 2018; Perazella & Shirali, 2020).

Considering the mechanism of action of ICIs which is based on the stimulation of the immune system, their use in transplant patients may raise doubts. These drugs have the effect opposite to what is anticipated in the organs of recipients as they stimulate the immune system and, therefore, may facilitate the occurrence of acute or chronic rejection. In the group of 119 KTx recipients to whom ICIs were administered due to other tu-

mours: cutaneous melanoma, hepatocellular carcinoma and cutaneous squamous cell carcinoma, 41.2% patients experienced acute rejection, 23.5% graft failure and immune-related adverse events (irAEs) developed in 18.5%. The overall objective response rate was 34.5%, with a median duration of response of 8.0 months (Portuguese *et al.*, 2022). The symptoms of acute rejection, which is the most frequent cellular rejection, were observed on average around three weeks after ICIs administration (Portuguese *et al.*, 2022; Manohar *et al.*, 2020). Moreover, the activation of T-lymphocytes may cause adverse effects resulting from excessive immune system stimulation (immune-related adverse events, irAEs). They may affect different organs and tissues: skin, lungs, heart, digestive system, liver, endocrine glands, central and peripheral nervous system and also the kidney (Perazella & Shirali, 2020). The kidney-related adverse effect that occurs most often, is deterioration of kidney function, and another one is proteinuria, usually non-nephrotic. Pyuria and haematuria are also quite frequent (Szychowska, 2021). The distinction between irAEs and rejection may be difficult in kidney recipients due to the fact that the symptoms may be similar. The treatment of irAEs depends on symptom severity and includes drug discontinuation and steroid administration (Sise *et al.*, 2019; Brahmer *et al.*, 2018).

One problem is the implementation of treatment with ICIs to the SOTRs with tumours, but another is the lack of recommendations for immunosuppression management. There are challenges concerning the continuation of immunosuppressive treatment or its minimization. The most frequently described alteration to the immunosuppression plan is the discontinuation of calcineurin inhibitors (CNI) or conversion to mTOR inhibitors (everolimus, sirolimus), the suspension of mycophenolate mofetil/sodium as well as the use of steroids in monotherapy. The minimization of immunosuppression which is frequently recommended in SOTRs with a cancer diagnosis may be one of the causes of such a frequent rejection noted in patients treated with ICIs. As the recent analysis showed, the maintenance of treatment with tacrolimus was associated with a reduction in post-ICI rejection without compromising the effectiveness of cancer response (Portuguese *et al.*, 2022). In another study, in the group of patients who were treated with the continuous dose of <10 mg/d of prednisone, there was a higher percentage of acute rejection of the kidney graft, but anticancer effectiveness was better: in 63% of patients' disease remission or stabilization were observed. In patients who continued CNI, acute graft rejection occurred less often, but the anti-cancer therapy was also less effective (Manohar *et al.*, 2020). In the Australian, phase 1 study, 17 kidney transplant recipients with low or intermediate immunological risk with various solid tumours were treated with nivolumab and baseline immunosuppression was left unchanged. Complete responses were observed in four of 17 patients, including one patient with microsatellite instability-high colorectal cancer, and three with squamous cell carcinoma of the head and neck. Partial responses were observed in five patients (with squamous cell carcinoma of the head and neck), one with bladder cancer, and one with hepatocellular carcinoma. Only two patients developed acute rejection (T-cell mediated) with a good response to antithymocyte globulin and plasmapheresis in one case, the other patient commenced hemodialysis. There were no treatment-related deaths or treatment-related serious adverse events. The most common adverse events were decreased lymphocyte count, fever or infection, decreased haemoglobin, and increased creatinine in three patients. Based on their observations, the authors concluded that maintaining baseline immunosuppression before treatment with ICIs in kidney transplant recipients might not affect expected efficacy and might reduce the risk of allograft rejection mediated by immune checkpoint inhibitors (Carroll *et al.*, 2022). In the management of acute graft rejection during oncologic ICIs therapy, it is considered reasonable to discontinue ICIs and use steroid pulse therapy (Venkatachalam *et al.*, 2020; Perazella & Shirali, 2020). As shown in Carroll RP *et al* study the antithymocyte globulin and plasmapheresis may also be a treatment option (Carroll *et al.*, 2022).

Some observations indicated that complications occur more often in patients treated with the anti-PD-1 group. The PD-1/PD-L1 pathway plays a significant role in the preservation of immunotolerance. PD-L1 present in the epithelium of renal tubules represses cytokines' production by T-lymphocytes, regulating T-lymphocytes' activation and anergy, and providing the immune balance. In view of the foregoing, blocking the PD-1: PD-L1 pathway may increase the risk of transplant rejection (Perazella & Shirali, 2020; Perazella & Shirali, 2018; Kumar *et al.*, 2020).

In conclusion, ICIs are a feasible option for transplant recipients with advanced malignancies but doctors and patients should be aware of the increased risk of acute rejection. Close monitoring and tailoring of immunosuppression are critical. Maintaining an appropriate balance between immunosuppressive treatment, the preservation of the graft function and anti-cancer management requires collaboration between oncologists and transplant physicians as well as the patients and their families.

Radiotherapy and proton therapy in transplant recipients

The kidneys are the dose-limiting organs for radiotherapy (RT) in case of gastrointestinal and gynecologic cancers, lymphomas and sarcomas of the upper abdomen as well as during total body irradiation (TBI). The cause of RT-induced kidney injury is poorly understood but the incidence of this complication largely depends on the use of whole-volume or partial-volume RT to one or both kidneys (Dawson *et al.*, 2010).

Even if short-term kidney function is preserved, radiation-induced kidney injury is subclinical and frequently presents during the subacute (3–18 months) and chronic (>18 months) periods and may have a negative consequence on patients' health in the future (Dawson *et al.*, 2010).

The KTx patients requiring RT treatment find themselves in a special situation: they have one kidney often with initial kidney impairment; moreover, the presence of a transplanted kidney in the pelvis can be a therapeutic challenge in patients who require pelvis radiation as management. The inferior border of KTx located at the iliac fossa usually lies at the bottom of S2 or S3. Therefore, radiotherapy that includes pelvic lymph nodes will need further evaluation to determine the benefits and the risks. Treatment of pelvic tumours with definitive or neoadjuvant radiotherapy usually includes iliac lymph nodes in the nodal target volume. This nodal target is also included in some cases of adjuvant radiotherapy. The location of the graft in relation to radiation therapy fields increases the risk of damage to the transplanted organ. In the presence of a transplanted kidney, the dose required for the region at risk must be balanced against the potential risk of graft injury (Detti *et al.*, 2011). Furthermore, during RT, the increased risk of urethral/ureteral stricture KTx dysfunction should be taken into consideration.

In proton therapy (PT) due to a phenomenon known as the Bragg peak, protons deposit their maximum energy at a specific depth with no exit. This allows for the delivery of a high therapeutic dose of radiation to tumours in challenging anatomic locations, close to critical organs and within damaged organs with a reduced risk of late toxicities in the surrounding tissues and a lower incidence of secondary malignancies (LaRiviere *et al.*, 2019). PT is being investigated as an alternative to intensity-modulated radiation therapy because of its potential to minimize radiation exposure to the transplanted kidney and other organs at risk. Dosimetric studies have demonstrated that PT improves organ-at-risk sparing compared with intensity-modulated radiation therapy, and it does not sacrifice the coverage of the target. There are only some papers based on clinical cases describing the utility of PT in KTx recipients, mainly as a treatment in the case of pelvic tumours (Buchberger *et al.*, 2019; Ileana *et al.*, 2020). Given the relative radiosensitivity of native kidneys, the tissue-sparing effects of proton therapy are of utmost importance in the treatment of patients with pelvic kidneys and pelvic malignancies.

SUMMARY

To identify key management issues in nephrology relevant to patients with malignancy, the panel of multidisciplinary specialists organized the conference on Nephro-oncology in Gdańsk (October 2020). The conference participants emphasized the importance of collaboration among nephrology, haematology/oncology, dermatology, urology and transplant specialists to improve medical care for cancer and kidney disease patients. The four main parts of the paper present the most current diagnostic and therapeutic approaches to cancer and kidney disease patients. This study is based on the authors' expertise and the most recently published relevant literature with their participation.

Knockdown of CD44 inhibits proliferation, migration, and invasiveness in hepatocellular carcinoma cells by modulating CXCR4/Wnt/β-Catenin Axis

Xiaojing Song[1]✉, Fanghui Ding[1], Wei Luo[1], Juan Tao[2], Kaili Yang[2], Qiaoping Li[2] and Zhitao Zhang[2]

[1]Department of General Surgery, The First Hospital of Lanzhou University, Lanzhou, Gansu, 730000, China; [2]The First School of Clinical Medicine, Lanzhou University, Lanzhou, Gansu, 730000, China

Hepatocellular carcinoma (HCC) has high mortality and incidence worldwide. The molecular mechanism associated with HCC is largely unexplored. Objective: To investigate the impact of CD44 knock-down on the proliferation, migration, and invasiveness in HCC cells. Methods: Colony formation and MTT assay were used to observe cellular proliferation and viability. In addition, cellular invasion and migration were studied by Transwell and wound healing assays respectively. Finally, western blotting was utilized to check the protein expression levels. Results: The cellular proliferation, invasion and metastasis in Huh7 cells were inhibited after the silencing of CD44. Furthermore, expression levels of MMP-2, MMP-9, CXCR4, GSK-3β and β-catenin was significantly decreased. However, opposite results were demonstrated when CD44 was overexpressed. Conclusions: Interference with the expression of CD44 significantly inhibits the invasion and metastasis in the HCC cell line, Huh7. Furthermore, CD44 was found to regulate the expression of MMP-2, MMP-9, CXCL12, CXCR4 and Wnt/β-catenin signal pathway.

INTRODUCTION

In the primary liver cancer class, HCC is the first one in frequency and accounts for 80–90% of all malignant tumors (Davis *et al.*, 2008; Ghouri *et al.*, 2017). Worldwide, HCC has emerged as a major health issue increasing continuously due to its association with viruses like hepatitis B and C (El-Serag, 2012). The world trends are unevenly distributed, finding the highest incidence in eastern Asia (McGlynn *et al.*, 2015). Incidence ratio of HCC varies among sex, and the reasons for such is still unknown (Wilson and Buetow, 2020). Concerning age distribution, it also varies depending on the geographic situation (Sung *et al.*, 2021). HCC is mostly found in the late stage when radiotherapy, chemotherapy and other treatments are ineffective. However, surgery in the early stage is currently the most effective treatment. Consequently, it has become one of the research focuses on exploring the detailed mechanism of metastasis and malignancy to explore novel treatment options for HCC.

The CD44 antigen, as an important epigenomic regulator, is involved in tumor development (Luo & Tan, 2016; Asai *et al.*, 2019). Numerous studies have confirmed that CD44 can be used as a molecular marker for different cancer (Malhotra *et al.*, 2010; Moldovan *et al.*, 2017). Zhang and colleagues demonstrated that CD44 could promote HCC progression by up-regulating YAP (Zhang *et al.*, 2021). Shah and colleagues found that interfering with CD44 could lead to the death of ovarian cancer cells (Shah *et al.*, 2013). It has been found that up-regulation of CD44 can promote metastasis and poor prognosis of Hepatocellular carcinoma, however, the mechanism by which CD44 regulates HCC is unclear (Asai *et al.*, 2019). Epithelial to mesenchymal transition (EMT) in cancer cells results in the acquisition of stem cell-like characteristics and increased CD44 expression (Mani *et al.*, 2008). Because of the clinicopathological effects that CD44 and its isoforms have on carcinogenesis, CD44 may one day serve as a molecular target for cancer treatment (Li *et al.*, 2014). Additionally, the demonstrated function of CD44 in preserving stemness and the ability of cancer stem cells to regenerate tumors after treatment raises the possibility that CD44 may play a significant prognostic marker. Clinical research on treatment plans that concentrate on CD44 or lessen CD44 expression is ongoing (Matzke-Ogi *et al.*, 2016; Todaro *et al.*, 2014). These methods include ectodomain mimics, aptamers, tumor-delivery shRNAs, and CD44 neutralizing antibodies (Orian-Rousseau and Ponta, 2015; Iida *et al.*, 2014). Consequently, it is crucial to further clarify the functional roles of CD44 as a focus of research.

Growing data indicates that cancer stem cells (CSCs) are responsible for the recurrence and metastasis of many malignancies (Vlashi *et al.*, 2011; Gao *et al.*, 2013). CSCs are essential for starting and maintaining tumour phenotypes because they can self-renewal and differentiation, which other cancer cells (non-CSCs) lack (Ayob & Ramasamy, 2018). The presence of CSCs in numerous malignancies, including those of the brain, breast, lung, colon, and liver, has been demonstrated utilizing particular CSC markers (Yang *et al.*, 2020). Epithelial adhesion molecule (EpCAM), CD13, CD44, and/or CD133 are among the markers that liver CSCs display and studies

have shown that the expression of these molecules on HCC cells is associated with a poor prognosis (Yamashita *et al.*, 2009; Zhu *et al.*, 2010). Although traditional therapies could eradicate non-CSCs, it is claimed that surviving CSCs eventually induce tumour recurrence and metastasis because they exhibit the characteristics of tumorigenicity and resistance to conventional chemotherapy and radiotherapy (Cross & Laidler, 1990; Gao *et al.*, 2013). Therefore, eliminating CSCs is crucial for fully curing cancer.

Tumor invasion and metastasis is a complex biological process (Nguyen *et al.*, 2009a). Gene regulation is crucial in different processes, like unlimited growth potential, epithelial-mesenchymal transition (EMT), and apoptosis avoidance (Perlikos *et al.*, 2013). Wnt signaling is an essential pathway affecting tumor cells' cellular migration and invasion ability. The Wnt/β-catenin signaling system is a conserved signalling axis involved various physiological processes, including tissue homeostasis, migration, invasion, differentiation, proliferation, and apoptosis (Salik *et al.*, 2020). There is mounting evidence that certain solid tumors and hematological malignancies were aided in their development and progression by deregulation of the Wnt/ß-catenin cascade (Gajos-Michniewicz & Czyz, 2020). Early events in carcinogenesis are brought on by aberrant regulation of the transcription factor ß-catenin, a crucial part of the Wnt signaling pathway, in the Wnt/ß-catenin pathway (Zhang *et al.*, 2020). GSK3ß and CK1a, two enzymes in the degradation complex, facilitate the phosphorylation of ß-catenin, boosting its ubiquitination and subsequent proteasomal destruction (Wiese *et al.*, 2018). When β-catenin is accumulated at a certain amount, it gets translocated to nucleus, and binds to the target transcription factor to form a transcriptional complex. This complex subsequently activates its downstream target genes matrix metalloproteinases (MMPs), p21, and C-myc (Wiese *et al.*, 2018; Tai *et al.*, 2015). MMPs are a group of proteolytic enzymes which are highly homologous and zinc-dependent. The extracellular matrix (ECM) holds cells together and is essential for cell survival, motility, differentiation, and proliferation. The ECM components that serve as the physical impediments to cell migration must be locally broken down for a tumour cell to spread from the main tumour to other organs. Matrix metalloproteinases (MMPs) are the primary enzymes responsible for the breakdown of the ECM (Conlon & Murray, 2019).

Chemokine (CXCL12) and its receptor (CXCR4) have emerged as key factors in the development of tumors and their metastasis. CXCL12 has been reported to induce signaling *via* AKT and ERK pathways and thereby induce cancerous growth (Scotton *et al.*, 2002). In breast cancer, CXCL12 expression has been linked with pathological features and clinical outcomes (Kang *et al.*, 2005). The expression levels of CXCL12 have been reported on the higher side in different human cancers, including HCC (Sakai *et al.*, 2012) (Ghanem *et al.*, 2014; Teng *et al.*, 2016). The essential role of CXCL12 is yet to be fully explored in most cancers. The involvement of the CXCL12/CXCR4 axis in tumor progression, survival, metastasis and angiogenesis is well known. The current investigation aims to study the effect of CD44 on proliferation, migration, and invasiveness in HCC cells for CXCL12/CXCR4/Wnt/β-Catenin Axis.

MATERIALS AND METHODS

Cell culture and cell transfection

The human hepatocellular carcinoma (HCC) cell line, Huh7 was purchased from ATCC. Huh7 were grown in DMEM containing 10% FBS (Sigma). The medium was put in a saturated humidity incubator at 37°C with 5% CO_2. SiRNA (Si-CD44) was obtained from Ruibo Biotechnology Co., Ltd (Guangzhou, China). Over-expressing plasmid pcDNA3.1-CD44 (CD44) along with control vector (Vector) was purchased from General Biol (Anhui, China). Huh7 cells were grown in 6-well plates and divided into six groups, namely: blank group (Blank), Si-CD44 group, Si-NC, CD44 and Vector. Lipofectamine was used for the transfection of different vectors into the cells.

MTT assay

Cell viability in each group was observed MTT assay (Gibco, USA). Huh7 cells were grown into 96-well plates (6×10^3 cells/well) for 48 h. It was followed by transfection studies using siRNAs (Si-CD44 and si-NC) and vectors (empty vector and vector-CD44) in the Huh7 cells, using lipofectamine and in accordance with the manufacturer's protocol. The efficacy of transfection was checked by western blotting. After incubation, the medium was removed from the wells, followed by the addition of 20 μl MTT reagent (5 mg/ml; Gibco, USA) to each well. At the end of the experiment, MTT (Sigma) stock solution of 5 mg/mL concentration and volume 100 μL was supplemented to cells with 4 h of incubation. The formazan crystals then produced are dissolved with DMSO, and thereafter, absorbance was measured at 540nm using a microplate reader. Each experiment for individual drug concentrations and controls was performed thrice.

Colony formation assay

Cell viability was observed via colony formation assay. Cells were rinsed twice with PBS. Afterward, individual cell in each group was obtained with 0.25% trypsin and then inoculated into culture dishes for one hour. Serially dilute the samples to obtain 100 cells in a 10 mL culture medium. At last, the cells were inoculated into other culture dishes for 10–14 days, followed by an observation of the cell colony formation under a microscope.

Transwell assay

The anti-invasive and anti-migratory effects of each group were monitored *via* transwell chambers assay. The upper chambers of the transwell were loaded with 600 μL of DMEM medium and 3×10^4 Huh7 cells (transfected or un-transfected) each well. In the transwell's lower chambers, only cultural medium of 800 μL with FBS 10% was filled. Cells in each group were cultured in upper chambers for 24 h at 37°C. Then clean off the non-migrated cells and the migrated cells were processed routinely by 10 minutes of fixation with formalin 4%. Afterward staining was accomplished with crystal violet (0.1%) for 12 minutes, followed by photographing the randomly selected 5 fields using microscopy with 100× magnification. Finally, the invasion was determined, except transwell chambers were coated with Matrigel.

Table 1. Primer sequences

Gene	Forward primer	Reverse primer
CD44	5'-ACTTGGAGGCCTTGGCTAAC-3'	5'-GACAGACAGACTGCGACCTG-3'
GAPDH	5'-TGTGTCCGTCGTGGATCTGA-3'	5'-TTGCTGTTGAAGTCGCAGGAG-3'

Wound healing assay

Huh7 cells were cultured in 12-well plate overnight for wound healing assay purposes. With the help of a 10μl tip, a scratch was created on the monolayer cells. After scratching, cells were washed with culture media to remove floating cells. Cells were kept untreated or either transfected with different vectors. The transfection of siRNAs (Si-CD44 and si-NC) and vectors (empty vector and vectore-CD44) was performed in the Huh7 cells, using lipofectamine and according to the manufacturer's protocol. The efficacy of transfection was checked by western blotting. Images of fresh scratch were captured immediately with the help of a digital camera. After treatment completion, cells were washed thrice with culture media and followed by capturing pictures of the scratch. The scratch area was determined using Image-Pro software. Cell migration was determined by calculating the scratch closure.

RT-qPCR assay

RNA from Huh7 cells was obtained using TRIzol method and then reversed to cDNA with RT Kit. Quantitative PCR was carried out using SYBRGreen (Takara) with appropriate primers designed by Primer 5.0 (Table 1) according to the conditions, including an initial step of 10 minute in 95°C, and then 40 cycles of amplification, which includes 10 s in 95°C, 20 s in 58°C and 25 s in 72°C. Quantification was determined by $2^{-\Delta\Delta CT}$ (26). The internal control used was GAPDH.

Western Blot

Total cellular protein from each group was extracted, followed by protein concentration determination using a BCA protein quantification kit (Pierce, 23225). From each sample, 45 μg of proteins were loaded and run on SDS-PAGE gels, which were processed for blotting to PVDF membranes. Blocking PVDF membrane with 5% non-fat dry milk was done at room temperature for 2 h. It was followed by overnight incubation with primary antibodies like anti-MMP-9 (abcam, ab58803, 1:1000) anti-MMP-2 (Santa Cruz, sc-13594, 1:800), anti-β-catenin (Sigma Aldrich, C7207. 1:1000), anti-GSK-3β (Santa Cruz, sc-81462, 1:1000), anti-CXCR4 (abcam, ab124824, 1:800) and anti-GAPDH (Cell Signaling Technology, 5174, 1:1000). Next day, after washing with PBS thrice, membranes were incubated with HRP-linked secondary antibodies (Cell Signaling Technology, 7074 and 7076, 1:3000) for 90 minutes at room temperature. Finally, ECL chromogenic substrate was added for color reaction.

Statistical analysis

The experimental data were expressed as mean ± standard deviation (S.D.), and SPSS 21.0 software was utilized for statistical analysis. In addition, t-test and ANOVA were used for comparison between groups. Each experiment was repeated thrice. $P<0.05$ was considered that the results were statistically significant.

Figure 1. Transfection efficacy (A) and Effect of CD44 expressions on proliferation and cell viability of Huh7 cells (B, C). Cell viability of Huh7 cells was detected by MTT while as Cell viability was detected by colony formation assay. *$P<0.05$ and **$P<0.01$ vs. si-NC group; #$P<0.05$ and ##$P<0.01$: vs. Vector group.

RESULTS

Inhibition of CD44 inhibits proliferation and cell viability

Knockdown of CD44 can inhibit its expression in Huh7 cells, while overexpression can reverse the result (Fig. 1A). The results of immunoblotting showed that CD44 is expressed in Huh7 cells. The expression level of CD44 significantly decreased in the Si-CD44 group compared to the Si-NC group. However, the expression level of CD44 increased significantly in the CD44 group compared to the vector group.

MTT assay showed that the proliferation ability of Huh7 cells were significantly reduced in the si-CD44 group compared to the si-NC group (Fig. 1B). On the contrary, the proliferation ability of Huh7 cells increased significantly in the CD44 group compared to the vector group. Furthermore, knockout of CD44 significantly in-

Figure 2. Effect of CD44 expression on invasion and metastasis of hepatocellular carcinoma cells. (**A**) The expression of MMP-2 and MMP-9 in Huh7 cells detected by western blot. (**B**) Effect of CD44 expression on invasive ability of Huh7 cells detected by Transwell assay. (**C**) Effect of CD44 expression on migration ability of Huh7 cells detected by wound healing assay. *$P<0.05$ and **$P<0.01$ vs. si-NC group; #$P<0.05$ and ##$P<0.01$: vs. Vector group.

hibited cell viability of Huh7 cells, while overexpression of CD44 significantly motivates it (Fig. 1C). The results showed that CD44 was involved in the proliferation and cell viability of hepatocellular carcinoma cells.

Inhibition of CD44 can inhibit invasion and metastasis

Further, we studied the role of CD44 on cellular invasion and metastasis in Huh7 cells. Transwell and wound healing assay were used to evaluate the invasive and migration ability of Huh7 cells. The results (Fig. 2A–B) suggested that the invasion and metastasis of Huh7 cells decreased significantly after silencing CD44 compared to si-NC group. Instead, cellular invasion and metastasis were significantly increased after overexpressing CD44 compared to the vector group ($P<0.05$). To investigate the possible mechanism through which CD44 regulates functional changes in Huh7 cells, MMP-2 and MMP-9 expressions were examined (Fig. 2C). The expression level of MMP-2 and MMP-9 was significantly increased after CD44 silencing and a reverse trend was observed after overexpressing CD44.

Inhibition of CD44 can inhibit the expression levels of CXCR4/CXCL12 proteins

The effect of CD44 expression on CXCR4 proteins associated with induction of cancer growth was detected. Western blot indicated (Fig. 3) that the expression levels of CXCR4 were significantly decreased in the si-CD44 group, and opposite results were observed in the CD44 group compared to the control group. These results confirmed that the activation of CXCR4 signal pathway was inhibited after silencing CD44.

Figure 3. Effect of CD44 expression on the expression levels of CXCR4.
The expression of CXCR4 in Huh7 cells was detected by western blot. *$P<0.05$ *vs.* si-NC group; #$P<0.05$: *vs.* Vector group.

Inhibition of CD44 inhibits the expression levels of Wnt/β-catenin signal proteins

The expression of β-catenin decreased significantly in the si-CD44 group compared to the si-NC group. On the other hand, GSK-3β expression increased significantly in the si-CD44 group compared to the si-NC group (Fig. 4). Thus confirming an association between Wnt/β-catenin pathway activation and CD44.

DISCUSSION

Wnt signal is divided into the typical Wnt pathway and two atypical Wnt pathways (Reya & Clevers, 2005). The typical Wnt signal pathway is currently the most widely studied in clinical practice. Studies have demonstrated that nearly 50% of currently known tumors show an association with abnormal Wnt/β-catenin signal path-

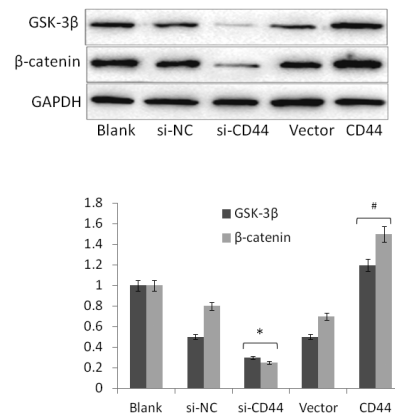

Figure 4. Effect of CD44 expression on Wnt/β-catenin signal pathway.
The expression of GSK-3β and β-catenin in Huh7 cells was detected by western blot. *$P<0.05$ *vs.* si-NC group; #$P<0.05$: *vs.* Vector group.

ways, such as intestinal cancer (Barker *et al.*, 2009), breast cancer (Shackleton *et al.*, 2006; Teissedre *et al.*, 2009), etc. Abnormal expression of proteins such as GSK-3β (Cho *et al.*, 2010), β-catenin (Clements *et al.*, 2002), and MMPs (Conlon & Murray, 2019) in the pathway triggers sustained cell proliferation, ultimately leading to cancer (MacDonald *et al.*, 2009). Meanwhile, it performs a crucial role in cellular invasion and metastasis (Nguyen *et al.*, 2009b; Stein *et al.*, 2006). Therefore, the present study investigated whether CD44 could mediate invasion and metastasis in HCC cells by regulating the Wnt/β-catenin signal pathway.

In the present study, cellular proliferation and invasion (Huh7 cells) reduced after silencing of CD44. However, the proliferative and invasive capacity of cells increased after overexpressing CD44 and thus confirmed that CD44 is involved in the progression of HCC. In addition, protein levels of MMP-2, MMP-9, and β-catenin were decreased; the expression of GSK-3β was increased after CD44 silencing in Huh7 cells. However, the opposite results were presented after over-expression of CD44. These findings suggest that down-regulation of CD44 inhibits the Wnt/β-catenin signal pathway and gradually inhibit invasion and metastasis of Huh7 cells.

The activated Wnt pathway stimulates CXCL12 release, a key paracrine molecule that controls different biological processes like cellular activation and migration, influences inflammation, and angiogenesis (Giordano *et al.*, 2019; Meng *et al.*, 2018). The earlier connection between CXCL12 expression and the Wnt/-catenin pathway has been reported in fibrosis, particularly in liver fibrosis (Akcora *et al.*, 2018). But no study involving CD44/CXCL12/Wnt/β-Catenin Axis has been reported to date. To support our current findings, additional in vivo research is necessary. Additionally, this study was conducted using a hepatocellular carcinoma cell line, which does not reflect a real-world scenario. However, this study offered the first proof-of-concept data indicating CD44/Wnt/CXCL12 signaling axis in hepatocellular carcinoma cells.

CONCLUSION

In summary, by silencing CD44 expression, invasion and metastasis of HCC cells could be inhibited. This result could possibly be obtained by mediating the Wnt/β-

catenin signal pathway. This provides the more comprehensive role of CD44 as a therapeutic target in patients with HCC.

Declarations

Author Contributions. XS, FD and WL contributed to the study conception and design. Data collection and analysis were performed by JT and KY, while analysis and interpretation of the results were performed by QL and ZZ. The manuscript was written by XS. FD, WL, JT, KY, QL and ZZ read, interpreted and revised the manuscript critically for important intellectual content. All authors approved the final manuscript.

MicroRNA-411-3p motivates methotrexate's cellular uptake and cytotoxicity *via* targeting Yin-yang 1 in leukemia cells

HuiJing Sun[1][#], ShuGuang Zhou[1][#], ZhouSheng Yang[1], MingYu Meng[1], Yan Dai[2], XinYe Li[2] and XiaoYu Chen[1]✉

[1]Department of Pharmacy, The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning City, Guangxi Zhuang Autonomous Region, 530021, China; [2]Department of Paediatrics, The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning City, Guangxi Zhuang Autonomous Region, 530021, China

This study aimed to figure out how microRNA (miR)-411-3p's impacts on methotrexate (MTX)'s cellular uptake and cytotoxicity in acute lymphoblastic leukaemia (ALL) CEM-C1 cells by targeting Yin-yang 1 (YY1). miR-411-3p and YY1 were detected by RT-qPCR or Western blot. Intracellular MTX concentration was measured by enzyme-linked immunosorbent assay. Cell viability and apoptosis were evaluated by CCK-8, clonal formation assay, and flow cytometry. Verification of miR-411-3p and YY1's targeting link was manifested. It came out that miR-411-3p mimic or si-YY1 elevated intracellular MTX, MTX-induced cytotoxicity and apoptosis rate in CEM-C1. However, the inverse results were noticed in cells introduced with miR-411-3p inhibitor or oe-YY1. Meanwhile, it was found that cell relative luciferase activity was reduced after co-transfection of miR-411-3p mimic with YY1-WT, indicating that miR-411-3p targeted YY1. Elevation of YY1 could turn around elevating miR-411-3p's impacts on MTX's cellular uptake and cytotoxicity in CEM-C1 cells. These findings convey that miR-411-3p motivated MTX's cellular uptake and cytotoxic impacts via targeting YY1 in leukemia cells. This study is helpful for learning about the mechanisms underlying MTX responses in ALL patients.

Keywords: MicroRNA-411-3p, Yin-yang 1, methotrexate, acute lymphoblastic leukemia

INTRODUCTION

Acute lymphoblastic leukaemia (ALL) is an extremely common malignant tumor, which frequently shows up in children, taking up about 80% of ALL cases, and occasionally takes place in adults (Liang *et al.,* 2021). ALL is featured by malignant transformation and proliferation of T- or B-cell progenitors which invade blood, bone marrow, and extramedullary sites, thereby preventing normal blood cell production (Ranjbar *et al.,* 2019). Methotrexate (MTX) is a chemotherapeutic drug for ALL and has been applied to cure leukemia and lymphoma patients (Woźniak *et al.,* 2021). Although most patients are available to achieve long-term disease-free survival *via* standardized treatments, including MTX, some ALL treatments for children are still ineffective, and drug resistance is a vital reason for this phenomenon (Jaramillo *et al.,* 2019). Therefore, discovering approaches to suppress chemotherapy resistance in ALL patients is crucial for ALL cure.

MTX is a folate antagonist, whose action is extremely complicated, involving some transporters determining intracellular drug levels and active MTX polyglutamate and some metabolic enzymes (Gervasini *et al.,* 2017). MTX enters cells by passive diffusion via the solute carrier 19A1 transporter (RFC1) (Ando *et al.,* 2013), while the drug is pumped out by some membrane efflux transporters of the ATP-binding cassette family (Aberuyi *et al.,* 2021). MTX is converted into active polyglutamate form (MTX polyglutamate, MTXPG) by folate polyglutamate synthase intracellularly (De Beaumais *et al.,* 2012). MTX and MTXPG inhibit thymidine synthesis by targeting dihydrofolate reductase and thymidine synthase (Rushworth *et al.,* 2015), thereby impairing DNA and RNA synthesis and leading to cell death (Oosterom *et al.,* 2018). In conclusion, the accumulation of MTX and its active metabolite methotrexate polyglutamate (MTXPG) in all cells is an important determinant of its anti-leukemia effect (Panetta *et al.,* 2010).

MicroRNAs (miRNAs), a cluster of endogenous single-stranded non-coding RNAs, modulate gene expression (Lin *et al.,* 2021). Much evidence illustrates that miRNAs participate in almost all biological processes, including drug resistance (Xian *et al.,* 2019; Naghizadeh *et al.,* 2020; Wei *et al.,* 2021). Genetic variation in MTX transporter genes has been reported to be implicated in toxicity, and these transporters are controlled by miRNAs (Iparraguirre *et al.,* 2016). Wang SM (Wang *et al.,* 2017). confirm that two miRNA-binding site polymorphisms (rs3737966 G>A and rs35134728 DEL/TTC) in the 3'-UTR of 5,10-methylenetetrahydrofolate reductase were linked with serum MTX concentrations. Xu Wen (Xu *et al.,* 2018). discovered that miR-29 family restrained MTX resistance but motivated apoptosis by targeting COL3A1 and MCL1 in osteosarcoma. MiR-411-3p, a newly studied miRNA, has been discovered to be aberrantly expressed in some human cancers (Huang *et al.,* 2021; Wang *et al.,* 2019; Wang *et al.,* 2020). However, no studies have been conducted to clarify its role in MTX resistance. In the research, the main focus was on miR-411-3p's function in controlling Yin-yang 1 (YY1) and its impact on ALL CEM-C1 cell uptake and MTX cytotoxicity.

MATERIALS AND METHODS

Cell culture

Growth of human ALL CEM-C1 cells was in Roswell Park Memorial Institute – 1640 medium replenished with 10% fetal bovine serum (Gibco, Grand Island, NY, USA), 100 U/ml penicillin, and 100 U/ml streptomycin (Beyotime Biotechnology, Shanghai, China). CEM-C1 cells were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China).

Cell transfection

Synthesis of miR-411-3p mimic/inhibitor, mimic/inhibitor negative control (NC), si-YY1/-NC, and oe-YY1/-NC was done by Invitrogen. Oligonucleotides or plasmids (8 μmol/ml) were transfected into CEM-C1 cells based on Lipofectamine 2000 reagent (Invitrogen; Thermo Fisher Scientific). After transfection, cells were treated with different concentrations of MTX (10, 20 and 40 ng/ml).

Intracellular MTX Concentration Determination

Cells were dispersed in 96-well plates at 5.0×10^5 cells per well prior to transfection and MTX treatment. Quantification of intracellular MTX was done using human methotrexate, MTX ELISA kit (HB1386-Hu, Shanghai Hengyuan Biotechnology Co., LTD). Absorbance at 450 nm was recorded on a microplate reader (ELX800, BioTek Instruments, Inc.) and MTX concentrations were calculated.

Cell proliferation assay

Cell proliferation assays were conducted using the Cell Counting Kit-8 (CCK-8; Beyotime Institute of Biotechnology, Inc.). CEM-C1 cells were combined with CCK-8 solution (10 μL) in each well. Next, 4-h cell incubation was conducted, followed by measurement of optical density (OD) value at 450 nm on a microplate reader (ELX800, BioTek Instruments, Inc.). Proliferation rate: {[(ODcontrol-ODblank)-(ODtreated-ODblank)]/(ODcontrol-ODblank)} 100%.

Colony formation assay

Treatment of transfected CEM-C1 cells was done with different concentrations of MTX (10, 20 and 40 ng/ml). The cells were then transferred to a 6-well plate (1×10^3 cells/well) and supplemented with RPMI-1640 medium containing 10% fetal bovine serum at 37°C. After 14 days, the cells were fixed with formaldehyde and stained with 0.1% crystal violet solution (Sigma Aldrich) at 25°C for 15 min and counted under a CKX41 microscope (Olympus).

Apoptosis assay

Annexin V-fluorescein isothiocyanate Apoptosis Detection Kit (BD, USA) was applied to detect apoptosis. In brief, cells were stained with 10 μl Annexin V and 5 μl propidium iodide for 15 min. Then, quantitative analysis was performed using BD FACSCalibur™ (BD, USA).

Reverse transcription quantitative polymerase chain reaction (RT-qPCR)

Total RNA's extraction was conducted using the miRNeasy extraction kit (Qiagen, Valencia, CA, USA).

MiR-411-3p's quantification was conducted using the Hairpin-it miRNA qPCR quantification kit (GenePharma, Shanghai, China) with U6 as a loading control. Detection of YY1 was implemented using Power SYBR Green PCR Master Mix (Applied Biosystems) with glyc-

eraldehyde-3-phosphate dehydrogenase (GAPDH) as internal control, and all PCR reactions were conducted on a 7500 Fast Real-Time PCR Systems (Applied Biosystems, CA, USA). All primer sequences were manifested in Table 1. Calculation of miR-411-3p or YY1 was implemented using the $2^{-\Delta\Delta CT}$ method (Wu et al., 2020).

Western blot

Isolation of total protein was done using mammalian protein extraction reagents (Thermo Fisher Scientific, Inc.) and 1% protease inhibitor cocktail (Merck KGaA, Darmstadt, Germany). The Bicinchoninic acid assay method (Thermo Fisher Scientific, Inc.) was applied for determining the protein concentration. 10 μg protein separated by 1% sodium dodecyl sulfate-polyacrylamide gel electrophoresis was electro-blotted onto polyvinylidene fluoride membranes (Millipore, Bedford, MA, USA), followed by blocking with 7% skim milk and incubation with primary antibody and horseradish peroxidase-conjugated secondary antibody (ab6721; 1: 2000; Abcam). Primary antibodies applied in this study included: YY1 (sc-7341; 1: 1000; Santa Cruz Biotechnology) and GAPDH (ab8245; 1: 1000; Abcam). Detection of proteins was done by enhanced chemiluminescence (Thermo Fisher Scientific, Inc.) (Liu et al., 2019).

The luciferase activity assay

Construction of the luciferase reporter gene plasmids (Promega, USA) covering the 3'-UTR of YY1 with forecast miR-411-3p target sites (Wild-type) or the mutated sites of 3'UTR of YY1 (Mutant) was implemented. Transient co-transfection of CEM-C1 cells was then done with reporters and miR-411-3p mimic or mimic NC. Detection of Firefly and renilla luciferase activities was conducted using a dual-luciferase reporter assay system (Promega) (Liu et al., 2020).

2RNA immunoprecipitation (RIP)

Cell lysates were collected. Incubation of the supernatant from cell lysates was implemented with human anti-Ago2 antibody (SCBT, Santa Cruz, CA, USA) or mouse Immunoglobulin G (SCBT, Santa Cruz). Detachment of proteins was done using Proteinase K buffer and the quantitative real time PCR examined co-precipitated RNAs.

2Statistical analysis

Data were presented as mean ± standard deviation (S.D.) unless otherwise noted. Two groups' comparisons were implemented using the unpaired two-tailed Student's *t*-test. Application of Graphpad Prism software version 4.0 was for all statistical analyses. $P<0.05$ emphasized obvious statistical meaning.

RESULTS

Elevating miR-411-3p motivates MTX's cellular uptake and cytotoxic influences

CEM/C1 cells were transfected with miR-411-3p mimic or mimic NC. miR-411-3p was elevated after transfection of miR-411-3p mimic (Fig. 1A). CEM/C1 cells were treated with disparate concentrations of MTX (10, 20 and 40 ng/ml). Detection of the intracellular MTX concentration was conducted, and the results displayed that the intracellular MTX was elevated in CEM/CI cells introduced with miR-411-3p mimic (Fig. 1B). The cell growth was tested. The results illustrated that after incubation with different concentrations of MTX, elevating miR-411-3p resulted in a clear augmentation in the repression rate of CEM/CI cells (Fig. 1C) and a memorable decline in the number of colonies (Fig. 2A). Considering that apoptosis is a mechanism by which MTX exerts its antitumor effect, the latent function of miR-411-3p in MTX-induced apoptosis in CEM/CI cells was then figured out. It turned out that the apoptosis index of CEM/CI cells in the miR-411-3p mimic introduced with different concentrations of MTX was elevated at all MTX concentrations (Fig. 2B). Moreover, after incubation with different concentrations of MTX,

(**A**) Clone formation assay detection of cell proliferation; (**B**) Flow cytometry detection of cell apoptosis; The data in the figures were all measurement data, and the values were clarified as mean ± S.D. (N=3); *vs. the mimic NC, $P<0.05$.

Figure 3. Depressing miR-411-3p restrains the cellular uptake and cytotoxic effects of MTX.
(**A**) RT-qPCR detection of miR-411-3p; (**B**) ELISA detection of intracellular MTX concentration; (**C**) CCK-8 detection of cell viability; (**D/E**) RT-qPCR and Western blot detection of Bcl-2 and Bax; the values were clarified as mean ± S.D. (N=3); *vs. the inhibitor NC, $P<0.05$.

enhancing miR-411-3p could restrain Bcl-2 but accelerate Bax (Fig. 1D–E). These results suggest that elevating miR-411-3p restrains CEM/C1 cell growth by motivating MTX's cellular uptake and cytotoxic influences.

Depressing miR-411-3p restrains MTX's cellular uptake and cytotoxic influences

To further testify miR-411-3p's function, miR-411-3p inhibitor or inhibitor NC was transfected into CEM/C1 cells, and the successful transfection was verified (Fig. 3A). It turned out that intracellular MTX was clearly reduced in CEM/CI cells introduced with miR-411-3p inhibitor (Fig. 3B). It came out after incubation with different concentrations of MTX, that depressing miR-411-3p resulted in a clear decline of the repression rate of CEM/CI cells (Fig. 3C) and a distinct elevation in the number of colonies (Fig. 4A). Meanwhile, CEM/CI cells' apoptosis index after depressing miR-411-3p was declined at all MTX concentrations (Fig. 4B). Moreover, after incubation with different concentrations of MTX, depressing miR-411-3p could motivate Bcl-2 but restrain Bax (Fig. 3D/E). Taken together, repressing miR-411-3p

motivates CEM/C1 cell growth by refraining MTX's cellular uptake and cytotoxic influences.

MiR-411-3p targets YY1

For further understand miR-411-3p's possible downstream mechanism, Starbase database was applied to forecast that miR-411-3p had a binding site with YY1 (Fig. 5A). YY1 was clearly reduced after elevating miR-411-3p, while depressive miR-411-3p could motivate YY1 (Fig. 5B). Then for further verification of their targeting link, the luciferase activity assay was conducted. Results illustrating co-transfection of YY1-WT with miR-411-3p mimic showed a clear decrease in cell luciferase activity (Fig. 5C). Moreover, miR-411-3p and YY1 were apparently abundant in Ago2 immuno-precipitates (Fig. 5D). These results clarify that miR-411-3p targets YY1.

Depressing YY1 motivates MTX's cellular uptake and cytotoxic influences

To figure out YY1's impact on MTX's cellular uptake and cytotoxicity in CEM/C1 cells, si-YY1/NC was

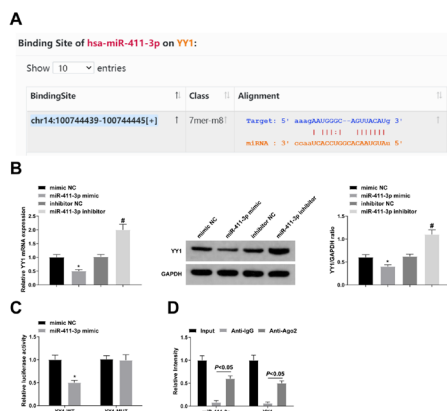

Figure 5. MiR-411-3p negatively modulates YY1.

transfected into CEM/C1 cells (Fig. 6A). It turned out that intracellular MTX was clearly elevated in CEM/CI cells transfected with si-YY1 (Fig. 6B). It came out that after incubation with different concentrations of MTX, repressing YY1 resulted in a clear elevation in the inhibition rate of CEM/CI cells (Fig. 6C) and a distinct decline in the number of colonies (Fig. 7A). It turned out that the apoptosis index of CEM/CI cells in the si-YY1 treated with different concentrations of MTX was elevated at all MTX concentrations (Fig. 7B). Moreover, after incubation with different concentrations of MTX, depressing YY1 could restrain Bcl-2 but motivate Bax (Fig. 6D/E). The above results illustrate that repressive YY1 can accelerate MTX's cellular uptake and cytotoxicity, thereby refraining CEM/C1 cell growth.

Enhancing YY1 restrains MTX's cellular uptake and cytotoxic influences

To further testify YY1's role, it was transfected oe-YY1/NC into CEM/C1 cells and successful transfection was verified (Fig. 8A). It turned out that intracellular

MTX was clearly declined in CEM/CI cells transfected with oe-YY1 (Fig. 8B). It came out that after incubation with different concentrations of MTX, strengthening YY1 resulted in a clear decline in the repression rate of CEM/CI cells (Fig. 8C) and a distinct elevation in the number of colonies (Fig. 9A). It turned out that the apoptosis index of CEM/CI cells in the si-YY1 treated with different concentrations of MTX was declined at all MTX concentrations (Fig. 9B). Moreover, after incubation with different concentrations of MTX, depressing YY1 could motivate Bcl-2 but restrain Bax (Fig. 8DE). Overall, elevating YY1 can restrain MTX's cellular uptake and cytotoxicity, thereby motivating CEM/C1 cell growth.

Elevating YY1 turns around enhancive miR-411-3p's impacts on MTX's cellular uptake and cytotoxicity in CEM-C1 cells

To further explore miR-411-3p/YY1 axis' impacts on MTX's cellular uptake and cytotoxicity in CEM/C1 cells, it was transfected with mimic NC-miR-411-3p mimic+oe-YY1 or miR-411-3p mimic+oe-NC into CEM/C1 cells, and the successful transfection was verified (Fig. 10A). All results clarify that elevation of YY1 can turn around elevating miR-411-3p's impacts on MTX cellular uptake and cytotoxicity in CEM-C1 cells (Fig. 10B–E, Fig. 11A/B).

DISCUSSION

MTX is a chemotherapeutic drug for ALL's, which majorly exerts its therapeutic impact in ALL by impairing the synthesis of DNA in cells. The ability of leukemic blasts to uptake MTX and MTX-polyglutamate has been reported to be vital for the survival of children with ALL. However, MTX has a narrow therapeutic range, its pharmacokinetics and therapeutic response display great variability in ALL's, and it exhibits serious toxicity in plentiful patients, often resulting in an interruption or discontinuation of chemotherapy (Hu et al., 2019). Recent studies have exhibited that miRNAs are implicated in the concentration of MTX in the blood of ALL patients (Wang et al., 2014), suggesting that miRNAs are likely to participate in controlling the uptake of MTX by ALL cells. This research illustrated originally that elevation of miR-411-3p could motivate MTX's cellular uptake and cytotoxicity in CEM/C1 cells, and restrain cell growth, whereas repressing miR-411-3p did the opposite. Meanwhile, it was also testified that miR-411-3p functioned by targeting YY1.

Multiple studies have clarified that miR-411-3p takes part in various human diseases. For example, miR-411-3p was reduced in the tumor tissues of patients with multiple myeloma, and mediated LncRNA ANRIL dysregulation through hypoxia-inducible factor 1α to suppress the malignant proliferation and tumor growth of multiple myeloma stem cell-like properties (Wang *et al.*, 2020)]. (Fu *et al.*, 2020) testified that miR-411-3p was reduced in oral squamous cell carcinoma cells, and elevating miR-411-3p restrained cell growth by targeting NFAT5. miR-411-3p mitigated silica-induced pulmonary fibrosis (Gao *et al.*, 2020). Meanwhile, miR-411-3p was linked with the improved overall survival in lung cancer patients treated with nivolumab (Halvorsen *et al.*, 2018). However, miR-411-3p's impacts on the efficacy of MTX treatment in ALL patients are uncertain. In this research, elevation of miR-411-3p memorably enhanced MTX concentration, cell repression rate and apoptosis index, reduced colony number and suppressed Bcl-2 but motivated Bax in CEM/C1 cells treated with disparate concentrations of MTX, whereas depressing miR-411-3p had the exact opposite effect. These results conveyed that miR-411-3p could control MTX sensitivity in CEM/C1 cells.

YY1 is an extensively expressed multifunctional transcription factor affiliated with the GLI-Krüppel class of zinc finger proteins (Zhang *et al.*, 2021), which takes on momentous roles in diversified biological processes and is linked with tumorigenesis (Li *et al.*, 2020). discovered that YY1-mediated elevation of lncRNA MCM3AP-AS1 motivated lung cancer angiogenesis and progression(Chen *et al.*, 2019). confirmed that YY1 targeted tubulin polymerization-promoting protein and restrained pancreatic cancer migration, invasion, and angiogenesis through p38/MAPK and PI3K/AKT pathways (Li *et al.*, 2021). verified that YY1-induced elevation of LncRNA SNHG5 motivated angiogenesis in AML through the miR-26b/CTGF/VEGFA axis. Recently (Antonio-Andres *et al.*, 2021). confirmed that YY1 was elevated in peripheral blood leukemia cells of children with ALL with Pro-B and T phenotypes, and its elevation is clearly linked with poor survival. Meanwhile, YY1 has also been shown to be linked with drug resistance to multiple leukemia chemotherapeutics. For example (Zhang *et al.*, 2021). demonstrated that in chronic myeloid leukemia, KDM6A motivated imatinib resistance through YY1-mediated transcriptional elevation of TRKA. The present study discovered that repressing YY1 motivated MTX's cellular uptake and cytotoxic impacts, but repressed CEM/C1 cell growth, while enhancing YY1 turned around strengthening miR-411-3p's impacts on MTX cell uptake and cytotoxicity in CEM-C1 cells, and enhanced CEM/C1 cell growth.

However, this research still has several limitations. First, animal experiments were not performed to clarify miR-411-3p's impacts on MTX sensitivity. Secondly, it only figured out the regulatory effect of miR-411-3p on MTX sensitivity in a single ALL cell line (CEM/C1 cells) and not in other leukemia cell lines. Finally, further exploration of the downstream mechanisms of YY1 was not conducted. It is hoped that in future studies, the regulatory mechanism of miR-411-3p in leukemia MTX resistance can be further improved.

CONCLUSION

In short, this research demonstrated that miR-411-3p motivated MTX's cellular uptake and cytotoxic influences by targeting YY1 in ALL cells. The findings not only offer new insights into the mechanisms of variable MTX responses noticed in ALL patients, but also new references for addressing MTX chemotherapy resistance in ALL patients.

Diabetes mellitus is one of the important independent risk factors for the development of neurological disorders such as ischemic stroke, transient ischemic attacks, vascular dementia and neurodegenerative processes. Hyperglycemia plays a crucial role as a trigger in the pathogenesis of these disorders. In this review, we summarize the existing data on the molecular mechanisms of diabetic encephalopathy development, consider the features of oxidative and nitrosative stresses, changes in the thiol-disulfide system, as well as mitochondrial and endothelial dysfunction in diabetes. We focus on the role of HSP 70 in cellular responses in diabetic encephalopathy. HSP70 protein is an important component of the endogenous system of neuroprotection. It acts as an intracellular chaperone, providing the folding, retention, and transport of synthesized proteins, as well as their degradation under both normoxic and stress-induced denaturation conditions. HSP70 can be considered a molecular marker and a promising therapeutic target in the treatment of diabetes mellitus.

INTRODUCTION

Diabetes mellitus (DM) is recognized by numerous studies as an independent risk factor for ischemic stroke, transient ischemic attacks and vascular dementia (Tun *et al.*, 2017; Maida *et al.*, 2022). In some cases, it can be associated not only with cerebral vascular disease but also with neurodegenerative processes, in particular Alzheimer's disease. At the same time, diabetic neuropathy is the most common complication of diabetes mellitus and the leading factor among the causes of reduced quality of life in patients with diabetes (Feldman *et al.*, 2019;

Aleidan *et al.*, 2020). One of the most difficult parts of diabetes mellitus treatment is the correction of its late neurological complications. Diabetic lesions of the nervous system inevitably occur even against the background of many years of compensation for the disease, achieved through the use of modern effective and affordable antidiabetic drugs. For example, diabetes increases the risk of acute cerebrovascular events 6 times, with a nearly three-fold increase in mortality from them (Maida *et al.*, 2022; Ergul *et al.*, 2012). The development of cerebral circulatory disorders in such patients is severe, and carbohydrate metabolism disorders are associated with high mortality and disability (Lin *et al.*, 2020; Hill-Briggs *et al.*, 2021). Chronic lesions of the brain in diabetes are called diabetic encephalopathy, which leads to a decrease in cognitive and mental functions, loss of performance and quality of life in this category of patients. The discovery of new mechanisms of many cerebrovascular diseases, in particular, disturbances of the functional state of the endothelium, inflammation of the vascular wall, and programmed cell death, has opened up opportunities for the development of effective pathogenetic correction measures. In the pathogenesis of diabetic encephalopathy, the trigger link is hyperglycemia (Shi *et al.*, 2016). An important mechanism of vascular complications against the background of hyperglycemia is the activation of the polyol pathway of glucose oxidation under the influence of the enzyme aldose reductase. As a result, glucose is converted into sorbitol under the influence of aldose reductase, which leads to depletion of NADPH and, subsequently, to depletion of the glutathione link of the thiol-disulfide system, reduction of endothelial NO synthase expression, necessary for NO synthesis. A special role in the formation of vascular complications in DM belongs to the activation of protein kinase C, and subsequently to the increase in the concentration of endothelin-1 and the production of growth factors: vascular endothelial growth factor VEGF, epidermal growth factor EGF and transformed growth factor TGF-β. Also, hyperglycemia leads to increased incorporation of glucose into the hexose substitutable pathway, resulting in increased transcription of inflammatory cytokine genes and hyperproduction of reactive oxygen species and NO. Currently, oxidative and nitrosative stress are considered a universal mechanism of development of all complications in DM, including neurodegeneration and endothelial dysfunction (Tota *et al.*, 2021; Pitocco *et al.*, 2013). Recently, experimental studies have discovered a new mechanism that explains many aspects of endothelial dysfunction and neurodegradation in DM (Sivitz &

Yorek, 2010; Teodoro *et al.,* 2019; Cheng *et al.,* 2020). This is mitochondrial dysfunction, which is one of the causes of the increase in oxidative stress. Endogenous mechanisms, limiting the harmful effects of cytotoxic derivatives of NO, are provided by the thiol-disulfide system, the derivatives of which have transport properties with respect to NO, thus increasing its bioavailability. In addition, many thiols (glutathione, cysteine, methionine) can significantly limit the cytotoxicity of nitrosative stress, increasing the chance of cell survival (Kükürt *et al.,* 2021; Ren *et al.,* 2017; Aoyama, 2021). A significant role in the mechanisms of endogenous cyto- and neuroprotection is attributed to the proteins shaperones (HSP) especially, with mM 70 kDa (Belenichev *et al.,* 2023; Zhang *et al.,* 2022). However, their involvement in the molecular and biochemical mechanisms of the damage cascade mechanism in DM has not been fully identified; experimental data are scarce and sometimes contradictory. All this has prompted us to analyze and systematize world achievements in this direction, taking into account our modest results as well.

DIABETIC ENCEPHALOPATHY

The term "diabetic encephalopathy" (DE) was proposed by R. de Jong in 1950 and represents a persistent cerebral pathology resulting from the effects of acute, subacute and chronic vascular disorders, which are clinically manifested as neurosis-like and psychosis-like defects, organic, mild to moderate cognitive deficit (Dejong, 1950). It has been established that the most significant pathogenic factors initiating the development of DE are the duration of the disease, degree of DM, level of glycosylated hemoglobin, diastolic BP and total cholesterol (Li *et al.,* 2023; Wang *et al.,* 2020). In clinical observations and experimental equivalents of diabetes in animals, the duration of DM is associated with pathological changes in the CNS, characterized by cognitive and emotional deficits, which can be considered a factor in the development of dementia, as well as the risk of vascular brain complications (Feldman *et al.,* 2019; Aleidan *et al.,* 2020; Ergul *et al.,* 2012; Li *et al.,* 2023). A probable correlation between DM and cognitive function was established as early as 1922 (Miles & Root, 1922). Over the past 20 years, a number of studies evaluating the relationship between type 2 diabetes and cognitive function have been completed (Moheet *et al.,* 2015; Alkethiri *et al.,* 2021; Antal *et al.,* 2022; Kinattingal *et al.,* 2023). In DM, memory and attention are the most frequently impaired cognitive functions. Hypoglycemic conditions have a pronounced effect on the development of mnemonic disorders. In some cases, the development of dementia is possible. Under the term dementia, we understand a diffuse disorder of mental functions as a result of organic brain damage, manifested by primary disorders of thinking and memory, as well as secondary emotional and behavioral disorders. A diagnosis of dementia can be made when impairments of memory and other cognitive functions are pronounced to an extent that significantly interferes with the performance of professional and social activities in previous amounts and quality (Hugo & Ganguli, 2014). In its development, DE passes through several stages of its formation, which fully depend on the age of the disease: subclinical (coinciding with the debut of DM), clinical (corresponding to the age of the disease – from 2 to 5 years), subcompensation (over 5 years), severe (10–15 years) and decompensation (with the age

of the disease over 20 years) (Cheon & Song, 2021; Popruga *et al.,* 2021).The clinical picture of DE is characterized by a typical triad of symptoms: headaches, dizziness, and memory impairment, which in general unite DE with other types of encephalopathies. However, DE has its own specific features: progressive cognitive decline, which is sometimes referred to as cognitive aging, and sometimes is considered as a pre-stage of Alzheimer's disease (Jayaraj *et al.,* 2020; Falvo *et al.,* 2023). Moreover, it has been established that the leading domains of cognitive impairment in type 2 DM patients are a decrease in short-term verbal memory and attention, correlating with atrophic changes in the cerebral cortex, which appear already in the early stages of diabetes and are not associated with vascular factors (Moheet *et al.,* 2015; Antal *et al.,* 2022).In addition, the clinical course of DE is characterized by frequent episodes of acute impairment of cerebral circulation, transient ischemic attacks and cerebral strokes. In particular, cerebral strokes are 6 times more frequently registered in DM patients (Maida *et al.,* 2022; Ergul *et al.,* 2012).Furthermore, chronic cerebral circulatory disorders are observed to a greater extent in patients with diabetes, leading to chronic cerebrovascular insufficiency syndrome, and the mechanisms of progressive memory decline are associated with chronic hypoxia, cerebral tissue ischemia, and neurometabolic disorders (Ergul *et al.,* 2012; Pitocco *et al.,* 2013).The concept of "brain insulin resistance", according to which insulin receptors exist in the limbic system along with neurotransmitter receptors, is of certain interest. Their role in the mechanisms of synaptic plasticity in the hippocampus has now been established. In particular, it has been shown that insulin rapidly mobilizes functional GABA-A receptors on postsynaptic membranes of hippocampal neurons and improves synaptic transmission. In addition, a regulatory role of insulin in the functioning of AMPA and NMDA receptors of hippocampal neuronal membranes has been established (Spinelli *et al.,* 2019). Insulin can act as a mediator by accelerating the synthesis and synaptic trafficking of acetylcholine, dopamine, and other mediators. With time there is a depletion of insulin receptors in the CNS and a weakening of the function of other neurotransport systems, which to some extent explains the processes of cognitive aging (Kleinridders *et al.,* 2014). In addition, it has been experimentally established that insulin also has a neuroprotective effect under conditions of oxidative stress or DM (Soto *et al.,* 2019). Pathomorphological studies have determined a decrease in the expression of insulin and insulin-like growth factor-1 (IGF) in the hippocampus, cerebellum, pons, and basal ganglia, as well as neuronal losses in the hippocampus and frontal neocortex (Jafferali *et al.,* 2000). In the brain, insulin and IGF-1 mediate numerous effects, including glucose utilization and energy metabolism, oxidative stress, genetic regulation of other neurotrophic factors and their receptors, cholinergic gene expression and tau-protein phosphorylation, and formation regulation. They also exhibit anti-inflammatory and anti-apoptotic effects (Dandona *et al.,* 2007). Decrease of insulin regulation inhibits early response genes c-fos and c-jun with subsequent expression of IGF1 and IGF2, nerve growth factor, neurotrophin-3 and their receptors (Griffiths *et al.,* 1998; Zhang & Li, 2017). Also, insulin and IGF provide neurotrophic support in the hippocampus. It is known that diabetic neurovascular pathology is a metabolic disorder whose pathogenesis is based on the lack of insulin requirement for glucose to enter both nerve

tissue and the vascular wall. Hyperglycemia contributes to a significant (up to fourfold) increase in neuronal glucose levels with subsequent disruption of intracellular glucose metabolism and neuronal damage (Barrett *et al.,* 2017). This results in the development of secondary processes in the form of oxidative stress and protein glycosylation. At the same time, it was found that insulin activates the movement of GLUT4 to the plasma membrane in hippocampal neurons by mechanisms similar to those observed in peripheral tissues. It is considered that due to this, hippocampal neurons can significantly increase glucose utilization during neuronal activity growth (Cisternas *et al.,* 2019). But it was found that elevated plasma glucose levels of up to 6.1 mmol/L were associated with greater atrophy of structures associated with aging and neurodegeneration processes, in particular, the hippocampus and amygdalin. This indicates the relevance of glycemic control and correction in the subclinical course of DM or its absence. Disregarding the interdependence and similarity of pathogenesis, damages to the neuronal and vascular systems are fundamentally different, including the therapeutic approaches. Studies have established the role of hippocampal dysfunction in diabetes mellitus and its role in the development of DE (Spinelli *et al.,* 2019). In particular, it was electrophysiologically discovered that behavioral and mnemastic deviations in diabetic animals are associated with a deficit of long-term potentiality in the CA1 area of the hippocampus (Kumar, 2011). This factor, which reflects the synaptic plasticity of the hippocampus, was prevented by insulin therapy, while interventional treatment to normalize hyperglycemia had only a partial effect on long-term potentiality (Ho *et al.,* 2013). The role of hyperglycemia in the activation of damage mechanisms and activation of apoptosis in the rat hippocampus has also been established (Chen *et al.,* 2019). Induction of apoptosis in the hippocampus may be associated with an increase in the Bax/Bcl-2 and Bax/Bcl-xl ratio as well as caspase-3 activity (Liu *et al.,* 2013). It was experimentally determined that streptozotocin-induced diabetes led to cholinergic receptor dysfunction and reduced the neuroprotective activity of the GABAergic system in the hippocampus, indicating a high vulnerability of neurons of this brain formation and a relationship between the development of cognitive impairment and deficit (Sherin *et al.,* 2012).

Processes of systemic neuronal inflammation in the CNS also correlate with manifestations of cognitive deficits and are associated with increased levels of inflammatory cytokines (IL-1β, TNF-α and IL-6) against a decrease in BDNF in the hippocampus (Fourrier *et al.,* 2019; Dugue *et al.,* 2017). Long-term hyperglycemia leads to the activation of cyclooxygenase-2 expression that in turn results in the increase in biosynthesis of prostaglandin E2, which inhibits glucose-stimulated insulin secretion that disturbs cell tolerance to glucose and plays a significant role in the pathogenesis of DM. It has been experimentally established that streptozotocin-induced diabetes leads to an increase in the immunoreactivity of the inducible form of cyclooxygenase-2 (Cox-2) in the dentate gyrus and CA3-zone of the hippocampus and can thereby influence the synaptic plasticity processes in this structure (Nam *et al.,* 2011).

In general, such disorders can be the cause of rapid development of neurodegenerative changes in DM. The leading role in the pathogenesis of these complications belongs to the negative impact of oxidative stress on the function of the cells of the central nervous system,

Figure 1. Molecular and biochemical cascade of links of diabetic encephalopathy pathogenesis.

and in particular the hippocampus, provided both high intracellular glucose levels and impaired microcirculation (Kükürt *et al.,* 2021; Li *et al.,* 2023). (Fig. 1).

OXIDATIVE STRESS

The main source of free-radical oxidation processes in DM is a state of chronic hyperglycemia. The development of neuronal dysfunction and the appearance of signs of cognitive deficit are based on disorders of carbohydrate metabolism, which lead to self-oxidation of glucose, to activation of the polyol (sorbitol) and hexozoamine pathways of glucose metabolism with intracellular accumulation of their reaction end products, to an increase in intracellular glutathione and ascorbate redox systems, as well as disorders of the metabolism of NO and prostaglandins, non-enzymatic glycosylation of proteins and formation of glycosylation end products with the subsequent development of neuroinflammatory processes and cytoxic edema of neuronal tissue (Kükürt *et al.,* 2021; Belenichev, 2013). Hypoxia observed in DM is an additional factor contributing to the increased formation of reactive oxidants. The accumulation of peroxidation products under conditions of hyperglycemia leads to the interaction of glucose with amino groups of proteins, increasing their glycosylation and oxidation (auto-oxidative oxidation). Non-enzymatic glycosylation of antioxidant defense enzymes leads to a decrease in their activity and even complete inactivation (Belenichev *et al.,* 2015). The greatest number of free radicals in the organism refers to combinations of reactive oxygen with a very short lifetime: the superoxide oxygen radical anion (O_2^-) and alkoxy radical (RO*) – 10^{-6} s, hydroxyl radical (OH^-) – 10^{-9} s, peroxyl radical (ROO) – 10^{-12} s (Collin, 2019; Edge & Truscott, 2021).

NITROXIDERGIC SYSTEM AND NITROSATIVE STRESS

The unique chemical nature and large number of intracellular targets for NO and its physiologically active oxidative-redox forms leave open the question of the way and the specificity in which the damaging effect of nitric oxide is mediated in the neuron under ischemic conditions. Numerous studies have shown the direct involvement of NO in the process of neuronal destruction in ischemia, arterial hypertension, and DM. A slight increase in NO concentration activates the synthesis of chaperone proteins and NO-dependent activation of HSP70 may constitute an important endogenous cellular defense mechanism. However, iNOS hyperexpression is suppressed by HSP70 by reducing the activation of the iNOS transcription factor (NFϰB), which leads to the limitation of nitrosative stress and neuroapoptosis (Belenichev *et al.,* 2015). Now, there is an active study of NO targets and whether NO is sufficiently cytotoxic, or whether its derivatives are more active (Aquilano *et al.,* 2011; Liu *et al.,* 2019). Studies in recent years have established that NO, and especially the products of its conversion, such as peroxynitrite (ONOO⁻), nitrosonium ion (NO⁺), nitroxyl (NO⁻) and diazotrioxide (N_2O_3), are major factors in the realization of nitrosative stress, which results in direct interaction of NO with metals (hem iron of hemoglobin, myoglobin, iron-containing enzymes, as well as non-heme iron of iron-sulfur proteins and DNA, copper and zinc of active enzyme centers), and indirect interaction of NO⁺ (S-, N-, O-nitrosation) with thiol, phenolic, hydroxyl and amino groups of proteins and DNA. Such interaction leads to receptor desensitization, inhibition of mitochondrial enzyme activity and fragmentation of nucleic acids (Belenichev *et al.,* 2015; Liu *et al.,* 2019).

GLUTATHIONE LINK OF THE THIOL-DISULFIDE SYSTEM

Hyperglycemia promotes the activation of the sorbitol pathway of glucose metabolism, which, together with activation of NADPH oxidase, leads to depletion of the NADPH cytosolic level and, consequently, of the reduced glutathione (GSH) level (Yan, 2018). (Fig. 2). A decrease in GSH levels below normal values can serve as an indicator of impaired cellular redox status and changes in the redox-dependent regulation of genes. The consequence of this disturbance is a significant change in the mechanism of cellular redox-dependent signaling, controlled both non-enzymatically and enzymatically with the participation of glutathione transferase and glutaredoxin isoforms (Luo *et al.,* 2016; Ohiagu *et al.,* 2021). It is known that GSH is a neurotransmitter and neuromodulator (in micromolar concentrations it is an agonist of glutamate receptors; in millimolar concentrations, it modulates the SH groups of NMDA receptors). Oxidized forms of glutathione in concentrations above 200 μM decrease the expression of early response genes, and in concentrations of 5 mM or more, it activates p53-dependent apoptosis and reduces HSP levels (Belenichev *et al.,* 2020). GSH, competitively binding to nitric oxide, forms a complex in the form of S-nitrosoglutathione, which forms a depot of endogenous NO (further NO release is catalyzed by the thioredoxin system). Also, the release of NO from S-nitrosoglutathione occurs with glutamyltranspeptidase to form S-nitrosocysteinylglycine as a producer of NO. Cystine, which is

Figure 2. Disturbance in the coupling of NO/SH system in diabetes mellitus and nitrosative stress activation.

reduced to cysteine, takes part in the transport of S-nitrosoglutathione. These reactions are controlled by glutathione reductase and glutathione transferase. Nitrosative stress results in oxidative modification of low molecular weight thiols, formation of homocysteine and its cytotoxic derivatives which enhance thiol oxidation (Ren *et al.,* 2017; Aoyama, 2021; Belenichev *et al.,* 2015). It should be noted that the increased intracellular levels of cytotoxic forms of NO and decreased levels of reduced glutathione may be associated with deprivation of the heat shock protein (HSP70) level (Belenichev *et al.,* 2020).The action of NO formed with the participation of mtNOS results in the opening of mitochondrial pores and the release of pro-apoptotic proteins into the cytosol. The opening of the pores is due to oxidation or nitrosylation of the thiol groups of the cysteine-dependent portion of the mitochondrial inner membrane protein (ATP/ADP-antiporter), and this converts it into a permeable nonspecific pore channel (Pavlov *et al.,* 2017). The interaction of NO with members of the Bcl-2 superfamily is also reflected in the fact that the action of nitric oxide in the cell decreases significantly the level of intracellular Bcl-2 protein, possibly through caspase-induced splitting or p53-dependent inhibition of its expression (Shamas-Din *et al.,* 2013; Fricker *et al.,* 2018; Török *et al.,* 2002). The proapoptotic effect of nitric oxide is also expressed in its induced increase in the expression of apoptogenic BaX proteins. GSH and its precursor N-acetylcysteine can modulate NF-ϰB, inhibit IL-1β expression, and exhibit anti-inflammatory effects (Belenichev *et al.,* 2020; Pavlov *et al.,* 2017). It is known that increased production of TNF-α, IL-1β, IL-6, and iNOS occurs against a background of GSH deficiency (Skelly *et al.,* 2013).

Figure 3. Formation of mitochondrial dysfunction in diabetes mellitus and its consequences.

MITOCHONDRIAL DYSFUNCTION

Mitochondrial dysfunction (MD) has no etiological and nosological specificity and is a typical pathological process. However, it leads to disruption of mediator re-uptake (noradrenaline, dopamine, serotonin), ion transport, impulse generation and conduction, protein synthesis, processes of transcription and translation, and activation of "parasitic" energy-producing reactions, resulting in significant energy expenditure in the neuronal cell. The role of MD in the development of various pathological conditions, including neurodegenerative ones, has also been confirmed in DM (Norat *et al.*, 2020; Wang *et al.*, 2020; Pessoa & Duarte, 2023).

It was experimentally determined that diabetes mellitus leads to a significant decrease in the membrane potential of rat brain mitochondria. These changes were accompanied by a decrease in the ATP content and ATP/ADP ratio in brain synaptosomes, which indicates diabetes-induced disorders in the functioning of the electron-transport chain and energy coupling of the electron transfer process with ATP synthesis (Belenichev *et al.*, 2015; Pinti *et al.*, 2019; Singh *et al.*, 2021).

In conditions of hypoperfusion of brain tissues, compensatory mechanisms are depleted and energy deficiency develops, which leads to an increase in Ca^{2+} levels in the cell cytoplasm because energy-dependent pumps that "load" Ca^{2+} into the cisterns of the endoplasmic reticulum or "unload" it from the cell are blocked. These processes activate Ca^{2+}-dependent phospholipases. One of the defense mechanisms preventing the accumulation of calcium ions in the cytoplasm is their capture by mitochondria. However, it increases their metabolic activity aimed at maintaining intramitochondrial charge and proton pumping. This is accompanied by an increase in ATP expenditure. In general, a vicious circle occurs when oxygen deficiency disrupts energy exchange and stimulates the formation of ROS damaging mitochondrial and lysosome membranes, which can lead to mitochondrial dysfunction. In turn, mitochondrial dysfunction leads to the initiation of apoptosis and irreversible damage and death of the neuron (Norat *et al.*, 2020). In addition, the key enzyme of the Krebs cycle, aconitate hydratase (aconitase), is highly sensitive to the effects of oxidative and nitrosative stress (Pessoa & Duarte, 2023). In DM its activity is significantly reduced, and this leads to impaired mitochondrial glucose oxidation, and ATP deficiency (Sivitz & Yorek, 2010; Kuretu, 2023) (Fig. 3).

Figure 4. Pathogenesis of endothelial dysfunction in diabetes mellitus.

ENDOTHELIAL DYSFUNCTION

Hyperglycemia is a trigger in the pathogenesis of diabetic encephalopathy. As a result of protein kinase C activation, there is an increase in the concentration of endothelin-1 and production of growth factors: vascular endothelial growth factor VEGF, epidermal growth factor EGF and transformed growth factor TGF-β (Ergul, 2011; Heydarpour *et al.*, 2020; Wu & Derynck, 2009; Chen *et al.*, 2020). Also in hyperglycemia, there is an increased incorporation of glucose into the hexose-substituted pathway, resulting in increased transcription of inflammatory cytokine genes, which also contributes to the formation of vascular inflammation and proatherogenic state (Shi *et al.*, 2016; Wang *et al.*, 2020). Currently, oxidative stress is considered the main universal mechanism of development of all complications in DM, in particular, as a result of endothelial dysfunction. Moreover, hyperglycemia-induced oxidative stress triggers damage reactions to protein structures of ion channels and receptors, as well as activation and phosphorylation of cytosolic phospholipase A2 (cPLA2) with increased formation of arachidonate and prostaglandin E2, which leads to changes in vascular permeability (Wang & Hsiao, 2020; Sun *et al.*, 2021). As a result of oxidative stress, DNA damage occurs, an obligatory stimulus for the activation of the nuclease enzyme poly(ADP-ribose) polymerase, which depletes the intracellular concentration of NAD+, reducing the level of glycolysis, slowing electron transport and ATP formation, blocking glyceraldehyde-3-fos activity, which leads to endothelial dysfunction and development of diabetic complications (Liu *et al.*, 2017; Pacher & Szabó, 2005) (Fig. 4).

HEAT SHOCK PROTEINS

Clinical studies of HSP70 levels in diabetes are limited. It is known that patients with DM1 had elevated blood levels of HSP72, which decreased significantly after treatment (Ludwig *et al.*, 2014). However, another case-control study reported reduced serum HSP70 levels in type 1 diabetic patients with and without microvascular complications (Atalay *et al.*, 2004). Increased

serum HSP70 levels were also found in patients with type 2 DM not treated with insulin (Nakhjavani *et al.*, 2010). A decrease in iHSP70 expression and an increase in eHSP70 expression are found in patients with obesity and metabolic diseases, including DM2. HSF-1, which is one of the HSP72 transcription factors, is also repressed in subjects with DM2 (Seibert *et al.*, 2022). HSF-1 expression in skeletal muscle was found to be five times lower in obese and DM2 patients than in a control obese group.

The family of heat shock proteins HSPs (Heat shock proteins) is considered to be one of the most studied cytoprotective factors (Kim *et al.*, 2020; Deka & Saha, 2018; Belenichev *et al.*, 2022). There is a class of proteins (chaperones) whose main function is to restore the correct tertiary structure of damaged proteins, as well as to form and dissociate protein complexes. Many chaperones are heat shock proteins, that is, proteins whose expression is initiated in response to increased temperature or other cellular stresses (Belenichev, 2013; Ortan *et al.*, 2018). HSPs act as intracellular chaperones that maintain cell proteostasis in normal and under various stress conditions (hyperthermia, hypoxia, oxidative stress, radiation, etc.).

The most interesting is the HSP70 protein as an important component of the system of endogenous cyto- and neuroprotection, which, first of all, performs the function of intracellular chaperones and provides the processes of folding, holding and transport of synthesized proteins, as well as their degradation, both in normoxia and under stress-induced denaturation (Turturici *et al.*, 2011). It is known that the heat shock protein family 70 includes: inducible/stress-inducible block HSP72/HSP70i, constitutive/physiological protein HSP73/HSC70, constitutive glucose-regulating mitochondrial protein GRP75, constitutive heme oxygenase-1 (HO^{-1}) participates in bilirubin metabolism (Belenichev *et al.*, 2023). The constitutive form of HSP70 is still present in all subcellular compartments and participates in the functioning of cell life support systems in normoxia. On the contrary, the inducible form of HSP70 appears in cells in response to stress, including ischemic stroke (Turturici *et al.*, 2011). In response to stress, ischemia, hypoxia, etc., a sharp increase in the level of HSP70 is registered, and its highest concentration is observed in vital parts of cells: nuclear, perinuclear space, mitochondria, endoplasmic reticulum, which indicates the importance of chaperone70 in protecting cells from death. As nuclear pre-ribosomes resume functioning, the concentration of HSP70 in the nucleus decreases and increases in the cell cytoplasm. Thus, the level of HSP70 can be considered as a marker of cellular and tissue damage. Hyperproduction of HSP70 in cells inhibits the development of autophagy as an alternative, more "radical" mechanism of cellular stress response (Belenichev, 2013; Ortan *et al.*, 2018). Recent studies have established a direct cytoprotective effect of HSP70, which is realized by regulating the processes of apoptosis and cell necrosis. HSP70 inhibits mitochondrial and cytoplasmic pathways of apoptosis. Thus, HSP70 inhibits the transition of procaspase 9 into active caspase 9 and disrupts apoptosome formation in the cytoplasm of cells. Against the background of HSP70 hyperexpression the level of anti-apoptotic protein Bcl-2 increases, which prevents the release of cytochrome c from mitochondria and translocation of apoptosis-inducing factor (AIF) into the nucleus preventing cell apoptosis. HSP70 protein inhibits TNFα-induced apoptosis and also effectively inhibits the development of Fas- and TRAIL- (TNF-related apoptosis-inducing ligand) mediated apoptosis in different cell types. Accumulation of HSP70 in cells increases their resistance to staurosporine, and doxorubicin, known as apoptosis inducers (Naka *et al.*, 2014). Ubiquitination of the insulin-like growth factor-1 receptor is inhibited by HSP10 and HSP60 which results in insulin-like growth factor-1 receptor signaling in cardiac muscle in streptozotacin-induced DM (Shan *et al.*, 2003). It is known that ischemia and hyperglycemia lead to the development of local inflammation. In this situation, HSP70 blocks the activation of the inflammatory transcription factor NF-κB and inhibits its cytokine-mediated translocation to the nucleus (Belenichev, 2013). HSP70 inhibits the production of proinflammatory cytokines (TNF-α, IL-6), inhibits the activity of matrix metalloprotein kinases (MMPs) and inducible nitric oxide synthase (iNOS) in models of ischemia *in vitro* and *in vivo* (Belenichev *et al.*, 2015). It was found that HSP70 in astrocyte culture under ischemia inhibits proapoptotic Jun N-terminal kinases (JNK) and p38 mitogen activating protein kinase (MAPK), disrupting the apoptosis signaling pathway (Giffard *et al.*, 2008). The studies demonstrated a direct relationship between HSP70 and TNFα expression levels, iNOS in microglia, and MMP-9 in astrocytes. When IL-1b interacts with receptors, the nuclear transcription factors AP-1 and NF-κB are activated, which alters the behavior of target cells and leads to the development of an acute cellular response, to the expression of other pro-inflammatory factors, to the stimulation of iNOS and cytotoxic NO produced by astrocytes, to an increase in mitochondrial pore permeability and to the initiation of neuroapoptosis. The IL-1b signaling pathway that enhances mechanisms of delayed neuronal death may be regulated by HSP70 (Kim *et al.*, 2020). An increase in HSP70 concentration within the physiological norm leads to an increase in IL-1β to levels necessary for its participation in cyto- and neuroprotection; while HSP70 deficiency can lead to a significant increase in IL-1. Overexpression of HSP70 attenuates IL-1β expression by inhibiting the C/EBPβ and C/EBPδ transcription factors (Senf *et al.*, 2008). HSP70 can prevent the production of inflammatory cytokines by inhibiting NF-κB-dependent transcription (Lyu *et al.*, 2020; Ferat-Osorio *et al.*, 2014). Many studies investigating the mechanisms of endogenous neuroprotection in ischemia show that the glutathione link of the thiol-disulfide system is reactivated against the background of an increase in the level of HSP70, and the introduction of exogenous HSP70 leads to an increase in the functional activity of the glutathione system (Belenichev *et al.*, 2020). HSP70 proteins mobilize antioxidant resources in neurons by increasing the level of both cytosolic and mitochondrial pools of reduced glutathione (Belenichev, 2013; Belenichev *et al.*, 2015; Zhang *et al.*, 2022). The data on the role of HSP in the stabilization of hypoxia-inducible factor (HIF-1a), which in conditions of ischemia is responsible for providing proliferation, apoptosis, angiogenesis, stabilization of protein molecules under oxidative stress, have recently emerged (Belenichev *et al.*, 2023). Under hypoxia conditions, HSP 70 is displaced from the complex with HIF-1a, thus, during 20–30 min of hypoxia, protecting the factor structure from targeted proteolysis. It is likely that HSP 70 is able to increase the lifetime of factor HIF-1a under pre- and post-hypoxia conditions and

is required for cells to respond appropriately to oxygen deprivation under ischemic conditions (Kim *et al.,* 2020). HIF-1a determines the ability to activate the compensatory energy shunt and HSP 70 determines the ability of its long-term function. This statement is supported by the works of other researchers. It was found that one of the chaperones, the HSP 90 protein, is able to bind to the PAS domain of B-factor and stabilize it. Another cellular chaperone, HSP 70, recognizes a different structural motif of the HIF-1a molecule, the so-called oxygen-dependent degradation (ODD) domain (Dery *et al.,* 2005). It should be noted that the role of these inter-protein interactions is unclear; it is assumed that they are required for the stabilization of HIF-1a under normoxia conditions. Under hypoxia conditions, at least one of the chaperones (HSP 70) is displaced from the complex with HIF-1a by the ARNT protein, which protects the factor structure from targeted proteolysis during 20–30 min of hypoxia. Thus, HSP 70 is able to increase the lifetime of the HIF-1a factor under pre- and post-hypoxia conditions and is required for cells for an appropriate response to oxygen deprivation (Belenichev *et al.,* 2022; Belenichev *et al.,* 2023; Kim *et al.,* 2019).

Under DM, HSP levels are higher in some tissues and lower in other tissues. Defects in response to heat shock are seen in diabetic wounds. Both chaperones play important roles in cardiac defense. HSP60 expression is impaired in the heart of diabetic animals and this may contribute to diabetic cardiomyopathy (Atalay *et al.,* 2004). Also, expression of HSP72 is suppressed in streptozotacin-induced DM. A decrease of HSP70 was found in the mitochondria and cytosol of neurons in the CA1 hippocampus and sensorimotor cortex of rats with streptozotocin-induced DM (Chen *et al.,* 2013)15. Lower levels of HSP70 expression have been reported in insulin-sensitive tissues such as muscle and heart. There is evidence of decreased HSP70 protein levels in exercising diabetic animals with increased mRNA expression. Insulin resistance may contribute to a decrease in HSP70 levels in the heart and brain. It is hypothesized that increased expression of HSP70 in the brain is found in insulin sensitivity, in the brain as well as in peripheral tissues (Moin *et al.,* 2021).

HSP70 demonstrates diverse mechanisms of action on the development of inflammation and insulin resistance. Extracellular eHSP70 plays a role as a ligand for TLR2 and TLR4 in surrounding cells, which activates JNK *via* MEKK4/7 and suppresses NF-ϰB through IRAK4 activation (Mulyani *et al.,* 2020; Zhang *et al.,* 2013). eHSP70 also regulates the expression of eNOS, iNOS and other cytokines such as TNFα and IL1β (Belenichev *et al.,* 2023; Kim *et al.,* 2020; Deka & Saha, 2018; Giffard *et al.,* 2008). Activation of JNK leads to increased inflammation, triggers insulin resistance mechanisms and enhances the formation of mitochondrial dysfunction. In contrast, intracellular iHSP70 inhibits JNK activation and suppresses pathological mechanisms associated with its activation such as inflammation, insulin resistance, mitochondrial dysfunction, and ROS production (Bironaite *et al.,* 2012; Nagai & Kaji, 2023). The effect of HSP70 action depends on the iHSP70/eHSP70 ratio. A higher level of iHSP70 compared to eHSP70 leads to a decrease in inflammation processes (Krause *et al.,* 2015; Oliveira *et al.,* 2022; Seibert *et al.,* 2022; Alemi *et al.,* 2019).

LABORATORY DIAGNOSTICS

As a molecular marker in DM, it is necessary to determine the iHSP70/eHSP70 ratio in patients' serum or lymphocytes instead of total HSP70, which leads to a departure from the real picture of the pathological process. In healthy people, it is about 1 (Krause *et al.,* 2015; Seibert *et al.,* 2022). An [eHSP70]/[iHSP70] ratio of more than 5 indicates a significant pathological process – inflammation, insulin resistance, and endothelial dysfunction in DM (Mulyani *et al.,* 2020). The lower the ratio or the dynamics are more negative, the better the outcome of the disease.

PERSPECTIVES ON THE DEVELOPMENT OF PHARMACEUTICAL PRODUCTS

Such a role of chaperone proteins in cellular responses in pathological conditions raises the question of developing new drugs capable of providing modulation/protection of the genes encoding the synthesis of HSP 70 and HIF-1a proteins. Strategies aimed at modulating HSP70 in DM (prolonged exercise, pharmacological modulation of HSP70) require adherence to and maintenance of iHSP70 expression, thus preventing progression toward more severe DM and allowing restoration of insulin sensitivity. Thus, HSP70 is attractive as a therapeutic target in the treatment of DM.

Silencing lncRNA EZR-AS1 induces apoptosis and attenuates the malignant properties of lung adenocarcinoma cells

Xianjing Yu[1], Lixue Wu[1], Zhongcui Lu[1], Junli Zhang[2] and Yunfeng Zhou[3]✉

[1]Department of Pathology, West China School of Public Health and West China Forth Hospital, Sichuan University, Chengdu, China; [2]Department of Pathology, The First Affiliated Hospital of Chengdu Medical College, Chengdu, China; [3]Department of Cardiothoracic Surgery, West China School of Public Health and West China Forth Hospital, Sichuan University, Chengdu, China

Adenocarcinoma is one of the major subtypes of lung cancer. This study aimed to investigate the effect of silencing long non-coding RNA (lncRNA) EZR-AS1 on the biological behaviors of lung adenocarcinoma (ADC) cells. EZR-AS1 expression levels in lung ADC tissues and cells, as well as in adjacent non-cancerous tissues, were determined using quantitative reverse transcription polymerase chain reaction (qRT-PCR). EZR-AS1 was knocked down in two lung ADC cell lines using small interfering RNA specific for EZR-AS1 (siEZR-AS1). Proliferation, migration, and apoptosis of EZR-AS1-knockdown cells were assessed using the CCK-8 viability assay, flow cytometry, or wound healing experiments. The levels of proteins related to migration pathways were evaluated using western blotting analysis. EZR-AS1 contents were significantly higher in lung ADC tissues and cells than in the levels in the non-cancerous tissues and cells ($p<0.01$). Transfection of ADC cell lines H1437 and H1975 significantly downregulated EZR-AS1 levels in both cell lines. Cytotoxicity assays revealed that the viability of EZR-AS1-knockdown cells significantly decreased over culture time, and a significant level of apoptosis was induced ($p<0.01$). Wounding healing experiments revealed that EZR-AS1-knockdown significantly reduced the migration rate of both cell lines ($p<0.01$). Furthermore, proteins related to migration pathways such as vimentin, MMP2, and MMP9 were significantly downregulated, whereas the E-cadherin level was significantly increased after EZR-AS1 knockdown. Our work demonstrated that EZR-AS1 is associated with ADC progression, and silencing this gene inhibits proliferation and reduces migration of ADC cells *in vitro*. The altered expression of metastasis-related genes was likely responsible for the reduced migration ability after EZR-AS1 knockdown.

Keywords: lung cancer; long non-coding RNA; cell viability; migration; apoptosis

INTRODUCTION

With the increasing number of cancer patients worldwide in recent years, the total prevalence and mortality rate of lung cancer have always been among the highest, particularly in China (Bade & Dela Cruz, 2020; Bai *et al.*, 2018; Cao & Chen, 2019). Annually, there are about 1.8 million new cases of lung cancer and nearly 1.6 million people die because of lung cancer. Studies show that the five-year survival rate of patients is 4–17% (Klimaszewska-Wisniewska *et al.*, 2018; Musika *et al.*, 2021). Histologically, lung cancer is divided into four types including small-cell lung cancer (SCLC), squamous cell carcinoma, adenocarcinoma (ADC), and large-cell carcinoma (Denisenko *et al.*, 2018). ADC accounts for the highest proportion of lung cancers and is responsible for up to 40% of all lung cancers in China (Wu *et al.*, 2021). However, the specific mechanisms of the occurrence, development, and metastasis of ADC are still largely unclear, and elucidation of these mechanisms will be of great significance in the management of the disease.

Long non-coding RNAs (lncRNAs) are endogenous RNAs that have more than 200 nucleotides in length but do not encode proteins (Saigoh *et al.*, 1998). They play various roles in numerous biological activities and processes, including epigenetic regulation, DNA methylation, histone modification, cell cycle regulation, post-transcriptional and post-translational regulation of DNA expression, and histone modification (Hosseini *et al.*, 2017). LncRNAs have been demonstrated to participate in the occurrence, proliferation, invasion, metastasis and prognosis of many tumors, including lung cancer. For example, the level of lncRNA DANCR is elevated in tissues isolated from high-grade lung cancer and DANCR knockdown reduces the progression of lung cancer in a xenograft mouse model (Figg *et al.*, 1978); HOTAIR level is upregulated in lung cancer and the level is correlated with the degree of metastasis and outcome with poor prognosis (Loewen *et al.*, 2014); and lncRNA ezrin antisense RNA 1 (EZR-AS1) is highly expressed in various cancers such as cutaneous squamous cell carcinoma (cSCC), colon cancer, breast cancer, and esophageal squamous cell carcinoma (ESCC) compared with non-cancer tissues (Bai *et al.*, 2018; Ghaffari *et al.*, 2019; Lu *et al.*, 2021; Xie *et al.*, 2011).

EZR-AS1, 362 bp in length, is an endogenous lncRNA transcribed from the antisense strand of the EZR gene that is located on chromosome 6q25.3 (Liu *et al.*, 2019). As a cytoskeletal-membrane linker protein, *ezrin* is highly expressed in lymph node metastases but not in matched primary tumors, and downregulating *ezrin* with a small-molecule compound could impede the migration

ability of cancer cells (Ghaffari *et al.*, 2019). Knockdown of EZR-AS1 results in reduced proliferation ability of breast cancer cells *in vitro* and arrests the cell cycle by inactivating the Wnt/β-catenin pathway (Bai *et al.*, 2018). In ESCC, high EZR expression was found to be the cause of poor overall survival and is considered a new molecular marker to predict the prognosis of ESCC patients (Xie *et al.*, 2011). However, the role of EZR-AS1 in ADC remains to be elucidated.

In the present work, the effect of silencing lncRNA EZR-AS1 on the growth, migration, and apoptosis of lung ADC cells was investigated in an attempt to explore the therapeutic option of ADC by lncRNA.

MATERIALS AND METHODS

Reagents and instruments

Fetal bovine serum (FBS; Cat. no. 26140079) was purchased from Sigma-Aldrich-Aldrich USA). The RPMI-1640 medium (cat. no. 11875119), Tris-buffered saline (TBS; cat. no. BP2471100), BCA protein assay kit (cat. no. 712853), and Annexin V-FITC kit (cat. no. 331200) was obtained from Thermo Fisher Scientific (USA). The BeyoRT III cDNA Synthesis Kit (with gDNA EZeraser) (cat. no. D7180M), Trizol total RNA extraction reagent (cat. no. R0016), and BeyoFast SYBR Green qPCR Mix (cat. no. D7260), and Lipofectamine 6000 transfection reagent (cat. no. C0526), cell counting kit-8 (cat. no. C0037), and RNase A (Cat. no. ST579) and E-cadherin (cat. no. AF0138; dilution 1:1500) and vimentin (cat. no. AF0318; dilution, 1:1000), MMP9 (cat. no. AF7935, dilution 1:1500), MMP2 (cat. no. AF1420, dilution 1:1500), and GAPDH (cat. no. AF2819, dilution 1:1200), goat horseradish peroxidase (HRP)-conjugated anti-rabbit IgG (cat. no. A0208, dilution 1:2000) and a chemiluminescent kit (cat. no. GS009) was purchased from Beyotime (Shanghai, China). A microplate reader (GloMax® Discover) was purchased from Promega (USA). Flow cytometry (FACS LSR) data were obtained from BD Biosciences (USA). An inverted light microscope (IX73P2F) was obtained from Olympus (Tokyo, Japan). A Real-time PCR Detection System (CFX96) was obtained from Bio-Rad, Hercules, CA, USA.

Cell culture

The human lung adenocarcinoma cell line H1437 (cat. no. CRL-5872), H1975 cells (cat. no. CRL-5908), lung epithelial cell line HBEC3-KT (cat. no. CRL-4051) and NL20 (cat. no. CRL-2503) were obtained from ATCC, Manassas, VA, USA. The cells were grown in RPMI-1640 medium added with 10% FBS, penicillin (100 U/ml), and mycomycin (100 µg/ml) in a humidified incubator with 5% CO_2 at 37°C. The medium was changed every 2–3 days when the cell culture reached the logarithmic phase.

Clinical specimens

Clinical specimens (lung ADC samples and matched paracancerous tissues) were isolated from 50 patients who underwent surgical treatment at The First Affiliated Hospital of Chengdu Medical College in Chengdu, China, between July 2017 and January 2019. All ADC were primary, and the patients had not received any radiotherapy or chemotherapy prior to surgery. This study was approved by the Ethics Committee of Sichuan Uni-

versity (approval no. SU3312D). Informed consent was secured from each patient.

Quantitative reverse transcription polymerase chain reaction (RT-qPCR)

Total RNA was prepared from tissues and cells using TRIzol reagent based on the manufacturer's protocols. RNA (1 µg) was reversely transcribed into cDNA using the BeyoRT III cDNA synthesis kit and the resultant cDNA was used as a template for RT-qPCR assays with primers designed using Primer Premier 5 (https://www.bioprocessonline.com/doc/primer-premier-5-design-program-0001). RT-qPCR was carried out on CFX96 Real-time PCR System using BeyoFast SYBR Green qPCR mix based on the manufacturer's instructions, with the cycling parameters: pre-denaturing at 95°C for 3 min, followed by 40 cycles of denaturing at 95°C for 10 s, annealing for 30 s with a final extension at 72°C for 30 s. The GAPDH gene was employed as the endogenous expression reference. The expression level relative to GAPDH was determined using the $2^{-\Delta\Delta Ct}$ method as outlined described (Livak & Schmittgen, 2001). The primers used for EZR-AS1 were forward: 5'-CCCTCTCCAATGAAGCCTCTC-3' and reverse: 5'-ACCGAAAATGCCGAAACCAG-3'; and for GAPDH forward: 5'-GTCTCCTCTGACTTCAACAGCG-3' and reverse, 5'-ACCACCCTGTTGCTGTAGCCAA-3'.

Transfection

Cells were cultured to 70–80% confluency and divided into aliquots for transfection using Lipofectamine 6000 transfection reagent, based on the manufacturer's instructions. The cells were either non-transfected (non-transfected, control), transfected with 0.5 µg siNC (siNC, scrambled control), siEZR-AS1 or pEZR-AS1 (positive control). siRNA (5'-AAA UAA UAC UAC AAU UAA A-3') was synthesized by Wigen Biomedicine (Shanghai, China). After transfection, cells were grown in 96 well plates containing RPMI-1640 medium at 37°C for 48 h and then used for subsequent experiments.

Cell viability assay

The viability of treated cells was determined using a CCK-8 cell counting kit based on the manufacturer's protocols. Briefly, cells were inoculated into the wells of 96-well plates at a density of 5×10^4 cells/well and grown in RPMI-1640 medium at 37°C in 5% CO_2. At predetermined time points, 20 µl CCK-8 solution was drop-added to the wells and the cells were incubated at 37°C with 5% CO_2 for 4 h. After the incubation, optical density (OD) of the plates was determined at 460 nm using a microplate reader. All assays were performed in triplicates. Cell viability was calculated as follows: $OD_{sample}/OD_{control} \times 100\%$.

Apoptosis analysis

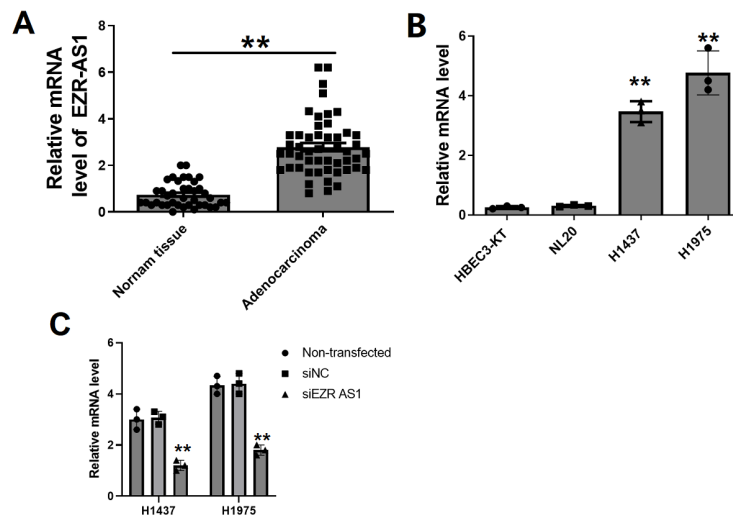
The apoptosis of treated cells was assessed using the ApoDETECT Annexin V-FITC kit based on the manufacturer's protocols. Briefly, after transfection, the cells were inoculated into the wells of 6-well plates at 5×10^4 cells/well containing RPMI-1640 medium. The cells were cultured at 37°C in 5% CO_2 to a confluence between 50 and 70%, harvested after centrifugation at $750\times g$ at 25°C for 10 min, washed with 1 ml PBS three times, and digested with RNase A (100 µg/ml) at 37°C for 20 min. The digested cells were resuspended in pre-chilled binding buffer in an ice bath, and stained with Annexin


Figure 1. Determination of expression level of long non-coding RNA EZR-AS1 (ezrin antisense RNA 1) in lung ADC tissues and cells by RT-qPCR.
(**A**) EZR-AS1 levels in lung ADC and healthy tissues. (**B**) EZR-AS1 levels in lung ADC cell lines (H1437 and H1975) and non-cancer lines (HBEC3-KT and NL20). (**C**) EZR-AS1 levels in ADC cell lines H1437 and H1975 transfected with siEZR-AS1 (si, small interfering RNA), siNC (NC, negative control). V-FITC (3 µl) and PI-PE (7 µl) in the dark at 25°C for 10 min. After the staining, the cells were loaded onto a FACS LSR flow cytometer for analysis with built-in software. All assays were carried out in triplicates.

Wound healing assay

To assess the migration ability, cells were cultured on slides in the wells of 6-well plate containing RPMI-1640 medium with 10% FBS at 37°C. At 100% confluence, a scratch was created on the monolayer with the tip of a 10 µl pipette as previously described (Justus *et al.*, 2014). Serum-free RPMI-1640 medium was added and cell migration was recorded at 0 and 48 h with an inverted light microscope (at 100× magnification) and cell migration distances were calculated using Image-Pro Plus software obtained from Media Cybernetics, Inc. USA.

Western blot analysis

To assess the levels of specific proteins, treated cells were collected after centrifugation at 500 g at 25°C for 10 min, rinsed twice with pre-chilled PBS, and lysed in the radioimmunoprecipitation assay (RIPA) buffer. The total levels of protein in the lysates were determined using a BCA protein assay kit following the supplier's instructions. After boiling at 100°C for 5 min, 60 µg denatured proteins were loaded to the gels and separated by 12% polyacrylamide gel electrophoresis (SDS-PAGE). The separated proteins on the gels were blot-transferred to polyvinylidene fluoride (PVDF) membranes, then blocked by gentle shaking in 5% non-fat milk solution in 1× TBS containing 0.1% Tween 20 (TBST) for 4 h at 25°C. After blocking, the membrane filters were incubated with antibodies to E-cadherin, vimentin, MMP9, MMP2, and GAPDH (served as internal control) at 4°C overnight, rinsed three times at room temperature with TBS buffer, reacted with goat HRP-conjugated anti-rabbit IgG at 25°C for 2 h. Immunoreactive bands on the blots were developed using a chemiluminescent kit in the dark following the manufacturer's protocols. The gray values of the reactive bands were determined using Quantity One software.

Statistical analysis

Data are shown as the means ± standard error derived from three independent experiments. One-way ANOVA with post-hoc Tukey's honest significant difference test was applied to compare the means among the groups. A value of *p*<0.05 was considered to be statistically significant.

RESULTS

EZR-AS1 level is highly elevated in lung ADC tissues and cells

We first determined the level of EZR-AS1 mRNA in lung ADC tissues and cells as well as in non-cancerous tissues and cells. RT-qPCR analysis showed that EZR-AS1 were significantly upregulated in ADC tissues in comparison with the adjacent healthy tissues obtained from patients undergoing surgical resection (*p*<0.01; Fig. 1A). Furthermore, EZR-AS1 mRNA levels in ADC cell lines H1437 and H1975 were significantly elevated compared to those in the non-cancer cell lines HBEC3-KT and NL20 (*p*<0.01; Fig. 1B).

EZR-AS1 knockdown reduces the viability of ADC cells

We then tested whether silencing EZR-AS1 inhibits the growth of ADC cells. H1437 and H1975 cells were transfected with siEZR-AS1 using Lipofectamine-mediated transfection. RT-qPCR analysis showed that siEZR-AS1 transfection resulted in significantly reduced EZR-AS1 levels in both cell lines compared with the controls (non-transfected cells or cells transfected with siNC) (*p*<0.01; Fig. 1C). The cell counting assay showed that the viability of H1437 and H1975 cells decreased over time compared to the controls (*p*<0.01; Fig. 2A). After 72 h of culture, the viability of H1437 and H1975 cells was less than 10%, while that of controls (non-transfected cells or cells transfected with siNC) was over 90% (*p*<0.01; Fig. 2A). Flow cytometry study revealed a significant increase in apoptosis after the cells were

transfected with siEZR-AS1 in both cell lines at 48 h after transfection compared with the controls ($p<0.01$; Fig. 2B).

EZR-AS1 knockdown suppresses the migration of ADC cells

To evaluate the functions of EZR-AS1 in lung ADC progression, cell migration assays based on wound-healing experiments were performed. The results showed that cell migration rates were significantly reduced af-

ter H1437 and H1975 cells were transfected with siEZR-AS1 compared to the controls ($p<0.01$; Fig. 3).

EZR-AS1 knockdown alters the levels of metastasis-related proteins

Since the migration rate of lung ADC cells was reduced after EZR-AS1 knockdown, the levels of a few selected genes that are related to invasion and metastasis pathways were analyzed. Western blotting was used to measure the protein levels of E-cadherin, vimentin, MMP2, and MMP9 in cells after EZR-AS1 knockdown.

**Figure 3. Migration of lung ADC cell lines H1437 and H1975 after transfected with siEZR-AS1.**

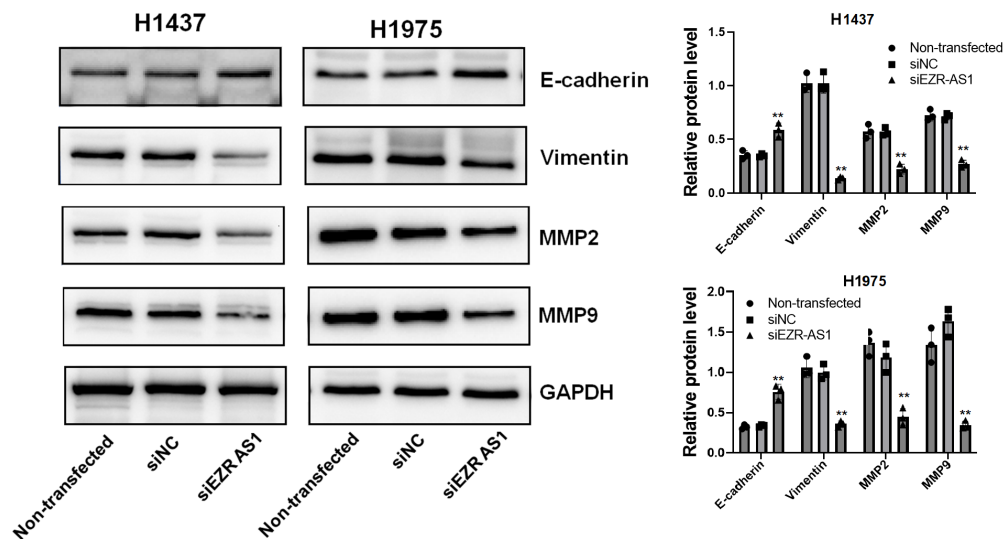
(si, small interfering RNA), siNC (NC, negative control) and pEZR-AS1 (positive control). All assays were repeated three times. **denotes $p<0.01$ compared to si-NC or non-transfected cells using one-way ANOVA.


Figure 4. Level of metastasis-related proteins in lung ADC cell lines H1437 and H1975 after transfected with siEZR-AS1.
Right panel: typical Western blots, **left panel**: statistical analysis of relative protein content. All assays were repeated three times. **denotes $p<0.01$ compared to si-NC or non-transfected cells using one-way ANOVA.

The band imaging showed that the levels of these proteins were all significantly downregulated, except for E-cadherin, which was significantly upregulated compared to the controls ($p<0.01$; Fig. 4).

DISCUSSION

EZR-AS1 is implicated in disease progression in various cancers, such as cSCC, ESCC, breast cancer, and colorectal cancer (Bai *et al.*, 2018; Liu *et al.*, 2019; Lu *et al.*, 2021; Peng *et al.*, 2017), its biological role of EZR-AS1 in lung ADC is largely unknown. In the present study, it was found that EZR-AS1 levels were significantly elevated in lung ADC tissues and cells compared to those in non-cancerous tissues and cells. After transfection with siEZR-AS1 specifically targeting EZR-AS1, EZR-AS1 levels in the lung ADC cell lines H1437 and H1975 were significantly downregulated compared to the controls. After EZR-AS1 knockdown, the viability and migration rates of H1437 and H1975 cells were remarkably reduced, while apoptosis was significantly increased. EZR-AS1 knockdown also leads to the altered expression of migration-related genes, thus reducing the migration ability of lung ADC cells and affecting ADC progression.

Previously, it was found that silencing EZR-AS1 inhibits TGF-β-mediated signaling, leading to reduced growth and EMT of colorectal cancer cells (Liu *et al.*, 2019), and EZR-AS1 knockdown significantly reduced phosphorylated (p)-PI3K/PI3K and p-AKT/AKT levels in cSCC, leading to reduced cell viability and migration ability (Lu *et al.*, 2021). Furthermore, silencing EZR-AS1 significantly suppressed the migration, tumorigenicity, and metastatic lymph nodes of ESCC cells in mice (Zhang *et al.*, 2018). In the present experiments, we first profiled the level of EZR-AS1 mRNA in lung ADC and revealed that EZR-AS1 was higher in both ADC tissues from patients and cells established from ADC patients than in non-cancer tissues and cells. This is consistent with previous findings in cSCC, ESCC, breast cancer, and colorectal cancer (Bai *et al.*, 2018; Liu *et al.*, 2019; Lu *et al.*, 2021; Peng *et al.*, 2017), further confirming that EZR-AS1 is deregulated in cancer cells and involved in cancer progression.

To evaluate the effect of EZR-AS1 knockdown on the malignant behavior of ADC cancer cells, we transfected two ADC cell lines with siRNA specific for EZR-AS1 using Lipofectamine-mediated transfection. RT-qPCR analysis revealed that in siEZR-AS1-transfected cells, EZR-AS1 mRNA levels were significantly lower than those in the controls (both non-transfected cells and siNC-transfected cells), demonstrating that siEZR-AS1 is effective in specifically knocking down EZR-AS1. Subsequent analysis revealed that ADC cell viability was significantly reduced following EZR-AS1 silencing, suggesting that EZR-AS1 is likely essential for the occurrence and development of ADC. lncRNAs have been shown to play various roles in cancer occurrence, development, growth, invasion, migration, and prognosis (Bhan *et al.*, 2017; Peng *et al.*, 2017). They can either promote or inhibit the proliferation and metastasis of cancer cells, and knockdown of lncRNAs often results in suppression of cancer cell proliferation(Kong *et al.*, 2019; Zhen *et al.*, 2018). Apoptosis is an important process that regulates tumorigenesis and cancer development (Wong, 2011). Increased apoptosis is often associated with reduced proliferation and viability of cancer cells (Kou *et al.*, 2020). For example, lncRNA NEAT1 knockdown inhibits cell proliferation and increases caspase 3 activity and apoptosis in hepatocellular carcinoma (HCC) cells (Kou *et al.*, 2020), and downregulation of lncRNA MAGI2-AS3 inhibits proliferation and triggers apoptosis in prostate cancer by acting as a microRNA-424-5p sponge (Wei *et al.*, 2022). Previously, downregulation of EZR-AS1 was found to increase apoptosis in breast cancer cells by modulating the Wnt/β-catenin pathway (Bai *et al.*, 2018) and in colorectal cancer cells by inhibiting transforming growth factor-β signaling (Liu *et al.*, 2019). These findings were consistent with our data. Apoptosis is also associated with the expression of specific proteins such as Bax, Bcl2, and cleaved-caspase3. In EZR-AS1 knockdown cSCC cells, Bax was significantly upregulated and Bcl-2 was significantly reduced, suggesting that EZR-AS1 likely functions as an oncogene that contributes to the malignancy of lung cancer (Lu *et al.*, 2021).

Several mechanisms have been reported in EZR-AS1-knockdown-induced loss of cell viability. Lu *et al.* found that the inhibition of the PI3K/AKT signaling path-

way was associated with EZR-AS1-knockdown-induced reduction in cell viability and increase in apoptosis in SCC13 and SCL-1 colon cancer cells (Lu *et al.*, 2021). Using LncTar, a software for predicting lncRNA-RNA interactions by means of free energy minimization, they found that focal adhesion kinase (FAK) is a target of EZR-AS1, and FAK is a crucial regulator in PI3K/AKT signaling pathway and its expression was suppressed after EZR-AS1-knockdown. This might be the reason that the PI3K/AKT signaling pathway is deactivated after EZR-AS1-knockdown. This signaling pathway plays a critical role in cell survival and in protecting cancer cells from apoptosis (Xu & Zhang, 2021). In breast cancer, EZR-AS1 protected β-catenin from degradation and EZR-AS1 knockdown inactivated the Wnt/β-catenin pathway (Bai *et al.*, 2018). Since cyclin D1 and c-Myc are target genes of β-catenin, EZR-AS1 knockdown would downregulate the expression of cyclin D1 and c-Myc leading to reduced cell viability and migration (Saroha *et al.*, 2022). Needless to say, more experiments such as ribonucleoprotein Immunoprecipitation (RIP) and chromatin immunoprecipitation (ChIP) may be carried out to further confirm and elucidate the mechanisms associated with the biological functions of EZR-AS1-knockdown.

Metastasis and treatment resistance are the main reasons for clinical recurrence and poor prognosis in patients with ADC. Several genes, such as RHOB and MMPs, and signaling pathways, such as the TGF-β/Smad signaling pathway, have been identified as metastatic effectors in ADC. Wound-healing experiments showed that after EZR-AS1 downregulation, the migration rate of ADC cells was significantly reduced, suggesting that silencing EZR-AS1 may regulate the expression of metastasis-related genes such as MMP2 and MMP9, as reported previously (Lu *et al.*, 2021). To confirm this is true for lung ADC cells, we also examined the levels of several metastasis-related proteins such as E-cadherin, vimentin, MMP2, and MMP9, in the cells after EZR-AS1 knockdown. E-cadherin is important for maintaining cell integrity, and reduced E-cadherin expression can lead to EMT events (Guilford, 1999; Wells *et al.*, 2008). Our analysis demonstrated that E-cadherin level was upregulated in EZR-AS1 knockdown-cells with reduced migration ability. It is possible that the increased E-cadherin may result in mesenchymal to epithelial reverting transitions (MErT) (Chao *et al.*, 2010). When E-cadherin is upregulated in bladder cancer cells, growth and metastasis are inhibited as a result of deactivation of the β-catenin/TCF target genes (Li *et al.*, 2018). As such, the upregulation of E-cadherin has been explored as a therapeutic option in cancer treatment (Howard *et al.*, 2008).

In addition, vimentin expression was downregulated following EZR-AS1 knockdown. Vimentin codes for one of the 71 human intermediate filament (IF) proteins that are required for the migration of cancer cells that have undergone EMT. Vimentin can integrate the mechanical input and signals from the surrounding environment to promote cell migration and various other signaling pathways, such as the AKT pathway, also participate in regulating the migration of cancer cells through vimentin (Sim *et al.*, 2021). The gene is highly expressed in various epithelial cancers, including prostate, gastrointestinal, and cervical cancers (Lin *et al.*, 2017; Satelli & Li, 2011). Overexpression and silencing of vimentin by manipulation of URI (unconventional prefoldin RPB5 interactor) expression increases or decreases the migration and invasion ability of cervical cancer cells, respectively and vimentin knockdown by vimentin small hairpin RNA de-

creases colorectal cancer (CRC) cell migration (Wang *et al.*, 2021).

Matrix metalloproteinases (MMPs) are prominent proteinases associated with tumorigenesis. They regulate signaling pathways that are responsible for cell growth, inflammation, and angiogenesis in a non-proteolytic manner and are involved in EMT, a crucial step in the invasion and migration of tumor cells, because they decompose and modify the extracellular matrix (ECM) and cell-to-ECM and cell-to-cell interface contacts, facilitating the detachment and separation of epithelial cells from the surrounding tissue (Radisky & Radisky, 2010). MMP2 and MMP9 are particularly potent in digesting the components that make up the basement membrane, such as laminin and collagen IV, or interstitial collagen fragments, resulting in cancer metastasis (Barillari, 2020; Cui *et al.*, 2017; Vandooren *et al.*, 2013). Our study showed that EZR-AS1 knockdown reduced MMP2 and MMP9 expression, which could be partially responsible for the reduced cell migration ability observed in siEZR-AS1-transfected ADC cell lines.

CONCLUSION

Taken together, our results demonstrated that EZR-AS1 is highly expressed in both lung ADC tissues and cells. Knockdown of EZR-AS1 with siRNA led to reduced cell viability, increased apoptosis, and reduced migration ability compared with the control. Alterations in the levels of metastasis-related proteins such as E-cadherin, vimentin, MMP2, and MMP9 likely contribute to the reduced migration ability after EZR-AS1 knockdown. Since silencing of EZR-AS1 results in reduced ADC viability, this strategy should be explored in animal models to confirm the therapeutic effect for potential application in human ADC therapy.

Could the lake ecosystems influence the pathogenicity of the SARS-COV-2 in the air?

Janusz Boratyński✉

Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Biomedical Chemistry "Neolek", 53-114 Wrocław, Poland

During the first 200 days of the Covid-19 pandemic in Poland, lower morbidity and mortality due to SARS-COV-2 infection were recorded in three regions covered by many small and large lakes (West Pomerania 5.8 deaths/100 000 population, Warmian & Masurian 7.6 deaths/100 000 population, Lubusz 7.3 deaths /100 000 population, compared to Poland average of 16.0 deaths/100 000 population). Moreover, in Mecklenburg (Germany), bordering West Pomerania, only 23 deaths (1.4 deaths/100 000 population) were reported during the same period (Germany 10 649 deaths, 12.6 deaths/100 000 population). This unexpected and intriguing observation would not have been noticed if SARS-CoV-2 vaccinations were available at that time. The hypothesis presented here assumes the biosynthesis of biologically active substances by phytoplankton, zooplankton or fungi and transfer of these lectin-like substances to the atmosphere, where they could cause agglutination and/or inactivation of pathogens through supramolecular interactions with viral oligosaccharides. According to the presented reasoning, the low mortality rate due to SARS-CoV-2 infection in Southeast Asian countries (Vietnam, Bangladesh, Thailand) could be explained by the influence of monsoons and flooded rice fields on microbiological processes in the environment. Considering the universality of the hypothesis, it is important whether the pathogenic nano- or micro particles are decorated by oligosaccharides (as in case of the African swine fever virus, ASFV). On the other hand, the interaction of influenza hemagglutinins with sialic acid derivatives biosynthesized in the environment during the warm season may be linked to seasonal fluctuations in the number of infections. The presented hypothesis may be an incentive to study unknown active substances in the environment by interdisciplinary teams of chemists, physicians, biologists, and climatologists.

INTRODUCTION

The global COVID-19 pandemic has led to an unprecedented mobilization of the scientific community. This defence is taking place on multiple fronts, similar to military operations, and the ongoing battle constantly brings new strategies into play. Pioneering research on transfection of conglomerates of mRNA and cationic lipids initiated by Robert Malone in 1987 (Malone *et al.*, 1989) and the intuition, perseverance, and efforts of Katalin Karikó (Karikó *et al.*, 2008), Uğur Şahin and Collaborators ushered perspectives for RNA vaccines (Niknam *et al.*, 2022; Dolgin, 2021; Yin *et al.*, 2022). In 2020 Food and Drug Administration office (USA) issued an emergency use authorization for RNA vaccines to the Pfizer–BioNTech and Moderna companies.

Independently, the effectiveness of many substances, ranging from low-molecular compounds to proteins, including antibodies and plasma of convalescent plasma therapy, has been tested. The first large-scale use of the convalescent plasma therapy was to stop the rinderpest epidemic in Poland in 1921 (Orzechowska *et al.*, 2018). For therapeutic use in humans, plasma is sterilized with oxidants that modify methionine and tryptophan residues. This may result in the weakening of the effector activities of antibodies, including their interaction with the Fc receptor and complement activation (Mo *et al.*, 2016). Therefore, it may be necessary to move away from routine sterilization technologies and reassess the effectiveness of improved plasma preparations (Li *et al.*, 2020; Pan *et al.*, 2022). Figure 1 illustrates the participation of the environment (bodies of water, atmosphere, pollens) that may modulate the activity of SARS-CoV-2 virus (Kisajno Lake, Warmia & Masurian Region, Poland) © Worldisbeautiful.eu)

MATERIALS, OBSERVATIONS, AND DISCUSSION

The hypothesis of influence of aquatic plankton and fungi on airborne pathogen agglutination/inactivation (referred to hereafter as "the hypothesis") is based on official reports, perceptiveness, and reflection. Although some conclusions may seem controversial, in the Author's view, they should inspire further investigations. Analyses of the course of the pandemic were prepared by Michał Rogalski (Report based on data from the Ministry of Health, Rogalski, 2022). During the initial stages of the pandemic, significantly fewer infections and deaths were recorded in three regions of Poland (LU, W&M, WP) as compared to the rest of Poland.

Figure 2 illustrates the epidemiological situation in Poland during the first 200 days of the COVID-19 pandemic. The curves are a collection of 2281 independent points, each of which represents one human tragedy. The chart is therefore a tribute to those who died during the global COVID-19 pandemic around the world.

Two events may be important for the hypothesis construction:

- 1. Despite the enormous effort of science the introduction of vaccination was not immediate and did not obscure the observation of the first period of pandemic progression,
- 2. The winter of 2019/20, preceding the pandemic in Poland, was mild and the lakes in question did not freeze. The liquid water, in which the microorganisms lived, was constantly in contact with the air, and the transport of biomass could happen all the time. Therefore, the alleged "antiviral substances of lake origin" could protect the inhabitants of the land of the lakes.

Statistical significance of the difference between mortality curves for lake districts and the rest of Poland was calculated in GraphPad Prism using Akaike's (Bozdogan, 2000) Information Criterion. Differentiation between the curves for each data set is >99.99%. (Poland lake districts – blue line: Y=0.0072×–0.1999. R²=0.943, the rest of Poland – red line: Y=0.0355×–0.3074. R²=0.9772) indicating a limited progression of the disease in areas covered with lakes

(LU+W&M+WP) compared to the rest of Poland. However, after 200 days of the pandemic, significant perturbations appeared. After this period, both insolation and temperature decreased, which affected the biological life in the lakes (Edwards *et al.*, 2016).

The further course of the pandemic is shown in the Fig. 3A and 3B and Table 1. Figures 3A and 3B show the ratio of the officially recorded data of SARS-CoV-2 infections or deaths in Poland to the numbers of infections in lake-covered regions for the first year of the pandemic. The ratio of (LU+W&M+WP)/PL shows differences in the dynamics of the pandemic in lake districts compared to the rest of Poland. The intersection of the blue and red curves coincides with the onset of temperatures at which the lakes reach their freezing point. The data may suggest the possibility of a protective role of lakes during the COVID-19 pandemic. Paradoxically, the protective role of lakes presumably delayed the induction of herd immunity, contributing to an increase in infections and deaths in the cold period while the lakes froze (winter 2020/21).

Figure 3A. Coronavirus infections/100 000 population in (LU+W&M+WP) (blue) and in the rest of Poland [PL- (LU+W&M+WP)] (red).
The bold purple line shows the ratio between cases per 100 000 population in the (LU+W&M+WP) and the cases in the rest of Poland (May 2020/March 2021). It should be added that the official reports on the number of SARS-CoV-2 infections in Poland can be considered as estimates (data for May 2020–March 2021).

Figure 2. Cumulative mortality per 100 000 population during the first 200 days of the COVID-19 pandemic in Poland (from March 2020 to 19 September 2020).
Blue line: deaths per 100 000 inhabitants in "lake-rich regions": LU+W&M+WP, red line: deaths per 100 000 inhabitants in the rest of Poland (source data: Rogalski, 2022). Statistical significance (different curves for all data set >99.99%). was calculated using GraphPad Prism, Akaike's Information Criterion (Bozdogan, 2000).

The impact of the inland water ecosystems and climate in neighbouring and distant countries on the COVID-19 pandemic

To further evaluate this hypothesis, the epidemiology of COVID-19, as of October 2020, was analysed in countries neighbouring Poland and having similar climate and inland water reservoirs. The observed mortality per 100 000 population in the five chosen regions was as follows: Lithuania, 4.0**, Latvia, 2.5**, Estonia, 5.3**, Finland, 6.2** (Worldometer COVID-19, 2023), Kaliningrad Oblast, 9.7**, while in the reference regions it reached 21.6** in Europe and 17,5** in Russia (Development of Number of Coronavirus, Russia, 2022). Due to the impact of soil and lakes acidification, Sweden was excluded from the present considerations (Almer & Dickson, 2021). As shown in Fig. 4 during the first period of the pandemic, each of the five analysed regions reported low mortality rates from COVID-19. For example, in Mecklenburg-Vorpommern, a German land bordering Western Pomerania and rich in lakes, only 23 (1.43**) deaths were recorded until November 1, 2020, while, at the same time, the mortality rate for the entire Germany amounted to 10 649 (12.8**) deaths. Also

Figure 4. Map of the selected fragment of Central Europe: (1) W&M – Warmian & Masurian (Poland), (2) WP – West Pomerania (Poland), (3) LU – Lubusz (Poland), (4) Mecklenburg (Germany), (5) Kaliningradskaja Obłast (Russia), (6) Lithuania, (7) Latvia, (8) Estonia, (9) Finland, (10) Sweden.
The map was made using ArcGIS 10.7.1 software and the geographical data were taken from WWF and Eurostat databases (https://www.worldwildlife.org/pages/global-lakes-and-wetlands-database, https://ec.europa.eu/eurostat/web/gisco/geodata).

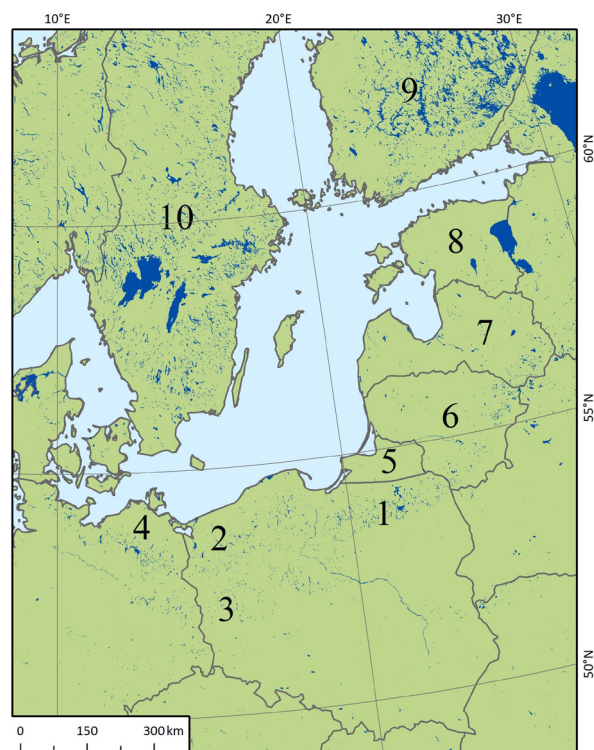
later, the pandemic situation in Mecklenburg (62.5**) remained more favourable than in the rest of Germany where it amounted to 101.6** (83292) deaths (2 May 2021). (Development of number of Coronavirus cases: Mecklenburg-Vorpommern, Germany, 2022)

In addition, the progression of the pandemic was analysed in three Asian countries: India, Bangladesh (Beaney et al., 2021), and Iran. These countries differ in climate and population density, which amounts to 460, 1260 and 52 inhabitants/km², respectively The official COVID mortality data for the period from the beginning of the pandemic to November 14, 2022 are as follows: India 37.7**, Bangladesh 17.5**, and Iran 168.2** (Worldometer COVID-19 Coronavirus Pandemic, 2023). These numbers, opposite to expected in terms of the relationship between population density and mortality due to COVID-19, prompt discussion. Two of the distinguishing features of these countries, apart from population density, are climate and rainfall. Bangladesh has tropical-monsoon warm climate, India is a hot tropical country, and Iran is mainly arid and semiarid. In the context of the presented hypothesis, the spread and growth of phytoplankton, zooplankton and fungi in rice-growing areas cannot be overlooked (Nam et al., 2022, Anyanwu et al., 2001). For example, in Bangladesh, rice fields cover over 7% of the country's land area. Other global rice producers also show low mortality due to COVID-19 (for example: Thailand – 47.4**, Vietnam – 43.6** (December 2022).

Moreover, in the light of this hypothesis, the microbiological status of the warm seas of Southeast Asia should also be considered (Cochran et al., 2017; Gao et al., 2021).

Therefore, it would be interesting to study and compare the antiviral properties of substances produced and released into the atmosphere by phytoplankton, zooplankton, and fungi in various climatic zones in Central Europe, Southeast Asia, Canada, etc.

Transfer of lake biomass into the atmosphere.

The aquatic environment is in constant equilibrium with the atmosphere. I assume that phytoplankton, under the influence of wind and waves, is blown off the surface of lakes or thrown out onto the coastline of small and large lakes to undergo biodegradation, biotransformation, drying, etc., and is disseminated by wind in the local atmosphere. In the case of the Great Lakes in the USA, biological matter from the lakes was found about 25 km from the coastline (May et al., 2018). Moreover, gas bubbles from the depths of the lakes transfer biological matter to the surface of water. These bubbles burst upon reaching the air/water boundary, transferring biomass into the atmosphere (Blanchard & Syzdek, 1970, Cochran et al., 2017, Kim et al., 2020). This can be compared to the behaviour of bubbles on the surface of carbonated beverages. A pioneering study on the transfer of biological matter (B. fluorescens liquefaciens and B. fluorescens putidus) from water reservoirs to the atmosphere was conducted in 1887 by Odo Bujwid (Bujwid, 1887).


The interaction of gas bubbles with the matter present in aqueous environment is a multifaceted process widely used in flotation technology (Krasowska, *et al.*, 2019). The surroundings of the lakes are sometimes accompanied by a subtle odor, which can result from biological life in the lakes. Phytoplankton content in Polish lakes fluctuates qualitatively and quantitatively from year to year and month to month (Napiórkowska-Krzebietke & Hutorowicz, 2006).

Cyanobacteria (blue–green algae), a constituent of phytoplankton, produce chemically diverse antiviral compounds such as lectins, cyclic peptides, lipopeptides, fatty acids, alkaloids, and saccharides (Codd *et al.*, 2016, Mazur-Marzec *et al.*, 2021, Sami *et al.*, 2020, Singh *et al.*, 2017). Aggregates of blue-green algae in water often display compact, strong, spongy structures resulting from specific and nonspecific interactions with a variety of macro- and nanomolecules.

For a long time, it was believed that lectins play a role in the plant world only. The overthrow of this dogma in 1975 opened new perspectives in science, medicine, and technology. The antiviral activity of lectins against SARS-CoV-2 has been investigated, but all studies have been conducted in an aquatic environment (Wang *et al.*, 2021, Gupta & Gupta, 2022, Nabi-Afjadi *et al.*, 2022, Stravalaci *et al.*, 2022, Simplicien *et al.*, 2022).The virus, being molecularly dispersed in air (Greenhalgh *et al.*, 2021, Nissen *et al.*, 2020), could interact with water (moisture) and/ or with organic and inorganic pollutants (Yang & Marr, 2020, Domingo & Rovira, 2020, Ishmatov, 2022, Damialis *et al.*, 2021, Rzymski *et al.*, 2022).

From the perspective of the presented consideration, the key point would be to investigate the interaction between viral oligosaccharides (Zhang *et al.*, 2021, Banerjee & Mukhopadhyay, 2016) and macro- and nanoparticles of lake origin in the air. A resulting hybrid nanoparticle, similar in architecture to a conjugate vaccine, could not only interact with the virus itself but could also activate the immune system.

The aim of this hypothesis is to explain the reasons for the lower COVID-19 infection and death rates in the lake-rich regions. Three regions of Poland (LU, W&M, WP) have a large number of lakes (covering 4.4% of the total region area) and low population density (70/km^2 *versus* 120/km^2 for the entire Poland). In Poland, the average population density relies on the number of cities rather than the uniform dispersion of the population. Moreover, the official population density reports do not include mass tourism to these lake areas. Despite many analyses, the search for consensus linking population density with pandemic progression is still ongoing (Moosa & Khatatbeh, 2021).

CONCLUSIONS

The hypothesis presented herein raises the following questions:
- How would the transfer of biological matter from the lakes to the atmosphere take place?
- How can the substances from phytoplankton potentially neutralize the SARS-CoV-2 virus?
- What is the epidemiological situation in Poland and its neighbouring lake-rich countries?
- What could be the practical consequences of the existence of antiviral bio-aerosols?

It should be added that the official reports on the number of SARS-CoV-2 infections in Poland can be considered as estimates. The observed fluctuations in the number of infections may be due to the seasonal presence of biological substances released into the environment. For example, it was shown that the presence of pollen in the air correlates with increased COVID-19 morbidity (Damialis *et al.*, 2021).

The type of chemical supramolecular bonds between a virus and a carrier (hydrogen bonds, van der Waals forces, ion-ion, and π-cation interactions) may be crucial for its biological activity. Hypothetically, interactions of pathogens with airborne contaminants could contribute to viral infectivity in two different ways. If, as a result of the interaction, the virulence factors are not blocked, the pathogen's activity may increase (Damialis *et al.*, 2021) in a mechanism of avidity. Conversely, if the molecules critical for viral infectivity are blocked, pathogenicity may be reduced.

The moderate sensitivity and selectivity of the interactions between lectins and sugars (Sharon & Lis, 2001) enables for the potential application of this mechanism to a broad range of viruses. If the mutations do not significantly alter the glycosylation of viral envelope, these "airborne lectins" could neutralize also the new strains (Markov *et al.*, 2022, Barre *et al.*, 2022). Interactions of pathogen's sugars with lectins in aerosols could contribute to local inactivation of the dispersed viruses. As an example, assuming this line of thinking is correct, the inactivation of the ASF virus could be a result of an interaction of its glycolipids (Del Val & Vinuela, 1986) or saccharides (Zhu, 2022) with molecularly dispersed lectins from selected legume seeds.

From a practical point of view, spraying of the nanocomponents present in phytoplankton in the air in populated areas (city centres, transportation vehicles, etc.) could entrap viral particles *via* lectin-virus interactions and lower the transmission rate at low cost and low risk. Hybrid nanoparticles (lectin-agglutinated viruses) suspended in the still air would sediment faster than virus particles alone, according to Stokes's law (though air turbulences would interfere with the sedimentation process) (Adamczyk, 2006). Agglutination and/or aggregation of viruses may affect their biological activity and modify their physicochemical properties (Gerba & Betancourt, 2017, Del Val & Vinuela, 1986, Szermer-Olearnik *et al.*, 2017).

The interpretation of the reasoning presented in the hypothesis goes beyond the environment of water bodies and includes the air temperatures.

This is prompted by the report on the course of the COVID-19 pandemic in 2020–2023 (Fig. 5).

Figure 5. Infectivity and mortality during the COVID-19 pandemic in Poland (2020–2023). Based on Worldometer COVID-19 Coronavirus Pandemic (2023).

Table 2. Infectivity and mortality during the COVID-19 pandemic in Poland in arbitrarily designated cold and warm periods of the year.

Period of year	Date	Average number of infections/day	Average number of deaths/day
Warm	01/05–01/10 2020	534	12.3
Cold	01/11–01/03 2020/21	10 800	316.6
Warm	01/05–01/10 2021	724	64.6
Cold	01/11–01/03 2021/22	21 550	290
Warm	01/05–01/10 2022	1 750	10.3
Cold	01/11-01/03 2022/23	676	6.4

Data source: Worldometer COVID-19 Coronavirus Pandemic (2023).

Comparing the infection rates in warm and cold seasons, it can be observed that low disease propagation was found in the warm periods and conversely, high incidence occurred in cold periods. The seasons of the year are arbitrarily determined (cold period: 1st Nov/1st March, warm period: 1st May/1st Oct). The reduced mortality observed at the end of 2022 may be due to the changes in the profile of viruses circulating in the environment.

Table 2 presents the influence of the seasons on the progression of the COVID-19 pandemic in Poland. According to the main idea of the hypothesis, this phenomenon could be explained by the release into the atmosphere of biologically active substances related to vegetation, agriculture, and putrefactive processes of decay, especially during warm periods (Góralska et al., 2022).

A similar correlation applies to the widely studied influenza. Viral hemagglutinins which are an integral part of viruses play a key role in the pathogenesis of infection through interactions with sialic acid terminated glycans.

One may ask why the number of flu cases decreases in the warm season. According to the hypothesis, one of the reasons that can be considered is the release of sialic acid derivatives into the atmosphere. Numerous bacteria species biosynthesize sialic acid polymers (González-Clemente et al., 1989) and fungi produce a variety of the derivatives of sialic acid (Alviano et al., 1999). These substances released into the atmosphere could agglutinate and/or neutralize influenza viruses.

Addressing these complex problems highlighted by the hypothesis presented here, would require interdisciplinary efforts in medicine, biology, chemistry, climatology, and biophysics. The first step could be the attempt at isolation of the alleged active substances from the atmosphere using electroseparators dedicated for biological components (Maineli et al., 2002). Another approach could be used to pass air through the filters containing immobilized oligosaccharides to specifically adsorb the sought-after biomolecules. The task of isolating the active substance from the air could prove similar in scale to the challenge of obtaining 8 mg erythropoietin from 2550 litres of urine (Miyake et al., 1987) (the value of the erythropoietin market in 2021 was USD 8.8 billion). The observation would not have been made if it had not been for two facts. Until January 2021, the progression of the pandemic was not hindered by vaccination programs as the introduction of vaccines followed the observed phenomena. Moreover, the winter of 2019/2020 was exceptionally warm and Polish lakes did not freeze for the first time in many years, enabling the "biology and biochemistry in water" to interact with the air constantly.

Appendix (Dec. 2022).

COVID-19 deaths/100 000 inhabitants: Poland 314** (LU 332**, WP 278**, W&M 326**), Finland 140**, Latvia 331**, Lithuania 355**, Estonia 213**, Germany 190**, Mecklenburg 162.5**, Canada 126** (more than 9% of Canada is covered by lakes), USA 332**, all countries 85.6** (Worldometer COVID-19 Coronavirus Pandemic, 2023).

Oil oxidation is important in terms of taste, nutritive component quality and toxic effect of the oil. In this study, the oxidized sunflower oil was used along with chia seed in rabbits for the determination of its effects on various hematological and serum biochemical parameters as well as on liver histopathology. Three rabbits were fed with oxidized oil (obtained by heating) at the dose rate of 2 ml/kg body weight by mixing it with green fodder. The other rabbit groups were fed with Chia seed at dose rate of 1, 2 and 3 g/kg along with oxidized sunflower oil. Chia seed was fed alone to three rabbits at the dose rate of 2 g/kg body weight. All rabbits were fed regularly for twenty-one days. For the determination of hematological and biochemical parameters, whole blood and serum samples were collected on different days during feeding period. For histopathology, liver samples were used. Significant changes ($p<0.05$) were noted in the hematology and biochemical indices in the rabbits that were fed with oxidized sunflower oil alone, and along with different doses of Chia seed. In a dose-dependent manner, all these parameters were significantly improved ($p<0.05$), when the amount of Chia seed was increased. The biochemical and hematological indices were in normal range in the group fed only with Chia seed. In oxidized oil fed group, liver histopathological analysis showed that cholestasis was present at both sides (bile pigment secretion) and zone 3 necrosis with mild inflammatory cells. Mild vacuolization of hepatocytes was also observed. In Chia seed fed group, hepatocyte vacuolization and mild necrosis was noted. It was concluded that oxidized sunflower oil alters the biochemical and hematological parameters and causes liver abnormalities. Chia seeds act as an antioxidant and retrieve those alterations.

Keywords: Chia seed, hematological parameters, oxidized sunflower oil, rabbits

INTRODUCTION

Vegetable oils and fats are important constituents of foods and are essential components of our daily diet (Brahmi *et al.*, 2020). Vegetable oils are obtained by mechanical expelling or solvent extraction of oleaginous seeds (soybeans, rapeseed, sunflower, etc.) or oleaginous fruit like palm and olive (Vidrih *et al.*, 2010). Vegetable oils generally contain triglycerides (about 98 g/100 g) (Qian *et al.*, 2020). Triglyceride is formed from a reaction between glycerol and fatty acids and other substances in a small proportion (Gnanaprakasam *et al.*, 2021). Some of them such as diglycerides, vitamins, phytosterols, tocopherols and polyphenols have important health benefits in humans (Gharby *et al.*, 2021; Chew *et al.*, 2016), and therefore, they should not be removed during processing. Other compounds known for their negative effect on the quality and stability of oils include free fatty acids, unsaponifiable matters, waxes, pigments, solid impurities (mainly fibers), oxidation products (peroxides, aldehydes, ketones, alcohols, and oxidized fatty acids) (Gharby *et al.*, 2016; Aliyar-Zanjani *et al.*, 2019; Said *et al.*, 2022). Several plants contain different chemicals which can be used for treatment of various diseases if they are consumed entirely or in parts with lower cost and less side effects (Sana *et al.*, 2022; Bisht *et al.*, 2021). Sunflower oil is one of the most widely grown essential oils in the world. The total world's oilseed production is forecasted at nearly 647 million tons (United States Department of Agriculture Foreign Agricultural Service Oilseeds: World Markets and Trade. 2022). In 1998, the world's seed oil was about 28.5 million tons and, as a vegetable oil, only soybean (*Glycine max*) and *Brassica* species (*Brassica napus* and *Brassica campestris*) produced more oil (Flagella *et al.*, 2002). Sunflower (*Helianthus annuus*) is used in food, for oil, as a dye, for medicinal purposes, and as an ornamental plant species. Sunflower oil has been used since ancient times as a food and as a medicinal plant to cure many ailments. From a dietary point of view, a diet enriched in monounsaturated fatty acids has been recommended to reduce cholesterol in blood plasma (Dimitrijevic and Horn 2018). Sunflower is often used to produce oils from seeds but is also used as a protein source for human consumption as well as food (Choe and Min 2006). Oil oxidation is important in terms of palatability, nutritional quality and acidity of edible oils. Various chemical compounds, autoxidation and photosensitized oxidation are responsible for the degra-

dation of edible oils during production and storage with respect to oxygen (Khan *et al.*, 2022; Knez *et al.*, 2019).

Salvia hispanica, also called Chia, is an annual herbaceous plant native to southern Mexico and northern Guatemala. It belongs to *Lamiales,* family Labiatae, subfamily Nepetoideae, and genus *Salvia* (Segura-Campos *et al.*, 2014). The *Salvia* genus comprises of about 900 species, which have been extensively distributed for thousands of years in many regions of the world, including South Africa, North, Central and South America, and Southeast Asia (Grancieri *et al.*, 2019; Ullah *et al.*, 2016; Campos *et al.*, 2016; Das *et al.*, 2018; Mohd Ali *et al.*, 2012).

Many studies have reported that Chia today is grown not only in Mexico and Guatemala, but also in Australia, Bolivia, Columbia, Peru, Argentina, America, and Europe. Today, Mexico is known as the largest producer of Chia in the world (Silva *et al.*, 2016). Chia is the dietary seed of *Salvia hispanica*, a flowering plant, known for its antioxidants that is often used in food production (Coorey *et al* 2016). Recently, Chia seeds have been given more consideration and have become one of the most popular foods in the world based on their medicinal values and nutritional properties (Ullah *et al.*, 2016; Das *et al.*, 2018; Mohd Ali *et al.*, 2012; Silva *et al.*, 2016). Coorey *et al.* (2016) demonstrated that Chia is an excellent food ingredient as it contains a huge amount of α-linolenic acid and is easily added to commercial foods. In addition to that it has also been reported that Chia seeds contain high percentage of fatty acids, which make it crucial for health, antioxidant, and antimicrobial property (Ullah *et al.*, 2016; Mohd Ali *et al.*, 2012; Ixtaina *et al.*, 2008; Reyes *et al.*, 2008). Furthermore, several other studies (Grancieri *et al.*, 2019; Silva *et al.*, 2016; Ixtaina *et al.*, 2008; Reyes *et al.*, 2008; Ayerza *et al.*, 2016; Muñoz *et al.*, 2012) demonstrated that the Chia is an oil seed composed of fats, carbohydrates, dietary fiber, proteins, vitamins (A, B, K, E, D), minerals and antioxidants and its benefits of using as a nutritional supplement are numerous, such as supporting digestive system, helping the intestinal mucosa, stronger bones, reducing the risk of constipation, irritable bowel disease, heart diseases, diabetes, and many more (Silva *et al.*, 2016; Correy *et al.*, 2016; Ixtaina *et al.*, 2008; Reyes *et al.*, 2008; Ayerza *et al.*, 2016; Muñoz *et al.*, 2012; de Falco *et al.*, 2018). In the region of Malakand, Khyber Pakhtunkhwa, Pakistan, different food items are fried and cooked using either ghee or oils. Persistent heating causes ghee and oil oxidation, hence, making it toxic. Therefore, the present study was aimed to check the toxic effects of oxidized sunflower (*Helianthus annus*) oil on hematological and biochemical parameters in rabbits. As Chia seeds (*Salvia hispanica*) are sources of one of the potent antioxidants, they were used to check its curing potential against the toxic effects of oxidized sunflower (*Helianthus annuus*) oil.

MATERIALS AND METHODS

Materials

Sunflower oil was purchased from local market of Matta, Swat, Khyber Pakhtunkhwa, Pakistan. The sunflower oil was selected based on its high linoleic acid and oleic acid content. Chia seeds and rabbits (*n*=60) were purchased in the local market of Chakdara, Lower Dir, Khyber Pakhtunkhwa. EDTA containing tubes and gel tubes were purchased from the local market for whole blood collection and serum isolation. Formaldehyde and chloroform were provided by organic chemistry laboratory, Department of Chemistry, University of Malakand.

Thermal oxidation of oil

Sunflower oil samples were subjected to a five-hour long regular heating on hot plates at 100°C. These samples were then kept at –20°C to prevent them from further chemical changes.

Experimental animal clustering and feeding

Rabbits were reared in Bio-park of University of Malakand. Food and water were freely available to all the animals. They had an average weight of 1200 grams at the start of the experiment, and among the 60 rabbits, 21 individuals were selected for the experiment based on body weight and health status. The study was started after the approval of the ethical committee, Department of Biotechnology, University of Malakand. Rabbits were divided into seven groups, each having three rabbits (*n*=3). Groups were labelled as NC, NO, OO, C, CO1, CO2 and CO3 representing negative control, normal sunflower oil, oxidized oil, Chia seed only, Chia seed with oxidized oil (low dose), Chia seed with oxidized oil (medium dose) and Chia seed with oxidized oil (high dose), respectively. The negative control group was fed with green fodder and water. NO was fed with normal sunflower oil at a dose of 2 ml/kg with fodder and water. Group OO was fed with oxidized sunflower oil at a dose of 2 ml/kg. Group C was given Chia seed at a dose of 2 g/kg. Group CO1 was fed with Chia seed at a dose of 1g/kg and oxidized sunflower oil at a dose of 2 ml/kg. Group CO2 was fed with Chia seed at a dose of 2 g/kg and oxidized sunflower oil at a dose of 2 ml/kg. Group CO3 was fed with Chia seed at a dose of 3 g/kg and oxidized sunflower oil at a dose of 2 ml/kg. The feeding was continued for 21 consecutive days and blood samples were collected at day 0, 11 and 21 for hematological parameters and serum biochemical parameters.

Hematological and serum biochemical parameters

The whole blood was used for the analyses of hemoglobin (Hb), platelets (P), white blood cells (WBCs), neutrophils (N), lymphocytes (L), monocytes (M), eosinophils (E) and basophils (B) count by using a fully automated blood hematology analyzer (ERBA – XL 1000). About 5 ml of blood was collected and transferred to gel tubes to isolate serum. The serum was used for the analyses of total triglyceride (TG), total cholesterol (C), blood glucose (S), alanine transferase (ALT), creatinine, urea, high density (HDL) and low density lipoproteins (LDL) level.

Histopathological examination of liver

At the end of the experiment, rabbits were slaughtered according to the method described by Hussain and others (Hussain *et al.*, 2022) and their liver was isolated and preserved in formalin buffer (10%). Tissues sectioning were made, stained and histopathologically examined as described by Khan and others (Khan *et al.*, 2022). Prepared slides were observed under the light microscope, model no. M 7000 D (SWIFT, Japan) and images were taken by a digital camera coupled with a microscope with a resolution of 2.4 Mpixel.

Table 1. Effect of oxidized sunflower oil and Chia seed on different hematological parameters in rabbits on different days.

Statistical analysis

Data were analyzed by one way analysis of variance (ANOVA) and Tukey test using online statistical software, prism demo version 05 (www.graphpad.com). Data were presented as mean from triplicate results (*n*=3) with standard deviation. The mean and standard deviation were sorted out for each parameter.

RESULTS

Effects on hematological parameters

Results showed no significant effect (*p*<0.05) on the Hb level; however, the platelet count remarkably decreased in all groups after the 21st day. The platelet count was the lowest in the CO3 group. Similarly, no significant change was observed for neutrophils and lymphocyte count. The monocyte count doubled in both CO2 and CO3 groups. The eosinophile number increased in all groups, but such increase was not remarkably high. The results from all measurements (day 0, 11th and 21st day) were combined in Table 1. Different biochemical parameters of the rabbits were shown in Fig. 1.

Effects on biochemical parameters

The glucose level was significantly (*p*<0.05) high in the oxidized oil (OO) group; however, groups C and CO1 also reflected substantial elevated sugar level. The urea level remained the same in all groups except for CO3 that showed a significant decrease at 21st day. The SGPT/ALT level were significantly (*p*<0.05) increased in all groups, especially among OO, C, CO1, CO2, and

CO3 variants. After the 21st day, the cholesterol levels in NC, NO and CO2 groups remained almost like day 0 values. However, in the OO group, the cholesterol level was high, and the result was the opposite in the C group, wherein cholesterol levels decreased. In CO1 variant, the total cholesterol level significantly (*p*<0.05) increased, as compared to CO3, where the cholesterol level decreased on the 21st day. The triglyceride values were significantly (*p*<0.05) elevated in all groups, but they were remarkably high in OO, CO1, and CO2 variants. The HDL levels in all groups showed no significant change. The LDL levels increased in all groups except CO3 wherein, a significant decrease was noted; pertinent to mention, the OO group showed the most negatively correlated LDL values. The results of biochemical parameters on days 0, 11 and 21 were combined in Table 2.

Histopathological pattern

At the end of the experiment, the rabbits were slaughtered, and liver samples were collected for the histopathological analysis. Liver slides were studied under 10X and 40X magnitude for detailed histopathological changes. Results have been presented in Fig 2. Liver histopathology of control variant showed that endothelial linings of central veins had normal morphology, and no evidence of pericentral fibrosis was noted. Kupffer cells were non-reactive. The orientation of the hepatic cord was very good. Hepatic portal veins and arteries showed a normal structure (Fig 2A). On the contrary, in the oxidized oil fed group, cholestasis was present on both sides (bile pigment secretion). Zone 3 necrosis with mild inflammatory cells was noted. Mild hepatocytic vacuolization was also observed (Fig 2B). However, in the normal oil fed group, there was mild zone 2 necro-

sis especially central vein inflammation and fatty changes (Fig 2C). In Chia seed fed group, there was hepatocyte vacuolization and visible signs of mild necrosis (Fig 2D).

DISCUSSION

It is common practice to repeatedly heat vegetable oils at high temperatures during cooking. Oils are heated during food preparation or deep frying. The present study aimed to sort out the effect of Chia seed against oxidized sunflower oil in rabbits. In our findings, lymphocyte count was significantly increased, while there was a low number of platelets, neutrophils, and monocytes after feeding with oxidized oil as compared to control. The results for these parameters were similar to control ones when fed with Chia seeds. Similar to our results, fresh palm oil was fed to rats, and it was observed that heated oil decreased PCV, Hb level, RBCs and increased WBCs (Mesembe *et al.*, 2004). Similarly, oxidized olive oil significantly altered hematological parameters in rats (Khan *et al.*, 2017). No effects of repeatedly heating cooking oil were observed on hematological parameters after its administration to Wistar rats (Shue *et al.*, 1968; Perumalla *et al.*, 2016), which is not in accordance with our findings. In our study, we heated the sunflower oil for 5 hours at 100ºC which may have led to the accumulation of free radicals and altered the hematological parameters. The consumption of Chia has shown good digestibility, hypoglycemic effects, improved lipid and glycemic profiles, and reduced fat deposition in the animal liver.

There was a statistically significant increase in creatinine and urea level in rabbits that were fed with oxidized sunflower oil, and the Chia seed reduced their levels to normal. The co-administration of oxidized oil and Chia seed decreased the creatinine and urea level in a dose-dependent manner. Much of the toxicity of severely heated food oils has been associated with a non-urea-adducting fatty acid (urea filtrate) fraction (Shue *et al.*, 1968; Billek *et al.*, 2000). Certain fractions of the heated oils, the total polar materials cause growth retardation, increased liver and kidney weights and disorders of the enzyme system, but only if fed in high doses (Billek *et al.*, 2000; Ani *et al.*, 2015).

The significant increase in serum creatinine concentration in the group fed with thermo-oxidized palm oil may be suggestive of possible renal system damage. Creatinine levels in plasma are usually measured to determine acute or chronic renal insufficiency. They are usually raised in renal disease (Ani *et al.*, 2015; Toscano *et al.*, 2014). Chia seeds contain high fiber and linolenic fatty acid which may reduce the creatinine level of the rabbits. *Salvia hispanica* controls blood pressure (BP) and its associated cardiometabolic factors. Also, Chia flour could reduce ambulatory and clinical BP in both treated and untreated hypertensive individuals (Toscano *et al.*, 2014; Al-Othman *et al.*, 2006).

For rabbits fed with un-oxidized sunflower oil, the ALT level was normal. Oxidized sunflower oil increased ALT level in rabbits. In the group which was fed with Chia seeds, ALT level was in normal range. Oxidized oil promotes serum ALT level significantly (Khan *et al.*, 2017; Al-Othman *et al.*, 2006; Zeb *et al.*, 2019), leading to hepatotoxicity. Unoxidized oil is beneficial for liver as it has oleuropein that protects hepatocytes from damage. It had been observed that oxidative stress induced by rancid oils leads to liver injury, which caused an increase in the ALT level (Zeb *et al.*, 2019; Aguilera *et al.*, 2002). In

our study, unoxidized oil had no effect on cholesterol level, while oxidized sunflower oil elevated the cholesterol level in rabbits. Chia seeds had a positive effect on lowering blood cholesterol level. Similar to our results, blood cholesterol levels were increased by oxidized olive oil in rats (Khan *et al.*, 2017; Kritchevsky *et al.*, 2000) and by oxidized sunflower in rabbits (Khan *et al.*, 2022). The Chia seed significantly decreased serum cholesterol level when compared to oxidized and un-oxidized sunflower oil treatments. Oxidized sunflower oil elevates the blood cholesterol level, while chia seed decreases its level. After absorption, it increases serum cholesterol level and may lead to atherosclerosis (Lou *et al.*, 2012).

The oxidized sunflower oil fed group significantly increased the triglyceride level of rabbits, while Chia seed decreased the triglyceride level in rabbits. Thermally oxidized oils keep users at risk to arteriosclerosis and cardiovascular diseases due to the depletion of phenolic as well as antioxidants in its constituents. A significant ($p < 0.05$) increase in the triglyceride level was observed when rabbits were fed with the oxidized olive oil (Khan *et al.*, 2017), oxidized sunflower oil (Zeb *et al.*, 2017) and mustard oil (Carmena *et al.*, 1996). The HDL concentration after feeding with oxidized sunflower oil was significantly decreased, whereas LDL values were increased as compared to normal group. Chia seed significantly increased HDL and decreased LDL level in rabbits. It has been suggested that HDL cholesterol and its constituents is increased after feeding sunflower oil, which helps in prevention of heart diseases (Lou *et al.*, 2012; Carmena *et al.*, 1996; Quiles *et al.*, 1998). A significantly higher LDL susceptibility to oxidation was observed after sunflower oil intake in comparison with virgin olive oil, despite an increase in LDL α-tocopherol concentration in sunflower oil group (Aguilera *et al.*, 2004). Histological studies revealed that un-oxidized sunflower oil caused no significant effect on the liver morphology and functions. Oxidized sunflower oil caused necrosis in centrilobular regions. It has also been reported that thermally oxidized ground nut oil leads to some liver diseases (Aguilera *et al.*, 2004; Jimoh *et al.*, 2004; Abdel Raouf *et al.*, 2012). On the other hand, Chia seed caused no significant changes, as hepatocyte vacuolization and mild necrosis were present in the liver.

CONCLUSIONS

In comparison to unoxidized oil, it has been determined that oxidized sunflower oil significantly affects hematological and biochemical parameters of serum and alters liver histological pattern in rabbits. Chia seed on the other hand, minimizes harmful effects of oxidized oil and display antioxidant potential.

Box 2455, Riyadh 11451, Saudi Arabia; [5]University College of Pharmacy, University of the Punjab, Lahore, Pakistan

Gastric ulcer is the most prevalent disorder affecting a large population. *Rosa brunonii* Lindl. fruit (RBF) has traditionally been used to treat stomach pains. Therefore, the current work aimed to isolate, characterize, and investigate the gastro-protective effect of *Rosa brunonii* Lindl. fruit chloroform extract (RBFCE) against ethanol-induced gastric ulcers in rats. Quercetin 3-O-glucoside (QUE-G) was isolated and characterized by modern spectroscopic techniques. RBFCE was orally administered at 250 mg/kg, 500 mg/kg, and 750 mg/kg doses for ten days. Gastric ulcer was induced by a single dose of absolute ethanol (5 ml/kg) on the last day of the study. Histological changes were calculated, along with ulcer inhibition and the ulcer index (UI). Gastric juice volume, pH, acidity, mucus content, and protein content were evaluated to understand the mechanism underlying its gastroprotective effect. Omeprazole (OMP) was used as the positive control. RBFCE at a dose of 750 mg/kg significantly ($p<0.01$) reduced the UI (3.54) and increased the protection rate (67.63%) compared to the negative (ulcer) control group. Treatment with RBFCE in a dose-dependent manner increased the gastric pH, mucus content, and total protein while decreasing gastric juice volume and total acidity. Histopathological studies showed severe gastric mucosal injury and edema in ulcer control animals compared to extract-treated groups. This study demonstrated that oral administration of RBFCE possesses a significant gastroprotective effect due to its anti-secretory and cytoprotective mechanisms. Our findings support the traditional use of RBF to treat the gastric ulcer.

Keywords: gastroprotective, *Rosa brunonii* Lindl. fruit, ulcer, quercetin 3-O-glucoside

INTRODUCTION

Gastric ulcer is one of the common digestive disorders affecting 10% of world population. It is a complex and multifactorial disease, characterized by pathological lesion in digestive tract, gastrointestinal bleeding, perforations and erosions of gastric mucosa (Saranya *et al.*, 2011). It occurs as a result of imbalance between invasive and defensive factors. Stress, smoking, alcohol consumption, nutritional deficiencies, infection by *Helicobacter pylori* (Yu *et al.*, 2022) and use of non-steroidal anti-inflammatory drugs (NSAIDs) cause imbalance in the gastric acid, pepsin, mucus secretion, prostaglandins and sulfhydryl compounds (Zakaria *et al.*, 2016b). The imbalanced secretions cause mucosal damage, which can lead to perforations and bleeding if not treated properly (Yuan *et al.*, 2006; Balan *et al.*, 2014; Kangwan *et al.*, 2014; Khoder *et al.*, 2016; Kim *et al.*, 2019). Conventional pharmacotherapeutic treatments for gastric ulcers include acid suppressants, that may have certain side effects like impotence, osteoporotic bone fracture, gynecomastia and iron deficiencies (Baiubon *et al.*, 2016; Zakaria *et al.*, 2016b; Yu *et al.*, 2017). Furthermore, the symptoms of gastric ulcers may usually reoccur on discontinuation of antiulcer therapy (Kangwan *et al.*, 2014). Consequently, antiulcer remedies with minimal side effects are required for possibility of their long use (Kang *et al.*, 2009). Mucosal protective agents can be a good alternative as they are considered to have relatively low side effects (Shim *et al.*, 2017). Beside use of synthetic drugs to cure gastric ulcers, people also rely on phytomedicines as an alternative therapeutic source which being natural are considered without side effects (Rozza *et al.*, 2012; Chatterjee *et al.*, 2014).

Rosa brunonii Lindl., also called "Himalayan musk rose," is a member of the *Rosaceae* family and found in the western Himalayas. Locals use the plant's roots, known as "*Rajatarini*," to cure inflammation in the eyes. Plant flowers are used to produce gulkand, a sweet preserve used as a laxative and a remedy for stomach aches. Literature reported substantial in-vitro antioxidant activity of crude extract from Rosa brunonii Lindl. flowers (Ahmad *et al.*, 2020). Some of the compounds such as quercetin-3-O-rhamnoside, astragalin and tiliroside were isolated from RBF such as quercetin-3-O-rhamnoside, astragalin with strong antioxidant properties (Ishaque *et al.*, 2017) which increased the medicinal value of RBF. RBFCE possess significant hepatoprotective potential against Rifampicin/Isoniazid induced toxicity in rats. It possess various classes of phytochemicals including cardiac glycosides, flavonoids, steroids, phenolic compounds, terpenoids, anthraquinones and proteins (Ahmad *et al.*, 2020).

Rosa brunonii Lindl. is of particular interest due to its widespread use in folklore medicine and the presence of

highly antioxidant bioactive secondary metabolites. Furthermore, no reports showing gastroprotective effects of RBFCE were found in the literature, which encouraged us to appraise the possible anti-ulcer potential of the plant (Aziz *et al.*, 2023; Saleem *et al.*, 2023, Sana *et al.*, 2022). Given the preceding, the current study sought to isolate and characterize bioactive metabolites from RBFCE and investigate its potential gastroprotective effects in ethanol-induced gastric ulcers in rats. The medium polar chloroform fraction was selected for the study due to the ease of separating bioactive secondary metabolites for further trials.

MATERIALS AND METHODS

Collection of plant material

Fruits and leaves of *Rosa brunonii* Lindl. were collected from Murree, Punjab Pakistan, identified at Department of Botany, GC University, Lahore (Pakistan) under voucher specimen number, GC.Herb.Bot.3314 for future reference.

Chemicals and Reagents

Omeprazole (Dr. Reddy Pharma, India) and carboxymethylcellulose (CMC) (India) were kindly provided by Next Pharmaceuticals (Pvt) Ltd. Pakistan. Silica gel (Merck), Bovine serum albumin (BSA) and Alcian blue dye 8GX were obtained from BioShop (Canada) and Uni-chem (China). Ethanol, methanol, hexane, dimethyl sulphoxide, chloroform ($CHCl_3$) and ethyl acetate were obtained from Sigma Aldrich Chemicals (Germany) and of analytical grade.

Preparation of extract

The fruits of *Rosa brunonii* Lindl. were washed with distilled water, shade-dried, and crushed using a mechanical grinder. Extraction was carried out by reported maceration method with slight modifications (Sambandam *et al.*, 2016). Finely ground powdered material (500 g) was dipped into 5 L of $CHCl_3$. The extract was filtered, and the solvent was evaporated using a rotary evaporator. The resulting semisolid residue was weighed and kept at –4°C in an airtight container for later use. The semisolid residue was fractionated using a solvent extraction technique that began with hexane and progressed through chloroform, ethyl acetate, and methanol. The chloroform fraction was dried, examined, and evaluated for anti-ulcer activity.

Isolation and characterization of compound

Isolation was carried out by using conventionally reported isolation method with slight modifications (Ahmadu *et al.*, 2007). Silica gel (60 mesh) was added in hexane to form slurry and loaded into the column. The column was packed carefully by minimizing the bubble interruption. Sample of RBFCE weighing about 187 g was loaded onto the column packed with silica gel. Separation was started with non-polar solvent, hexane as an eluent. Polarity of the eluent was raised by mixing 10% $CHCl_3$ at one time and up to 100% $CHCl_3$. In order to further raise the polarity of the eluent, 10% ethyl acetate was added at each step. Thin layer chromatography (TLC) was continuously carried out after every 10% rise in polarity of eluent. Fractions showing same Rf values were combined and at the end (1-6), (11-16) and (19-25) fractions were obtained.

On the basis of TLC, fractions (19-25) were loaded onto the Sephadex LH-20 column and eluted with ethyl acetate and polarity was increased by adding 25% CH_3OH at each step. At 100% CH_3OH as an eluent, polarity was further raised by adding 1.0% water in the eluent. At polarity of 97.0% CH_3OH and 3.0% water, the pure compound was eluted and showed single spot on TLC plate under UV light at mobile phase ratio of ethyl acetate, methanol and water (10:5:3) and (7:5:3). The isolated compound was weighed using calibrated Sartorious TE214S weighing balance. Melting point of compound was determined using Melting point apparatus (SMP-10), FTIR of the compound was performed on IR Prestige-21, NMR spectra was obtained on NMR, Bruker (500 MHz) and mass was determined by LC-MS/MS (Agilent).

Experimental animals

The experiment was carried out on healthy adult Wistar albino rats of either sex (172–204 g) obtained from a local animal house facility and acclimatized for 1 week under standard environmental conditions with free access to food and water ad libitum. The study was carried out according to the protocols approved by the Animal Ethical Committee of the University of Punjab, College of Pharmacy. The animals were divided into different groups, detailed in the proceeding text.

Acute toxicity study

The acute toxicity of RBFCE was studied to determine the safe dose of the extract. Rats were divided into three groups (n=6 in each) and given a vehicle (CMC, 5 ml/kg), a low dose (1000 mg/kg), a medium dose (2500 mg/kg), and a high dose (5000 mg/kg) of RBFCE. Before dosing, rats were deprived of food for 24 h with free access to water. Food was also withheld for another 4 hours after dosing. Animals were monitored for morbidity and mortality for 4 hours and then daily for 14 days.

Determination of gastroprotective effect

The gastroprotective effect of RBFCE was studied in an ethanol-induced gastric ulcer rat model, which was deprived of water just 2 h before starting the experimental procedure. The animals were randomly divided into six groups (n=6) and treated for 14 days with extract and drug as follows:

Normal control group: Animals received drinking water to show the normal gastric parameters.

Negative control group: Animals were given vehicle solution 5 ml/kg 0.5% CMC. (Hariprasath *et al.*, 2012; Rahim *et al.*, 2014). This group was only included to check the effect of CMC on gastric parameters.

Positive control group: Animals were given OMP (20 mg/kg p.o, OD) for 14 consecutive days (Al-Wajeeh *et al.*, 2016).

Low dose RBFCE group: Animals were given RBFCE (250 mg/kg/p.o, OD) for 14 consecutive days.

Medium dose RBFCE group: Animals were given RBFCE (500 mg/kg/p.o, OD) for 14 consecutive days.

High dose RBFCE group: Animals were given RBFCE (750 mg/kg/p.o, OD) for 14 consecutive days.

All therapies were given through intragastric gavage. After 30 min of above mentioned treatments, 10% ethanol solution was given orally to all animals on the first day of the trial, with the exception of the normal control group. From second day of trial, animals in all other

groups received 30% (v/v) ethanol orally for 14 days, except normal control group.

Sample collection and processing

On the 14th day, all animals were anesthetized with an overdose of xylazine and ketamine and sacrificed after 1 h of ethanol administration (Ketuly *et al.*, 2013). After cutting stomach tissues along the larger curvature, gastric contents were collected in glass tubes. Gastric mucosa was inspected after stomach tissues were cleaned with ice-cold normal saline (Das *et al.*, 2012). The number of lesions, their details, and their scores was all recorded. Stomach tissues were then fixed in 10% formalin solution to evaluate histopathological parameters (Qaiser *et al.*, 2018).

Macroscopic and microscopic evaluation

The excised stomach tissues were observed under magnifying glass and dissecting microscope to count lesions present on inner side of the stomachs (Dashputre *et al.*, 2011; Qaiser *et al.*, 2018).

Ulcer scoring

Ulcer scoring was carried out as follows on the basis of their intensity (Raju *et al.*, 2009).

0	No ulcer
0.5	reddish mucosa
1	red spots
1.5	hemorrhagic streaks
2	profound ulcers
3	punctures/perforations

Ulcer index

Ulcer index was calculated using the formula (Ahmad *et al.*, 2015; Gul *et al.*, 2015).

Ulcer Index=[UN+US+UP]×10^{-1}

Where UN=average number of ulcers per animal, US=average of severity score, and UP=percentage of animals with ulcer.

Percentage protection

The percentage protection by RBFCE was calculated by the following formula and compared with negative control group (Raju *et al.*, 2009).

$$\% \text{ age protection}= \frac{[\text{Ulcer index of ethanol treated group}]-[\text{Ulcer index of treated group}]}{[\text{Ulcer index of ethanol treated group}]} \times 100$$

Estimation of gastric content volume, pH and total acidity

Following the stomach opening, the entire gastric contents were put into the test tubes and centrifuged for 10 minutes at 1000 rpm. The volume and pH of the supernatant were determined using a 5 mL burette and a pH metre (Thermo Orion thermoscientific 3-star). The supernatant (1 ml) was titrated against freshly prepared 0.1N NaOH using phenolphthalein as an indicator (Shukla *et al.*, 2017). Correction factor of 0.1 N NaOH was also calculated.

$$\text{Total activity}= \frac{[\text{Volume of NaOH used}]\times[\text{Normality of NaOH used}]\times 100}{0.1}$$

Results were expressed in terms of the clinical units (mEq/L).

Gastric mucous content determination

Estimation of gastric mucous content was carried out by using standard curve of alcian blue according to the reported protocol (Hajrezaie *et al.*, 2015).

Protein content determination

Protein content was assessed by using standard curve of bovine albumin solution (BSA standard curve) (Markwell *et al.*, 1981).

Histopathological investigations of gastric ulcer

The separated stomachs were sliced along the larger curvature and rinsed in ice-cold normal saline. The stomach tissues were partially preserved in a 10% formalin solution and further processed by embedding them in paraffin wax. For histological investigation, 3–5 mm thick slices were cut and stained with hematoxylin and eosin (Hajrezaie *et al.*, 2015). The sections were photographed after being evaluated under a light microscope for histological changes such as ulceration, decongestion, necrosis, congestion, and erosions on an arbitrary scale (Bancroft *et al.*, 2013).

Statistical analysis

Data was articulated as the mean ± S.E.M., where applicable. Data for gastric content volume, pH, total acidity, percentage protection and protein content were analyzed using one-way analysis of variance (ANOVA). Tukey's post hoc multiple comparison test was applied for determination of statistical difference among all groups. $p<0.05$ considered significant. Graph Pad Prism® (Version 8.0.1 (244) for Windows) was used for statistical calculations and plotting graphs.

RESULTS

Acute oral toxicity

During the observation period, no behavioral changes or signs of toxicity were observed in any of the treated rats. During the 14-day observation period following oral administration of all three doses of RBFCE, none of the rats died.

Characterization of isolated compound

Characterization of the isolated compound was carried out by spectral studies such as IR, NMR, and mass spectroscopy and melting range. The observed data was examined and compared with the published data for pos-

sible flavonoid glycoside and found matched with QUE-G. The observations regarding compound under study are as follows in Table 1.

The proton NMR showed peaks in aromatic region and the presence of a sugar moiety. The splitting of aromatic proton exhibited two distinct coupling patterns, one was meta coupling (J – 2.0 Hz) and the other 1,4,5 coupling pattern. As hydroxyl was normally appeared at carbon number 5 in flavonoid that normally hydrogen bonded with carbonyl, therefore meta coupling could be suggested in A ring and 3,4-disubstituted pattern in B ring of flavonoid that was also matched with the published data (Table 2). Anomeric proton appeared at δ 5.2 ppm as doublet and six other protons from 3.60 to 3.25 δ ppm due to possible sugar moiety. The experimental data was matched with the NMR data of QUE-G according to literature.

IR spectrum confirms the characteristic of flavonol system. Peaks at wave numbers 3214 cm⁻¹ indicates OH-stretching and at 1671 cm⁻¹ conforms presence of –C=O group. Similarly, the molecular formula of isolated compound was determined as $C_{21}H_{20}O_{12}$ by NMR and mass spectrum. The molecular weight (464.30 g/mol) of the isolated compound also confirms the isolated compound as QUE-G (Fig. 1). Melting range of the isolated

Figure 1. Structure of quercetin-3-O-glucoside.

compound (233–237°C) confirms that compound under study is QUE-G as it has melting point 236°C.

Macroscopic evaluation of stomach tissue treated with RBFCE

Macroscopic evaluation of control animals showed the normal mucosa without any signs of erosion/ulceration. Gross appearance of ulcer control tissue exhibited various notable lesions and signs of ulcerations. No remarkable signs of ulcerations were observed in the positive control group. On the other hand, macroscopic evaluation of low dose RBFCE treated group showed marked degree of erosion as compared to medium and high

dose treated groups. Gross appearance of gastric mucosa showed milder injuries in low dose extract treated group compared to medium and high dose and negative control groups as shown in Fig. 2.

Effect of RBFCE on ulcer score, ulcer index and percentage protection

Ethanol administration significantly ($p<0.001$) increased the ulcer score (Mean=4.91±1.11) and ulcer index (Mean=10.94) in negative control group compared to the normal animals (0 ± 0.00). Low dose of RBFCE decreased ($p>0.05$) the ulcer score to −26.80% (Mean=3.60±1.00), ulcer index to −18.72% (Mean=8.90) and increased the percentage protection by 18.72% compared to the negative control group. Likewise, oral administration of medium dose of RBFCE reduced ($p<0.05$) the ulcer score to −45.80% (Mean=2.70±0.90), ulcer index to −−32.70% (Mean=7.40) and increased the percentage protection by 32.67% compared to the negative control group. Moreover, high dose of RBFCE reduced ($p<0.01$) the ulcer score to −61.0% (Mean=1.92±0.70), ulcer index to −45.10% (Mean=6.00) and increased the percentage
Figure 3. Mucous content of normal, negative control, positive control, low dose RBFCE, medium dose RBFCE and high dose RBFCE groups.
The results of low, medium and high dose RBFCE groups were compared with negative control group.

protection by 45.10 % compared to the negative control group (Table 3).

Effect of RBFCE on Gastric content volume, acidity, pH

Ethanol administration significantly ($p<0.001$) increased the gastric content volume and acidity ($p<0.001$) by 197.5% (Mean=3.96±1.19) and 226.70% (Mean=89.83±7.35) while decreased the pH −28.10% (Mean=2.90±0.64), respectively compared to the normal group. Low dose of RBFCE reduced ($p<0.05$) the gastric content volume to -36.13% (Mean=2.53±0.30), acidity ($p<0.05$) to −24.70% (Mean=67.66±7.80) and increased the pH ($p<0.05$) by 10.92% (Mean=3.22±0.34) compared to the negative control group. Likewise, medium dose of RBFCE reduced ($p<0.01$) the gastric content volume to −42.90% (Mean=2.30±0.29), acidity to −34.70% (Mean=58.60±5.10) and increased the pH by 23.0% (Mean=3.60±0.40), compared to the negative control animals. High dose of RBFCE reduced ($p<0.01$) the gastric content volume to −50.84% (Mean=1.95±0.50), acidity ($p<0.01$) to −42.10% (Mean=52.00±6.00) and increased the pH by ($p<0.01$) 50.60% (Mean=4.40±0.30) in comparison with negative control group (Table 4).

Effect of RBFCE on mucous and protein content

Ethanol administration to negative control group significantly decreased the mucous and protein content ($p<0.05$) by −18.32% (Mean=323.33±45.46) and protein by −47.94% (Mean=36.24±5.57) ($p<0.01$), respectively, compared to the normal group as shown in Fig. 1 and 2, respectively. Oral treatment of low dose of RBFCE increased ($p<0.05$) the mucous content by 9.28% (Mean=368.17±12.27), and protein content 10.82% (Mean=45.50±2.03) compared to the negative control group. Likewise, oral administration of medium dose of RBFCE increased the mucous content ($p<0.05$) 18.60% (Mean=380.16±10.12) and protein content by 29.70% (Mean=53.17±2.04) ($p<0.01$), compared to the negative control group. Oral treatment of high dose of RBFCE increased the mucous content (Fig. 3) (p<0.05) by 21.40% (Mean=392.66± 9.01) and protein content by 56.92% (Mean=56.87±2.41) ($p<0.001$) compared to the negative control group as shown in Figs. 4 and 5.

The low, medium and high dose RBFCE groups were compared with negative control group.

Figure 6. Histopathological evaluation of stomach tissues of :
(**a**) normal rats (**b**) Rats pretreated with CMC (negative control group) (**c**) OMP 20 mg/kg (positive control group) (**d**) RBFCE 250 mg/kg treated group (**e**) RBFCE 500 mg/kg treated group (**f**) RBFCE 750 mg/kg treated group. Histopathological images (a), (c) and (d) were magnified at 200X. However, images (b), (e) and (f) were magnified at 400X.

Effect of RBFCE on histopathology of stomach tissue

Histological evaluation of gastric tissue of normal control rats showed the normal looking mucosa without any surface erosion/ulceration. Submuscosa and muscularis properia were unremarkable. Rats of negative control group (CMC pre-treated) showed marked degree of mucosal surface ulceration and inflammation. Metaplastic change was also present. On the other hand, animals of positive control group showed only focal erosion. However, no mucosal or submucosal inflammation was seen. Animals of low dose RBFCE (250 mg/kg) treated group

reflected mucosa with focal erosion and inflammation. The histopathological investigations of medium dose RBFCE treated group (500 mg/kg) showed normal surface epithelium having only focal erosion without inflammatory changes. The high dose RBFCE group (750 mg/kg) showed normal looking mucosal epithelium without surface erosion/ulceration and inflammation (Fig. 6).

DISCUSSION

The present study investigated the acute oral toxicity and gastroprotective effect of RBFCE on ethanol-induced gastric ulcer model and its possible mechanism. Characterization of isolated compound, QUE-G confirms the presence of flavonoid class of compound. Flavonoids are safe and effective therapeutic agents for the treatment of gastrointestinal diseases. Previously, QUE-G has been isolated from *Azadirachta indica* (Tatke et al., 2014), *Prangos ferulaceae* (Razavi et al., 2009), *Manihot glaziovii* (Hakim et al., 2020), and *Byrsocarpus Coccineus* etc. (Ahmadu et al., 2007). However, this compound was the first report from RBF. QUE, a naturally occurring bioflavonoid is commonly found as QUE-G in herbs, fruits, and vegetables. Presence of glucose moiety makes QUE more stable compared to aglycone form. Only, a very small quantity of naturally occurring QUE lacks a glycoside chain. Bioavailability of QUE-G is much better then aglycone form (without glycoside chain) (Kaşıkcı et al., 2016), which is commonly available form of QUE as a supplement. It is a globally recognized safe complementary or alternative medicine used for different a various comorbidities including heart (Patel et al., 2018), liver (Li et al., 2018), and stomach (Ekström et al., 2011). It also possess anticancer (Vafadar et al., 2020) and neuroprotective potential (Khan et al., 2018; Salehi et al., 2020). QUE inhibits several cytochrome P450 isoenzymes, i.e., CYP3A4, CYP2C8 CYP2C9 and CYP1A2 (Umathe et al., 2008; Samala et al., 2016) and considered to be involved in herb-drug interactions (HDIs). Therapeutic profile of glucoside form is identical to that of aglycone form. QUE also possess significant antiulcer and gastroprotective activity due to its antioxidant, anti-secretory, antihistaminic and proton pump inhibiting properties (de Lira Mota et al., 2009). QUE-G possesses cardiovascular benefits (Terao, 2023).

The toxicity study demonstrated that rats treated with RBFCE did not show any sign of toxicity or mortality and LD50 value was found above 5000 gm/kg. All the three orally administered once daily doses of RBFCE (250, 500, 750 mg/kg) to rats for 10 days for gastroprotective activity, were safe. OMP, a widely used proton pump inhibitor for the treatment of gastric ulcers, was used as positive control, in line with the literature (Nordin et al., 2014). After one hour on last (14th) day of treatment, single dose (5 ml/kg) of absolute ethanol was orally administered to animals. Ethanol is most widely used in experimental models to assess the gastroprotective activity in rats (Sidahmed et al., 2015). It rapidly penetrates into the gastric mucosa, increases mucosal absorptivity (Sidahmed et al., 2013) and releases vasoactive mediators (histamine, leukotrienes C4 and endothelin-1). The vasoactive mediators cause blood flow stasis in circulation of mucous membrane and increasing lesions in mucosa. In addition, ethanol also reduced the mucus production, gastric mucosal blood flow, bicarbonate secretion, prostaglandin production, tissue levels of DNA, RNA and proteins, which leads to tissue injury. Formation of superoxide and reactive oxygen species generates oxidative stress which, in turn results rupturing of the blood vessels that contributes to the hemorrhage, tissue necrosis and disrupting the protective mucosal layer (Fahmy et al., 2015). In the present study, oral administration of ethanol to rats produced hemorrhagic red streaks of various sizes on the gastric mucosa of the control group. RBFCE pre-treated groups (250, 500, 750 mg/kg) showed protected gastric mucosa and significantly reduced the rate of ethanol-induced damage to the gastric mucosa, compared to the negative control group. RBFCE showed gastroprotective effect in dose dependent manner, comparable to the OMP group (Table 1). Pretreatment with RBFCE significantly reduced UI, maximum being seen at 750 mg/kg, similar to that of the OMP.

Any agent that reduces the gastric acid secretion or increases the mucous secretion is an effective gastroprotective agent (Oliveira et al., 2014). Gastric secretions in rats were studied because they may contribute to RBFCE's gastroprotective action. The ulcer control group had a lower pH, a higher volume of gastric juice, and total acidity. Pre-treatment with either OMP or different doses of RBFCE significantly decreased gastric juice volume and total acidity, coupled with a significant increase in gastric pH when compared to the ulcer control group. Oral administration of RBFCE for 10 days strengthened the gastrointestinal system in such a way that gastric volume and the total acidity was significantly reduced in the treated rats with a corresponding increase in pH compared to the negative control group. A decrease in gastric juice volume could be due to less acid production, as evidenced by the pH and total acidity of the gastric juice. These findings indicated presence of therapeutically active compounds in RBFCE that reduced the acidity of gastric acid secretions, which was increased by ethanol administration. Therefore, anti-secretory effect RBFCE could be a possible mechanism of gastroprotection. The gastric epithelium, which is surrounded by a continuous mucous layer, acts as the first line of mucosal defense against luminal acid by acting as a barrier against luminal pepsin to protect the underlying mucosa from proteolytic digestion. Mucus comprises mucin-type glycoproteins detectable by amount of *alcian blue* binding (Zakaria et al., 2016a). Microscopic evaluation revealed the comprehensive damage to gastric mucosa in ulcer control group (Fig. 2). Animals treated with RBFCE showed protection to gastric mucosa with significant reduction in inflammation in dose dependent manner. The daily RBFCE treatment for 10 days found to amplify the amount of gastric mucous as compared to the vehicle. Increased mucous content may be liable to gastric cytoprotection. Therefore, it may be another possible mechanism of gastroprotective effect of RBFCE.

Stomach from normal control animals in histopathological examination showed normal-looking mucosal surface which indicates absence of any signs of ulceration in normal control group. The presence of focal mucosal inflammation and metaplastic changes in stomach of negative control animals indicates development of ulceration. Gastric metaplastic cells may transform into precancerous cells which increase the risk of gastric cancer if untreated. While the positive control group revealed mucosa and part of submucosa with only focal erosion, but no mucosal or submucosal inflammation was observable. Stomach section from low dose (250 mg/kg) RBFCE treated animals showed mucosa with focal erosion and mild chronic inflammation while the medium dose RBFCE treated group (500 mg/kg) exhibited normal surface epithelium with mild degree of erosion. Rest of the

mucosa was normal looking without evidence of inflammation. On the other hand, high dose RBFCE treated animals (750 mg/kg) revealed normal looking mucosal epithelium without surface erosion/ulceration, metaplastic and inflammatory changes which indicates protective potential of RBFCE at medium and high doses. A high dose of RBFCE could significantly reduce gastric lesions and histological damage in a dose-dependent manner comparable to OMP. The present findings supported the ethnopharmacological use of RBF and highlighted its potential to be used as herbal gastroprotective medicine. Some of the limitations of the research work include (1) study was performed in rats but not in humans (2) only preliminary data was collected (3) study was performed on extract, not on isolated compound.

CONCLUSIONS

RBFCE showed a significant gastroprotective effect against ethanol-induced gastric ulcer, as reflected by a decreased gastric juice volume and acidity, parallel to an increased gastric mucus secretion. The above activity could be attributed to QUE-G, major bioactive flavonoid isolated from RBFCE in this study. These findings deliver considerable evidence in favor of the folk use of RBF in the treatment of gastric disorders.

Molecular cloning of glutathione reductase from *Oryza sativa*, demonstrating its peroxisomal localization and upregulation by abiotic stresses

Pamela Chanda Roy and Gopal Chowdhary✉

Plant Molecular Biology Laboratory, School of Biotechnology, KIIT, Bhubaneswar-751024, Odisha, India

Abiotic stress is a major constraint on crop productivity and in the agricultural field, multiple abiotic stresses act synchronously leading to substantial damage to plants. A common after-effect of abiotic stress-induced damage in plants is an increased concentration of reactive oxygen species (ROS) leading to oxidative damage. Glutathione reductase (GR) plays a significant role in curtailing ROS. Apart from the GR enzyme, the peroxisome as an organelle also plays a significant role in ROS homeostasis. Here, we report a peroxisome localized GR, whose expression was found to be upregulated by various abiotic stresses. The *in silico* analysis also revealed that the peroxisomal localization of GR could be a common phenomenon in angiosperms, suggesting that it could be a suitable candidate against abiotic stress combinations.

INTRODUCTION

Abiotic stress is one of the significant factors which limits the yield of crops. Due to the untimely onset of abiotic stress conditions, crops worth millions of dollars are lost annually worldwide (Wang *et al.,* 2003; Wania *et al.,* 2016). Abiotic stress leads to a series of detrimental activities in the plant, which cause either partial or complete loss of yield (Yousuf *et al.,* 2012; Harshavardhan *et al.,* 2017). One such after-effect is an increase in the cellular concentration of reactive oxygen species (ROS), which has been observed as a common phenomenon in the case of all types of abiotic stresses. Uncontrolled increase and accumulation of ROS can lead to oxidative damage to the cell, such as oxidation of nucleic acids, protein denaturation, breakdown of cell and organelle membrane, lipid peroxidation, and carbohydrate oxidation (Scandalios, 1993; Noctor & Foyer, 1998). This imbalance in the redox state of the cell is dangerous and could be lethal if left unchecked. ROS also plays a significant role in regulating the response of plants, against environmental stimuli by a redox-dependent reprogramming of signalling pathways (Harshavardhan *et al.,* 2017), thereby making ROS not only an oxidative deterrent but also a signalling molecule (Mittler *et al.,* 2004; Miller *et al.,* 2010). Hence, a delicate balance between ROS production and scavenging needs to be maintained, making ROS homeostasis very crucial. To defend themselves from this abiotic stress-induced oxidative damage, plants have developed various mechanisms. One such mechanism is the glutathione reductase (GR) mediated ascorbate-glutathione pathway, also known as the Foyer-Halliwell-Asada pathway (Asada, 2006; Foyer & Noctor, 2011). In plant cells, GR activity has primarily been found in the chloroplast (70–80%) with a minor presence in mitochondria and cytosol (Edwards *et al.,* 1990; Creissen *et al.,* 1994). However, with recent development in molecular and proteomic techniques, the peroxisomal localization of *Arabidopsis thaliana* GR has also been demonstrated (Kataya & Reumann, 2010). Also, it is pertinent to mention that the peroxisomes in association with chloroplast and mitochondria are primarily responsible for cellular ROS homeostasis (Foyer & Noctor, 2003; Habib *et al.,* 2016; Dietz *et al.,* 2016; Huang *et al.,* 2016). The significant role of peroxisomes in ROS scavenging and abiotic stress tolerance makes a peroxisome-localized GR of special significance.

Peroxisomes are small, single membrane-bound organelles whose proteome is encoded by nuclear genes, synthesized on cytosolic ribosomes, and imported in a signal-dependent manner (Hu *et al.,* 2012; Emmanouilidis *et al.,* 2016). Depending upon the protein location, peroxisomal proteins could be divided into two broad categories- peroxisomal membrane and matrix proteins, both of which are imported in entirely different manners. GR happens to be a peroxisomal matrix protein (Kataya & Reumann, 2010). The peroxisomal matrix proteins are largely imported either by peroxisomal targeting signal (PTS) type one or PTS type two (Gould *et al.,* 1987; Swinkels *et al.,* 1991). The bulk of the matrix proteins is imported by PTS type 1 while a comparatively smaller number of matrix proteins are imported by PTS type 2 (Brocard & Hartig, 2006; Lazarow, 2006). After being synthesized on cytosolic ribosomes, PTS1 and PTS2 containing proteins are recognized by their respective cytosolic receptors, PEX (peroxin) 5 and PEX7 respectively, which ultimately bring them to peroxisome with the help of other PEX proteins (Kunze, 2019; Kim & Hettema, 2015; Kunze *et al.,* 2011; Kiel *et al.,* 2009; Niederhoff *et al.,* 2005; Reumann, 2004; Bottger *et al.,* 2000; Lametschwandtner *et al.,* 1998; Albertini *et al.,* 1997). The PTS1 is located at the C-terminus of protein and

is primarily represented by the last three amino acids, however, the upstream residues also play a significant role in PEX5 binding (Neuberger et al., 2003; Brocard & Hartig, 2006; Lingner et al., 2011; Lametschwandtner et al., 1998; Reumann, 2004; Fodor et al., 2012; 2015), while the PTS2 is located at N-terminus, represented by a nonapeptide (Petriv et al., 2004; Lazarow, 2006). It has also been observed that depending upon the composition of amino acids present at the C-terminus, the PTS1 shows a varying degree of efficiency in peroxisome targeting (Gatto et al., 2000; Stanley et al., 2006) and this has led to the classification of PTS1 into a canonical and noncanonical type (Skoulding et al., 2015). The canonical ones lead to efficient and strong targeting while the noncanonical ones are comparatively less efficient and lead to weak targeting of the protein to the peroxisome. The strong and weak efficiencies have been explained based on the time required for the fluorescent detection of the peroxisome targeting under in vitro conditions (Skoulding et al., 2015; Chowdhary et al., 2012).

In this work, we reported the peroxisome localization of GR and its involvement in abiotic stress tolerance in the monocot model plant Oryza sativa (rice) which is a crop of global significance and is responsible for feeding more than half of the world's population, especially in Asian, African continents, and other third world nations.

MATERIALS AND METHODS

Data retrieval for in silico work

The protein sequences of A. thaliana and O. sativa GR were retrieved from The Arabidopsis Information Resource (TAIR, Tanya et al., 2015, https://www.arabidopsis.org/) and the rice genome annotation database (Kawahara et al., 2013, http://rice.uga.edu/) respectively. For multiple sequence alignment, CLUSTAL W 2.1 program (Larkin et al., 2007) was used at pir.georgetown.edu (Cathy et al., 2003). The OsGR was used as a query in protein BLAST at NCBI and 80 GR orthologs were obtained.

Plant material and growth condition

For all experiments, O. sativa IR 64 (Indica rice) variety was used. This is an abiotic stress-sensitive variety. The seeds were obtained from National Rice Research Institute, Cuttack, India. The seeds were sterilized with 70% ethanol for 2 min followed by rinsing with distilled water three times each for 2 min. The sterilized seeds were kept in germination paper pre-wet with distilled water, which was incubated in dark for 24 h followed by shifting to the plant growth room maintained at 28±2°C, 60% humidity, and a light/dark cycle of 16/8 h. For all experimentation, 11 days old seedlings were used. The abiotic stresses were induced by treatment with 200 mM sodium chloride (saline stress), 4±2°C (cold stress), and 45±2°C (heat stress) for 2 h. The untreated seedlings served as a control and were used for the calculation of the relative transcript level of OsGR.

RNA extraction and cloning of OsGR

For RNA extraction, 100 mg of seedling was used and crushed in liquid nitrogen followed by extraction using RNeasy plant mini kit (Qiagen) as per the manufacturer's protocol, with the modification of inclusion of in-column DNase digestion step (RNase free DNase set, Qiagen). The extracted RNA was checked for its quan-

tity and quality using a microvolume spectrophotometer (ThermoFisher Scientific) and agarose gel electrophoresis.

The extracted RNA was converted to cDNA using Revert Aid First Strand cDNA Synthesis Kit (ThermoFisher Scientific) as per the manufacturer's manual. The obtained cDNA was used for polymerase chain reaction (PCR) amplification using the primers: Forward AATTGCGGCCGCGATGGCTAGGAAGATGCT-CAAG, Reverse TATGTCTAGAGCTACAAGTTT-GTCTTTGGCTTGGATGATGG, using HiFidelity polymerase (Qiagen), with PCR cycle of denaturation 94°C for 20 s, annealing 60°C for 30 s and extension 72°C for 90 s. The obtained PCR product was checked for amplification using agarose gel electrophoresis followed by digestion using NotI and XbaI restriction enzymes. The digested product was resolved in an agarose gel followed by gel purification using the GenJET gel extraction kit (ThermoFisher Scientific). The digested product was cloned into the pCAT plant expression vector, as an enhanced yellow fluorescent protein (EYFP) fusion product under the control of a double 35 S cauliflower mosaic virus (CaMV) promoter (Fulda et al., 2002). The insert was verified using automated DNA sequencing.

Subcellular localization of OsGR

For subcellular localization studies, the biolistic bombardment method was used, in which onion epidermal cells were transformed with plasmid constructs coated on gold particles, which were further examined under a fluorescent microscope after an appropriate incubation time. Under standard conditions, the transformed onion epidermal cells are examined after 18–24 h post-transformation. However, it has also been observed that the sensitivity of detection of the reporter protein in peroxisome increases after an extended incubation time at reduced temperature (Lingner et al., 2011, Chowdhary et al., 2012).

The gene of interest (OsGR) was cloned as an EYFP fusion product and as a peroxisomal marker, Ds-Red-SKL was used (Matre et al., 2009). In the case of single transformation experiments pCAT plasmid containing EYFP-OsGR was coated with gold particles, while in the case of double transformation experiments pCAT plasmid containing EYFP-OsGR and peroxisomal marker (Ds-Red-SKL) together were coated with gold particles and bombarded to onion epidermal cells (Ma et al., 2006). The onion slices were placed on wet blotting paper in Petri dishes and stored at room temperature in the dark followed by analysis using fluorescent microscopy or after additional incubation at 10°C for 1 to 6 d. Image capture and analysis were done as explained in Chowdhary et al., (2012).

Expression analysis by real-time PCR

The expression analysis of peroxisomal GR was carried out by real-time PCR technique using SYBR green chemistry. For this, the total RNA was extracted from stress-treated and control (untreated) plants as explained above, its concentration was determined, equalized, and converted to cDNA using high-capacity cDNA reverse transcription kit (ThermoFisher Scientific) as per the manufacturer's manual. Total RNA, 1 μg, was converted to cDNA, which was diluted and further used for quantitative real-time PCR using SYBR green chemistry. Real-time PCR was performed using QuantiNova 2X PCR master mix containing SYBR green dye with ROX as passive reference dye (Qiagen) in QuantStudio 5 (ThermoFisher Scientific) real-time PCR

Figure 1. Multiple sequence alignment of GRs from *Arabidopsis thaliana* and *Oryza sativa*.
GR sequences were obtained from the database and aligned using CLUSTAL W 2.1. "*"represents the same amino acids, ":"represents the similar amino acids present in both the sequences. The red rectangle highlights the PTS1 tripeptide with seven upstream residues. The figure at the bottom shows the diagrammatic representation of the interaction of PEX5 with the C-terminus end of GR. The solid black and blue rectangle represents the OsGR and PEX5, respectively.

machine. The conditions for real-time PCR were as follows: initial denaturation at 95°C for 2 min, followed by 40 cycles of 95°C for 15 s, 60°C for 60 s, and 72°C for 60 s. To obtain the melting curve a program of 95°C for 15 s and 60°C for 1 min was followed. All qPCR analyses were performed in three biological replicates. *O. sativa* actin was used as an endogenous control for the normalization of the transcript. The relative transcript level or "fold change" (degree of change in expression between the treated sample and untreated sample) was calculated by the $\Delta\Delta CT$ method using the formula, relative transcript level/fold change = $2^{-\Delta\Delta CT}$, where $\Delta\Delta CT = \Delta CT$ test sample $- \Delta CT$ calibrator sample (ΔCT test sample = CT test $-$ CT reference, ΔCT calibrator = CT calibrator $-$ CT reference; test sample = stress treated sample, calibrator = untreated sample, reference = endogenous control) (Livak & Schmittgen, 2001). The data provided represents an average of three biological replicates of independent samples and the values depicted represent mean $\pm$ standard deviation. The primer used for expression analysis were, *OsGR* Forward primer – CGACCTTTGA-CAGCACTGTTGG, reverse primer – TGGTCAAGGTC-CGCATTGTCAC, OsActin forward primers – CAGCCA-CACTGTCCCCATCTA, Reverse primer – AGCAAG-GTCGAGACGAAGGA.

RESULTS

Bioinformatics analysis of OsGR

The protein sequence of *A. thaliana* and *O. sativa* GR were aligned using CLUSTAL W 2.1 and the alignment revealed the significant conservation among both sequences (Fig. 1). The peroxisome targeting of *A. thaliana* GR is dependent on the PTS type 1, which is localized at the C-terminus of the protein. In the case of AtGR the PTS1 is represented by TNL> (Kataya & Reumann, 2010, the symbol ">" represents the end of the polypeptide). The presence of the same tripeptide in *O. sativa* GR provided a hint for peroxisomal localization of OsGR *via* PTS1 (Fig. 1). Hence, OsGR was fused at the C-terminus of the EYFP, so that the targeting signal is freely available for the cytosolic receptor, PEX5 binding followed by peroxisome targeting (Fig. 1).

Molecular cloning and subcellular localization of OsGR

The cDNA of the *O. sativa* was used as a template for PCR-based cloning of GR. The primer sequences and PCR cycle are explained in the materials and method section. The PCR amplified product was found to be of 1500 bp and was cloned in the pCAT vector under the control of a double 35 S CaMV promoter. The gene was cloned as a C-terminal fusion of enhanced yellow fluorescent protein (EYFP, Fig. 1). The sequence of the cloned gene was verified using automated DNA sequencing. No mutations were detected.

Onion epidermal cells transformed with EYFP, which served as a negative control showed uniform cytosolic fluorescence (Fig. 2A). The OsGR, which was expressed as a fusion protein with EYFP, showed green cytosolic fluorescence after 24 h of incubation (Fig. 2B1), however the same was observed in small punctuate structures after an extended time of incubation (Fig. 2B2). The identity of fluorescing punctuate structures was confirmed by double transformation experiments co-expressing peroxisomal marker DsRed-SKL. The double transformation experiments demonstrated the overlapping of both green and red fluorescence from
Figure 2. Experimental validation of peroxisome localization of *Oryza sativa* GR by *in vitro* subcellular targeting.
The *OsGR* was cloned in the pCAT plant transient vector under the control of a double 35 S CaMV promoter. The plasmids were coated with gold particles and bombarded biolistically to onion epidermal cells. The onion epidermal cells were incubated in dark for 24 h at room temperature or low temperature for an extended time period (24 h RT plus 6 d cold ca. 10°C) followed by analysis using fluorescent microscopy. EYFP alone was included as negative control (**A**). 24 h p.t., EYFP fluorescence was detected in cytosol only (**B1**), while after extended incubation the EYFP fluorescence was detected in punctuate structures (**B2**). The identity of the dot-like punctuate structure was confirmed by double transformation experiments, where peroxisomes were labelled with Ds-Red-SKL. The green (**C1**) and red fluorescence (**C2**) from EYFP and Ds-Red-SKL> respectively merged to show yellow fluorescence (**C3**) confirming the punctuate structure to be peroxisomes. The green rectangle bar fused to black depicts the diagrammatic representation of OsGR fused at the C-terminus of EYFP, while the red rectangular bar represents the Ds-RED-SKL>. The upper and bottom halves of the image show the single and double transformation experiments respectively.

EYFP and peroxisomal marker respectively, (Fig. 2C), confirming the identity of the punctuate fluorescing organelle to be peroxisome. Since fluorescence could not be detected in peroxisome 24 h post-transformation and it took an extended time of incubation for the fluorescence to be detected in peroxisome it was presumed that the GR is targeted to peroxisome with lesser efficiency and hence the PTS1 present in GR was termed as weak or non-canonical PTS1.

Expression analysis of *OsGR*

For *OsGR* gene expression analysis, the abiotic stress-treated seedlings were used for RNA extraction, followed by cDNA synthesis and real-time PCR. The untreated seedlings were used as a control. The expression data were represented as relative transcript level or "fold change" which essentially means the change in the degree of expression between the treated sample and untreated samples. The details are explained in the materials and method section. Expression analysis was performed with respect to heat, cold, and salinity (sodium chloride) stresses. All the treatments were provided for 2 h. In the case of heat stress, the change in the transcript accumulation was observed to a tune of 3.1-fold (Fig. 3), meaning that GR gene transcripts accumulated 3.1 times more in the heat stress as compared to untreated samples. This was followed by cold and saline stress with transcript level accumulation of about 3.7 and 10.4-fold respectively (Fig. 3). This demonstrated that the expression of peroxisomal

Figure 3. Expression analysis of *OsGR*.
The expression analysis was performed using the RNA isolated from *Oryza sativa* seedlings after the treatments. RNA extraction was done by RNeasy plant mini kit, (Qiagen) followed by cDNA synthesis (High-Capacity cDNA Reverse Transcription Kit, ThermoFisher Scientific). The cDNA obtained was used for expression analysis by real-time PCR using SYBR green chemistry. OsActin was used as endogenous control. The assays were repeated with a minimum of three replicates and ΔΔCT values were calculated, relative transcript level (fold change) was determined, and the graph was plotted. The x and y-axis show the various abiotic stress treatments and fold change, respectively. The data represent three biological replicates and error bars have been shown.

localized GR in *O. sativa* upregulated in the presence of heat, cold, and salinity stress conditions.

DISCUSSION

Abiotic stress is the major bottleneck in the sustainability of the global agricultural system. The harmful effect of abiotic stress is further compounded when more than one abiotic stress factor negatively affects the plant in synchrony, which is more often the case in field conditions. This phenomenon has been termed stress combinations (Zandalinas *et al.* 2020; 2021) or stress matrix (Mittler, 2006). This necessitates the development of crop varieties that would be tolerant to multiple abiotic stresses. Hence, candidate genes are required which would be effective against most if not all the abiotic stresses. Since the production of ROS is a common factor among all abiotic stresses, we intend to investigate the problem of abiotic stress combinations from the perspective of ROS homeostasis.

Since, peroxisomes play a significant role in cellular ROS homeostasis, a peroxisome-localized candidate participating in ROS homeostasis would be of greater significance. Using *in vitro* subcellular localization techniques, we reported a GR isoform from *Oryza sativa* to be localized in peroxisomes. Previously, Kataya & Reumann, (2010) have reported the localization of *A. thaliana* GR in peroxisomes. The peroxisome targeting of GR is mediated *via* a non-canonical type of PTS1. The PTS1 tripeptide of GR is represented by TNL> in both *A. thaliana* (Kataya & Reunann, 2010) and *O. sativa*. In the case of non-canonical PTS1, the seven upstream residues also play a significant role in binding with the cytosolic receptor PEX5 (Fodor *et al.*, 2012; Brocard & Hartig, 2006; Lingner *et al.*, 2011), which is represented by SPSSKPKTNL> and AHKPKPKTNL> (underlined residues PTS1 tripeptide, others, seven upstream residues) in the case of *O. sativa* and *A. thaliana* respectively. Being a non-canonical type of PTS1, the targeting is not very efficient and requires an extended incubation time for the fluorescence to be detected in the peroxisome (Lingner *et al.*, 2011; Chowdhary *et al.*, 2012). To further understand the peroxisome targeting signal of GRs in angiosperms we
Figure 4. Graphical representation of PTS1 domain present in GR of various angiosperm plants.
The 80 numbers of GR sequences from various dicot and monocot plant species were obtained from NCBI. The sequences were aligned using CLUSTAL W 2.1 (Supplementary Fig. 1 at https://ojs.ptbioch.edu.pl/index.php/abp/). From the multiple sequence alignment, the consensus amino acids were derived. The y-axis shows the propensity of the presence of specific amino acid at a specific position while the x-axis represents the position of amino acids in the C-terminus of the respective protein. ">" denotes the end of the polypeptide chain. Each square represents one amino acid. The bigger the size of the squares, the higher the propensity of amino acids to remain present at that specific position. The empty squares represent the high variability.

obtained GR protein sequences from 80 plant species, and the last ten amino acids were aligned by multiple sequence alignment (Supplementary Fig. 1 at https://ojs.ptbioch.edu.pl/index.php/abp/). The alignment revealed that all the sequences were terminating with TNL> suggesting that the presence of a peroxisomal GR could be a common feature among angiosperms. At the -4 position, all the 80 GR orthologs have lysine while at the -5 position 73 sequences have proline except six sequences, one each from *Elaeis guineensis, Gossypium hirsutum, Gossypium Raimondi, Amborella trichopoda, Cinnamomum micranthum,* and *Phoenix dactylifera* have alanine and one sequence namely *Brachypodium distachyon* had leucine. At the -6 position, 75 sequences had lysine while asparagine was present at four places (one sequence each from *Citrus clementina, Olea europaea* and two sequences from *Citrus sinensis*) and glutamine was present at one place (*Phoenix dactylifera*). The most favourable amino acid at the -7 position is glycine which is present in 35 sequences followed by serine present in 29 sequences. At -8, -9 and -10 positions variability increases. The analysis curtailed here reveals that the consensus PTS1 sequence for peroxisomal GRs present in the angiosperms would be [G/S/T/N/A/V][L/N/Q] [P/A/L] [K] [T] [N] [L]> at -7, -6, -5, -4, -3, -2 and -1> positions, respectively. Figure 4 demonstrates the diagrammatic representation of the propensity of specific amino acids to remain present at specific positions.

Further, the expression pattern of peroxisomal GR was investigated under various abiotic stress conditions. It was found to be upregulated upon heat, cold, and salinity stress in increasing order. GR expression has been reported to get affected due to stress conditions in various plant species, however, all previous reports are of either chloroplastic or cytosolic variants. Salinity and drought stress-dependent upregulation of GR has been demonstrated in *Cicer arietinum* and *O. sativa* respectively (Yousuf *et al.,* 2012). A positive correlation between tolerance to low temperature (LT)-induced photoinhibition and high GR activities has been observed in *O. sativa* (Guo *et al.,* 2006; Huang & Guo, 2005), *C. sativus* (Hu *et al.,* 2008), (Xu *et al.,* 2008), *Glycine max* (Sun *et al.,* 2011), *Cucumis melo* (Fogelman *et al.,* 2011) and *Citrullus lanatus*

(Gill *et al.,* 2013). Increased GR activity has been widely observed in plant species like *T. aestivum* (Hasanuzzaman *et al.,* 2012), *Z. mays* (Kumar *et al.,* 2012), *Cucumis sativus* (Dai *et al.,* 2012), *N. tabacum* (Tan *et al.,* 2011) and *Phaseolus aureus* (Kumar *et al.,* 2011) under high temperature (HT) stress. Thus, the upregulation in the expression of GR is postulated to play an important role in plant protection against various forms of abiotic stresses (Trivedi *et al.,* 2013; Gullner *et al.,* 2001; Reisinger *et al.,* 2008).

The overexpression of enzymes of the ascorbate-glutathione (AsA-GSH) pathway has been demonstrated to confer abiotic stress tolerance in plants by reducing the stress-induced cellular reactive oxygen species (ROS). The work has been critically reviewed by Hasanuzzaman *et al.,* (2019). It has been observed that in *Vigna radiata* (Nahar *et al.,* 2016) and *Solanum lycoperisum* (Sabeeha *et al.,* 2022), the upregulation of AsA-GSH cycle components leads to saline stress and heavy metal (mercury) stress tolerance, respectively. The overexpression of AsA-GSH enzymes from *Pennisetum glaucoma* in *S. lycopersicum* has been reported to be responsible for the reduced accumulation of malondialdehyde and H_2O_2 (Raja *et al.,* 2022). The impairment of AsA-GSH cycle enzymes has been demonstrated to increase saline stress sensitivity in *A. thaliana* (Huang *et al.,* 2005). Further, the overexpression of *Malpighia glabra* monodehydroascorbate reductase (MDHAR) leads to saline stress tolerance in *Nicotiana tabacum* (Eltelib *et al.,* 2012). The transgenic *O. sativa* plants overexpressing MDHAR from *Acanthus ebracteatus* were found to demonstrate enhanced saline tolerance (Sultana *et al.,* 2012). The overexpression of MDHAR and dehydroascorbate reductase (DHAR) in *N. tabacum* (Eltayeb *et al.,* 2007) and *A. thaliana* (Ushimaru *et al.,* 2006) have been demonstrated to increase saline stress tolerance. The overexpression of APX has been demonstrated to reduce the toxic effects of stress-induced H_2O_2 and enhance salinity tolerance in *N. tabacum* (Badawi *et al.,* 2004). Similarly, the overexpression of APX in *N. tabacum* has been demonstrated to relieve it from high and low-temperature stress (Yabuta *et al.,* 2002).

It has also been suggested that different GR isoforms can be stimulated by varied environmental signals and can have different functional manifestations in the response to stress in plants (Stevens *et al.,* 1997). This further supports our analysis that a peroxisomal localized GR could have a more pronounced effect in imparting ROS scavenging properties to plants and hence providing better abiotic stress tolerance. It is also pertinent to mention here that ample literature is available about chloroplastic and cytosolic forms while no work has yet been reported on peroxisomal GR. This would be the first report of a full-length GR to be localized in peroxisome from a monocot plant and its involvement in abiotic stress tolerance. Since both peroxisome and GR are the key entities in cellular ROS homeostasis, a peroxisome localized GR would be of much significance in contributing to the abiotic stress tolerance in plants. The *in silico* analysis also revealed that the peroxisomal localization of GR could be a universal feature among angiosperms. Further, we also reported that the GR was induced by multiple abiotic stress conditions, suggesting that this could also be effective in providing stress tolerance under stress combination or stress matrix situations as well, however, further studies need to be done in this regard.

CONCLUSION

In the nutshell, we reported a peroxisome localized GR from the monocot model plant *Oryza sativa*. The *in silico*

analysis also revealed that the peroxisomal localization of GR could be a common feature amongst angiosperms. The peroxisome localized GR was also found to be induced by multiple abiotic stress conditions. The role of GR in ROS homeostasis combined with its peroxisome localization and induction by multiple abiotic stress conditions suggests that it could be a prime candidate for the development of tolerance against abiotic stress combinations.

Box 2455, Riyadh 11451, Saudi Arabia

The current study investigated the *in-vivo* and *in-silico* anti-inflammatory effect of *Aloe barbadensis* in edema induced rat and its blood biomarkers. 60 albino rats (160-200 g) were divided into 4 groups. The 1st group (control) comprised of 6 rats that were treated with saline. The 2nd group (standard) comprised of 6 rats that were treated with diclofenac. The 3rd and 4th experimental groups consisted of 48 rats, treated with *A. barbadensis* gel ethanolic and aqueous extracts respectively at doses of 50, 100, 200 and 400 mg/kg. According to paw sizes, groups III and IV showed 51% and 46% inhibition respectively at the 5th hour, as compared to group II with 61% inhibition. Correlation was negative between biomarkers in group III, while, positive in group IV. Blood samples were collected; C-reactive protein and interleukin-6 were measured using commercially available ELISA kits. Similarly, biomarkers showed significant effect in dose-dependent manner. In molecular docking, for CRP both ligands aloe emodin and emodin showed –7.5 kcal/mol binding energy as compared to diclofenac with –7.0 kcal/mol. For IL-1beta, both ligands showed –4.7 kcal/mol binding energy as compared to diclofenac –4.4 kcal/mol. Hence, we concluded that *A. barbadensis* extracts can be used as an effective drug for managing inflammation.

INTRODUCTION

Inflammation is an immunological reaction of vascular tissues to detrimental stimuli like foreign organisms and allergens (Riddle *et al.*, 2022) It involves an intricate array that modulates enzyme activation, mediator discharge, tissue damage and repair. Carrageenan is a phlogistic intermediary causing edema in pathophysiological reactions (Rahmawati *et al.*, 2022) Macrophage releases IL-6, in addition to resident cells into circulation at the site of infection. IL-6 stimulates the production of CRP in the liver. IL-1β and TNF-α also triggers IL-6. Increasing CRP levels causes a discharge of TNF-α, IL-1β and IL-6 leading to an inflammation cascade (Mahnashi *et al.*, 2021) Many NSAIDs or SAIDs encompass an edge to manage diseases but often pose serious health issues, so there should be remedies with natural origins with fewer adverse effects (Grzybowski *et al.*, 2018)

The traditional medical system is an ancient healthcare system dating back to 5000 years and includes many indigenous practices including Ayurveda, Siddha, and Unani (Maurya *et al.*, 2022) Research on remedial plants has been intended to authenticate its traditional exploitations in the management of different kinds of ailments through the inflection of molecular and biochemical pathways (Zhang *et al.*, 2019) According to the World Health Organization, 80% of the world's inhabitants use phytotherapeutic drugs to meet their basic health and 11% of essential therapeutic drugs are of plant origin (Annad *et al.*, 2019) Asphodelaceae family includes the largest genus "Alloeh," and 548 accepted species possessing potential biological activities. Among them, *Aloe barbadensis* possesses a legendary medicinal reputation. It is a multifunctional xerophytic medicinal plant having 75 bioactive compounds (Leitgeb *et al.*, 2018) The gel is transparent mucilaginous jelly present in parenchyma cells. It has the ability to penetrate the deepest body tissues and ensures good health. *A. barbadensis* has effective anti-inflammatory activity through the inflection of molecular and biochemical pathways (Alven *et al.*, 2021)

A. barbadensis is cultivated worldwide and broadly dispersed in arid regions. It grows in an extensive variety of habitats. PH ranges from 7.0 to 8.5 and the required temperature ranges from 4°C to 21°C. Fully drained grimy topsoil is considered to be ideal for the nurture of the Aloe plant. The Egyptians called it the "Plant of immortality" due to its ability to colonize and ameliorate severe conditions in completely denuded or less vegetated landscapes (Salehi *et al.*, 2018) *A. barbadensis* has abundant therapeutic applications like anti-inflammatory, anti-diabetic, antioxidant, antiseptic, anticancer, immunomodulatory, antipyretic and analgesic activity (Majumder *et al.*, 2019) These properties have been credited to a range (100) of secondary metabolites called phytochemicals present in them. The outer green epidermis consists of mostly glycosides, pre-anthraquinones and anthraquinones. Acemannan and phenolic compounds are the main component of the outer pulp. Salicylic acid, proteins, vitamins, minerals, and enzymes are present in the inner leaf pulp (Wu *et al.*, 2022)

A. barbadensis reduces the leukocyte adhesion and pro-inflammatory cytokines like IL-β, interleukin 17, TNF-α and interleukins by inhibiting cyclooxygenase pathway and lessens prostaglandin E2 production *via* arachidonic acid (Gupta *et al.,* 2020) Increasing CRP levels causes the discharge of TNF-α, IL-1β and IL-6. Whilst, promoting edema, CRP has some anti-inflammatory effects by stimulating the discharge of anti-edemic mediators such as IL-1ra and IL-10 (Del Giudice *et al.,* 2018) Bioinformatics is a promising field based on the application of computational techniques to resolve biological problems. It is an effective approach that provides favors such as ligand-receptor binding affinity, time organization and drug-drug interactions. Hence, it aids researchers to design the latest drugs for disease management. Anti-edematous effect of *A. barbadensis* and the molecular docking of some of its constituents by inflammatory proteins identified its potential inhibitors (Dali *et al.,* 2019) The current study is designed to investigate the effect of *A. barbadensis* in the induced inflammatory rat model and its blood biomarkers with molecular docking assay.

MATERIALS AND METHODS

Sample collection and preparation of *A. barbadensis* gel extract

Fresh leaves of *A. barbadensis* were collected as a sample from the University of the Punjab, Lahore and were identified by the staff members of the botany department. After the identification, the leaves were washed with water. Lower 1 inch of leaf base and spines around the leaf were removed using a clean knife. Aloe gel was collected, dried, weighed and mixed with distilled water and 70% ethanol (semi-polar solvent) Bottles were placed at room temperature for 15 days. Extracts were filtered by Whatman no.1 paper and filtrate was permitted to peter out in rotary and glass Petri plates for 1 week as shown in Fig. 1A. When dried, the extract was scratched, measured and stored in labelled Eppendorf for further use (Abubakar *et al.,* 2020).

Experimental rats

Albino rats of either sex weighing (160–200 g) were purchased from the University of Lahore and kept in polypropylene cages in the animal house of (UOL) Before experimental work, rats were kept in fasting condition. After that, they were given distilled water and balanced feed (Alyas *et al.,* 2020)

Drugs used in the experiment.

A. barbadensis gel ethanolic and aqueous extracts were prepared at concentrations of 50, 100, 200 and 400 mg/kg. Diclofenac, normal saline was given at 10 ml/kg and 100 mg/kg respectively. Carrageenan for inducing inflammation was given at 100 mg/kg.

Procedure

Carrageenan-induced paw edema.

1% carrageenan of 100 mg/kg was injected into all rat groups in the left hind paw in the sub-planter region for inducing edema. Paw sizes were taken with a Vernier caliper before and after the injection of carrageenan (Ou *et al.,* 2019)

Figure 1. (A) Filtrate of plant extract in glass Petri plates to dry at room temperature. **(B)** Prepared *A. barbadensis* gel extracts at 4 different concentrations of 50, 100, 200 and 400.

Grouping and treatment schedule

In group I (control) rats were injected with normal saline 10 ml/ kg in the sub-planter region of the hind paw. Paw size was measured with a Vernier calliper. At first, paw size increased due to edema but after 4or 5 hours it begins to decrease and normalized after 18 hours.

In group II (standard) rats were injected with diclofenac 100 mg/kg in sub-planter region of the hind paw. Paw size was measured with a Vernier calliper. At first paw, size was increased due to edema but after injecting diclofenac, it has begun to decrease and got normalized after 3 hours.

In group III and IV *A. barbadensis* gel extracts at doses of 50, 100,200 and 400 mg/kg, were injected Fig. 2A. Paw size was measured with a Vernier calliper. The Formula for calculating the anti-inflammatory activity is given below (Choudhury *et al.,* 2016)

$$\% \text{ inhibition} = \frac{\text{control mean} - \text{treated mean}}{\text{control mean}} \times 100$$

Collection of blood samples and assessment of inflammatory biomarkers

At the end of the experiment blood samples were collected *via* cardiac puncture in EDTA tubes exclusive of anticoagulant, Fig. 2B, left for 10 minutes. Tubes were centrifuged at 4000 r/min for 10 minutes and obtained serum was put at –20ºC for further treatment (Sakr *et al.,* 2019) Different values of edema biomarkers like C-reactive protein and interleukin-6 were examined using commercially available ELISA kits (DiaMetra, Italy) Different concentrations of inflammatory biomarkers were evaluated at different concentrations of dose. Protocols of the above-mentioned parameters are attached in annexure-I and annexure-II.

Anti-inflammatory activity model

Inflammation in the albino rats' paw was caused by the carrageenan and reduced by the diclofenac and ethanolic leaf extracts of *C. paradisi* (50, 100, 200 and 400 mg/kg)

Figure 2. (A) Rats were injected with *A. barbadensis* gel extract in the sub-planter region of the left hind paw. **(B)** Blood samples collection by cardiac puncture for blood biomarker.
Figure 3. 3D structure of ligand molecules.
(**A**) Emodin and (**B**) Aloe-emodin are chemical compounds of aloe gel, selected as ligand molecules to target inflammatory proteins. (**C**) Diclofenac is a standard drug to target edema proteins.

A total of 36 albino rats were equally divided into three groups (control, standard, and experimental) In the control group, rats were treated with normal saline. In the standard group, rats were treated with diclofenac (100 mg/kg), and in the experimental group, rats were treated with the *C. paradisi* leaf aqueous extract. First, the size of the hind paw of rats was measured, followed by injecting the carrageenan doses (50, 100, 200, and 400 mg/kg) into the hind paw at the sub-planter region. The carrageenan doses start producing inflammation in the rat's hind paws. After 3 hours of carrageenan injection, the doses of *C. paradisi* leaf extract and diclofenac (12.5, 25, 50, and 100 mg/kg) were injected into the hind paw, and the paw size was measured at the time interval of 1, 2, and 3 h.

Anti-pyretic Activity Model

Pyrexia is induced in antipyretic activity in albino rats by normal saline and yeast and then treated with leaf ethanolic extracts of *C. paradisi* (50, 100, 200 and 400 mg/kg) for reducing fever. The rats in this model were also divided according to the anti-inflammatory activity model. In the control group, rats were treated with normal saline (2 ml/kg) below the nape of the neck, and in the standard group, rats were treated with normal saline + brewer's yeast. In the experimental group, rats were treated with doses of ethanolic leaf extracts of *C. paradisi*. After injecting yeast, fever developed after 21 hours, and the highest temperature, 101.81 Fahrenheit was measured.

In silico anti-inflammatory activity of *A. barbadensis*

To begin with *in silico* analysis, different computational tools including chemskech, chimera, pymol, pyrx, depth

residue and discovery studio were used in support of the anti-inflammatory effect of *A. barbadensis*.

Selection and preparation of ligands

Aloe emodin and emodin are chemical compounds of the anthraquinone family present in the Aloe gel, which possesses an anti-inflammatory role. Therefore, analysis was done targeting these intermediates using as it may control the undue inflammation and consequently prevents acute inflammatory infections. Three ligand molecules emodin, aloe emodin and diclofenac were selected for molecular docking studies. ChemSketch was assessed for the 3D structure of ligand molecules as shown in Fig. 3A, B, C.

Protein preparation and prediction of the active site

CRP and IL-1β were selected for *in silico* studies as target proteins. The 3D structures of CRP and IL-1β were occupied from Swiss prot, subsequent to open in Chimera. Out of four, one chain of IL-1β was selected. All unnecessary ions and metals were removed. The geometry of all hetero groups was assured and the structure of the protein was saved as a PDB file. The active sites of CRP and IL-1β were found in depth residue.

Protein-ligand docking

To identify the potential anti-inflammatory drug or ligand molecule for a particular protein, PyRx was used for virtual screening. In this procedure, both target proteins CRP and IL-1b and ligand molecules were opted from pdb files; fasten to the binding pocket of the receptor protein. Following to docking run, results were estimated on the strength of bond interaction, binding site energy and ligand-molecule interface. Discovery studio was used to fashion complexes of proteins-ligand molecules and 3D structure of complex for high-quality observation respectively. The Chimera tool was operated to generate the 3D structure of the complex for high-quality observation.

Emodin, aloe-emodin and diclofenac have molecular formulas $C_{15}H_{10}O_5$, $C_{15}H_{10}O_5$ and $C_{14}H_{11}Cl_2NO_2$ with PubChem ID 3220, 10207 and 3033 respectively.

Statistical analysis

The data were subjected to homogeneity of variance to check normality and preceded to one-way ANOVA

Table 1. % age inhibition of paw size in group III (*A. barbadensis* gel ethanolic extracts) in dose-dependent manner exhibiting significant *p*<0.05 decrease at 5th hour (mean±S.D 30.83^d±0.60) with 51% inhibition *p*-value<0.0001. While no such effect was demonstrated in group I (control) (mean ±S.D. 62.33^a±1.67).

Treatment	Reaction Time with mean ±S.D. (% inhibition) per hour

using PROC GLM in SAS software (version 9.1) Duncan's multiple range test, Pearson correlation method and Dunnett's *t*-test were used considering $p \leq 0.05$.

RESULTS

In this study, the anti-edematous effect of *A. barbadensis* gel ethanolic and aqueous extracts at different concentrations (50, 100, 200 and 400 mg/kg) was observed against rat models of acute edema. The results showed a significant difference between the groups of rats treated with the extracts and the control group.

Effect of *A. barbadensis* on paw sizes in rat

All groups showed a significant increase in paw edema volume injected with 1% carrageenan. Group I showed the most pronounced increase in paw volume (45.17ᵃ±1.66, 47.83ᵃ±2.29, 55.67ᵃ±2.58, 64.17ᵃ±1.66 and 62.33ᵃ±1.67) after 1 to 5 hours of injection. While, group III and IV treated with *A. barbadensis* gel extracts at different concentrations (50, 100, 200 and 400 mg/kg) reduced paw edema at 1 to 5 hours as compared to group I. showed an improvement in the edema volume as compared to group I. The improvement was more pronounced at the 5th hour in a dose-dependent manner with PI 23, 45, 49 and 51% closer to diclofenac treated group 61% as shown in Table 1. Group IV treated with *A. barbadensis* gel aqueous extracts showed

($p<0.05$) % inhibition activity 29, 36, 41 and 46 % closer to group III. *A. barbadensis* gel ethanolic extract (group III) showed the most pronounced effect as compared to *A. barbadensis* gel aqueous extracts (group IV) as shown in Table 2.

Effect of *A. barbadensis* on immunological and biochemical parameter

Carrageenan is an intermediary of edema cascade. C-reactive protein is produced in the liver by IL-6 and is involved in edema and innate immune reactions. In response to inflammation, IL-6 is triggered by macrophages and neutrophils into the bloodstream and increases CRP and IL-6 levels in the blood. Hence, both CRP and IL-6 are broadly recognized as edema biomarkers. To additionally expose the means of the action of *A. barbadensis* gel extracts, the immunological and biochemical parameters in inflammation and pro-inflammatory cytokines like CRP and IL-6 were analyzed by ELISA method. *A. barbadensis* gel extracts significantly ($p \leq 0.05$) reduced the elevated levels of CRP and IL-6 in blood. CRP biomarker values significantly differ in group III (4.75ᵈ±0.02) and IV (6.94ᵈ±0.04) as compared to group I (control) with elevated levels of CRP (9.48ᵃ±0.22) IL-6 values also differ significantly ($p \leq 0.05$) at different doses in extract-treated groups III (13.48ᵈ±0.02) and IV (14.23ᵉ±0.03) as compared to group I control (17.21ᵃ±0.10) as shown in Table 3.

Table 3. Effect of *A. barbadensis* gel extracts on biomarkers CRP (ng/ml) and IL-6 (pg/ml) in group III and IV representing significant p-value<0.0001 reduction in edema as compared to group I (control).

Dose 400 *vs* group II	4.45833	4.24521	4.67145	***

In a comparison of the experimental group IV with the control and standard group, our results showed a significant difference where, ***$p < 0.001$.

The most significant ($p \leq 0.05$) effect of both extracts was observed at a dose of 400 mg/kg closer to group II (standard) treated with diclofenac drug ($2.48^{e \pm 0.08}$) in a dose-dependent manner, where *p*-value<0.0001.

Comparison study of biomarker CRP

By comparing CRP biomarker in group III and IV doses *vs* group I and II, there is a significant $p < 0.001$ mean difference between treated groups at different doses. Group III was treated with a dose of 400 mg/kg *vs* control and standard group has a mean difference of –4.7300 and 2.26500 respectively. Group IV was treated with a dose of 400mg/kg *vs* control and standard group has a mean difference of -2.5367 and 4.45833 respectively as shown in Table 4.

Comparison study of biomarker IL-6

By comparing IL-6 biomarker at different doses, group III treated with a dose of 400 mg/kg *vs* control and standard has a mean difference of –3.73167 and 3.05667, respectively. Group IV treated with a dose of 400 mg/kg *vs* control and standard group has a mean difference of –3.19264 and 3.80333, respectively as shown in Table 5.

Correlation study

The study of correlations is fundamental to the comprehension of biological methods. Correlation analysis is abundantly used to interpret, quantify, and visualize the association between measured values.

According to Pearson's correlation, there was a strong positive correlation (0.19) between biomarker CRP and IL-6 ($p < 0.05$) in the control group. While, it was negative (–0.18) in the standard group and all doses of 50, 100, 200 and 400 mg/kg as highly strong negative correlation (–0.71), weak negative (–0.07), strong negative correlation (–0.27) and (–0.29) correspondingly. In group IV there was a strong negative correlation at higher doses of 200 and 400mg/k (–0.69) and (–0.06) respectively.

A positive correlation was observed between the IL-6 marker and paw size where the correlation was significant at ($p < 0.05$) A strongly positive association was evident with increasing dose rate at 100, 200 and 400 mg/kg i.e. 0.18, 0.58 and 0.89 in group III and 0.2, 0.21 and 0.74 in group IV correspondingly.

Based on the results, CRP marker and paw sizes depicted a negative correlation of –0.37 in both the control group and the standard group. At the 4th hour, there was a positive correlation at a dose of 50 and 100 mg/kg as (0.22) and (0.4) However, the correlation was weakly negative at a dose of 200 and strongly negative at 400 mg/kg i.e. –0.06 and –0.51 correspondingly. At the end of the 4th hour, there was a negative correlation between the biomarker IL-6 and paw sizes ($p < 0.05$) in the experimental group IV at doses 50, 100 and 200 as (–0.9), (–0.36) and (–0.05), respectively as shown in Table 6.

In-silico analysis

In-silico analysis examined the potential of *A. barbadensis* to target cytokine IL-1b and CRP. The molecular binding energy of ligands against CRP scored –7.5Kcal/mol for aloe emodin and emodin and –7.0 Kcal/mol for diclofenac. IL-1b has –4.7Kcal/mol energy for aloe emodin and emodin and –4.4 Kcal/mol for diclofenac. While aloe emodin exhibited the highest score among the three as shown in Fig. 4.

Protein structure analysis and binding pocket with ligands

IL-1b has one chain, and CRP has five chains. All ligand molecules and proteins were adjusted in the grid box.

Table 5. Comparisons of IL-6 biomarker means through Dunnett's *t*-test

clofenac with IL-1β has 1 hydrogen bond at TYR-237 (2.42 Å) and 2 hydrophobic bonds at GLU-227 (3.86 Å) and TYR-237 (4.95 Å) Emodin with IL-1β has 2 hydrogen bonds at GLU-227 (1.96 Å) and ASN-254 (2.54 Å) Aloe-emodin with IL-1β has 1 hydrogen bond at GLU-227 (2.21 Å) shown in Fig. 7.

DISCUSSION

The present study was evaluated to assess the medicinal capacity of *A. barbadensis* against induced inflammation in rat paw. Plant-derived remedies exhibit high medicinal properties when extracted *via* organic solvents. Previous studies reported carrageenan for its biphasic outcomes triggered by the production of endogenous mediators in addition to the discharge of serotonin and histamine in the earliest hour compelling vasodilatory cores, following period is mediated by the discharge of prostaglandins, free radicals, interferons, interleukins, tumor necrosis factor, lysozyme and bradykinin in the progression of inflammation from two to six hours post carrageenan injection. Major cells of the immune system are concerned in these processes including mast cells, basophils, and neutrophils. This time is insightful to evaluate the anti-edematous effect of natural and clinically efficient drugs. These natural antioxidants have the ability to detoxify and neutralize free radicals to protect against oxidative stress-induced cellular injuries (Jyothi *et al.,* 2022; Rosales *et al.,* 2020)

In our study, inflammation was significantly ($p<0.05$) reduced in groups III and IV in dose-dependent manner. A higher dose of 400 mg/kg showed 51% and 46% inhibition of paw edema effective as imitating the action of the drug diclofenac with 61% inhibition. High concentration of anthraquinones, like aloe-emodin, carboxylic acid and polysaccharides in aloe-gel may trigger an immune response, while lower dose do not persuade such an effect. Results of another study were concurrent with our findings (Gupta *et al.,* 2020; Pradhan *et al.,* 2021)

Previous studies have shown that edema may be clarified by reducing cyclooxygenase and PGE2 levels from arachidonic acid. Presence of phytoconstituents, phenolic compounds, flavonoids like quercetin and salicylic acid, choline, vitamins, folic acid, B1, B2, B6, C, β-carotene and α-tocopherol in aqueous extract of *A. barbadensis* gel may be accountable for anti-inflammatory activity in sub-acute edema model. The results of another study were concurrent with our findings (Gul *et al.,* 2023; Naureen *et al.,* 2023, Naveed *et al.,* 2022b; Jhundoo *et al.,* 2020) CRP is an acute phase protein and IL-6 is a reliable biomarker (cell signaling agent) which amplifies at the inflammation site. The previous studies reported CRP as a key role in inflammatory courses and host retorts to infections together with the complement pathway, nitric oxide (NO) release, apoptosis, phagocytosis, and the assembly of cytokines, predominantly tumor necrosis factor-α and interleukin-6. Group I demonstrated a noteworthy elevation in serum levels of CRP and IL-6 post-carrageenan injection. In a similar trend, others reported remarkable elevation in serum levels of IL-6 and CRP in rats subsequent to 4 hours post carrageenan injection (Acharya *et al.,* 2019)

A higher dose of extract (400 mg/kg) has exposed an enhanced inhibitory effect in IL-6 than the lower dose (50mg/kg) in groups III and IV. For CRP, it demonstrated inhibition of increased serum cytokines and proteins in dose-dependent manner. The use of *A. barbadensis* in some inflammatory cascades confirmed the occur-

rence of active biochemical compounds and minerals and gallic acid related to these edema inhibition activities (Asci *et al.*, 2017) The correlation was positive between biomarkers CRP and IL-6 in group IV in our findings. Similarly, other reports are in concurrence with our data set showing that classic and trans-pathways together take part in the inflammatory bout, although, both pathways are diverse. Through classic signaling in the liver, IL-6 up-regulates the production of CRP, with lipolysis. IL-6 correlates well with the severity of other inflammatory processes interceding the edema reaction (Vreugdenhil *et al.*, 2018)

Molecular docking is a new strategy to analyze binding energy or interaction. Results evidenced that phytoconstituents emodin and aloe-emodin showed interaction with active sites of protein concerned with inflammation and have utmost inhibitory potential against CRP and IL-1beta and could be practiced in the treatment of edema disorders. The binding interaction of the phytoconstituents of *A. barbadensis* and standard drug diclofenac against edema cytokines like IL-1beta and protein CRP exhibited maximum affinity –7.5 by aloe emodin, diclofenac with –7.0 Kcal/mol and emodin with –4.5 Kcal/mol binding score. Aloe-emodin demonstrated the utmost part for inhibiting edema, which are in accordance with our findings (Syed *et al.*, 2023; Sana *et al.*, 2023; Khushnuma *et al.*, 2023; Aziz *et al.*, 2023; Ahmad *et al.*, 2023; Naureen *et al.*, 2023; Kaloni *et al.*, 2019; Modak *et al.*, 2021; Saleem *et al.*, 2023; Naveed *et al.*, 2022a)

CONCLUSIONS

Use of SAID and NSAIDS possibly helpful in disease management but their adverse impacts pretence health problems. Therefore, therapies with safe natural sources are mandatory. Our study concluded that potentially bioactive phytochemicals in *A. barbadensis* detoxify and counteract free radicals to reduce edema. Hence, our study supports the traditional use of *A. barbadensis* gel extract as an effective and safe drug against inflammation.

The aim of this study was to examine the protective role of various lipids (olive and soya oil) and vitamin (E and C) against the toxicity of thermally oxidized ghee in rabbits. Vanaspati ghee was thermally oxidized on a hot plate at 100°C for ten consecutive hours, and the oxidized ghee was stored in a refrigerator at –20°C until administration. Thirty male rabbits were purchased as experimental animals at a local market and were divided into ten corresponding groups of three based on their body weight. The blood samples of 5 ml were collected on day 0, 7, and 14 of the experiment for the analysis of hematological and biochemical serum parameters. We observed that oxidized ghee significantly elevated ALT level by affecting liver hepatocytes. Furthermore, vitamin E rapidly decreased the ALT levels compared to vitamin C and other oils. The oxidized ghee caused a significant increase in cholesterol compared to the other groups. Vitamin E and C showed the best antioxidant activity and decreased cholesterol levels to normal. Histopathological examinations of the normal rabbits' liver sections revealed no significant histological abnormality. The liver of the rabbits fed with oxidized ghee had an intact lobular architecture but the portal tracts showed inflammation and mild fibrosis, the bile ducts showed proliferation, and the hepatocytes showed feathery degeneration. In the liver sections from the groups fed with oxidized ghee and different doses of olive oil inflammation in portal tracts and large vacuoles in the hepatocytes were observed. The group fed with oxidized ghee and vitamin E had intact lobular architecture with no significant histological abnormality in portal tracts but fatty changes were present in the hepatocytes. These findings support the antioxidant activity of vitamins C and E as they reduced liver infection caused by oxidized ghee. It was concluded that oxidized ghee was highly toxic and not safe for consumption. The present study indicated that soya bean oil and vitamin E were more effective in protecting against the toxicity of thermally oxidized ghee than olive oil and vitamin C.

INTRODUCTION

Vegetable oils and fats make up a significant portion of our daily diet. Lipids comprise triglycerides, cholesterol, and antioxidants, among others, and when subjected to cooking or heating can convert into oxidized compounds like hydroperoxides, epoxides, and hydroxides (Fatiha *et al.,* 2020; Zeb & Khan, 2019; Kamal *et al.,* 2003). The three above types of oxidized compounds produced during heating usually convert into other compounds; however, the hydroperoxides convert into a variety of oxidized products that have been documented to be toxic for humans; and some of them are deemed to contribute to liver cancer (Zeb & Mehmood., 2012). Lipids, react with reactive oxygen species in a process is known as lipid peroxidation, which proceeds by a free radical chain reaction mechanism enhancing the production of free radicals (Gutteridge 1995; Halliwell & Gutteridge 1990). Free radicals significantly contribute to developing diseases like diabetes, atherosclerosis, cancer, chronic inflammatory disorders, and neurodegenerative diseases (Mobin, 2012). Free radicals are usually neutralized by enzymes (superoxide dismutase, catalase, and glutathione peroxidase) and antioxidants (vitamin E, vitamin C, carotenes, flavonoids, glutathione, uric acid, and taurine) (Jadhav & Priyanka, 2016). The benefits of olive oil for human health have been well reported and documented in the literature. Olive oil comprises monounsaturated fatty acids, like oleic acid, vitamin E, and polyphenols, which have beneficial effects on cardiac health (Nocella *et al.,* 2018). Particular attention has been given to VOO (virgin olive oil) because it contains antioxidants such as lipophilic and hydrophilic phenols (Kiritsakis *et al.,* 2020). Olive oil also contains 3,4-dihydroxy phenyl ethanol, an antioxidant with antithrombotic action (Paiva *et al.,* 2017). Vitamins E and C are known antioxidants that prevent the harmful effect of free radicals (Chan & Alvin, 1993). The co-loading of antioxidant vitamins E and C in olive oil emulsions has shown to be effective in maintaining the peroxide values (Cuomo *et al.,* 2020). Soybean oil is the leading edible vegetable oil in the world and is usually consumed in partially hydrogenated forms (Cinelli *et al.,* 2020). It contains many aromatic compounds, such as eugenol, which have antioxidant properties; it is worth mentioning that this oil is also one of the richest sources of vitamin E (Applewhite, 1981; Lee & Shibamoto, 2000). Commonly known as hydrogenated vegetable oils, Vanaspati ghee and banaspati ghee are high in trans fats, are hazardous to health, contributing to diseases like cardiovas-

cular diseases, obesity, and cancer (Rusin & Krawczyk, 2011). Ghee, when heated up to 120°C, becomes oxidized and hazardous for health, and is known as thermally oxidized ghee (Iqbal, 2014). It has been reported that thermally oxidized ghee causes *in vivo* toxicity by increasing hydroperoxide production and decreasing the radical scavenging assay (RSA) value. Oxidized ghee's toxicity increases with the oxidation time, leading to hypertriglyceridemia, and increase in total cholesterol and LDL-cholesterol level (Zeb & Mehmood, 2012). As ghee is used to fry and cook food in our society, and persistently heated for a long time, hence, ghee oxidation occurs and its oxidative products, toxic to humans, accumulate in food. Therefore, in this study we describe the toxic effects of the heated ghee on a number of hematological and biochemical parameters and liver histology in rabbits. Moreover, a number of antioxidant oils and vitamins were used along with oxidized ghee to determine their effect against the ill effects of thermally oxidized ghee.

MATERIALS AND METHODS

Materials:

The Vanaspati ghee used in this research was from Halal Associated Industries Limited. The olive oil was packed and exported by Aceites Borges Pont, S.A.U, marketed in Pakistan by Zaitoon Pakistan (Pvt) Ltd, Islamabad, Pakistan. The soya bean oil utilized in this experiment was from Agro Processors and Atmospheric Gasses Pvt Ltd. The vitamin E: DL-alpha tocopherol acetate was from Merck Pharmaceuticals (Private Limited, 200 mg), and the Vitamin C was from Abbot Laboratories (Pak, 500 mg).

Thermal oxidation of ghee:

Vanaspati ghee was thermally oxidized on a hot plate at 100°C for ten consecutive hours, and oxidized ghee was stored in the refrigerator at –20°C until administration.

Experimental animals

Approval of the study was granted by Advanced Studies and Research Board and Ethical committee of Islamia College University, Peshawar, Pakistan. Rabbits were purchased from the dealers in Chakdara city and kept in the Bio-Park for two weeks. Green fodder and water were provided *ad libitum*. The experiments were conducted in the Biotechnology Department, University of Malakand, Chakdara, Dir (Lower), Khyber Pakhtunkhwa, Pakistan.

Experimental groups

After acclimatization, thirty rabbits were divided into ten replicate groups based on their body weight. Each group comprised three male rabbits. Group A (NC) served as negative control and was fed a regular diet.. Group B (OG) was provided with oxidized ghee at the dose rate of 2 g per a kg of body weight. Group C was fed with oxidized ghee at the dose rate of 2 g/kg, and 1 g/kg of olive oil as an antioxidant. Group D was fed with oxidized ghee at 2 g/kg and an extra virgin olive oil at a dose rate of 2 g/kg body weight. Group E was fed with oxidized ghee at 2 g/kg, and 1 g/kg of soya bean oil. Group F was fed with oxidized ghee at 2 g/kg, and

2 g/kg of soya-bean oil. Group G was fed with oxidized ghee at 2 g/kg, and vitamin E at 100 mg/kg. Group H was fed with oxidized ghee at 2 g/kg and vitamin E at 200 mg/kg. Group I was fed with oxidized ghee at 2 g/kg, and vitamin C was given as an antioxidant at 100 mg/kg.. Group J was fed with oxidized ghee at 2 g/kg with vitamin C as an antioxidant at 200 mg/kg.

Blood collection

The 5 ml blood samples were collected on experimental day, 0, 7, and 14, to analyze hematological and biochemical parameters of the serum. Strict aseptic conditions were applied during the blood sampling.

Hematological parameters

Three milliliters of the whole blood samples were transferred to heparinized tubes. A fully automated blood hematology analyzer (SYS MIX, Japan) was used to measure total red blood cells number, hemoglobin concentration, hematocrit value, mean corpuscular cell volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, total leukocyte count, and neutrophils, eosinophils, lymphocytes, and platelets count.

Analysis of the biochemical parameters

Biochemical parameters of the serum were analyzed using total cholesterol and triglycerides test kits (Merck, Germany) and human HDL-c, LDL-c, ALT, and glucose assay kits (HUMAN Diagnostics, Germany).

Histopathology

The rabbits were sacrificed at the end of the experiment, and their livers were dissected and stored in a formalin solution as previously described in Ayaz and others (Ayaz *et al.,* 2017). Each animal's liver was washed in normal saline solution and cut into slices. The slices were embedded in paraffin after dehydration with 100% ethanol and fixation with 10% formalin. The slices were then cut into 4 to 5 micrometers thick sections and stained with hematoxylin-eosin (HE, M 7000 D, SWIFT, Japan). A light microscope was used to examine the sections, while a 1.3 MP digital camera placed atop the microscope was used to capture images.

Statistical Analysis

All the experimental points consisted of 3 different samples. Data were analyzed by one-way analysis of variance (ANOVA) using GraphPad Prism version 5.

RESULTS

Analysis of blood biochemical parameters

After 7 days of the experiment, rabbit blood samples were collected, and serum was isolated from the samples for biochemical measurements.

It was observed that oxidized ghee significantly elevated the ALT level, suggesting affecting liver hepatocytes. Vitamin E decreased ALT level to the greatest extent, as compared to vitamin C and other oils that were fed.

The oxidized ghee diet caused significant raise in cholesterol levels that was mitigated with vitamins C and E, olive oil and soybean oil. The groups fed with vitamin E and C showed the greatest improvement of cholesterol

Table 1. Biochemical parameters in the studied groups of rabbits measured on day 7 and day 14 of the treatment.

OO, olive oil; SO, soya bean oil; NC, normal control; OG, oxidized ghee

level parameters, that were close to normal. . A significant decrease in cholesterol level was observed also in the groups that were fed with olive oil and soya bean oil, but it still remained above the normal range.

As shown in Table 1, oxidized ghee significantly elevated the level of triglycerides in serum. Vitamin E and C significantly decreased the triglycerides' level increased by oxidized ghee. At day 14, no significant difference ($P<0.05$) was observed between the mean values of triglycerides' levels in soya bean oil (2 g/kg) and vitamin E 200 g/kg fed groups. There was also no significant difference ($P<0.05$) between vitamin E (100 mg/kg) and vitamin C (100 mg/kg) fed groups. The triglycerides' levels differed significantly ($P<0.05$) between the remaining experimental groups. Olive oil lowered the triglycerides' level, but to a smaller extent than other antioxidants tested.

Oxidized ghee significantly lowered HDL serum levels. Soya bean oil and olive oil counteracted this effect, increasing HDL level close to normal. Vitamin E and C also increased HDL level but still it was below normal. There was significant difference in HDL serum level among all the groups except vitamin E and C groups. Figure 1 demonstrates that oxidized ghee significantly increased LDL level. There was a significant decrease in LDL level in the groups that were fed with soya bean oil, vitamin E and C but still it was above the normal range. Olive oil also lowered LDL level, but its effect was weaker than other antioxidants.

Statistical significance of the comparison between the means in a row is denoted with letters: the same letter shows no significant difference between the means, while different letters represent a significant difference ($P<0.05$).

Effects on hematological parameters

Whole blood samples were analyzed for complete hematology for each of the groups. As shown in Table 2; at day 14, the groups fed with soya bean oil and vitamin E had increased TRBC, Hb, PCV, and MCH level compared to the ghee fed group. Vitamins E and C showed better antioxidant activity as compared to other oils in reference to MCHC. Oxidized ghee significantly elevated TLC and decreased neutrophil number whereas olive and soya bean oils counteracted this effect on neutrophiles. In addition, soya bean oil significantly decreased lymphocytes count increased by the oxidized ghee. Soya bean oil and vitamin C significantly increased platelets count lowered by the oxidized ghee.

Liver histopathology

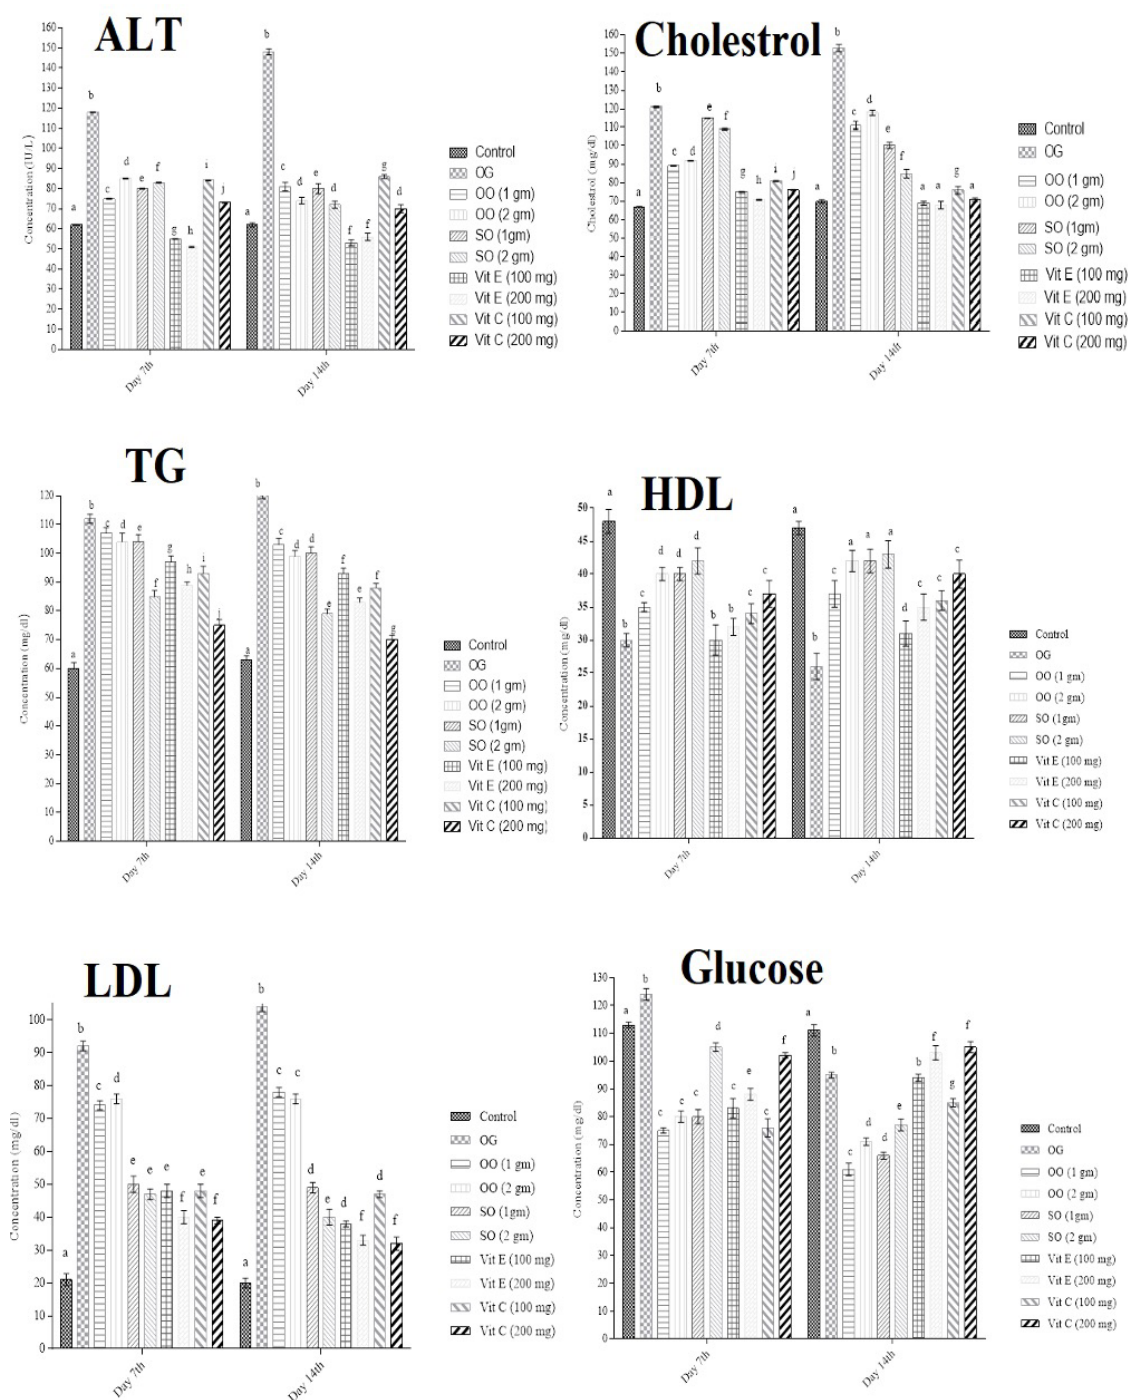
Histopathological examination of the rabbits' liver sections are demonstrated in Fig. 2. Hepatocytes of the Group A (normal control) revealed no significant histological abnormality (Fig. 2A–2B). Liver sections from the Groups B and C showed intact lobular architecture but the portal tracts showed inflammation and mild fibrosis. The bile ducts showed increased proliferation and the hepatocytes displayed feathery degeneration. (Fig. 2C–2D and 2E–2F). In the liver sections from Groups D to G; the portal tracts showed inflammation; and large vacuoles were present in the hepatocytes (Fig. 2G–2H to 2M–2N). The liver sections of rabbits in groups H and I showed intact lobular architecture with no significant histological abnormality in portal tracts but fatty changes in hepatocytes were present (Fig. 2O–2P and 2Q–2R). Liver sections of rabbits in Group J showed abnormalities similar to the rest of the non-normal control groups,


Figure 1. Hematological and biochemical parameters in the studied groups pf rabbits at different timepoints.
Significant difference (*P*<0.05) in glucose levels at day 14 was observed among all the groups, however, glucose levels were all in normal reference range in each group.

namely, sinusoidal dilation due to fats (Fig. 2S–2T). These findings revealed that vitamin E had superior antioxidant activity among the tested antioxidants because it effectively decreased liver inflammation caused by oxidized ghee.

Statistical significance of the comparison between the means in a row is denoted with letters: the same letter shows no significant difference between the means, while different letters represent a significant difference (*P*<0.05)

DISCUSSION

This study showed that feeding rabbits with oxidized ghee at 2 g per kg body weight resulted in elevated ALT, triglycerides, total cholesterol and LDL levels, and overall decrease in HDL levels. Although this intervention decreased blood glucose levels, they remained in the reference range. These results corroborate similar recent study, where high triglycerides, cholesterol and LDL levels as well as low glucose level were observed in mice fed with heated ghee. Also, HDL level was low in ani-
Figure 2. Histopathology of the rabbit liver samples

mals that were fed with thermally oxidized oils (Zahid *et al.*, 2022; Hina *et al.*, 2022; Sana *et al.*, 2022; Chinu & Rajamohan., 2011). Another study conducted in 2015 supports the findings of this study, i.e., high level of ALT, total cholesterol, triglycerol and LDL, as well as low glucose were observed in rabbits fed with oxidized corn oil (Aziz *et al.*, 2023; Uddin *et al.,* 2015). In the current paper, a decrease in TRBC, Hb, PCV, MCH, MCHC, neutrophils was observed in the rabbits fed with oxidized ghee. The platelets count was low but still in the normal range. Conversely, total leucocytes and lymphocytes numbers were increased above norm. When oxidized

ghee was fed to animals, it led to harmful effects on the blood cells (Sana *et al.*, 2022; Zeb & Ullah, 2015). Uddin and his coworkers (Uddin *et al.*, 2015) observed a decrease in TRB, hemoglobin, HCT, and an increase in WBC count in rabbits fed with oxidized corn oil. In the present study, it was observed that oxidized ghee was hepatotoxic and had adverse effect on liver histopathology. The liver tissue showed intact lobular architecture but the portal tracts showed inflammation and mild fibrosis, as well as accumulation of fat deposition in portal tract. The bile ducts showed signs of proliferation. The hepatocyte showed feathery degeneration. Similar results

OO, olive oil; SO, soya bean oil; NC, normal control; OG, oxidized ghee

were reported by Rahman and his team (Rahman et al., 2012), in Long Evans rats, which showed scattered hepatocellular necrosis and degeneration of hepatocytes when fed with ghee (Zeb & Ullah, 2015; Rehman et al., 2012).

The effect of olive oil and its high polyphenol contents have been studied before and the results support the present study's findings, i.e., increased HDL levels, decreased cholesterol, TG, and LDL levels in oxidized ghee fed rabbits (Covas et al., 2006). However, our study's results are a little different from one of the earliest papers published in 1996 that stated that olive oil protects low-density lipoprotein from oxidative activities (Jassim et al., 2010). It has also been observed that feeding of olive oil along with mercuric chloride gradually normalized serum ALT level (Wiserman et al., 1996; Youcef et al., 2014). Administration of olive oil appeared to decrease Hb concentration, WBC, platelet, and lymphocyte numbers in the treated rats, however, the difference was statistically significant only in the case of the platelet count (Nandakumaran et al., 2014).

In the present study, rabbits fed with olive oil along with oxidized ghee had intact lobular architecture of the liver but their portal tracts showed inflammation and their hepatocytes contained large vacuoles. Szende and colleagues observed that olive oil reduced hepatotoxicity of oral carbon tetrachloride (CCl4) (Szende et al., 1994). Olive oil partially protected the liver from mercuric chloride (HgCl₂) induced damage. A prominent recovery in the form of normal hepatocytes and greatly reduced centrilobular necrosis were observed. Pronounced sinusoid with granular hepato-cytoplasm were also present (Nandakumaran et al., 2014). Similar results were reported by another study in rats, in which the ingestion of olive oil protected the liver from ethanol-induced oxidative damage by affecting the cellular redox potential (Kasdallah et al., 2008).

A significant mitigating effect against ghee-induced hepatotoxicity was observed for soya bean oil. This effect was dose dependent. One study showed that feeding rats with non-oxidized soya bean oil alone induced significant and dose-dependent alteration in biochemical and hematological parameters (Robaina et al., 1995; Salahuddin et al., 2013). Another study conducted using soybean oil showed that animals fed with the oil had changes in the liver, including distinct enlargement of central veins and erythrocyte accumulation, enlargement and congestion of sinusoids (Salahuddin et al., 2013).

In the present study, we observed a protective role of vitamin E against the oxidized ghee-induced toxicity. Rabbits fed with oxidized ghee and vitamin E at 100 mg/kg or 200 mg/kg had decreased ALT, triglycerides, total cholesterol, and LDL levels, and increased HDL level in the direction of norm but still outside of the reference range. Similar results have previously been reported in case of mice fed with hight fat diet and high-fat and high-cholesterol diet by increasing serum total trigylcerides, cholesterol, and altered alanine aminotransferase, aspartate aminotransferase, and alkaline phosphatase (Liang et al., 2021). It was also observed that vitamin E increased TRBC, Hb, PCV, MCH, MCHC, and neutrophil counts, and decreased TLC and lymphocyte count, but not to such an extent that these indicators were within the normal range. Amer and his research team also support these results showing that. vitamin E and C reduce oxidative damage to RBC and platelets (Amer et al., 1991).

In our study, the protective effect of vitamin E against oxidized ghee induced toxicity was also observed in the liver histopathology,. An intact lobular architec-

ture with no significant histological abnormality in portal tracts was observed, however mild inflammation and mild fibrosis were detected in the portal tracts. These results are in agreement with the results of earlier studies which showed that vitamins E and C significantly improved liver fibrosis (Amer *et al.,* 2006). Also, vitamin C, when fed along with sodium fluoride (NaF) partially protected the liver from NaF toxicity (Stawiarska *et al.,* 2012). Uboh and his colleagues in 2012 demonstrated that in a model of gasoline vapor-induced liver injury in rats, vitamin E and C had protective effect on liver histopathology. The hepatoprotective effect was significantly higher in case of vitamin E than vitamin C (Uboh *et al.,* 2009). These findings support the results obtained in our study. In the previous studies, oxidized ghee caused inflammation and degeneration of hepatocytes (Zeb & Uddin 2017b), which is in concordance with our results. Also, both, enlargement of hepatic capillaries and severe liver necrosis were observed in the previous studies (Jimoh *et al.,* 2004). .In our histopathological findings, we observed a protective role of olive oil, soybean oil, and vitamins E and C against the oxidized ghee effects, and only mild liver inflammation and fibrosis (groups that received antioxidants together with the oxidized ghee) were observed in oxidized ghee fed animals co-fed with these antioxidants.

CONCLUSIONS

The experiment presented here was designed to examine a protective role of various lipids (olive and soya oil) and vitamins (E and C) against thermally oxidized ghee toxicity in rabbits. Oxidized ghee diet altered the hematological and biochemical parameters and induced abnormalities in liver histopathology in rabbits. Soya bean oil and vitamin E were the most effective against the toxic effects of thermally oxidized ghee as compared to olive oil and Vitamin C. It is recommended that ghee can be substituted with soya bean oil. Further studies can be conducted to identify the oxidative products accumulated in oxidized ghee and test other antioxidants' potential against the toxic effects of the oxidized ghee.
