Acta Biochimica Polonica (ABP) | 2023-2024 Retrospective

Dear Acta Biochmica Polonica community,

It is my pleasure to present this eBook compiling the manuscripts published in Acta Biochimica Polonica in 2023 and 2024. This period was special for the journal which joined Frontiers within the Publishing Partnerships program. This collaboration has a significant impact on publishing the journal, by combining the experience and expertise of editors with the excellent editorial service provided by the publisher.

I would like to express my warm thanks to all the authors, editors, and reviewers who have been contributing to Acta Biochimica Polonica. Because of their passion, dedication and hard work it was possible to publish excellent papers in virtually all fields of biochemistry in this broadly scoped journal, devoted to all biochemical specializations, from gene expression regulation to medical biochemistry, and from basic biochemistry to immunology.

Because of the broad biochemical scope of Acta Biochimica Polonica, this collection contains papers representing a diverse range of topics, methods and research subjects. However, all of these are connected to biochemistry, as the common point of all articles included in this eBook.

After successfully joining Frontiers, we look forward to the continued growth and impact of Acta Biochimica Polonica. I invite researchers, students and all people interested in biochemistry to engage with the content of this eBook. I hope you will enjoy reading the papers which can provide a field for discussion and encourage starting new research in the fascinating field of biochemistry.

The emergence of biological homochirality

Agnieszka Kiliszek and Wojciech Rypniewski✉

Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznań, Poland

The homochirality of biological molecules is one of the basic mysteries of biogenesis. The predominance of L-amino acids and D-hydrocarbons in living matter stands in contrast to the chemical principle of symmetry between enantiomers. An answer to the puzzle needs to include a plausible explanation of how the natural racemic balance was initially tipped in favor of one enantiomer and how the initial tiny excess was amplified to significant levels. It is also necessary to consider how the imbalance was sustained from returning to a thermodynamic equilibrium. This is a review of the main concepts and observations, followed by a brief discussion.

The processes by which life had arisen from nonliving matter are almost certainly beyond our cognitive horizon, but we can consider the milestone events that needed to occur at the onset of life's evolution. One of them is the selection from the "primordial soup" of the enantiomers that henceforth have determined life on Earth.

The biological predominance of L-amino acids and D-sugars needs to be explained because it stands in contrast to the chemical principle of equivalence between enantiomers (Fig. 1). As a rule, the chemical synthesis of chiral compounds from nonchiral components results in a balanced mixture of enantiomers, known as racemate. This natural balance was evidently broken in the early days of life's evolution on Earth, resulting in the observed homochirality of biological molecules. By an unknown mechanism, one enantiomer outweighed its symmetric counterpart and then the initial imbalance was somehow enhanced, leading to the near exclusion of the other enantiomer. The predominance of L-amino acids and D-sugars is found in all known life forms, indicating that the initial enantioselectivity and the following enantioenhancement must have occurred at the earliest stages of life's evolution.

Several models have been proposed of how the chemical symmetry was broken. They use physical factors, both internal and external to the molecules, probabilistic effects that could break the symmetry and chemical processes that could drive chiral resolution.

The purpose of this paper is to survey only the main concepts and observations concerning enantioselectivity, and to consider how any emerging imbalance could be sustained from returning to thermodynamic equilibrium.

Deterministic models rely on symmetry-breaking forces in nature. The natural place to look for the origin of chiral bias is the very fabric of nature, which is known to contain a chiral component. One of the fundamental forces, the weak interactions, violate parity-symmetry (Wu *et al.*, 1957). Weak interactions occur in the atomic nuclei, but their effect permeates the electronic structure, modifying its wave function and energy. Being chiral, the weak interactions should stabilize one enantiomer and destabilize the other (Fig. 2). This can possibly be detected, but there are no conclusive observations of such an effect (Avalos *et al.*, 2000). Initial theoretical calculations yielded energies of approximately 10^{-14} J/mol for simple amino acids or sugars (Tranter, 1985; Tranter, 1987; Mason & Tranter, 1985). Subsequent calculations on simple molecules indicated that the effect could be as high as 10^{-11} J/mol (Quack, 2002). This is taken as a free energy difference and corresponds to an excess of 10^6-10^9 molecules of one enantiomer in a mole of the racemic mixture, correlating to one molecule in ~10^{15}–10^{18} (Ava-

Figure 1. Biological molecules have distinct chirality.
Nucleic acids and carbohydrates (sugars) have the D-configuration, while proteins have the L-configuration.

Figure 2. Parity violating weak interactions break the mirror symmetry in nature.
This is effectively demonstrated in particle physics but their effect on the stability of small chiral molecules has only been estimated. The electronic potential profile for enantiomers is not symmetric but the predicted value of the parity violating energy difference (PVED, $\Delta_{pv}E_{el}$) is very small, amounting to 10^{-11} J mol^{-1}.

Figure 3. Scheme illustrating an autocatalytic reaction, with an "isotope enantiomer" stimulating the production of one enantiomer and inhibiting the other.

los *et al.*, 2000). These amounts are orders of magnitude below the statistical noise level; the Poisson noise is 8×10^{11} molecules per mole (Quack, 2012). To claim that the weak forces are responsible for life's homochirality one would need to propose a mechanism *via* which this tiny difference could be amplified to give the observed imbalance in life forms.

If the inner chirality of atoms is insufficiently chiroselective, one might look for external chiral factors that could shift the balance between enantiomers in the "primordial soup". Circularly polarized photons or spin-polarized cosmic particles have been considered, especially those produced as a result of parity-breaking weak interactions (Lee & Yang, 1956). Particles whose electric vector spirals (clockwise or counterclockwise) along their direction of motion are chiral in the same sense that screws are right- or left-handed, and when they interact with matter, they are absorbed differently by different enantiomers. It was proposed that photons resulting from β-decay should be circularly polarized and could have a stereoselective effect on organic matter (Vester *et al.*, 1959). A number of experiments were performed to verify the Vester-Ulbricht hypothesis, leading to the conclusion that this was not an effective mechanism for creating a chiral imbalance. This was reviewed in (Bonner, 2000).

To conclude, the parity-breaking weak interactions would be the best natural candidate to explain the non-parity of biological molecules, were it not for the very large energy gap between the parity violating energy difference (PVED) and the energy regime of chemical interactions. An extensive perspective on the issue of parity violation in chiral molecules and its possible role in the emergence of biological homochirality was published recently (Quack *et al.*, 2022).

Probabilistic models rely on chance events. To explain the observed homochirality of biological molecules, the models require two components: an initial breaking of the balance between enantiomers (enantioselectivity), followed by an amplification of the initial imbalance (enantioenrichment). In this scenario, the initial imbalance stems from random fluctuations at the molecular level, followed by amplification *via* asymmetric autocatalysis in which a chiral molecule assists its self-production (Mislow, 2003). Such autocatalytic reactions have been inves-

tigated by Soai and coworkers (Soai *et al.*, 1995; Soai *et al.*, 1999). Once set in motion, these self-propelling reactions could amplify a small initial imbalance between the enantiomers. One scenario that was considered involved "isotope chirality", as the source of the initial imbalance. Isotope chirality is a result of ^{13}C substituting a ^{12}C atom in otherwise achiral organic compounds (Kawasaki *et al.*, 2009). The authors demonstrated that the presence of an isotope bestowed sufficient chirality on an achiral compound to set off enantioenrichment in an autocatalytic mechanism (Fig. 3). The question remains how to achieve the necessary initial imbalance between the "isotope enantiomers", even a tiny one, that could then be amplified. The isotope substitution in a molecule appears to be random and therefore expected to result in a 1:1 racemic mixture.

The Soai autocatalytic reaction, using an isotopically ($^{13}C/^{12}C$) chiral molecule as the initiator, was recently used to estimate the amount of energy needed to trigger enantioselectivity (Hawbaker & Blackmond, 2019). Multiple runs of the reaction were performed at various dilutions of the initiator to assess its threshold concentration sufficient to break the balance between the produced enantiomers. The threshold enantiomeric excess for the initiator was estimated to be between 1 and 0.1% of the initiator molecule. The authors then turned to stochastic simulations to estimate the amount of energy required to break the balance between the enantiomers under autocatalytic conditions and they obtained values between 1.5×10^{-7} and 1.5×10^{-8} kJmol^{-1}. This energy is five to seven orders of magnitude larger than the current estimates of PVED quoted in the previous section (Quack, 2002), confirming that the weak forces were unlikely to be the cause of biological homochirality. On the other hand, this symmetry-breaking energy threshold also is unlikely to be achieved by chance in the stochastic scenario. Thus, the probabilistic models also have a problem with delivering the necessary initial imbalance which could then be amplified *via* an autocatalytic chain reaction. Stochastic events tend to balance out, and if, by chance, an imbalance between enantiomers arises at some place, it is likely, that a compensating imbalance arises somewhere else. To circumvent this, the size of the "pool of the primordial soup" could be reduced, and then the number of possibilities would be reduced. Therefore, a fluctuation would have a better chance of not being canceled out by another fluctuation in the opposite direction. However, reducing the size of the pool

Figure 4. Chiroselective self-assembly leading to independently evolving "libraries" of polymers having different chiralities. As the populations evolve, they begin to differ. Eventually, homochiral "winner sequences" emerge from one of the libraries.

also reduces the chance of a significant fluctuation occurring in the first place.

Another approach to breaking the symmetry of the primordial racemic soup relies on the "chiroselective self-assembly" of nucleobase sequences. In this model, the chiral templates facilitate the synthesis of more oligomers of the same chirality. In time, the L- and D-libraries grow and evolve independently. Eventually, they diverge because the number of possibilities is greater than what is able to be obtained in the limited pool of resources. Eventually, "winner sequences" emerge in one of the libraries, having no symmetric equivalents in the other library (Fig. 4). Thus, homochiral seeds of biological molecules could arise (Bolli *et al.*, 1997).

CRYSTAL-BASED MODELS

Some of the proposed models for enantioselectivity and enhancement rely on crystallization. Crystals begin as seeds consisting of a small number of molecules and grow as regular lattices, often reaching macroscopic dimensions. Thus, crystallization can be considered a means to amplify interactions occurring at the molecular

Figure 5. (A) When crystals grow from a solution of a racemate, they can be either racemic compounds (containing both enantiomers) or conglomerates (enantiomers form separate crystals). In specific cases, conglomerates can be nudged to homochirality by a physical factor (see text). **(B)** In racemic compounds, the enantiomers sometimes pack asymmetrically, which means that they can differ significantly in their structures and lattice contacts in the crystal (see Kiliszek *et al.*, 2021). **(C)** Section of electron density (*blue contours*) of the crystal structure reported by Kiliszek and others (Kiliszek *et al.*, 2021), showing asymmetry between the L- and D-RNA oligomers, with major differences in their interactions with the solvent and crystal lattice contacts.

level up to the macroscopic scale. Due to its amplifying effect, crystallization is analogous to autocatalysis.

A racemate can crystallize in two different ways, forming either separate crystals of L- and D-enantiomers ("conglomerates") or crystals containing both enantiomers ("racemic compounds") (Fig. 5A). In themselves, these crystals do not change the enantiomeric balance, but some mixtures of conglomerates can be nudged to homochirality by a physical factor, such as stirring or heating. This is possible under specific conditions. One condition is that the compound remaining in the liquid phase can undergo racemization, which enables the shifting of the balance between the L- and D-crystals (Kondepudi *et al.*, 1990). Another possibility exists for nonchiral molecules that can form chiral conglomerates (Viedma, 2005).

With racemic compounds, the main concept is that crystallization removes equal amounts of L- and D-molecules from the solution. Therefore, any initial imbalance in the quantities of the enantiomers is enhanced in the liquid phase (Klussmann *et al.*, 2006; Breslow & Levine, 2006). For this model to work, a preexisting imbalance, however small, is needed.

EXPERIMENTAL REPORTS

A number of research papers have been published that report on observations considered to be significant deviations from parity, with implications for the origin of biological homochirality. In a study published in 1999, crystals were grown from racemic solutions of sodium ammonium tartrate as well as chiral complexes of cobalt and iridium (Szabó-Nagy & Keszthelyi, 1999). The crystals were collected, dissolved and the optical activity of the resulting solution was analyzed, showing a chiral balance in the tartrate but an imbalance in the heavy metal compounds. This result indicated that from the balanced enantiomeric mixtures of the Ir and Co compounds, one enantiomer crystallized more easily than the other. This was interpreted as a sign of the parity-violating weak forces biasing the intermolecular interactions. The authors stated that "there is hope of detecting parity-violating energy difference in crystallization because macroscopic crystals consist of a large number of molecules". Further statistical analysis showed that the asymmetry of the Ir data was significant, while the effect for Co was inconclusive; thus, it could not be ruled out that the observed effect was due to other factors (Avalos *et al.*, 2000).

A paper from 2006 describes a study of L- and D-polypeptides in solution by means of circular dichroism (CD) and isothermal titration calorimetry (ITC) (Scolnik *et al.*, 2006). Subtle differences in the helix-coil transition energies of the different enantiomers were reported. The authors argued that the tiny effect of parity-violating interactions could be amplified in the cooperative process of helix formation. They also proposed that the *ortho* spin isomers of H_2O, having a magnetic field, could have a preference for interacting with the L-polypeptides due to their magnetic component induced by the weak forces. A related work from the same research group reported differences in solubility between L- and D-tyrosine, discerned by their rate of crystallization (Shinitzky *et al.*, 2002; Deamer *et al.*, 2007). The authors suggested this was due to the energy differences originating from parity violation. This was challenged by (Goldberg, 2008), who, having performed a series of crystallization experiments, concluded that the difference "is the result of a diastere-

omeric interaction between an airborne, non-racemic, chiral influence – probably a fungal spore – and the tyrosine enantiomers, enhancing the degree of crystal nucleation of D-tyrosine over L-tyrosine". Another critique came from (Lahav et al., 2006), who repeated the crystallization experiments in their lab and observed that "samples provided by Shinitzky indeed displayed the effect he reported in his article, however, their results could not be repeated with samples obtained from other sources"; thus they concluded that the observed bias was most likely caused by impurities in the samples. In response to this, the Shinitzky group published "Comments in a Discussion", in which they acknowledged impurities as a major problem in their experiments aimed at pinpointing a very small effect (Shinitzky & Deamer, 2008). They concluded that it would be easier to look for any parity violating effects "in bulk phases, rather than in dynamic processes such as crystallization" and referenced papers reporting a Raman spectroscopic study of L- and D-RNA oligomers in solution (Bolik et al., 2007) and a CD study of L- and D-polyglutamate undergoing temperature-dependent helix-coil transitions (Kodona et al., 2008). The authors of both of these papers attributed the observed differences to parity-violating weak interactions.

A more recent report describes a study of crystalline D-alanine by means of Raman scattering and neutron powder diffraction (Belo et al., 2018a). The authors claimed to have observed significant differences in the hydrogen bonding in comparison with L-alanine. Their results were challenged by (Bürgi & Macchi, 2018) who raised a number of methodological objections and then stated that "the conclusions drawn by Belo et al. are deemed inappropriate as the data presented do not contain sufficient information to reach such a conclusion". They added that the same objections also applied to the Raman spectroscopic study (see the paragraph above) of RNA oligomers (Bolik et al., 2007). In response, Belo and others (Belo et al., 2018b) denied that they had drawn any conclusions concerning the parity-violating energy difference in their original paper and added that "properties of L- and D-alanine, and the L- and D-amino acids in general, are a fascinating and important area of study for our understanding of nature, irrespective of whether they are related, or not, to the weak nuclear force and parity violation.".

A recent paper reported a crystal structure with clear differences between the L- and D-enantiomers of an RNA oligomer (Kiliszek et al., 2021). The enantiomers assembled in the crystal in an asymmetric manner (Fig. 5B), made different lattice contacts and had different exposures to the water and metal ions present in the crystal (Fig. 5C). Crystals in which enantiomers are not constrained by crystallographic symmetry are known as kryptoracemates; these have been observed in small-molecule crystallography and represent *circa* 1% of structures in which enantiomers are cocrystallized (Clevers & Coquerel, 2020). These crystals could be relevant to the issue of biological enantioselectivity/deracemization because enantiomers exposed to different environments should have different stabilities. Consequently, different amounts of L- and D-molecules will remain after a certain time. Two types of such RNA-containing kryptoracemates were obtained, being mirror images of each other; therefore, in large volumes, their effects on the balance between the enantiomers should average out. However, in small volumes, with a small number of crystals, or perhaps just one crystal, the chances of a significant imbalance developing between enantiomers are greatly increased. The authors noted that this model required no initial imbalance between the enantiomers, as both enantioselection and enantioenrichment were included in the model; the crystal lattice provided a stable asymmetric environment for the enantiomers, while crystal growth amplified the effect up to the macroscopic scale.

Another recent paper describes the crystallization of ribo-aminooxazoline, an RNA precursor, on uniformly magnetized surfaces, demonstrating a significant enantioselective effect under some conditions (Ozturk et al., 2023). The authors discuss possible scenarios of enantioenrichment occurring on the surface of magnetized sedimentary rocks on the prebiotic Earth. Small magnetite particles can sediment uniformly even in the Earth's weak magnetic field.

DISCUSSION

The formative events that defined life's basic characteristics, including the chirality of biological molecules, are shrouded in the distant past. We may never know exactly how life developed on Earth, but we can make informed retrospective speculations based on our knowledge of life's present form and the knowledge of universal mechanisms that govern life's processes. The natural candidate for tipping the balance of a racemic "primordial soup" toward homochirality would be the chiral weak force, but it appears that the energy it imparts on molecules is orders of magnitude less than what is needed for a significant effect on chemical processes. Chance fluctuations have larger amplitudes locally but tend to average out over space and time. We simply do not know an enantioselective process that would deliver a significant effect. Therefore, we need a massive amplification mechanism to turn any slight, innate or transient imbalance into a dominant form. One possibility is an autocatalytic process or rather some yet unknown "series of persistent chemical and physical processes that act synergistically and stepwise" (Hawbaker & Blackmond, 2019). The other possible means of "enantioenrichment" is crystallization. Two models contain both of the required steps of enantioselection and enantioenrichment: the evolutionary model of template-based "chiroselective self-assembly" (Bolli et al., 1997) and the model based on the crystallization of kryptoracemates (Kiliszek et al., 2021).

The deterministic and probabilistic models are different in nature but share a common aspect: both operate on an infinitesimal scale, meaning that the probability of a significant outcome of their action is also low. Chiral resolution (enantioselection) was an unlikely event. After the racemic balance was tipped, the initial small excess of one of the enantiomers was expanded (enantioenrichment) by one of the proposed mechanisms or by some other mechanism that remains unknown. Notably, however, such an expansion, even if significant, is still insufficient to explain the persistence of the enantiomeric imbalance over time. A lasting imbalance needs a mechanism to support it. Otherwise, the system will spontaneously return to thermodynamic equilibrium, while entropy is maximized. For instance, we can envision a scenario in which a minute initial excess of one enantiomer is greatly expanded by some autocatalytic mechanism. A significant imbalance appears, but there is no reason why a corresponding autocatalytic reaction should not also occur for the other enantiomer. At best, we can get a head start in multiplying one enantiomer before the symmetric process undermines the imbalance. The

Figure 6. Result of enantioselection and enantioenrichment has to be sustained from returning to a thermodynamic equilibrium. Living organisms are well suited for maintaining a nonequilibrium thermodynamic state. It is probable that an enantioenriched solution evolved in or was engulfed by a primordial living organism or some other dissipative thermodynamic system, and thus it was stabilized.

likely result is the reestablishment of an equilibrium. To maintain an imbalance, a cascade of processes, such as the autocatalytic reaction is needed, and this is even less likely to occur than a single such event. An alternative way to maintain a thermodynamically unfavored state is to establish a lasting nonequilibrium thermodynamic system with a continuous flow of energy and matter. Life is such a system. Therefore, it is possible that the enantioselection and enantioenrichment were closely knit with the emergence of early life in which the imbalance was promptly embedded and has been sustained ever since (Fig. 6).

Were academic promotions in biochemistry and other research disciplines improperly controlled in Poland between 2011 and 2020?
A response to the recently published "Who controls the national academic promotion system" article

Grzegorz Węgrzyn[1,2]✉

[1]Research Excellence Council, pl. Defilad 1, Warsaw, Poland; [2]Department of Molecular Biology, University of Gdansk, Gdańsk, Poland

In the recently published article by Koza *et al.* (SAGE Open, 2023, 13, doi: 10.1177/21582440231177974), the authors analyzed the academic promotion system in Poland between 2011 and 2020. They concluded that "the Polish system of academic promotions in the past decade can hardly be regarded as based on pure merit", suggesting the impropriety, based on the participance of the members of the Central Board for Degrees and Titles in panels of experts evaluating the applications. Biochemistry was provided as a research discipline in which such an "impropriety" was the most pronounced, though other disciplines were only slightly less "improperly affected". Although the calculations presented by Koza and others (Koza *et al.*, 2023) were proper, their conclusions were affected by fundamental errors in assessing the roles of the panelists and misinterpretation of the data. The drawbacks of the interpretations of the facts and in drawing conclusions are presented and discussed in this paper, underlining the necessity of being very careful when assessing any phenomenon and concluding about any mechanism. Indeed, only very well substantiated conclusions, strongly supported by objective data, should be published. This rule is very well known in biochemistry and other exact and natural sciences, and should be mandatory in all other research disciplines.

INTRODUCTION: THE ANALYSIS OF THE ACADEMIC PROMOTION SYSTEM IN POLAND, PERFORMED BY KOZA *ET AL.* (2023)

There are various systems of academic promotion operating in different countries. Their analyses might show interesting processes, and could indicate strengths and weaknesses of such systems which then could be improved.

The academic promotion system, used in Poland between 2011 and 2020, was recently analyzed by Koza and others (Koza *et al.*, 2023). The authors presented the system, based on two degrees, PhD and habilitation, and the title of professor. During the analyzed period of time, the procedures of academic promotions were overseen by the central (national) body called Central Board for Degrees and Titles (henceforth Central Board). In habilitation procedures, the crucial role was played by the habilitation panel, composed of the president, secretary, three reviewers, and two ordinary members. In the procedures of processing the professorship applications, the Central Board indicated five reviewers.

The analysis of the members of habilitation panels and reviewers of the professorship applications, led Koza and others (Koza *et al.*, 2023) to the conclusion that "the Polish system of academic promotions in the past decade can hardly be regarded as based on pure merit". In their opinion, members of the Central Board were too often members of habilitation panels, and thus they "controlled a substantial majority of academic promotions beyond the PhD degree". They also stated that they "found that this relatively small group of academics held dominant control over academic promotions by repeatedly serving on promotion panels". The analyses presented in their article indicated that biochemistry was one of the most "affected" research disciplines, and the members of the Central Board were present in 100% habilitation panels, mostly as presidents of these panels (Supplementary Table S3 in Koza *et al.*, 2023). Nevertheless, a similar tendency was observed in most other disciplines (Koza *et al.*, 2023).

The above-mentioned conclusions might indicate that the Polish academic promotion system "is appropriated by the so-called old boys", and that there are mechanisms "used to distribute power and prestige among those old boys". Such conclusions are strong, but the question is whether they are substantiated. Unfortunately, the analysis of the work by Koza and others (Koza *et al.*, 2023) indicated that the authors made several fundamental errors in interpretation of the data and even in describing the system which severely influenced their conclusions, making them unsubstantiated. Below, I will present the most important errors showing the crucial problems with the above-mentioned conclusions. I suppose that as a former member of the Central Board (abbreviated by Koza and others (Koza *et al.*, 2023) as 'CK') and current President of the Research Excellence Council (the successor of the Central Board), I have a sufficient knowledge about the system of academic promotion in Poland and I am qualified and commissioned to professionally comment on the work analyzing this system.

MAJOR ERRORS, MISINTERPRETATIONS, AND UNSUBSTANTIATED CONCLUSIONS

Let me describe shortly the major weaknesses and drawbacks of the analyses performed by Koza and others (Koza *et al.*, 2023). First, the authors informed that: "CK members are elected by other senior academics" seemingly overlooking that the members of the Central Board were chosen by other researchers in the procedure of democratic election form all scientists with the title of professor. It should be highlighted that in each research discipline all scientists with the title of professor could cast their votes. Therefore, one should assume that they were recognized as leaders in specific research disciplines, and persons who are able to oversee the academic promotion processes objectively. In other words, they obtained the mandate of trust as scientists who were elected to ensure the correctness of the procedures. Koza and others (Koza *et al.*, 2023) did not mention that this relatively small group of persons was responsible for proposing reviewers for all habilitation and professorship procedures which was an especially hard and responsible task. If so, this may put the members of the Central Board in a different light, in contrast to the statement of Koza and others (Koza *et al.*, 2023) suggesting that they were the group of "old boys", keeping the strong power in their hands, and acting for their own purposes. I my opinion, this is a totally improper suggestion, presented by Koza and others (Koza *et al.*, 2023). Members of the Central Board had no interest in promoting one researcher and declining application of another apart from ensuring that all requirements for the promotion are fulfilled to guarantee that academic degrees and titles were awarded to researchers having appropriate achievements. In contrast, the "old boys" model should only be valid if the members of such a group had personal interest in making specific decisions.

The errors found in the paper by Koza and others (Koza *et al.*, 2023) include even a wrong description of the habilitation panel (further used as the major model in their analyses). They wrote "Of these seven panel members, three were pre-selected by the degree-granting university: the secretary, one of the referees, and one ordinary member" which is true. However, in the next sentence they stated: "The CK selected the other four: the chair, two referees, and two ordinary members" which is an evident error, as 1 chair, 2 referees, and 2 ordinary members would mean five, not four, members selected by CK. Obviously, this error is not crucial for further analyses, but indicates imprecision and inattention of the authors in performing and describing their work.

The serious erroris, however, a lack of the information that each member of the panel had a single vote, and all these votes were equivalent during the procedure of making the final decision. In other words, after analyzing all the habilitation documents and thorough discussion during the panel meeting, the decision was based on voting of seven members of the panel, and the results dependent solely on the number of voices "for" and "against", without any "weights of votes", i.e. the power of each vote was exactly the same. Moreover, written evaluations, presented by reviewers, and oral opinions presented by other members, had to be seriously considered, thus, any single vote could not easily change the opinion of the whole panel. This also indicates another serious oversight of Koza and others (Koza *et al.*, 2023). The voting system determined that each member of the habilitation panel had to carefully analyze all documents submitted by the candidate and evaluate his/her achieve-

ments, irrespective of the formal function played in the panel (president, secretary, reviewer or ordinary member – the only difference was that reviewers were obligated to write formal evaluation reports, whereas other members should present their opinions during the panel meeting).

Koza and others (Koza *et al.*, 2023) strongly criticized the fact that members of the Central Board were often presidents of habilitation panels. In their opinion "This level of concentration of power is made possible by the high degree of centralization in the Polish system of academic promotions, with just a handful of influential players (or, in extreme cases, just a single individual) being in control of academic promotions in a given discipline". In the light of the procedure described in the preceding paragraph, such a statement does not make sense, as being one of seven (equal) members of the habilitation panel it is not possible to control the academic promotion. The authors wrote "We have shown that being selected to a panel of judges is positively related to membership in a central administrative body". Yes, this is true, and it was also reflected by the statistical analyses performed by Koza and others (Koza *et al.*, 2023). However, this fact has never been questioned or hidden. In contrast, it was a common decision of the Central Board to select their members as presidents of most of the habilitation panels. However, this was not to "control the academic promotion" in the sense of arbitrary decisions who should be promoted and who not, but to help the panels to properly analyze achievements of the candidates in the light of the obligatory rules and required criteria which should be met. Actually, this is a very responsible job which requires from the president of the panel not only high competence in the specific research discipline but also knowledge about the necessary procedures and specific criteria in the process of awarding the habilitation degree. Therefore, the statement of Koza and others (Koza *et al.*, 2023) that the role of the president of the panel is "least absorbing yet most prestigious (and influential) (…), as opposed to that of referee" is totally untrue. In fact, the Research Excellence Council which replaced the Central Board, decided to refrain from nominating its members as presidents in most habilitation panels. However, this resulted in many mistakes in the procedures and serious problems arising from a lack of experience and required knowledge about procedures by some presidents of panels who were not involved in works of the Council or formerly of the Central Board. Simply, some such presidents of panels were high level experts in the specific fields, however, they were not familiar with obligatory criteria and formal rules. In fact, as researchers not formally involved in the administrative procedures of the academic promotions, they were not obliged to know details of such rules during their daily work, contrary to members of the Central Board or the Council. This can be another argument for the importance of the role of the president of the panel and can corroborate the validity of the previous decision of the Central Board.

It is not my role to judge what was the reason of such a false statement described by Koza and others (Koza *et al.*, 2023), misunderstanding of the procedure or a lack of appropriate knowledge on roles of all members of the habilitation panels. Nevertheless, such a level of ignorance gives rise to serious doubts about the quality of any conclusions about the academic promotion system by the authors who either do not know or do not understand the system. The claim about the ignorance of the authors in this point is supported by

their another statement: "The secretary was a crucial role, because, despite being a glorified paper-pusher, it was the secretary's job to make sure the procedure ran smoothly and conformed with the relevant laws and regulations". Again, this statement is completely invalid. It is true that the secretary's role was extremely important, not only because he/she should – like all other members of the panel – analyze and evaluate the candidate's achievements, but also because of his/her responsibility to prepare all documents, like the protocol from the panel's meeting and the drafts of the final resolution and its justification. However, "to make sure the procedure ran smoothly and conformed with the relevant laws and regulations" was the job of the president of the panel, not the secretary. Thus, the suggestion of Koza and others (Koza *et al.*, 2023) that the members of the Central Board selected themselves as presidents of habilitation panels to occupy the position which was "least absorbing yet most prestigious (and influential)" is totally false, as actually the president's role was one of the hardest and most absorbing among the members of the panel. This serious error of Koza and others (Koza *et al.*, 2023) can be corroborated by another statement of these authors: "The easiest jobs were those of the chair and ordinary members, who were just additional voting members of the panel". As I mentioned above, all members of the panel, including the president (the chair) and ordinary members, were obligated to thoroughly analyze all the documents and especially the achievements of candidates, as their votes were as strong as votes of reviewers. Saying that they "were just additional voting members of the panel" shows such a high level of ignorance of the authors about the system they analyzed that in my opinion they should never attempt to analyze it.

Another ridiculous suggestion found in the text of the article by Koza and others (Koza *et al.*, 2023) is that selecting the members of the Central Board as presidents of habilitation panels "might be related to the financial remuneration received by all panel members". It is true that all members of the panel received financial compensation for their work (a few hundred Euro per application). However, this was just a remuneration for the extra job which had to be done, and as indicated above, this was neither easy nor quick work. Each member of the panel was obliged to analyze all achievements of the candidate which normally takes at least several hours (or even a few days in the case of a more complex or disputable application), and then a few hours for the panel meeting. Suggesting that there was "money for nothing" or "easy money" is simply absurd.

CONCLUDING REMARKS

The Polish system of academic promotions is neither easy nor perfect. It is obvious that detailed analyses of the procedures are important and can indicate points that should be improved. However, such analyses must be professional and performed with care and deep understanding the problem if one should treat them seriously. In fact, the statistical analyses performed by Koza and others (Koza *et al.*, 2023) using data from academic promotion procedures between 2011 and 2020 in Poland were correctly performed and provided some interesting results. However, the conclusions presented by the authors were highly influenced by serious errors and misinterpretation of the data. The authors ignored significant aspects of these procedures, and presented statements and conclusions which were unsubstantiated and false, at best. Therefore, the academic promotion system should be deeply analyzed but with significantly more care and with consideration of actual rules as well as roles played by researchers involved in the procedures. Biochemistry was indicated by Koza and others (Koza *et al.*, 2023) as a discipline which was the most severely affected by inadequate composition of the habilitation panels, nevertheless similar accusation was indicated for many other disciplines. However, such an incrimination appears unsubstantiated as it apparently arose from errors in data analysis and ignorance of the authors in assessing the roles of habilitation panels and their various members.

Secondary structure in polymorphic forms of alpha-synuclein amyloids

Warszawa, Poland; [4]Chair of Medical Biochemistry, Jagiellonian University, Medical College, Kraków, Poland

Numerous Alpha-synuclein amyloid structures available in PDB enable their comparative analysis. They are all characterized by a flat structure of each individual chain with an extensive network of inter-chain hydrogen bonds. The identification of such amyloid fibril structures requires determining the special conditions imposed on the torsion angles. Such conditions have already been formulated by the Authors resulting in the model of idealised amyloid. Here, we investigate the fit of this model in the group of A-Syn amyloid fibrils. We identify and describe the characteristic supersecondary structures in amyloids. Generally, the amyloid transformation is suggested to be the 3D to 2D transformation engaging mostly the loops linking Beta-structural fragments. The loop structure introducing the 3D organisation of Beta-sheet change to flat form (2D) introduces the mutual reorientation of Beta-strands enabling the large-scale H-bonds generation with the water molecules. Based on the model of idealised amyloid we postulate the hypothesis for amyloid fibril formation based on the shaking, an experimental procedure producing the amyloids.

INTRODUCTION

Alpha-synuclein (A-Syn) is a protein whose biological role and structural changes, despite advanced research, remain to be identified (Burré *et al.*, 2018). The mutations in A-Syn are considered as risk conditions (Ottolini *et al.*, 2017; Ghosh *et al.*, 2016). A large spectrum of forms of A-Syn in the context of health and disease is discussed in the paper of Lashuel and others (Lashuel *et al.*, 2013). Post-translational modifications identified in neurodegeneration in patients with Parkinson's disease concern

the aggregation propensity of A-Syn (Beyer 2006). A significant contribution of chaperones in the process of A-Syn amyloid transformation is presented in the paper of Burmann (Burmann *et al.*, 2020). There is also a certain degree of synergy between amyloid proteins, including A-Syn and Tau, especially concerning land others iquid-liquid phase separation (Guiney *et al.*, 2020; McDowall *et al.*, 2016). Difficulties in designing therapy arise from the complexity of the amyloid formation mechanism (Dehay *et al.*, 2015; Sivanesam & Andersen 2016). Despite the failure to recognize the amyloid transformation mechanism, analyses of the relationship between structure, function and toxicity are being conducted, focusing on the pathogenesis mechanisms of the synucleopathies phenomenon (Villar-Piqué *et al.*, 2016).

The transformation of A-Syn (described as a 'natively unfolded' monomer adopting an α-helical secondary structure only under the condition of binding to the lipid vesicles) into a highly β-structural one in the amyloid fibril is studied using many experimental techniques: ultracentrifugation, *in vitro* cell-crosslinking and scanning transmission electron microscopy (Bartels *et al.*, 2011). Adopting multivariate conformations identified under diverse conditions, including complexing to nanoscale surfaces, is treated as a potential way of targeting conformational plasticity (D'Onofrio *et al.*, 2020). The A-Syn affinity to the membrane and its ease of interaction is considered a stimulus for therapy design (Bozelli *et al.*, 2020; Kachappilly *et al.*, 2022). The concept of amyloid transformation proposed for prion proteins is also being considered (Lassen *et al.*, 2016.

Concentration-dependent transformation conditions allow the identification of the minimum concentration for fibril production (Afitska *et al.*, 2019). This observation is broadened by research on the impact of various types of interphases on the reaction process, including air-water and hydrophobic surface-water interphases (Ben-Amotz 2022; Schutzius *et al.*, 2015; Yi-Jie & Qu 2014; Eremin & Fokin 2021; Kaplaneris *et al.*, 2022; Ishiyama *et al.*, 2022; Gupta *et al.*, 2022; Cannalire *et al.*, 2022). The possibility of transformation into an amyloid form – thus rich in β-structure – as well as proteins with a high helical structure presence, is surprising in the first stages of these studies (Jayawardena *et al.*, 2017). Another example here may be A-Syn, which in 2/3 of the chain length in the WT form exhibits a helical structure, with the remainder being a loose section with random coil configuration (Ulmer *et al.*, 2005; Tuttle *et al.*, 2016). Considering the breadth of literature on experimental studies, the availability of an increasing number of amyloid structures in PDB resources makes it possible to analyse the structure of amyloid fibrils as such (Goedert *et al.*, 2017; Eisen-

Table 1. Summary of the amyloids A structures discussed in this paper (as available July 20, 2022).

The middle column shows the sections of the A-Syn chain present in a given structure. In the case of superfibrils, the chain identifier is provided, thus indicating the protofibril included in the analysis. *In the case of 2N0A, only the fragment showing the fibrillar form is included.

berg & Sawaya 2017; Wei *et al.*, 2020). Experiments conducted in different environmental conditions indicate a significant impact on the environment, and therefore, the impact of external conditions (Ben-Amotz 2022; Sawaya *et al.*, 2021; Serpell 2000; Rana *et al.*, 2008; Lambley *et al.*, 2020).

Identification of amyloid fibril structures as consisting of chains with a planar structure requires determining the conditions that should be met in order to obtain just such a form, additionally involving almost all C=O and H-N peptide bond groups in the construction of the hydrogen bond network. Such conditions have already been defined when constructing a model of idealised amyloid (Roterman *et al.*, 2022). The main aim of the present study is to investigate the fulfillment of the conditions formulated for idealised amyloid in the group of A-Syn amyloid fibrils. We also describe the specificity of the secondary structures in amyloids. The primary specificity of amyloid structures is the flatness (2D) of single-chain structures comprising fibrils with a high presence of the β-structure. The combination of several flat-structured chains in the β-form in a parallel chain arrangement makes it possible to engage almost all -N-H and -C=O groups of peptide bonds in the construction of inter-chain hydrogen bonds. Thus, it is possible that each amino acid – in the *i-th* chain – through these groups participates in the construction of two hydrogen bonds (-N-H atoms engaged in the *i-1*-th chain and -C=O group with *i+1*-th chain). It significantly stabilizes the fibril structure, which is observed in experiments. Such engagement is exhibited by amino acids in the helix structure – with H-bonds oriented parallelly and β-structure – with H-bonds oriented antiparallelly. However, globular proteins contain chain fragments in which H-bonds are not generated – like loops and twists in hair-pin structures (Roterman *et al.*, 2022; Roterman 1995). Additionally, the helical form introduces the structure's spatiality (3D), while in theory, the β-structure has the potential of unlimited propagation in a linear form and, in the case of β-sheet, in 2D form as a flat plate. The β-sheet structure – can be generated by different sections of the same chain with different amino acid sequences, while in the amyloid, the β-sheet is formed as a result of a combination of sections of the same sequence originating from many adjacent chains in parallel mutual orientations.

It is shown in this paper that the flat structure of the chain can be reached for β-structural fragments representing special Phi, Psi angles with bends introduced by single R- or L-helical conformation. The identification of such an organisation in polymorphic forms of A-Syn is shown (Peng *et al.*, 2018). Two reference non-amyloid proteins: all-helical and all-β-structural – are also present in the analysis to verify the proposed model.

The role of α-sheet in amyloid construction in comparison to Beta-structural-based amyloids is also discussed (Prosswimmer & Daggett, 2022; Lee *et al.*, 2002; Trexler & Rhoades E. 2012; Balupuri et al. 2019, Milner-White *et al.*, 2006, Hayward & Milner-White 2021). The hypothesis of the external force field of 2D form influence of flat structure construction is presented with the main role of loops linking Beta-structural fragments of chains in native structures of proteins is presented.

Moreover, based on the already proposed model of idealised amyloid we postulate the hypothesis for amyloid fibril formation.

MATERIALS AND METHODS

Data

The structures of A-Syn amyloids (as available in PDB July 2022) analysed in this paper are provided in Table 1.

Two reference proteins are present in the analysis: the GPCR bovine rhodopsin (PDB ID 1GZM – (Li *et al.*, 2004)) mainly Alpha Up-down bundle (CATH classification 1.20.1070.10) representing the structure dominated

by helical form and a FeS cluster assembly protein SufD from *Escherichia coli* (PDB ID 2ZU0 (Wada *et al.,* 2009)) The structure of the second protein is characterised by the presence of large domain build by almost all Beta-structural form.

The torsion angle-based relationship characterizing the amyloid structures

The specificity of amyloid structures is, apart from a high presence of β structure, the flatness of every single chain, a component of the fibrils. The planarity of a polypeptide chain (i.e. its linear propagation) is provided by the rectilinear β-segments (satisfying the Psi=−Phi condition) together with single R-α or L-α helical conformations which introduce a local bend while maintaining a flat structure. Those single helical conformations are characterized by the Psi≈Phi condition. This is why those two characteristics can be put in the common expression |Psi|=|Phi| constituting the basis of the model of idealised amyloid (described in detail in (Roterman *et al.,* 2022).

Quantification of the fit of the idealised amyloid model

The |Psi|=|Phi| relationship of idealised amyloid is assumed here as the hypothetical criterion for amyloid structure identification. The closer to this relationship is the distribution of (Phi, Psi) angles, the more probable the construction of a flat structure.

To enable the assessment of the degree of fit of the idealised amyloid model, the operation of replacing the Phi and Psi values with |Phi| and |Psi| respectively is performed. This leads to a situation where all three lines are in a common position (see the illustration in Figure 3 based on the amyloidogenic fragment (30-100) of the 2N0A).

The degree of fit of chain's (Phi, Psi) angles to the model of idealised amyloid is measured by a Pearson correlation coefficient:

$$C = \frac{\sum_{i=1}^{N}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{N}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{N}(y_i - \bar{y})^2}}$$

where x_i stands for $|Phi_i|$ and y_i stands for $|Psi_i|$.

The correlation coefficient CC for the $(|Phi_i|, |Psi_i|)$ angles of residues in an analysed chain was calculated in the following cases:

For all residues in an analysed chain (coefficient marked as CC-0).

For the residues after elimination of outstanding points: i.e. by eliminating them until a value of 0.8 is reached (coefficient marked as CC-F).

For the residues participating in β-strands and satisfying the condition |Psi|=|Phi| with a tolerance of ± 10 deg distance from |Psi|=|Phi| line (coefficient marked as CC-β). Residues with a high CC-F coefficient value are identified as responsible for the stabilization based on a hydrogen bond network.

The described type of analysis will be used to identify the amyloid form providing the maximum proportion of residues with a conformation satisfying the condition |Psi|=|Phi|.

The polypeptide's geometry-based model

This model has already been described on many occasions (see for example Roterman 1995). Here, only the basic assumptions facilitating an interpretation of the discussed results will be recalled. The main idea is to rep-

resent the structure of the polypeptide chain using two geometrical parameters. One of them is the curvature radius R which is low and well-defined for the helical structures and very large (theoretically infinitely large) for the β-structures (straight line for certain Phi, Psi angles). The value of the curvature radius is the result of the mutual orientation of two neighbour peptide bond planes expressed by the angle between two peptide bond planes versus the axis defined by virtual Cα-Cα bonds. This angle – called the V-angle – is close to zero (parallel mutual orientation) for helical forms and close to 180 deg for the β-structure (anti-parallel mutual orientation) (Fig. 1). There is one special β-structure with a V-angle=180 deg which produces an ideal straight line (Fig. 1B).

Figure 1. The hydrogen bond system (marked with red arrows): A – parallel in helical form, B – antiparallel in β-structural forms. The arrows just simply visualise the mutual orientations of hydrogen bonds.

Programs used

To visualise the 3D structures of discussed proteins the program VMD was used (https://www.ks.uiuc.edu/Research/vmd/accessed July 2022; Humphrey *et al.,* 1996).

RESULTS

General characteristics of secondary structures in amyloids

In this section, the general characterization of amyloid secondary structures based on the proposed earlier model of idealised amyloid will be presented,

The basic feature of amyloids is the flatness of the structure of single chains that make up the fibril. The planar amyloid structure of each polypeptide chain in a fibril is stabilized by a specific system of hydrogen bonds. In the β-structure with the Psi=−Phi conformation (corresponding to the idealised amyloid), each amino acid participates in the construction of two hydrogen bonds with the adjacent chains. The arrangement of the chains is parallel, which causes residues from corresponding positions from adjacent chains to interact with each other. Such a structure ensures the maximum use of hydrogen bonds, thus providing much stability. Rectilinear chain segments are terminated by single residues with R- or L-helical conformation. A single residue with such a helical conformation does not disturb the planar structure, changing only the turn by introducing a bend (Fig. 2B). The presence of two residues with such a conformation introduces a three-dimensional arrangement disturbing the planarity (Roterman *et al.,* 2022).

Introducing such a single residue with helical conformation results in a change of hydrogen bond ordering. In contrast to a helical structure (which represents a parallel hydrogen bond system – see Fig. 1A), in the ideal β-structure, the arrangement of hydrogen bonds is antiparallel (Fig. 1B). A single residue with the R- or L-helical conformation introduces a local perturbation to this arrangement changing it to a parallel one.

Figure 2. The β-structure propagation:
A – a hair-pin system, B – amyloid. The bend in the form of a hair-pin engages four residues with N-H and O=C groups – H-bonds system locally absent and introduces spaciousness. The one helical residue in the β-structural chain introduces a bend maintaining the flat structure of the chain and additionally continuing the system of H-bonds. The fragment presented in B is the fragment 36-53 of the A-Syn chain in amyloid form (PDB ID 2N0A)

Figure 3. Ramachandran map with the superimposed (Phi, Psi) angles from the A-Syn amyloid (A) and after transformation based on the absolute value of torsion angles (B).
The points representing the residue conformations in the fibrillar sections are marked in navy blue. (30-100 aa).

Figure 4. Section 36-53 of the A-Syn chain present in amyloid form (PDB ID 2N0A) in two perspectives.
Residues marked as red – single helical conformations introducing the bend in chain propagation.

The planarity of a polypeptide chain (i.e. its linear propagation) is provided by the rectilinear β-segments (satisfying approximately the Psi=−Phi condition) together with single helical conformations meeting the Psi≈Phi condition (Fig. 4).

In contrast to the above-described structure present in amyloids, changing the turn by means of hair-pins (Fig. 2A) engages more than one residue (most frequently 4 residues) and introduces spatiality. Moreover, the mutual orientation of residues in the hair-pins does not allow the formation of a hydrogen bond system in such bends.

It must be emphasized that the beta-sheet super-secondary structure in amyloids is different from the known, classical structure in other proteins. The classical beta-sheet structures are characterized by a system of hydrogen bonds binding fragments of the same chain. This allows the presence of loops, including the beta-turn (hair-pin) type, which just introduce spatiality. Beta-strand fragments in amyloids remain in one plane due to

Figure 5. The profiles of Phi (red) and Psi (navy) angles for the complete chain of A-Syn (1-140 aa) (Tuttle et al., 2016).
Grey lines – mark the β conformation fulfilling the Psi=−Phi relation. Vertical lines denote positions of amino acids: red – with L-α conformation, cyan – with R-α conformation. The purpose of this picture is to visualise the differences between 30-100 aa – amyloid fragment to N- and C-terminal fragments, where the Phi, Psi angles relation is significantly different with respect to 30-100 aa fragment.

Figure 6. A-Syn structure in the amyloid form (2N0A):
A – the structure of a complete fibril (chain A marked in red); B – two chains with distinguished residues representing the R-α (cyan) and L-α (red) conformation according to the identification provided in Fig. 5.

Figure 7. The plot of |Phi| versus |Psi| and 3D representation of the discussed amyloids.
The eliminated residues (by CC-F calculations) are marked in red on both the plots and 3D presentation. The points marked in blue – are the positions for residues satisfying the condition |Psi|=|Phi| for β-structural forms. For 6UFR the residues representing the highly ordered β-structural fragments are in space-filling representation (blue).

Table 2. Summary of CC-0 and CC-F values for the set of A-Syn amyloid forms analysed in this paper.
Residue d numbers eliminated in CC-F calculation are given. The CC-β values are given to express the high fulfillment of |Phi| = |Psi| relation. The % of residues in β-structural form for which the CC-β was calculated is given.

a turn introduced by a single R- or L-helical conformations as shown in Fig. 4. Such a radical turn allows the chain to propagate in one plane.

Figure 4 visualises the real conformation present in 36-53 fragment of A-Syn which appears to be almost ideally accordant with the proposed model of idealised amyloid. Linear propagation of β-structural fragments with single residues representing helical conformation results in a flat form with well-defined bends. The orientation of hydrogen bonds in β-fragments is antiparallel with local, parallel orientation in single helical residues.

Analysis of the fit of the idealised amyloid model 2N0A protein

In this section, the procedure of fitting the idealised amyloid model will be presented based on the reference A-Syn amyloid structure (2N0A – section 36-53). In Fig. 4, the fragments of the chain (marked as navy blue) show a rectilinear system obtained using the Phi and Psi torsion angles satisfying the relation Psi=–Phi. The residues marked in red have an α-helix conformation resulting in a turn of the chain while maintaining its flatness.

Figure 8. Presentation of the 7LC9-F amyloid with the highest CC-0 value (and the lowest number of outstanding residues).
A – distribution of points representing |Phi| and |Psi|. Only two residues are considered outstanding (red points). Their location in the chain is highlighted in red (space-filling) on the 3D representation (B).

Figure 9. Examples with low CC values:
A – CC-0 – all points; CC-F blue points; The circled dot is the only point satisfying the |Psi|=|Phi|. C – red points eliminated for CC-F calculation, gray points – CC-F calculation, blue points – CC-β calculation. B, D – 3D presentation of 6CU8 and 7C1D respectively with red residues – residues eliminated for CC-F calculation

The torsion angle profiles of the mentioned fragment are shown in Fig. 5. The fulfillment of relations Psi=–Phi is visible for the amyloid part (positions 30-100 aa), which is marked in gray. Within the clearly ordered and constant values of the Phi and Psi angles for the β form, single positions with the Phi and Psi angles corresponding to the R (cyan) and L (red) helical conformations are visible. The visualization of structures In this analysis is shown in Fig. 6.

Analysis of the structure of A-Syn amyloid forms

Table 2 provides the CC-0 and CC-F values of the chain as described in the Materials and Methods section. The values of CC-β express the status of residues satisfying the condition |Psi|=|Phi| in relation solely to the β-structural form. The % of residues satisfying the condition for CC-β is also given to characterise the degree

of the presence of such restrictive structure in a particular protein.

Figure 9 shows examples with high values of CC-0 and CC-F arising from the location of the Phi and Psi angles in accordance with the Psi=-Phi relationship. In a 3D visualization, these sections are represented by a rectilinear arrangement. The highlighted residues – red points – on the plots of |Phi| and |Psi| angles are residues treated as outstanding, the elimination of which results in a CC-F value > 0.8 (Table 2).

In the amyloid with PDB code 7NCG, the rectilinear β-structure sections are visible (Fig. 7B) and the corresponding locations of the |Phi|*versus*|Psi| plot (Fig. 7A). Items that do not satisfy the |Psi|=|Phi| condition specified by the model are marked in red. The number of residues that do not satisfy the model is low and they do not disturb the overall form of this amyloid leaving it close to the principles of the proposed model.

A similar arrangement is identified in the case of 6URF (Fig. 7). It should be noted that this structure is characterised only by a few residues with conformations not satisfying model conditions.

The significant portion of a chain in 6PEO amyloid meets the |Psi|=|Phi| condition, but a fairly significant scattering of several residues deviating from the model can also be observed.

The highest CC-0 value and the low number of residues deviating from the model are characteristic for amyloid 7LC9-F (Fig. 8). Eliminating only two residues results in a very high value of CC-F=0.851.

Further examples are the structures present in 6CU8 and 7C1D exhibiting the lowest CC-0 values (Fig. 9). In these two examples, no rectilinear propagation, but rather an "undulating" form is observed. This means, that the chain propagation is composed of sections with a smaller radius R. This reduction of radius applies to short sections, which, with an alternating arrangement similar to the R- and L-helical conformations, does not result in a spatial form. In this case, the hydrogen bonding arrangement is not parallel, although the deflection from the perpendicularity to the chain's plane is compensated, resulting in maintaining the structure's flatness.

Analysis of the structure of reference examples

Two reference proteins (Table 3) represent mainly helical and β-structural proteins. As shown in Fig. 10 their structure is highly ordered. The FeS cluster assembly of SufD from *Escherichia coli* is a protein which for the most part shows the β-structure (Banach *et al.*, 2020). The analysed fragment of this protein is limited to the beta-sheets (Fig. 10B).

The parallel orientation in the β-sheet (Fig. 10B) indicates a structural similarity to amyloids. However, the sequential β-strands represent a different sequence, while in amyloids the sequences in all neighbouring chains are identical.

The status expressed by CC-β of sequential β-strands and β-sheets reveals differences with respect to the amyloid forms discussed (Table 4). The fragments showing high accordance with the |Psi|=|Phi| criterion (having high CC values) are accompanied by the fragments with completely opposite characteristics (low CC val-

Table 3. Characteristics of the reference proteins

Figure 11. Phi, Psi profiles in the fragment with high (A) and low (B) correlation according to Table 4.

ues). The non-β-structural conformations are present in the selected fragments (values given in parentheses in Table 4). Visual analysis of two β-sheets suggests the perfect β-structural organisation (Fig. 11). However, the analysis of Phi and Psi angles reveals some residues in the lower left quarter of the Ramachandran map. Some β-strands having torsion angles typical for β-structure appear to be not organised as expected in amyloids. The differentiation of β-strands can be observed. The status of sequential β-strands in the amyloid is identical for all fragments belonging to a common β-sheet. The distribution of |Psi|, |Phi| angles (Fig. 12A) identifies the large number of points satisfying the |Psi|=|Phi| relation, however, it also shows their dispersion over the chain. The highest similarity is observed in the 181-192 fragment (marked in Fig. 12B).

The mainly-helical protein is difficult to evaluate with the |Phi|=|Psi| criterion due to the very low presence of β-structural conformations. The distribution of Phi, Psi angles along the chain (Fig. 13) shows high accordance with the helical forms (dark lines on Fig. 13). The CC-0 for this protein is equal to 0.347, the CC-F=0.807 (the eliminated residues marked as blue dots – Fig. 13.). The number of eliminated residues constitutes 19.2% of the whole length of the chain. The linear relation between torsion angles is mostly due to the Psi≈Phi relation present in the helical conformation.

The eliminated amino acids (in the CC-F calculations) represent the unstructured fragments like loops particularly those external with respect to the surrounding membrane. The space filling presentation (Fig. 12C and 12D) distinguishes the segments satisfying to a large extent the |Psi|=|Phi| relation, however, they belong mostly to the helical region.

The proposed hypothetical mechanism of amyloid fibril formation

The proposed hypothesis of amyloid fibril formation presented here concerns the method and the reasons of the transformation of a 3D structure into a planar form characteristic to the amyloid structures.

We also want to refer here to the existing, different hypothesis ((Prosswimmer & Daggett, 2022; Lee *et al.,* 2002; Trexler & Rhoades, 2012; Balupuri *et al.,* 2019) of the formation of the amyloid based on the α-sheet structure as an intermediate in the aggregation process.

Shaking an aqueous solution of proteins as a laboratory technique for obtaining amyloid forms of proteins consists in increasing the presence of air-water interphase in the solution. Such a shaking process can simu-

Figure 12. Characteristics of all-β and all-helical proteins.

late the conditions in a cell of a living organism. The air-water interphase has a surface structure, so it introduces an external force field with 2D characteristics.

Occasionally, a protein undergoes some conformational changes resulting in aggregation competent polypeptide chain. Such a chain, avoiding contact with air strives for maximum contact with water, which is available only on one side. The most thermodynamically favora-

Figure 13. Profiles of Phi and Psi angles in rhodopsin.
The black lines mark the range for the helical structure to visualise the closeness to the Psi=Phi relation for helical fragments. Positions not satisfying this relation are marked by blue dots on the x-axis.

Figure 15. Profiles of Phi and Psi angles for the amyloid and WT forms of transthyretin with highlighted fragments responsible for changing the orientation of the chain propagation as shown in Fig. 14.

Amyloid transformation mainly requires conformational changes within the loops that change from 3D orientation to 2D one.

The influence of the environment on amyloid transformation with an unchanged sequence is widely recognized (Serpell, 2000). The particular form of the environment in the form of mentioned 2D interphase seems to favour the formation of the flat structure of the chains – components of amyloid fibrils.

The proposed hypothesis for amyloid fibril formation is illustrated in Fig. 14. It refers to the transthyretin (Ueda, 2022) which undergoes amyloid transformation relatively easily. A special object is a fragment of a beta-sheet identified as A (11-19), G(104-112) and H (114-124). Both the WT form (PDB ID 1DVQ (Klabunde et al., 2000) and the amyloid form (PDB ID 6SDZ (Schmidt et al., 2019)) are available in PDB. Another reason is the possibility to compare with the hypothesis proposed in the works (Prosswimmer & Daggett, 2022, Armen et al., 2004) and based on α-sheet structure as intermediate.

Fragment beta-strand A(11-19) remains in this form in range (13-15), fragment G (104-112) changes its form to a disordered linearly propagating segment, while fragment H (114-124) remains in beta form on (118-124) fragment. The shortening of beta-stand segments can be observed.

The water-directed beta-structural fragment 104-111 can form hydrogen bonds with water molecules. The shape of the loop directs the second part of the beta-strand above the water surface, i.e. to the air zone. This is due to the orientation imposed by the loop (113-115) present in the native form of the transthyretin (green fragment in Fig. 14A and C). The same fragment after changing the conformation of the loop results in a planar structure of the entire fragment 104-124 (green fragment in Fig. 14B and D).

It should be noted that the native Beta-structure segment (104-112) changes its form to a disordered pattern, while the native-form beta-structure segment (114-124) is limited to the amyloid segment (118-124). This means that the conformational change within the loop (green fragment in Fig. 14A–D) also applies to a short fragment of the Beta-ordered segment. As a result of these changes, the structure of the entire fragment 104-124 becomes planar, allowing the generation of hydrogen bonds with water molecules along its entire length (Fig. 14E and F). The same analysis applies to loops 97-103 (Fig. 14G and H), where a change in conformation within the loop (red fragment Fig. 14G and H) allows backbone contact

Figure 14. Structure of the transthyretin:
A, C– native form 104-125 fragment of transthyretin – green fragment loop 113-115 – different orientation – orange – residues 104 - 112. B, D – amyloid form 104-125 fragment of transthyretin – green fragment loop 113-115, orange residues – fragment 104-112. E – as in A with water phase shown in gray with orange fragment in contact with a water phase. F – as in B with water phase shown in gray – complete chain in contact with water. G – native form of transthyretin – red fragment loop 97-103. H - amyloid form of transthyretin – red fragment loop 97-103. The orientation in A, B, E and F figures is as follows: the H-bonds (red arrows) system is perpendicular to the plane of the water surface. The gray area – water, white area – air. The green fragment – the loop causing the propagation of the chain in 3D space in native form and in 2D space in the amyloid form. The red arrow crossed out on D – the H-bonds system between two fragments of the same polypeptide chain is not present. The groups participating in H-bonds are oriented perpendicularly to the paper plane on C and D.

ble situation is the formation of a system of hydrogen bonds with a planar chain where the polypeptide chain "lies" on the water surface. In this way, the backbone chain engages as many C=O and N-H groups of peptide bonds as possible in such an interaction. This explains the reason for the almost planar form of the chain in amyloid fibril.

A planar polypeptide chain formed due to the shaking finds a thermodynamically favorable opportunity to interact with another planar chain and the process of attaching the next flat chains continues until the aggregation nucleus is formed. The next phase starting from the nucleus is characterized by a rapid formation of fibrils composed of beta-sheet structures.

(groups -C=O and -N-H of peptide bonds) with water molecules leading to the formation of hydrogen bonds with water molecules. The exact conformation changes within the discussed loops are shown in Fig. 15.

The proposed amyloid formation hypothesis relies on the 3D to 2D transformation engaging mostly the loops linking beta-structural fragments. The loops structure introducing the 3D organisation of beta-sheet change to a flat form introducing the mutual reorientation of beta-strands enabling the generation of large-scale hydrogen bonds initially with water molecules to change into an inter-chain H-bonds system in the next step.

The α-sheet structure, widely discussed in the context of amyloids (Prosswimmer & Daggett, 2022; Lee et al., 2002; Trexler & Rhoades, 2012; Balupuri et al., 2019) is the structure formed by amino acids with the R- and L-helical conformations alternating in the polypeptide chain. Similarly to the Beta-sheet structure, the α-sheet structure is characterized by the rectilinear form (Fig. 2 in Prosswimmer & Daggett, 2022). The distribution of Phi and Psi angles in α-sheet structures discussed in Prosswimmer & Daggett (2022) is consistent with the model assumed in this work. The difference is only quantitative. In the case of the α-sheet, the concentration of points on the Ramachandran map is significantly greater in the positions corresponding to the R- and L-helix with the presence of the Phi and Psi angles representing the β-structure in a linear relationship. In the current work, for the β forms, a much greater concentration of points on the Ramachandran map is observed. The main point is concentrated on the 3D to 2D transition. The structure discussed in (Prosswimmer & Daggett, 2022) introduces the 3D structuralisation which is not present in amyloid formation. The linear propagation of the chain in the form of Beta is the most frequently observed secondary form. The linear propagation of the chain is also possible in the form of R- followed by L-helix by turns. Such a system allows the generation of an H-bonds network. The mutual orientation of chains shall be parallel to allow propagation in fibril formation. However, the flat construction for individual chain is the most important one.

DISCUSSION

The amyloid structure of the flat form of each polypeptide chain is stabilized by a specific hydrogen bond arrangement. Each amino acid in an idealized form contributes to the construction of two hydrogen bonds with adjacent chains. The chain arrangement is parallel, causing identical residues to interact with each other in adjacent chains. The maximum use of C=O and H-N groups for the construction of hydrogen bonds is ensured by the β-structure with the Psi=–Phi conformation. A rectilinear form with C=O groups facing in the opposite direction to the H-N group of the same amino acid is an arrangement that makes maximum use of the possibilities of the hydrogen bonding structure. The rectilinear sections are terminated by single residues with R-α or L-α conformations. A single residue with such conformation does not disturb the flat structure, only changing the direction (introduction of a turn/bend). In this case, the form of arranging hydrogen bonds is changed. In a structure with the Psi=–Phi conformation, the hydrogen bond arrangement perpendicular to the plane of the chain represents an anti-parallel arrangement (if a turn is applied to the hydrogen bond).

Numerous amyloid forms of A-Syn allow tracking the structural variation of these amyloids. Among the structures satisfying the |Psi|=|Phi| condition, there are structures showing some deviations from this condition. The deviation also provides fibrillar structures.

On the Ramachandran map presenting the distribution of radius of curvature R and V-angle (Roterman et al., 2022; Roterman, 1995) the area fulfilling the Psi=–Phi condition represents the one with the highest value of R (i.e. a straight chain section). A reduction of the curvature radius R is observed moving up and down versus this line gradually introducing the arc form. If this procedure is performed stepwise (i.e. one above the Psi=–Phi line followed by one representing Phi, Psi angles below that line), this introduces the structural form as shown in Fig. 9 for 7C1D (symmetrically located |Psi|, |Phi| angles). The result of such Phi, Psi angle combination is the sinusoidal arrangement of the chain as can be seen in 7C1D (Fig. 9) and others. The local introduction of an arc-like form in one direction is compensated by an ark form oriented in the opposite direction. In consequence, the linear propagation of the flat form can be continued. Nevertheless, this symmetrical (with respect to |Phi|=|Psi| line) set of altered Phi and Psi angles generates a flat arrangement, but probably with reduced stabilization derived from the hydrogen bonds (change of angle between the C=O and H-N groups in the hydrogen bonding arrangement of peptide bonds derived from adjacent polypeptides).

The condition of the presence of an R- or L-helical conformation at the turn of the chain can be satisfied in a less perfect form by a conformation with a low curvature radius R. Cyan and red lines in Fig. 5 and Fig. 6 illustrate the area with low values of V-angle and the R-radius of curvature. The presence of Phi and Psi angles from this area satisfies the condition for obtaining a turn, although the hydrogen bond arrangement is not as perfectly ordered as in the case of Phi and Psi angles accurately representing the R-α- or L-α-helical conformation.

The phenomenon of polymorphism in the case of amyloids is conditioned by environmental factors, as indicated by numerous experimental studies (Ben-Amotz, 2022; Schutzius et al., 2015; Zuo & Qu 2014; Eremin & Fokin, 2021; Kaplaneris et al., 2022; Ishiyama et al., 2022; Gupta et al., 2022; Cannalire et al., 2022; Jayawardena et al., 2017; Ulmer et al., 2005; Tuttle et al., 2016).

This analysis complements the detailed structural analysis of A-Syn fibrils (Roterman et al., 2023) as well as the transthyretin (Roterman et al., 2022), where the characteristics of fibrils were considered from the perspective of the tertiary structure and characteristics of those fibrils. Microenvironmental conditions were also indicated as the cause of structural changes in A-Syn (Candelise et al., 2020; Stephens et al., 2019).

The problem of describing the field in the form of 3D analyzed on a large-scale provides many forms of mathematical notation to express its presence (Cheng et al., 2023).

CONCLUSIONS

The flat structure of single chains – components of amyloid fibril – is a characteristic of amyloid forms. This flatness is achieved through a β-type structure satisfying the Psi=–Phi condition resulting in a rectilinear chain propagation. Turns in chain arrangement are obtained by single residues with R-α or L-α helical conformation

(satisfying Psi≈Phi condition). The combination of such β-structures and single conformations allows the introduction of the general model expressed by |Psi|=|Phi|. The hypothesis introduced in this paper is to treat the presence of conformations satisfying this relation as a criterion for amyloid identification and description. The stabilization of such a form is achieved through the special hydrogen bond arrangement. In β-structured sections, the hydrogen bond arrangement is antiparallel. Each individual residue of the L-α or R-α conformation introduces a local arrangement of these bonds as parallel. Access to multiple structural forms of A-Syn amyloids reveals variation in the form of this ordering. This variation is likely a result of different environmental conditions (Roterman et al., 2023). Particularly, the impact of the presence of air-water interphase (increasing this presence during shaking) is most likely indicated as a factor affecting the structuring, including the form of arranging the hydrogen bond network in amyloids.

External conditions in the form of air-water interphase also direct protein structuring to the planar form, which can be stabilized by a significantly high number of hydrogen bonds of -N-H and -C=O groups of peptide bonds. The accessibility of these groups for hydrogen bonds also includes segments that in their native form represent loops introducing 3D structuring (e.g. two parallel β-sheets) resulting in a flat structure for the entire polypeptide chain (Fig. 14G and H).

Calcium-dependent peptidases of the calpain family are widespread in eukaryotes but uncommon in prokaryotes. A few bacterial calpain homologs have been discovered but none of them have been characterized in detail. Here we present an in-depth substrate specificity analysis of the bacterial calpain-like peptidase Tpr from *Porphyromonas gingivalis*. Using the positional scanning hybrid combinatorial substrate library method, we found that the specificity of Tpr peptidase differs substantially from the papain family of cysteine proteases, showing a strong preference for proline residues at positions P2 and P3. Such a degree of specificity indicates that this *P. gingivalis* cell-surface peptidase has a more sophisticated role than indiscriminate protein degradation to generate peptide nutrients, and may fulfil virulence-related functions such as immune evasion.

INTRODUCTION

Periodontal disease is the most prevalent chronic infection in the world, affecting up to 90% of the global population (Pihlstrom *et al.*, 2005). Inflammation of the gingival tissues is caused by dysbiosis, a pathogenic shift in the microbial community (Loesche & Grossman, 2001). Chronic inflammation leads to the destruction of tooth-supporting tissues such as the gingiva, periodontal ligament, and alveolar bone (Loesche, 1996). If left untreated, periodontitis can result in tooth loss and the systemic dissemination of periodontal pathogens and/or their products (Cobb *et al.*, 2009). This increases the risk of cardiovascular disease (Friedewald *et al.*, 2009; Wegner *et al.*, 2009), rheumatoid arthritis (de Pablo *et al.*, 2009), aspiration pneumonia (Olsen & Potempa, 2014), diabetes (Chee *et al.*, 2013) and adverse pregnancy outcomes (Ide & Papapanou, 2013).

The primary etiological agents of human periodontitis include *Porphyromonas gingivalis*, *Tannerella forsythia*, and *Treponema denticola* (Griffen *et al.*, 1998; Rôças *et al.*, 2001). The virulence factors these pathogens secrete include peptidases that contribute to the initiation and progression of periodontal disease (Dashper *et al.*, 2011; Potempa *et al.*, 2003). In particular, the aggressive periodontal pathogen *P. gingivalis* produces multiple proteolytic enzymes (Potempa *et al.*, 1995) that are required for important bacterial processes such as nutrient acquisition and immune evasion, driving pro-inflammatory responses within the gingival pocket. The proteolytic enzymes secreted by *P. gingivalis* include serine proteases (Nonaka *et al.*, 2014), cysteine proteases such as lysine-specific (Kgp) and arginine-specific (Rgp) gingipains (Bhogal *et al.*, 1997), PrtT protease (Tokuda *et al.*, 1998), periodontain (Nelson *et al.*, 1999) and thiol protease (Tpr) (Staniec *et al.*, 2015). Gingipains (Kgp & Rgp) account for 85% of all extracellular protease activity for *P. gingivalis* (Potempa *et al.*, 1997). Accordingly, the influence of gingipains on *P. gingivalis* virulence has been demonstrated but the role of the other peptidases remains unclear (Imamura, 2003).

Tpr is a functional cysteine peptidase encoded by the *PG1055* gene (Staniec *et al.*, 2015). Distant sequence homology and calcium dependence suggest that Tpr belongs to the calpain family (EC 3.4.22.17; MEROPS family C2) of calcium-dependent cysteine peptidases produced by almost all eukaryotes and some bacteria, but not archaea (Rawlings, 2015). Calpains are ubiquitously expressed in mammalian cells and are involved in essential cellular processes such as cytoskeletal remodeling (Lebart & Benyamin, 2006), cell migration (Franco & Huttenlocher, 2005), cell differentiation (De Maria *et al.*, 2009; Garach-Jehoshua *et al.*, 1998) and apoptosis (Momeni, 2011). Gain-of-function calpain mutations are associated with muscular dystrophy (Wadosky *et al.*, 2011), rheumatoid arthritis (Morita *et al.*, 2006), Alzheimer's disease (Huang & Wang, 2001), improper platelet aggregation (Kuchay & Chishti, 2007), and Wolfram syndrome (Lu *et al.*, 2014). However, no examples of the pathological effects of prokaryotic calpain-like peptidases have been reported thus far.

Eukaryotic calpains are highly-conserved intracellular enzymes that can be assigned to the categories μ or m according to their micromolar or millimolar requirements for calcium *in vitro* (Suzuki *et al.*, 1995). Intriguingly, the specificity of both categories appears identical (Sorimachi *et al.*, 1997). The calcium-mediated regulation of proteolytic activity (Hanna *et al.*, 2008) may require cooperative interactions between several calcium binding sites, including three EF hand motifs, the negatively charged segments around the active site cleft, and an exposed acidic loop (Reverter *et al.*, 2001). However, the precise molecular mechanism is unknown. Although the physiological substrates remain poorly characterized, several

have been identified *in vitro*, including selected β-integrins (Du *et al.*, 1995), focal adhesion kinase (Cooray *et al.*, 1996), paxillin, and talin (Carragher *et al.*, 1999).

The autoprocessing and maturation of the Tpr precursor requires millimolar levels of calcium (Staniec *et al.*, 2015). This requirement prevents the premature activation of Tpr in the cytoplasm and ensures the structure is resistant to degradation by gingipains (Staniec *et al.*, 2015). The elevated expression of the *tpr* gene under nutrient-limited conditions (Lu & McBride, 1998) and the location of the enzyme in the outer membrane (Park *et al.*, 1997; Staniec *et al.*, 2015) suggest that Tpr is involved in the production of small peptides that are used as substrates for amino acid fermentation. Given that multiple physiologically relevant proteins are degraded, including key elements of the innate immune system and proteins abundant in gingival crevicular fluid, Tpr may also contribute to the pathogenesis of periodontitis (Staniec *et al.*, 2015).

A detailed analysis of Tpr substrate specificity is required to understand its contribution to the pathogenicity of *P. gingivalis*, but only a superficial characterization has been reported thus far (Staniec *et al.*, 2015). Here, we fully characterized the substrate specificity of the most active form of Tpr using Hybrid Combinatorial Substrate Library (HyCoSuL) approach to gain insight into the proteolytic mechanism and thus the function of this cell-surface peptidase.

MATERIALS & METHODS

Regents and equipment

Isopropyl-1-thio-β-D-galactopyranoside (IPTG), ethylenediaminetetraacetic acid (EDTA), lysogeny broth (LB), L-glutathione, Tris-HCl, NaCl, dithiothreitol (DTT), sodium azide, and L-cysteine were purchased from Sigma-Aldrich. A MonoQ column was obtained from Cytiva.

Protein expression

The inactive Tpr zymogen (Tpr55) was expressed in *Escherichia coli* BL21 (DE3) cells and purified as previously described with some modifications (Staniec *et al.*, 2015). Briefly, the *PG1055* coding sequence without the signal peptide was transferred to the expression vector pGEX-6P-1, which provides the sequence for an N-terminal glutathione S-transferase (GST) tag. This construct was then introduced into electrocompetent *E. coli* BL21 cells, which were cultivated in LB at 37°C. As soon as the culture reached an optical density at 600 nm (OD_{600nm}) of 0.7, Tpr55 expression was induced by supplementing the medium with 0.5 M IPTG and incubating for a further 3 h at 37°C.

Protein purification

Transformed *E. coli* BL21 cells were harvested by centrifugation (8000×*g*, 20 min, 4°C) and resuspended in PBS containing 10 mM EDTA to bind any residual Ca^{2+} that would induce the premature autoprocessing of Tpr55. To recover intracellular Tpr55, the bacterial cell pellet was disrupted by sonication (60% amplitude for 5 min with 30-s pulses) and the cell debris was removed by centrifugation (18000×*g*, 20 min, 4°C). Tpr55 was recovered by passing the supernatant through a glutathione-Sepharose column and eluting the bound Tpr55 stepwise with increasing glutathione concentration in elution buffer (50 mM Tris-HCl, 20 mM L-glutathione, pH 8.0).

To remove small molecular contaminants, the eluted Tpr55 was dialyzed against PreScission Protease cleavage buffer (50 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 1 mM DTT, pH 7.0) and the GST tag was cleaved off with 40 U PreScission Protease at 4°C for 16 h. The sample was then dialyzed against 20 mM ethanolamine (pH 9.0) and applied to a MonoQ column equilibrated in dialysis buffer to separate Tpr55 from GST. Final purification was accomplished by gel filtration on a Superdex 75 column in 50 mM Tris-HCl (pH 7.6) containing 150 mM NaCl. The full-length Tpr55 was routinely purified with a yield >1 mg/L starting culture.

Proteolytically active Tpr (Tpr33) was obtained by autoprocessing the purified Tpr55 as previously described (Staniec *et al.*, 2015). Briefly, purified Tpr55 was incubated in activation buffer (50 mM Tris-HCl pH 7.6, containing 150 mM NaCl, 5 mM $CaCl_2$, 0.2% sodium azide, and 10 mM L-cysteine) for 7 h at 37°C.

Analysis of substrate specificity

Tpr33 substrate specificity was assessed using the HyCoSuL screening approach and a defined P1 library with the general structure Ac-Ala-Ala-Pro-P1-ACC, where P1 comprises one of either 19 canonical amino acids (except cysteine) or norleucine, synthesized as previously described (Kasperkiewicz *et al.*, 2015; Larsen *et al.*, 2007; Poręba *et al.*, 2014, 2017). Cleavage of the peptide substrate was detected by monitoring the release of the fluorescent label 7-amino-4-carbamoylmethylcoumarin (ACC).

To determine Tpr33 substrate specificity at the P4, P3 and P2 positions, we used a HyCoSuL with arginine fixed in P1 (Fig. 1). Each of the tetrapeptide sublibraries featured an equimolar mixture of 19 amino acids (without cysteine and methionine, but including norleucine) at two positions and one of 19 canonical amino acids plus 102 non-standard amino acids in the position selected for analysis (Fig. 1).

Tpr33 was activated by incubating 500 nM of the enzyme in activation buffer for 30 min at 37°C. To determine the enzymatic activity of Tpr33 in each sub-library, fluorescence was recorded (excitation=355 nm, emission=460 nm) 30 min after the addition of substrates. The P4, P3 and P2 sub-libraries were tested at an initial concentration of 100 µM whereas the P1 library was tested at 10 µM. The slope of the linear range of each curve was recorded as relative fluorescence units per second (RFU/s). Data from each sub-library were normalized to the highest RFU/s value for each specific sub-library.

Kinetic measurements

Selected substrates (Table 1) were prepared by solid phase peptide synthesis as described elsewhere (Poręba *et al.*, 2014). To determine the catalytic parameters of Tpr against these substrates, Tpr33 was titrated with the irreversible cysteine protease inhibitor E-64 as previously described (Staniec *et al.*, 2015). Peptidase activity was determined at increasing concentrations of each substrate in 50 mM Tris-HCl (pH 7.6) containing 150 mM NaCl, 5 mM CaCl₂ and 0.02% sodium azide. Velocities of substrate hydrolysis were plotted against the substrate concentration, and the k_{cat} and K_M values were calculated using GraphPad Prism macro.

RESULTS

Substrate specificity of the Tpr33 protease

In our previous explorative study (Staniec *et al.*, 2015) we found that Tpr33 preferentially hydrolyzes substrates containing arginine at the P1 position (nomenclature according to Schechter & Berger, 1967). Therefore, we initially investigated the amino acid preference at the S4–S2 subsites of Tpr33, followed by a more thorough interrogation of the amino acid preference at the S1 subsite. Accordingly, the P2, P3 and P4 sublibraries had arginine fixed at the P1 position (Fig. 1).

Tpr33 showed exclusive specificity for substrates that incorporated proline or alanine at the P2 position (Fig. 2A). This exclusivity was maintained when nonproteinogenic amino acids were included. None of the D stereoisomers of standard amino acids and only six of 83 non-standard amino acids resulted in hydrolysis when incorporated at the P2 position. Among these non-standard residues, only the thiazolidine-based residue L-Thz, which structurally resembles proline, resulted in hydrolysis with similar efficiency to the proline-P2 sub-library (Fig. 2B).

Figure 2. Specificity of Tpr33 for substrates containing canonical and non-proteinogenic amino acids at the P2 position as determined using the HyCoSuL screening approach.
The substrate preferences at position P2 were determined using a combinatorial tetrapeptide library with the general structure Ac-Xaa-Xaa-P2-Arg-ACC, where P2 represents (**A**) canonical or (**B**) non-proteinogenic amino acids and Xaa represents an equimolar mixture of 19 amino acids (all standard proteinogenic amino acids except cysteine and methionine, supplemented with norleucine). Abbreviated amino acid names are shown on the x-axis and explained in the Supplementary Materials at https://ojs.ptbioch.edu.pl/index.php/abp/. The y-axis shows the mean activity expressed as relative fluorescence units per second [RFU/s]. The data are means of three independent measurements.

Figure 4. Specificity of Tpr33 for substrates containing canonical and non-proteinogenic amino acids at the P4 position as determined using the HyCoSuL screening approach.
The substrate preferences at position P4 were determined using a combinatorial tetrapeptide library with the general structure Ac-P4-Xaa-Xaa-Arg-ACC, where P4 represents (**A**) canonical or (**B**) non-proteinogenic amino acids and Xaa represents an equimolar mixture of 19 amino acids (all standard proteinogenic amino acids except cysteine and methionine, supplemented with norleucine). The y-axis shows the mean activity expressed as relative fluorescence units per second [RFU/s]. The data are means of three independent measurements.

The specificity of Tpr33 at subsite S3 was less stringent than at S2. Proline was the most preferred proteinogenic amino acid, but Tpr33 also accepted amino acids with short side chains (alanine and glycine) or large hydrophobic side chains (norleucine, phenylalanine and tyrosine) (Fig. 3A). The less stringent specificity compared to S2 was maintained when substrates containing non-standard amino acids were analyzed. More than half of the substrates containing non-standard amino acids were hydrolyzed at least as efficiently as the proline-P3 substrates (Fig. 3B). Multiple non-standard amino acids were accepted including certain D stereoisomers of proteinogenic amino acids (Fig. 3A, B). The proline analog L-Thz was among the most preferred residues, matching the pronounced preference of S3 subsite for proline at P3 of a substrate. Interestingly in the context of substrate design, the most efficiently hydrolyzed substrate in the P3 sub-library featured an indoline-based residue (L-Idc) at P3. Tpr33 showed more than five-fold increase in activity against this L-Idc-P3 substrate than the standard L-Pro-P3 substrate.

In contrast to the other subsites, Trp33 showed broad tolerance for the residue at subsite S4, accepting D stereoisomers almost as well as L stereoisomers, and also tolerating multiple non-standard amino acids at P4 position of a substrate (Fig. 4A, B). Interestingly in the

context of substrate design, several non-proteinogenic amino acids were better substrates than canonical amino acids. The most efficiently hydrolyzed substrate featured a piperidine-based residue (L-Pip). Tpr33 showed almost 2.5-fold increase in activity against this substrate than

Ac-Ala-Ala-Pro-P1-ACC

Figure 5. Specificity of Tpr33 for substrates containing different proteinogenic amino acids at the P1 position as determined using using the defined P1 substrate library.
The substrate preferences at position P1 were determined using defined library with the general structure Ac-Ala-Ala-Pro-P1-ACC, where P1 represents a standard proteinogenic amino acid. The y-axis shows the mean relative activity expressed as a percentage of the most efficient amino acid in the same position. The data are means of three independent measurements.

against the best substrate containing a canonical amino acid (Fig. 4B).

Having documented the restricted substrate preference of Tpr33 at subsite S2, we reevaluated the substrate specificity at position S1 using a library containing proline fixed at P2 (Ac-Ala-Ala-Pro-P1-ACC). Tpr33 preferred arginine at position P1 in a substrate, consistent with the results of our previous explorative study (Staniec *et al.*, 2015). However, several other residues with different physicochemical characteristics were also efficiently recognized, indicating that Tpr33 has low specificity for a residue in position P1 of a substrate (Fig. 5).

Kinetic analysis of Tpr33 activity

The randomization of amino acids at certain positions in the HyCoSuL as well as cooperation between subsites may affect the efficiency of Tpr33. To validate the results generated by the HyCoSuL method, we designed and synthesized a selection of substrates and determined their kinetic parameters.

The k_{cat}/K_M value of the substrate containing the preferred canonical amino acids at each position (Ac-Phe-Gly-Pro-Arg-ACC) was 96 μM^{-1} (Table 1). A near-identical substrate containing lysine at the P4 position (Ac-Lys-Gly-Pro-Arg-ACC) had slightly inferior kinetic parameters (k_{cat}/K_m=71±7 μM^{-1}) reflecting the lower efficiency of the Lys-P4 sub-library. Another near-identical substrate, this time containing L-Dap at the P4 position (Ac-Dap-Gly-Pro-Arg-ACC) was superior to both of the above (k_{cat}/K_m=121±1 μM^{-1}), in agreement with the Hy-CoSuL library screening data. Substrates containing proline at position P3 (Ac-Idc-Pro-Arg-ACC) or glycine at the same position (Ac-Dap-Gly-Pro-Arg-ACC) shared comparable k_{cat}/K_M values, which appeared to contradict the results of the HyCoSuL screening. However, Ac-Dap-Gly-Pro-Arg-ACC is one residue longer than Ac-ldc-Pro-Arg-ACC, and longer substrates are generally better recognized by peptidases, so this may explain this apparent discrepancy. Finally, substrates with Idc (Ac-Gly-Idc-Cha-Arg-ACC and Idc-Cha-Arg-ACC) or Thz (Ac-Gly-Thz-Cha-Arg-ACC and Ac-Thz-Cha-Arg-ACC) at the P3 and Cha at P2 positions, respectively, were hydrolyzed 17–150-fold less efficiently (based on k_{cat}/K_M values) than substrates with Gly-Pro and Idc-Pro at the same positions. This contrasts with the efficiency of hydrolysis of the P2 Cha and P3 Idc/Thz sub-libraries.

Tpr33 activity against the synthetic substrates mostly agreed with the HyCoSuL screening method. Substrates with non-standard amino acids were better recognized than those containing the most preferred canonical amino acids at positions P4–P2. Furthermore, the best-recognized substrate (Ac-Idc-Pro-Arg-ACC) had the lowest K_M value. These data suggest that substrate recognition site S4 is poorly defined, resulting in weaker interactions between amino acids and the S4 pocket.

DISCUSSION

We investigated the substrate preference of the calpain-like peptidase Tpr33 at the S4–S2 subsites and reevaluated the specificity at the S1 subsite using a comprehensive library of defined and highly efficient substrates including the incorporation of non-standard amino acids. Calpain-like peptidases are widespread among eukaryotes, but homologous genes are present only in a few bacterial phyla (Rawlings, 2015). Thus far, Tpr is the only bacterial calpain-like peptidase that has been functionally characterized (Staniec *et al.*, 2015). Given the

small number of calpain-like peptidases in prokaryotes, it is not unlikely that *P. gingivalis* acquired Tpr by horizontal transfer from a mammalian host.

Like the m-calpains, a millimolar concentration of calcium is required to activate the Tpr zymogen and such concentrations are found in the extracellular fluid where Tpr is secreted. The calcium-mediated activation of Tpr prevents intracellular activation of the enzyme, which may be cytotoxic. Due to their potential cytotoxicity if left unregulated, peptidases are tightly controlled. Similar mechanisms to prevent the deleterious activity of misdirected secreted peptidases are widespread, including trypsin inhibitors produced by pancreatic cells (Hirota *et al.*, 2006).

The HyCoSuL method allowed us to explore the substrate specificity of Tpr, revealing the repertoire of physiologically accessible substrates. As previously reported for papain (Choe *et al.*, 2006) and calpain (Cuerrier *et al.*, 2005; Shinkai-Ouchi *et al.*, 2016; Tompa *et al.*, 2004), the specificity of Tpr is determined at the S2 subsite whereas S1 is much less selective, albeit with some preference for positively charged residues in all three enzymes. However, the specificity of the S2 subsite differs between Tpr, papain and calpain. Tpr strongly selects proline whereas papain prefers valine but also accepts bulky aromatic and large hydrophobic residues, and calpain accepts several medium-sized residues. The S3 subsite also shows a degree of selectivity, but again this differs between the three enzymes. All three accept proline, but Tpr also accepts bulky aromatic and small side chain residues, whereas papain prefers arginine, lysine and medium-sized side chain residues, and calpain tolerates multiple residues with dissimilar physicochemical properties while simultaneously excluding several residues. Tpr shows broad specificity for amino acid residues in position P4 in a substrate.

Peptidases play a key role in nutrient acquisition by *P. gingivalis* (Potempa & Pike, 2009). We found that Tpr is not restrictively specific at any substrate-binding subsites, but the combination of relatively high selectivity at the S2 and S3 subsites may limit the number of substrates susceptible to Tpr proteolytic activity. Such characteristics are unexpected for a digestive peptidase and suggest a more specialized role, possibly associated with the evasion of host immune defenses.

Peptidases attack the most sterically accessible regions of substrates, often cutting in loops and other unstructured regions. Proline residues are often overrepresented in such regions (Fontana *et al.*, 1986), which also tend to be functionally significant – for example, proline-rich regions are known to be involved in protein–protein interactions (Yu *et al.*, 1994). The relative preference of Tpr for proline residues at positions P2 and P3 in substrates may suggest the involvement of Tpr in the modulation of protein–protein interactions. Eukaryotic proline-specific proteases mediate cell signaling events by modulating protein–protein interactions (Dunaevsky *et al.*, 2020) and the possibility that Tpr has a similar role should be evaluated in future studies.

CONCLUSION

HyCoSuL screening revealed that the substrate specificity of Tpr is primarily determined at the S2 and S3 substrate-binding subsites, with proline being the most preferred residue in both cases. The specificity of Tpr therefore differs from that of the related eukaryotic proteases papain and calpain, and is likely to play a more

sophisticated role in bacterial physiology than indiscriminate protein degradation for the provision of nutrients, which would be facilitated by non-specific protease activity.

Review

Emerging relationship between hydrogen sulfide and ferroptosis: A literature review

Xiaoming Gao#, Ke Lu# and Chong Li✉

Department of Orthopedics, Affiliated Kunshan Hospital of Jiangsu University, 91 West Qianjin Road, Suzhou, Jiangsu, 215300, China

Gaseous hydrogen sulfide (H_2S) can function as a signaling molecule similar to nitric oxide or carbon monoxide under physiological conditions, ultimately exerting anti-inflammatory, anti-apoptotic, and antioxidant activities. Many studies have investigated the role of H_2S in a variety of biological contexts, and both endogenous H_2S and H_2S donors have been leveraged as tools for fundamental biomedical research, and it has been suggested that they may provide value for the design of novel therapeutic strategies in the years to come. Ferroptotic cell death is a distinct programmed cell death resulting from excessive lipid peroxidation in an iron-dependent manner, and is characterized by high levels of iron accumulation, reactive oxygen species (ROS) production, and peroxidation of cellular lipids. Several recent studies have revealed a close relationship between ferroproteins and their precursors, H_2S, and the enzymes that produce them. This review summarizes the current information pertaining to the relationship between ferroptosis and H_2S, with a particular focus on the underlying mechanisms and biological applications of this knowledge.

INTRODUCTION

Hydrogen sulfide (H_2S) is a gas that can serve as a signaling intermediary and that, in mammals, it is produced by several enzymes including cystathionine β-synthase (CBS), cystathionine γ-lyase (CSE), and 3-mercaptopyruvate sulfur-transferase (3-MST) (Wang, 2012). Many recent studies have sought to elucidate the biological roles of H_2S and have demonstrated that its endogenous production is related to processes ranging from vasodilation, microbial antibiotic resistance, oxidative stress, and mitochondrial function to inflammatory activity, neuroprotection, and endoplasmic reticulum stress (Kozich et al., 2019). H_2S functions as a reductant at physiological concentrations, providing protection against inflammation, oxidative stress, and apoptotic cell death (Kimura et al., 2010). In plasma, endogenously derived H_2S levels are negatively correlated with oxidative stress and aging (Hine et al., 2015). In addition, owing to the essential roles of H_2S in various physiological and pathological processes, its practical applications have been explored. For example, a novel fluorescent probe, Rho-HS, was developed to detect H_2S and can be used for biological imaging (Guo et al., 2022). Furthermore, a surface-filled H_2S-releasing silk fibroin (SF) hydrogel was developed to achieve small-dose local administration and avoid volatile and toxic side effects (Chen et al., 2022). These investigations shed light on the potential clinical application of H_2S. The production and functionality of H_2S have been identified as promising targets for the treatment of a range of conditions owing to its significant role in regulating cell death and interactions with the cell death pathway.

Multiple cell death pathways contribute to the occurrence and progression of various diseases, and H_2S plays a vital role in regulating or suppressing cell death, including necroptosis, pyroptosis, and apoptosis (Rodkin et al., 2023) (Table 1). For instance, H_2S upregulates the expression of Bcl-2 and P62 (Chen et al., 2022; Guo et al., 2014) or downregulates NF-κB to reduce apoptosis in organ ischemia/reperfusion (Kuo et al., 2013; Weirather et al., 2014). Moreover, H_2S can reduce the expression of caspase-1 to exert an anti-pyroptosis effect on bone-derived macrophages and aortic endothelium (Castelblanco et al., 2018; Xi et al., 2016).

Ferroptosis is a subtype of regulated cell death (RCD) with features distinct from those of necrosis, autophagy, or apoptosis (Hadian & Stockwell, 2020; Jiang et al., 2021). It often results from iron-dependent accumulation of toxic concentrations of lipid peroxides within cells (Rodkin et al., 2023; Stockwell et al., 2017), characterized by the production of high levels of lipid peroxides, accumulation of iron, and downregulation of glutathione peroxidase 4 (GPX4) (Fuhrmann & Brüne, 2022; Mahoney-Sánchez et al., 2021). These characteristics offer markers that can be used to specifically detect RCD (Hadian & Stockwell, 2020). Ferroptotic cells exhibit a rounded, small morphology with intercellular separation, an intact crenulated plasma membrane, and the absence of nuclear condensation. Mitochondria in these cells often have ruptured outer membranes, increased membrane density, and shrunken or absent cristae (Liang

Table 1. Mechanisms of H$_2$S on different cell death in disease models.

Cell death	Character	Disease model	Mechanism	Reference
Necroptosis	Following the activation of the tumor necrosis receptor (TNFR1) by TNFα	Diabetic cardiomyopathy	Alleviated myocardial oxidative stress, necroptosis and NLRP3	(Gong et al., 2022)
		Diabetic vascular complications.	p38 MAPK signaling pathway	(Lin et al., 2021)
		Atherosclerosis	Attenuated the increased RIP3 expression	(Lin et al., 2018)
Pyroptosis	A type of cell death culminating in the loss of plasma membrane integrity and induced by activation of so-called inflammasome sensors. These include the Nod-like receptor (NLR) family, the DNA receptor Absent in Melanoma 2 (AIM2) and the Pyrin receptor	Ischemia-reperfusion (I/R)-induced acute kidney injury (AKI)	Inhibited the NLRP3/Caspase-1 axis	(Ni et al., 2021)
		Chronic obstructive pulmonary disease (COPD)	Targeted the TLR4/NF-κB pathway	(L. Wang et al., 2022)
		Nephrotoxicity caused by U exposure.	Upregulation of PI3K/AKT/mTOR pathway	(Hu et al., 2023)
Apoptosis	The release of cytochrome c from mitochondria, regulated by a balance between proapoptotic and antiapoptotic proteins of the BCL-2 family, initiator caspases (caspase-8, -9 and -10) and effector caspases (caspase-3, -6 and -7).	Asthma	Reduced the airway inflammatory infiltrate	(Mendes et al., 2019)
		Lipopolysaccharide (LPS)-induced memory impairment (MI)	Decreased c-Jun and caspase-3 levels	(Kshirsagar et al., 2021)
		Myocardial reconstruction	Blocked ER stress-autophagy axis	(Li et al., 2020)
		Experimental glaucoma model	Suppressed Bax, caspase-3 and p53 activations	(Erisgin et al., 2019)
		Methotrexate (MTX) hepatotoxicity	Modulated IL-6/STAT3 pathway	(Fouad et al., 2020)

et al., 2019). Many diseases have been linked to ferroptosis, including osteoporosis and cancer, and this form of RCD also arises in the context of reproductive system functionality and organ damage (Proneth & Conrad, 2019; Stockwell et al., 2020). Ferroptosis is also associated with the efficacy of a range of therapeutic modalities, such as chemotherapy, radiotherapy, and immune checkpoint blockade treatments (Lei et al., 2020). Several studies have reported the anti-ferroptosis effects of H$_2$S in diseases such as cardiovascular disease (Wang et al., 2023; Wu et al., 2023), air inflammation (Zhang et al., 2020), intracerebral hemorrhage (Zhang et al., 2020) and acute lung injury (ALI) (Li et al., 2022). For instance, H$_2$S reduces ferroptosis by regulating the Nrf2-PPAR-ferritinophagy signaling pathway in PM-induced emphysema (Wang et al., 2022). It also protects DOX-induced cardiotoxicity from ferroptosis by targeting the OPA3-NFS1 axis (Wang et al., 2023). Overall, its functional pathways are diverse and complex.

This review provides a summary of the role of H$_2$S metabolism in mammals and the signaling pathways associated with H$_2$S-mediated ferroptosis.

ENDOGENOUS MAMMALIAN H$_2$S PRODUCTION

In mammals, H$_2$S is generated via enzymatic and nonenzymatic mechanisms (Fig. 1). Both CSE and CBS are cytosolic pyridoxal 5'-phosphate (PLP)-dependent, whereas 3-MST is a mitochondrial enzyme that functions independently of PLP (Cao et al., 2019).

CBS is formed by tetramerization subunit proteins of 63 kDa in size and generates H$_2$S via the catalytic processing of L-homocysteine and L-cysteine, yielding H$_2$S and L-cystathionine through a mechanism comparable to its role as a component in the trans-sulfuration pathway. When L-cysteine is present, CBS mediates a β-replacement reaction to generate H$_2$S, while produc-

ing L-serine. An up to 23-fold higher rate of H$_2$S generation was observed when l-homocysteine was available compared to when only L-cysteine was available. CBS is thought to be the main producer of H$_2$S in the central nervous system (CNS) and is expressed throughout the brain, with the highest levels of expression in the cerebral cortex, cerebellum, and hippocampus (Zuhra et al., 2020). CBS expression is also detectable in lymphocytes and organs, such as the liver, kidneys, pancreatic islets, uterus, and placenta (Kaneko et al., 2006; Patel et al., 2009).

Similar to CBS, CSE catalyzes the processing of homocysteine (Hcy) to produce H$_2$S, α-ketobutyrate, and ammonia, in addition to catalyzing the processing of L-cysteine to yield H$_2$S, along with ammonia and pyruvate. When L-cysteine and Hcy are present at physiological levels, CSE catalyzes the α- and β-elimination of L-cysteine to generate approximately 70% H$_2$S, whereas the α,γ-elimination of Hcy catalyzed by this enzyme generates only 29% of the total H$_2$S. However, when Hcy levels are elevated to concentrations similar to those observed in the context of hyperhomocysteinemia (HHcy), such α,γ-elimination generates approximately 90% CSE-derived H$_2$S, indicating that relative Hcy and L-cysteine concentrations within mammalian cells are pivotal determinants of the primary substrate utilized by this enzyme (Chiku et al., 2009).

Mitochondrially localized 3-MST is an H$_2$S-generating enzyme that was most recently discovered. Following the initial cysteine aminotransferase (CAT)-mediated conversion of L-cysteine to 3-mercaptopyruvate (3MP), 3-MST transfers sulfur atoms from 3MP to 3-MST, resulting in persulfide generation. When a reductant such as thioredoxin is present, H$_2$S is released from the persulfide (Nagahara et al., 1998). Regulation of CAT activity ultimately shapes the ability of 3-MST to generate H$_2$S. CAT inhib-

Figure 1. Endogenous generation mechanism of H$_2$S in cells.
The enzymatic and nonenzymatic generation pathway was presented in the above figure, in which the enzyme CBS, CSE and 3-MST play pivotal role in producing H$_2$S in enzymatic generation pathway, with L-cysteine being the main substrate. CAT, Cysteine aminotransferase; CBS, Cyststhionine β-synthase; CSE, Cyststhionine γ-lyase; GSH, glutathione; GSSG, glutathione disulfide; 3-MST, 3-mercaptopyruvate sulfurtransferase.

itors, such as aspartate, largely suppress the biosynthesis of H$_2$S and can therefore be leveraged as tools for pharmacological studies to explore the functional importance of H$_2$S generated by this enzyme (Shibuya *et al.*, 2009).

Some endogenous H$_2$S is also generated via the non-enzymatic chemical reduction of sulfane sulfur through the action of the ubiquitous cellular electron donor nicotinamide adenine dinucleotide (NADH), its reduced state nicotinamide adenine dinucleotide phosphate (NADPH), or other reductive equivalents (Searcy & Lee, 1998). Under these conditions, the reduction of reactive sulfur species present in polysulfides, persulfides, and thiosulfate can give rise to a range of metabolites, including H$_2$S (Olson *et al.*, 2013).

ENDOGENOUS H$_2$S AND FERROPTOSIS

In mammalian cells, the transsulfuration pathway produces H$_2$S as a byproduct of Hcy and cysteine processing by CSE, CBS, and 3-MST. The functional Xc-system subunit xCT (SLC7A11) is responsible for the import of cystine into cells, where it is converted into cysteine, which functions as the rate-limiting substrate necessary for the biosynthesis of glutathione (GSH) (Liu *et al.*, 2020; Stockwell *et al.*, 2017). GSH functions as a substrate for GPX4, which mitigates ferroptosis by reducing membrane phospholipid hydroperoxides to produce lipid alcohols. When xCT expression or activity is suppressed, immunotherapy- or radiotherapy-induced ferroptosis is enhanced (Lang *et al.*, 2019). The commonly utilized xCT inhibitor erastin (Era) can also activate ferroptosis, although long-term treatment with Era may contribute to enhanced cellular resistance to ferroptotic death. Moreover, Era treatment for extended periods has been shown to improve CBS and CSE expression, independently regulating ferroptosis (Liu *et al.*, 2020). Disrupting xCT activity increases both CSE and CBS expression yet significantly reduces endogenous H$_2$S production. The supplemental addition of the H$_2$S donor GYY4137 [GYY, morpholin-4-ium-4-methoxyphenyl (morpholino)

phosphinodithioate] reversed the loss of resistance to 5-fluorouracil (5-FU), which emerges upon the inhibition of xCT, highlighting the functional importance of H$_2$S as a mediator of xCT-associated chemoresistance activity (Chen *et al.*, 2021). Interestingly, supplementation with H$_2$S increased the protein levels of xCT without influencing its mRNA expression, suggesting that H$_2$S has a post-transcriptional regulatory effect on xCT. The H$_2$S axis maintains xCT stability through persulfidation of OTUB1 at cysteine 91 (Chen *et al.*, 2021). Correspondingly, xCT and the trans-sulfuration pathway have been identified as key ferroptotic regulators in cancer cells, functioning primarily by producing cysteine as a precursor for the production of the critical antioxidant glutathione (GSH). When cells are treated with both Era and AOAA, which inhibit CBS, the levels of GSH present within cells are markedly reduced, thus contributing to higher rates of ferroptosis associated with increased PTGS2 expression at the mRNA level and higher levels of MDA, which is a lipid peroxidation end-product (Marrocco *et al.*, 2017).

Hcy is an amino acid that contains sulfur and is important for methionine metabolism, gene methylation, phospholipid biosynthesis, neurotransmission, and nucleic acid biosynthesis (Shen *et al.*, 2020). Given its essential role as a mediator of Hcy transsulfuration, inhibition of CBS increases the concentration of Hcy in hepatocellular carcinoma cells, triggering ferroptosis (Wang *et al.*, 2018). Patients with excessively high levels of methionine, vitamin B12, or folic acid deficiencies can have high serum Hcy concentrations in the form of HHcy. This condition, in turn, contributes to the development of abnormal bone metabolism and mitochondrial dysfunction through oxidative stress and modification of collagen cross-linking (Levasseur, 2009). Hcy may contribute to more severe oxidative stress in nucleus pulposus cells and aggravate the induction of ferroptosis, resulting in increased lipid peroxidation, ROS production, and reduced GPX4 expression. Fer-1 is a ferroptosis inhibitor that protects nucleus pulposus cells from degeneration (Zhang *et al.*, 2020). It also reduced Hcy-induced injury

in ovarian granulosa cells in a dose-dependent manner (Shi et al., 2022). Vascular smooth muscle cells (VSMCs) may become dysfunctional due to high hydrostatic pressure (HHP) levels. HHP exposure induces ferroptosis in VSMC, accompanied by high levels of ROS production, lipid peroxidation, iron accumulation, downregulation of CSE/H2S, and suppression of GSH production (Jin et al., 2022).

The transcription factor nuclear factor erythroid 2-related factor 2 (Nrf2) is a vital mediator of ferroptosis induction, and H2S has repeatedly been shown to activate antioxidant activity mediated by Nrf2 in respiratory diseases, including rhinitis, sinusitis, conjunctivitis, acute lung injury (ALI), chronic obstructive pulmonary disease (COPD), and asthma (Han et al., 2011; Khattak et al., 2021). Wang et al. demonstrated that H2S was capable of inhibiting ferroptosis and ferritinophagy, while this activity was impaired in mice or cells lacking Nrf2 expression, and on the other hand, the anti-ferroptosis capability of H2S was enhanced when Nrf2 was overexpressed because the ability of H2S to protect against injury is regulated by Nrf2 activation and PPAR-γ signaling (Y. Wang et al., 2022). These results showed that the upstream of the whole protective pathway is Nrf2 because the activation of PPAR-γ and the inhibitory effects of H2S on ferritinophagy and ferroptosis were significantly restricted when Nrf2 was knocked out, both in vivo and in vitro.

The deubiquitinating enzyme OTUB1 stabilizes proteins through specific mechanisms (Wiener et al., 2012), and OTUB1 overexpression stabilizes xCT in oncogenic settings, thereby interfering with the ability of xCT to regulate ferroptotic pathways (Koppula et al., 2021; Yasuhara et al., 1997). Endogenous H2S production is closely linked to interactions between xCT and OTUB1, with H2S stabilizing xCT via the persulfidation of cysteine 91 of OTUB1 (Chen et al., 2021).

H2S DONORS AND FERROPTOSIS

Inorganic sulfurized salts, including NaHS and sodium sulfide (Na2S), are among the earliest known H2S donors and are commonly used as H2S equivalents in research. Currently, multiple H2S donors have been applied in various disease models and achieved remarkable effect via different signal pathways (Table 2).

C2C12 cells treated with exogenously administered NaHS could remediate abnormal redox conditions induced in response to RSL3 through the upregulation of GPX1 and GPX4, thereby normalizing lipid metabolism and mitochondrial function while also increasing acetyl-

CoA levels. NaHS also inhibits the expression and acetylation of ALOX12, thus protecting C2C12 cells from ferroptosis via the CSE/H2S signalling pathway (Wang, Yu, et al., 2021). Increased GSH content and GPX4 activity took place in response to NaHS treatment. Decreases in ROS, lipid ROS, and MDA levels have been reported in both BV2 cells and in the prefrontal cortex (PFC) of diabetic mice administered with NaHS. Mechanistically, these effects were found to be mediated by the increased expression of SLC7A11 protein in these BV2 cells or in the PFC, indicating that NaHS may act in an antidepressant-like manner via the upregulation of SLC7A11. NaHS can also improve PFC cysteine levels in a murine model of type 1 diabetes, resulting in upregulation of GPX4 (Wang, Wang, et al., 2021), indicating that NaHS may exert its protective effect by upregulating the protein expression of SLC7A11 and cysteine levels.

In plants, bacteria, and some fungi, H2S is converted to cysteine through sulfur assimilation. In contrast, studies have also found that the addition of Na2S as a donor of H2S could promote the generation of cysteine in mammalian cells in the presence of cystine. Since H2S exists as HS$^-$ in a neutral solution, disulfide compounds such as cystine can react with HS$^-$ in the culture medium as well as in the cell. This study demonstrated that after the addition of Na2S solution to the culture medium, HS$^-$ was transiently generated and disappeared immediately through the reaction between HS$^-$ and cystine to form cysteine persulfide and polysulfides (see Fig. 10 in Koike et al., 2017). A significant increase in cystine concentration was observed after treatment with Na2S. The mechanism by which Na2S protects SH-SY5Y cells from MG cytotoxicity is via the activation of Nrf2, but not HS$^-$ itself. However, this mechanism has not been verified in ferroptosis, and further investigation is needed to elucidate its molecular mechanism.

The slow-acting H2S donor GYY4137 can release this gas for several hours (Chen et al., 2016). Ferroptosis is an important component of sepsis-associated ALI, and GYY4137 has been reported to protect against ALI by alleviating oxidative stress through the removal of ROS. GYY4137 also markedly suppressed COX-2 and NOX1 expression while increasing sepsis-induced GPX4 and SLC7A11 expression, thereby inhibiting the occurrence of ferroptosis in sepsis-induced ALI (Li et al., 2022).

H2S AND IRON METABOLISM

The metabolism of iron is integral to the induction and progression of ferroptotic pathways, whereas H2S has a complex relationship with iron metabolism. Iron is

Table 2. Summarization of current H2S donors application in different disease models.

Disease model	H2S donor	Mechanism	Reference
Myocardial fibrosis	AP39	PINK1/Parkin pathway	(Yang et al., 2023)
Hypertension	NaHS	Upregulated the VSMC GSH content and cystathionine gamma-lyase (CSE)/hydrogen sulfide (H2S)	(Ruxi Jin et al., 2022)
Intracerebral hemorrhage (ICH)	NaHS	Improved GPX4 and SLC7A11 via the CBS/H2S system	(Y. Yu et al., 2023)
Retinal degenerative diseases.	NaHS	AMPK- and p62-dependent non-canonical NRF2-KEAP1 pathway	(M. Yu et al., 2023)
Sepsis-induced cardiomyopathy (SIC)	NaHS	Inhibited the phosphorylation of BECN1 and increased expression levels of SLC7A11 and GPX4	(Cao et al., 2022)
Beryllium disease	NaHS	Decreased the accumulation of Fe2+and lipid peroxides	(Liu et al., 2023)
Sepsis-induced acute lung injury (ALI)	GYY4137	Stimulated autophagy by blocking mTOR signaling	(Jianhua Li et al., 2022)

involved in H_2S production *via* non-enzymatic processes. Meanwhile, the uptake, transport, and accumulation of iron is regulated by H_2S. The interactions between H_2S and iron shape the cellular homeostasis of H_2S and define the relevant signaling crosstalk.

In addition to the enzymatic mechanisms mentioned above, non-enzymatic H_2S in eukaryotes may come from a cysteine reaction with iron and vitamin B6 or from the reduction of elemental sulfur (Kolluru *et al.*, 2013; Yang *et al.*, 2019). Nucleophilic attack by vitamin B6 on cysteine forms a cysteine-aldimine, which reacts with free or heme-bound iron to yield a quinonoid containing cysteine. Subsequently, iron ions remove the thiol group from H_2S, and the resulting de-sulfureted aldimine is hydrolyzed to produce vitamin B6, ammonia, and pyruvate.

Free iron (Fe^{2+}) is taken up by the cell through ion channels or transporters, such as L-type Ca^{2+} channels on cellular membranes. H_2S is also an endogenous gaseous ATP-sensitive K+ (KATP) channel opener that induces vasodilation (Arif *et al.*, 2022). H_2S and iron may interact to suppress L-type Ca^{2+} channels via S-sulfhydration, as shown in mouse pancreatic β-cells (Tang *et al.*, 2013). The influx of iron into cells through L-type Ca^{2+} channels has been demonstrated in cardiomyocytes (Arif *et al.*, 2022). The inhibition of these processes by H_2S decreases the amount of iron entering the cell. Ferroportin 1 (Fpn1) and transferrin receptor 1 (TfR1) are essential regulators of iron homeostasis in most cells. Injecting NaHS *in vivo* significantly increases serum iron levels and transferrin saturation while significantly downregulating TfR1 and Fpn1 at the protein level (Zhang *et al.*, 2019). Under the influence of ferric ions, cysteine catalyzes the generation of H_2S through a protective mechanism that mitigates excessive iron concentrations by reacting with iron and generating acid-labile iron sulfide, such that excessive iron cannot cause further oxidative stress (Tang *et al.*, 2023; Yang *et al.*, 2019).

Recently, it was found that CBS is essential for iron homeostasis, and the hepatic, splenic, cardiac, and serum iron levels in CBS-deficient mice are elevated together with oxidative stress-related marker levels; mice homozygous for the knockout of CBS failed to survive for more than 4 weeks (Zhou *et al.*, 2018). Moreover, hepcidin can accelerate the degradation of Fpn1 by interacting with it, thereby reducing intracellular iron release into the systemic circulation. Upregulation of hepcidin in both the liver and systemic circulation has been reported to lead to decreased Nrf2 expression. Elevated hepcidin levels resulted in a marked decrease in Fpn1 expression and exacerbated iron retention, causing severe liver damage. An adenoviral vector was used to restore CBS expression, and this attempt was able to reverse the damaged phenotypes (Zhou *et al.*, 2018). Inflammatory cytokines such as IL-6 promote the upregulation of hepcidin via JAK-STAT3 signaling through interactions with activin B and the SMAD1/5/8 pathway. In contrast, H_2S suppresses the upregulation of hepcidin *via* JAK-STAT signaling *via* the suppression of STAT3 phosphorylation, thereby reducing IL-6 production (Zhang *et al.*, 2019). Similar findings were also reported by Xin and others who demonstrated that H_2S promoted the expression of SIRT1, stabilizing SIRT1-STAT3 interactions to reduce the acetylation of STAT3, thereby decreasing hepcidin levels (Xin *et al.*, 2016). Collectively, these results indicate that H_2S reduces hepcidin levels by acting upstream of STAT3, which provides an opportunity for further investigation. A better understanding of the mechanism underlying the regulation of STAT3 *via* H_2S may shed light on its clinical potential.

H₂S AND LIPID PEROXIDATION

Lipid peroxidation is a hallmark of ferroptosis, which results from the generation of excessive levels of ROS due to increased intracellular iron concentrations, together with the simultaneous depletion of GSH. The antioxidant enzyme GPX4 is responsible for lipid peroxide neutralization and can utilize GSH as a cofactor to preserve membrane fluidity, thus shielding the membrane against peroxidation-related damage (Su *et al.*, 2019). Inhibition of GPX4 contributes to high levels of ROS production, and its overexpression can conversely reduce ROS generation and prevent ferroptosis induction. Iron metabolism-related ROS generation is a major cause of lipid peroxidation, given that iron is required for numerous physiological processes, and excessive iron levels ultimately disrupt normal cellular function through the resultant oxidative damage, contributing to cell death (Su *et al.*, 2019).

H_2S has been reported to exhibit concentration-dependent pro- or antioxidant activities, such that plasma lipid peroxidation is suppressed and enhanced by low (10 μM) and high (1000 μM) concentrations of NaHS (Sun *et al.*, 2012). Sun and others found that the use of NaHS to pretreat neonatal rat cardiomyocytes resulted in the generation of lower concentrations of ROS during hypoxia/reoxygenation, and that H_2S suppressed the activity of mitochondrial complex IV while simultaneously enhancing superoxide dismutase activity (Sun *et al.*, 2012). *In vivo*, Wu and others reported that 50 μmol/kg NaHS per day for 16 weeks with a high-fat diet prevented the increase in diet-induced lipid oxidation (Wu *et al.*, 2009), suggesting that NaHS has protective effects against lipid oxidation. H_2S is traditionally known for its toxic effects on living organisms. Current studies are still focused on cell and animal experiments, and relevant data and safety for clinical use are needed.

Hcy has been suggested to increase the severity of oxidative stress owing to the generation of free radicals through the autooxidation of excessive Hcy concentrations (Malinowska *et al.*, 2012). Yan et al. further reported that H_2S protected against HHcy-induced cellular injury through its antioxidant activity, leading to a 55.8% decrease in the overproduction of $O^{2-•}$ induced by Hcy (Yan *et al.*, 2006). Chang et al. found that the administration of H_2S decreased total plasma Hcy concentration and lipid peroxidation. CBS- and CSE-knocked out mice exhibit lower GSH levels and are more susceptible to oxidative stress, further confirming the link between stress and endogenous H_2S (Chang *et al.*, 2008).

Lipid metabolism is closely related to the conversion of carbohydrates into fat. The cytoplasmic hydrolysis of lipids is the first step in metabolism, resulting in the production of glycerol and fatty acids. The two compounds are then glycolyzed and β-oxidated, and H_2S regulates glycolysis and fatty acid metabolism through protein S-sulfhydration (Cheung & Lau, 2018). Activated glycolysis and the pentose phosphate pathway can increase antioxidant activity (D'Alessandro *et al.*, 2014). Exposure of clonal HepG2 hepatocyte cells to NaHS (–10–100 μM) reduced glucose consumption and glycogen levels (Zhang *et al.*, 2013). In addition, the CSE/ H_2S pathway has recently been shown to play a key role in the regulation of glucose synthesis through pyruvate carboxylase S-sulfhydration in gluconeogenesis (Ju *et al.*, 2015).

Further details regarding the association between H_2S and ferroptotic activity are shown in Fig. 2. The interaction pathway between H_2S and ferroptosis is shown in Fig. 3.

Figure 2. The effect of H2S on ferroptosis.
Cystine is imported by the Xc-system and converted into cysteine, which in turn serves as a GSH precursor. GSH is a GPX4 substrate. Both cysteine and Hcy are also substrates for the production of H_2S, and the H_2S equivalent NaHS can increase GSH levels and GPX4 activity while suppressing the activity of the lipoxygenase ALOX12, thus remediating dysregulated lipid metabolism. Overly high Fe^{2+} concentrations can contribute to ROS generation *via* the Fenton reaction, whereas HHcy can drive enhanced ROS production and aberrant mitochondrial functionality. HHP promoted ROS generation by suppressing CSE/H2S expression and reducing GSH generation. TfR1 and FPN are important regulators of cellular iron homeostasis and NaHS can suppress their downregulation at the protein level. Hepcidin interacts with Fpn1 to facilitate its degradation, whereas H_2S reduces hepcidin expression *via* JAK-STAT signaling. The deubiquitinase OTUB1 is capable of stabilizing the xCT Xc-system subunit via cysteine 91 persulfidation. The xCT inhibitor Era, when used to treat cells for an extended period of time, upregulates CBS expression and enhances the resistance of cells to ferroptosis. In contrast, the CBS inhibitor AOAA, when administered together with Era, downregulated cellular GSH levels and enhanced ferroptotic death.

H_2S AND FERROPTOSIS-ASSOCIATED MicroRNAs

MicroRNAs (miRNAs) are short RNAs of ~22 nucleotides in length that lack coding ability and function by suppressing translation and/or promoting the degradation of complementary target mRNAs. Inhibiting miR-30b-5p expression reportedly results in FPN1 and SLC7A11 upregulation in trophoblasts, while the upregulation of this mRNA under hypoxic conditions leads to the downregulation of these two genes, causing trophoblast ferroptosis (Zhang *et al.*, 2020). Members of the miR-30 family have also been confirmed to target CSE expression, thereby directly regulating the generation of H_2S (Shen *et al.*, 2015). By targeting GPX4, miR-15a can control ferroptotic induction in colorectal cancer cells, whereas overexpression of miR-15a suppresses GPX4 expression *in vitro* and *in vivo,* resulting in elevated ROS generation, intracellular Fe^{2+} accumulation, and increased MDA levels (Liu *et al.*, 2022). Fan et al. found that miR-15a overexpression resulted in elevated GPX4 protein levels, with a concomitant decrease in ferroptotic induction associated with fewer severe myocardial inju-

Table 3. An overview of H₂S and ferroptosis-associated proteins and miRNAs

Protein or miRNA	Relation with H_2S	Relation with ferroptosis	Disease involved
Nrf2	Enhances the anti-ferritinophagy and anti--ferroptotic effects of H_2S	Anti-ferroptotic	COPD
OTUB1	H_2S maintains the stability of xCT through persulfidation of OTUB1 at cysteine 91	Stabilizes xCT	Colorectal cancer
TfR1	NaHS inhibits the downregulation of TfR1 protein expression *in vivo*	Regulates cellular iron balance	LPS
FPN1	NaHS inhibits the downregulation of Fpn1 protein expression *in vivo*	Regulates cellular iron balance	LPS
Hepcidin	H_2S reduces hepcidin expression	Accelerates the degradation of FPN1	Anemia of inflammation
MiR-30b-5p	Regulates H_2S production	Downregulates SLC7A11 and FPN1	Myocardial ischemia/reperfusion injury
MiR-15a	H_2S upregulates miR-15a	Positively regulates ferroptosis *via* directly targeting GPX4	Broiler thymus
MiR-194	Decreasing H_2S can downregulate miR-194	Activates the Nrf2/HO-1 signaling pathway	Cerebral injuries.

Figure 3. The pathway of H2S interacting with ferroptosis.
NaHS is a donor of H$_2$S, and once entered cells, it regulates ferroptosis-associated proteins to exert protective effect. First, it can be converted into cystine, increasing the content of GSH and upregulating the activity of GPX4, resulting in reduced ferroptosis *via* antioxidant effect. At the same, it maintains the stability of xCT through persulfidation of OTUB1 at cysteine 91. Second, it inhibits ferroptosis and ferritinophagy via upregulating Nrf2. It reduces the expression of hepcidin *via* the JAK-STAT pathway, preventing the downregulation of FPN1. Thirdly, NaHS itself upregulates the expression of FPN1 and TfR1 with or without inflammation, further regulating the metabolism balance of iron *in vivo*.

ries (Fan *et al.*, 2021). Exposure to H$_2$S also results in miR-15a upregulation (Xueyuan *et al.*, 2021). Additional evidence suggests that miR-194 can mitigate the severity of ischemia-reperfusion injury through the inhibition of Bach1 and introduction of signaling *via* the Nrf2 /HO-1 pathway. Therefore, miR-194 inhibition reversed these effects by reducing HO-1 and Nrf2 protein levels (Li *et al.*, 2021). Reduction in H$_2$S production reduces miR-194 expression and drives the deposition and realignment of collagen under diabetic conditions to attenuate fibrosis and renovascular constriction (John *et al.*, 2017). The proteins and miRNAs associated with ferroptosis are summarized in Table 3.

CLINICAL POTENTIAL APPLICATION

In cancer, the clearance of H$_2$S and the regulation of the enzymes involved in its pathways are essential for cancer therapy. A biocompatible fusiform iron oxide-hydroxide nano-spindles nano system (FeOOH NSs) was designed, which could be applied to magnetic resonance imaging (MRI) to monitor ferroptosis. It can efficiently scavenge endogenous H$_2$S by a reduction reaction to inhibit the growth of CT26 colon cancer cells (PMID:32789963). The biosafety of this nano-system has been verified in animal models for three months, indi-

cating its potential clinical translation. In addition, zinc oxide-coated virus-like silica nanoparticles (VZnO) were also tested to establish an H$_2$S-responding nano-system to scavenge H$_2$S to alleviate ferroptosis in colorectal cancer (Pan *et al.*, 2021). Additionally, fluorescent probes that can be used for selective detection of hydrogen sulfide have been developed to explore the biological and pathological effects of H$_2$S during ferroptosis (Di *et al.*, 2021; Guo *et al.*, 2022). The two-photon fluorescent probe (PSP) exhibited excellent photostability and two-photon imaging performance, and elevated levels of H$_2$S were observed during ferroptosis in tumors (Di *et al.*, 2021). Needless to say, these tools will enable a more extensive expansion of H$_2$S-related technologies and knowledge for broad therapeutic applications in the near future.

FUTURE DIRECTIONS

In recent decades, a broad range of physiological functions of H$_2$S have been gradually recognized. Accumulating evidence has indicated that H$_2$S plays a role in various types of cell death. However, it is still not clear whether the suppression of cell death occurs simultaneously across cell death or is more potent toward one type of cell death than the others. As a relatively new

area, the interactive mechanisms between H_2S and ferroptosis need to be further explored, and the implications of H_2S and ferroptosis interactions in various diseases, such as chronic organ fibrosis, diabetes-associated diseases, stroke, and other degenerative diseases, have not been studied. More experiments are needed to develop a safety profile and treatment regimens for H_2S in various disease models and human subjects. Currently, the time and dosage of H_2S in animal experiments are being investigated, but the results are inconsistent (Wang et al., 2022; Zhang et al., 2023). In addition, newly developed nanoparticles or fluorescent probes have not been applied in clinical trials and require further validation and biosafety tests. Minimizing H_2S-induced toxicities remains a challenge and H_2S associated biomarkers need to be identified for the better clinical use of H_2S.

CONCLUSION

In summary, H_2S functions as a key gastronomist closely tied to ferroptosis with the substrates, enzymes, and donors involved in the production of H_2S, all of which are related to ferroptosis. The metabolism of iron, process of lipid peroxidation, and inactivation of antioxidation systems all participate in the process of ferroptosis. H_2S can also regulate the uptake, transport, and accumulation of iron, and reduce lipid oxidation by enhancing superoxide dismutase activity and regulating glucose production. miRNAs are involved in nearly every biological process, and several miRNAs have been found to be involved in both H_2S metabolism and ferroptosis. As the interplay between H_2S and ferroptosis has only been explored in recent years, much work remains to be done to adequately understand the relationship between them. For example, additional research exploring the production, storage, and release of H_2S is needed, as are efforts to understand how H_2S affects mammals in vivo under a range of settings and how it shapes the process of ferroptosis.

This report describes a comprehensive approach to local random mutagenesis of the *E. coli* Ntn-amidohydrolase EcAIII, and supplements the results published earlier for the randomization series RDM1. Here, random mutagenesis was applied in the center of the EcAIII molecule, i.e., in the region important for substrate binding and its immediate neighborhood (series RDM2, RDM3, RDM7), in the vicinity of the catalytic threonine triplet (series RDM4, RDM5, RDM6), in the linker region (series RDM8), and in the sodium-binding (stabilization) loop (series RDM9). The results revealed that the majority of the new EcAIII variants have abolished or significantly reduced rate of autoprocessing, even if the mutation was not in a highly conserved sequence and structure regions. AlphaFold-predicted structures of the mutants suggest the role of selected residues in the positioning of the linker and stabilization of the scissile bond in precisely correct orientation, enabling the nucleophilic attack during the maturation process. The presented data highlight the details of EcAIII geometry that are important for the autoproteolytic maturation and for the catalytic mechanism in general, and can be treated as a guide for protein engineering experiments with other Ntn-hydrolases.

Introduction

N-terminal-nucleophile amidohydrolases (Ntn-amidohydrolases) are enzymes that hydrolyze the amide bonds of amino acids, peptides, glycopeptides, and sphingolipids (Linhorst and Lübke, 2022), using an N-terminal residue as the primary nucleophile. Ntn-amidohydrolases are produced as inactive precursors which develop their enzymatic activity in an autocatalytic cleavage maturation process that releases the nucleophilic residue (Thr, Ser, Cys) at the newly formed N-terminus of subunit β (Michalska and

Panels **(B, C)** show detailed views (in different orientations) of the active site with color-coding of the randomization regions (the color code is the same as in Panel **(D)**); randomized residues are in stick representation. **(D)** A fragment of EcAIII sequence with randomization positions and numbers of the randomized residues marked below the sequence; sequence numbers of the Thr triplet are marked in red; the full EcAIII sequence is presented in Supplementary Figure S1.

Jaskolski, 2006). The *Escherichia coli* EcAIII protein is an Ntn-amidohydrolase with the L-asparaginase activity (Michalska et al., 2005). L-asparaginases are a large group of enzymes that convert L-Asn to L-Asp and ammonia. According to the most recent classification, EcAIII is a potassium-independent member of Class 2 L-asparaginases (Loch and Jaskolski, 2021; da Silva et al., 2022), formerly called plant-type L-asparaginases (Borek and Jaskólski, 2001).

The catalytic center of EcAIII is made of a threonine triplet: Thr179 (the nucleophile), Thr197, and Thr230. In the close vicinity of the triplet, other residues involved in substrate stabilization are located. Among them, the most important is Arg207, which acts as an anchor for the substrate α-carboxylate group, and Asp210, which stabilizes its amino group (Figure 1). The EcAIII molecule also features a sodium-binding (stabilization) loop, which is important for securing the proper orientation of Thr179 nucleophile (Michalska et al., 2008).

As all known Ntn-hydrolases, EcAIII requires a maturation step to develop its enzymatic activity. Upon maturation, the peptide bond between Gly178 and Thr179 is cleaved by the same Thr179 nucleophile (Michalska et al., 2008). The precursor protein is a homodimer, while the mature form of EcAIII is a dimer of two heterodimers, each comprised of subunit α and subunit β. After the autocleavage process, a flexible linker of ~20 residues remains at the C-terminal part of subunit α. The linker is naturally disordered and undergoes degradation over time (Linhorst and Lübke, 2022).

Our recent studies of the impact of random substitutions (series RDM1, Supplementary Table S1) on EcAIII performance revealed that initiation of autocatalytic cleavage is a complex and multistep process, highly sensitive to even small changes in protein geometry and hydration pattern near the scissile Gly178-Thr179 bond (Loch et al., 2022). Following the previous run of local random mutagenesis, we performed further randomization trials to probe how the selected regions of the EcAIII molecule tolerate simultaneous multiple amino acid substitutions. Moreover, we also hoped to identify new EcAIII variant(s) with improved catalytic efficiency (k_{cat}) or substrate affinity (K_m), for potential utilization in leukemia therapy (Tosta Pérez et al., 2023).

In this work, segments of the EcAIII sequence for local random mutagenesis (Figure 1; Supplementary Table S1) were selected on the basis of crystal structure analysis. Residue randomization was carried out in the center of the EcAIII molecule, i.e., in the region important for substrate binding and its immediate neighborhood (series RDM2, RDM3, RDM7), in the vicinity of the catalytic threonine triplet (series RDM4, RDM5, RDM6), in the linker region (series RDM8) and in the sodium-binding loop (series RDM9). Although mutations usually led to inactive precursors, we were still able to identify several factors that affect the enzyme performance. Our report is one of few studies (Kim et al., 2010; Karamitros and Konrad, 2016; Xu et al., 2018; Loch et al., 2022) describing mutagenetic modification of Ntn-hydrolases.

Methods

Random mutagenesis was performed according to the QuikChange protocol with the use of the mutagenic primers

listed in Supplementary Table S1. In the naming scheme applied in this work, mutants are labeled as "RDMY-X," where X is the ordinal number of a particular bacterial colony that was screened, and Y is the number of the mutagenesis trial (Supplementary Table S1; Figure 1). All SDS-PAGE gels marked with names of the mutants are presented at the end of Supplementary Material (as Supplementary Appendix – raw experimental data).

As a matrix for PCR reaction, the EcAIII sequence cloned to the pET11d (or pMCSG92) vector was used. After PCR reaction, the matrix was digested using *DpnI* enzyme (Thermo Scientific). Products of the PCR reaction were transformed to BL21 (DE3) Gold cells. Clone selection procedure, L-asparaginase activity test in cell lysate, and monitoring of autocleavage were performed according to previously described protocol (Loch et al., 2022). After monitoring of maturation by SDS-PAGE and testing for activity in cell lysate, several clones (active or inactive) were selected for plasmid DNA isolation and sequencing (Genomed SA, Poland) to check the mutations present.

Large-scale expression and purification of selected variants were performed according to previously described procedures (Loch et al., 2022, 2023). L-asparaginase activity of mutants was detected using Nessler method as describes earlier (Janicki et al., 2023). Structure prediction for selected mutants was made using AlphaFold2 (AF2) (Jumper et al., 2021) with the utilization of Amber relaxation refinement to assure the correct stereochemistry of the models.

Results and discussion

The results presented herein are a continuation and complementation of the random mutagenesis report on EcAIII published previously as the RDM1 series (Loch et al., 2022). The randomization trials RDM2 - RDM9 were performed in eight selected regions of the EcAIII sequence (Figure 1; Supplementary Figures S1, S2). Screening was carried out manually for relatively small numbers of clones (Supplementary Table S2). The differences in the numbers of analyzed clones in each series were correlated with the analysis of the SDS-PAGE gels: if in a particular series a small number of clones were capable of autoprocessing, we did not continue the screening.

As the screening process was manual (not in a high-throughput mode), not all clones were submitted to sequencing due to a large number of plasmid isolations that would be too laborious for manual protocol. We decided to carry out sequencing for several clones from each series (Supplementary Table S3). The randomization trails allowed us to identify new EcAIII variants with interesting properties and to make several important observations related to the enzymatic activity of EcAIII, as well as to sequence variability observed in bacterial proteins annotated as Ntn-amidohydrolases (Janicki et al., 2023).

Role of residues 210 and/or 211 (RDM2 series) in EcAIII activity

In the RDM1 mutagenesis trial, four residues at the substrate binding site, namely, Gly206, Arg207, Asp210, and Ser211, were randomized (Loch et al., 2022). In the RDM1 series 64 new EcAIII variants were analyzed. Most of them were not cleaved into subunits, and those which were processed did not exhibit L-asparaginase activity. In the RDM1 variants processed to subunits α and β (Loch et al., 2022), L-Asn hydrolysis was abolished by the absence of Arg207, which is crucial for substrate binding (Figure 1). In order to analyze the behavior of new variants with intact Arg207 (and Gly206), we decided to run the mutagenesis trial RDM2, in which only Asp210 and Ser211 were randomized (Supplementary Table S1).

Screening of 33 clones of the RDM2 series showed that only 11 variants were cleaved into subunits, and among them only eight retained the L-asparaginase activity (Supplementary Table S2). Sequencing revealed that six of the active clones had the wild type (WT) sequence of EcAIII, while the two other active clones carried the mutations D210A/S211P (RDM2-25) and D210P (RDM2-27) (Supplementary Table S3). We also found in the RDM2 series three clones that were processed to subunits but did not show L-asparaginase activity during screening. We sequenced two of them, and identified the following mutations: D210A (RDM2-17) and D210A/S211V (RDM2-32) (Supplementary Table S3).

Although variants RDM2-25 and RDM2-27 were active, they had a very slow autoproteolysis rate. These observations indicate that the absence of Asp210 and/or Ser211 significantly slows down the maturation process. Although residues 210 and 211 do not seem to be directly involved in autoprocessing, as a polar residues they are part of an H-bond framework that assures the correct positioning of water molecules w3, w4, and w5 near the Gly178-Thr179 scissile bond, as visible in the crystal structure (Michalska et al., 2008) (Figure 2A). Although the AlphaFold2 models do not include water molecules, comparison of the predicted structures of mutants RDM2-25, RDM2-27, RDM2-17 and RDM2-32, and the crystal structure of the EcAIII precursor (PDB: 3c17) shows that in the absence of side chains Asp210 and/or Ser211 the correct network of water-mediated H-bonds near the nucleophilic Thr179 cannot be formed (Figure 2A). These observations can explain the slow autoproteolysis rate of the RDM2 mutants, as well as the low enzymatic performance, as Asp210 is also involved in substrate stabilization.

For the active mutants RDM2-25 and RDM2-27, large-scale expression and purification were carried out. We observed that only about ~50% of the RDM2-25 and RDM2-27 mutant proteins were processed into subunits after 48 h. When autoprocessing progressed, we observed the development of L-asparaginase activity of variants RDM2-25 and RDM2-27. As it was impossible to separate the populations of mature and immature EcAIII molecules, we were not able to

FIGURE 2

AF2-predicted structures of the new EcAIII variants. **(A)** Superposition of the RDM2-25 mutant (light pink) on the EcAIII precursor (PDB: 3c17, gray); water molecules (red spheres) present in the precursor structure are H-bonded (gray dashed lines) to Asp210 and Ser211; due to the mutations, this network of H-bonds is perturbed in the RDM2-25 mutant. **(B)** Superposition of the EcAIII structure (PDB: 2zal, gray) with bound L-Asp (black sticks) and the RDM3-9 mutant (dark green); the presence of Arg209 in the mutant affects the position of Arg207. **(C)** Structural changes in variant RDM3-11 (dark green); the side chain of Gln209 blocks the space reserved for the α-carboxylate group of the L-Asp substrate (black sticks, PDB:2zal). **(D)** Superposition of the RDM3-34 model (green) and WT EcAIII (PDB: 2zal; gray); there are no significant conformational changes. **(E)** Superposition of WT EcAIII (PDB: 2zal, gray) and the predicted model of mutant RDM7-12 (pink); the mutations resulted in atomic shifts and the formation of new H-bonds (red dotted lines), not present in the WT structure. **(F)** Superposition of the predicted structure of the EcAIII precursor (gray) and model of the RDM8-15 mutant (light green); major conformational changes were induced by the presence of Pro174 and Lys173; new H-bonds are marked by red dotted lines.

determine the kinetic parameters for preparations of partially cleaved proteins.

The data above suggest that mutations at positions 210 and 211 significantly reduce the autoprocessing rate, but mature variants develop L-asparaginase activity. On the other hand, reported earlier variants from the RDM1 series carrying similar mutations, e.g., RDM1-3, RDM1-12 or RDM1-29, did not exhibit any L-asparaginase activity at all (Loch et al., 2022). However, in the RDM1 mutants the Arg207 residue was absent, while the RDM2 mutants have intact Arg207 required as an anchor for the α-carboxylate group of the substrate. These observations indicate that the presence of Arg207 is absolutely necessary to maintain substrate affinity, while stabilization of the amino group of the substrate by a H-bond to Asp210 plays a less important role in substrate positioning.

Random mutagenesis near the substrate binding site (RDM3 and RDM7)

For the RDM3 series, the SDS-PAGE analysis showed that most of the mutants were not cleaved into subunits. The only clones that were mature and active, RDM3-12 and RDM3-19, had sequence identical to WT EcAIII. We also made attempts to sequence several other immature RDM3 clones. Unfortunately, sequencing was successful only for three mutants (Supplementary Table S3): RDM3-9, RDM3-11, and RDM3-34. These three variants were produced at large scale and purified. Although at the screening stage we did not observe autoproteolysis, the large-scale purification revealed a very slow maturation process. Nevertheless, RDM3-9 and RDM3-11,

remained enzymatically inactive, while variant RDM3-34 developed L-asparaginase activity. The predicted AF2 model of this variant did not reveal any significant conformational changes (Figure 2D), therefore, the reduced autoproteolytic efficiency of RDM3-34 has unknown origin.

Screening of the RDM3 mutants indicated that simultaneous mutations in the close neighborhood of Arg207 (positions 208, 209, 211, 212) is usually fatal for the catalytic activity of EcAIII because of conformational changes leading to incorrect positioning of the Arg207 side chain in the active site. In the RDM3 trial we randomized the highly conserved Gly209, while the rest of the mutated residues have only moderate or low conservation (Supplementary Figure S1). These observations indicate that Gly209 is important for maintaining the correct geometry of the active site. Gly209 is located very close to Arg207 and incorporation of residues with large side chains, such as Arg209 (in RDM3-9) or Gln209 (in RDM3-11) results in a positional shift of Arg207. An AF2 model of the RDM3-9 variant revealed that Arg209 and His211 strongly affect the position of Arg207, making substrate binding ineffective (Figure 2B). The predicted structure of mutant RDM3-11 reveled that Gln209 disturbs substrate binding by affecting its positioning (Figure 2C).

Most of the RDM7 clones, with randomization introduced at positions Pro212, Leu213, Gly217 and Cys218 (Figure 1), retained the ability to mature, but they lost their L-asparaginase activity. Most of active RDM7 clones (Supplementary Table S2) turned out after sequencing to be WT EcAIII. The predicted structure of inactive mutant RDM7-12 revealed a positional shift of the entire 207–217 loop, resulting in the formation of new H-bonds, the most important of which links Asp210 and Thr179 (Figure 2E). Such an interaction most probably disturbs substrate binding and affects the nucleophilic character of Thr179.

In the RDM7 series we detected a high proportion of WT sequences. A simple explanation might be an ineffective digestion of the PCR matrix by *DpnI*. However, we rather exclude this possibility as we always run control transformations in parallel. Another explanation might be that degenerated RDM7 primers with WT sequence were annealed in the PCR reaction to the DNA matrix with similar frequency as the degenerated oligonucleotides with non-complementary sequences. This observation suggest that the efficiency of random mutagenesis depends on the DNA sequence itself. In some (rare) cases, when it is not possible to produce new variants using only degenerated primers, other mutagenic approaches must be considered.

Mutagenesis in conserved sequence regions (RDM4, RDM5, RDM6 and RDM9)

SDS-PAGE analysis of clones from the RDM4, RDM5, RDM6 and RDM9 series (Supplementary Table S1) revealed that in most cases the new EcAIII variants were incapable of splitting themselves into the α and β subunits. Absence of L-asparaginase activity was observed for all clones of RDM4 series. Plasmid sequencing revealed that selected clones in the RDM5 and RDM6 series that were active had the native WT EcAIII sequence (Supplementary Table S2). In series RDM4, RDM5 and RDM6, sequence randomization took place in the close vicinity of the conserved region of the threonine triplet (Thr179, Thr197, Thr230; Supplementary Figure S1). Mutants of the RDM9 series possessed random mutations in the conserved region of sodium-binding (stabilization) loop (Glu61, Cys63, Phe66, Ala68). In this series, the one active variant had sequence identical to WT protein (Supplementary Table S2).

These findings indicate that random mutagenesis in the highly conserved fragments of the sequence is ineffective, and it should be avoided or replaced by rational site-directed mutagenesis. However, our recent analysis of residue conservation near the catalytic triplet and the stabilization loop (Janicki et al., 2023) revealed that in bacterial EcAIII orthologs, substitutions in the Thr triplet and its close vicinity are possible but very rare. For example, the most variable position near Thr179 corresponds to Met177 in EcAIII sequence, which in other proteins can be substituted by Phe, His or Tyr, while the most mutation-prone position in the stabilization loop is Cys63 which can be replaced by Asp, Asn or Ser (Supplementary Figure S1).

Mutagenesis within the variable linker region (RDM8)

It would seem that the chance of obtaining functional EcAIII variants via random local mutagenesis depends on the sequence element that is randomized: the more conserved the designated sequence fragment (associated with a particular function), the lower the probability of obtaining functional clones. From this point of view, the most promising segment is the least-conserved fragment of the EcAIII sequence, namely the flexible Glu159-Gly178 linker immediately preceding the nucleophilic Thr179 (Supplementary Figure S1). The linker does not participate in substrate binding and L-Asn hydrolysis of the mature enzyme. The role of the linker in autoproteolysis is not clear; however, recently we reported that correct positioning of the linker is essential for efficient autocleavage of the scissile Gly178-Thr179 bond (Loch et al., 2022).

The entire linker of ~20 residues is usually not fully visible in the electron density maps, suggesting high mobility or progressive digestion. As the only available experimental model of EcAIII with part of the linker visible (residues 165–178) is the crystal structure of the T179A mutant (PDB: 3c17) (Michalska et al., 2008), we attempted to generate

AF2 models of unprocessed EcAIII. The AF2 predicted conformation of the linker was significantly different from the 3c17 crystal structure. That structure of the inactive T179A mutant showed that residues Glu173 and Lys176 might be important for the stabilization of the scissile bond (which is a part of the linker), as Lys176 is H-bonded to Glu234 and Glu173 forms a salt bridge with Arg149 (Supplementary Figure S3). These interactions were absent in the predicted model of immature WT EcAIII. Instead, we observed an H-bond between the main chain carbonyl O atom of Glu173 and nitrogen of Lys176 (Supplementary Figure S3), as well as an H-bond between the side chains of these residues.

In the RDM8 series we randomized four residues: Glu173, Lys174, Lys176 and Met177, from the linker (Supplementary Table S1). Sequencing revealed that in the RDM8 trial four out of the seven active variants had WT sequence (Supplementary Table S2). However, clones RDM8-6 and RDM8-15 (and RDM8-17) carried mutations (Supplementary Table S3). SDS-PAGE analysis showed that in variants RDM8-6 and RDM8-15 autoprocessing was rather slow, however, ultimately the proteins were converted to mature αβ subunits and attained their L-asparaginase activity (as the active site region was not mutated). Variant RDM8-6 carried four mutations: E173I/K174Q/K176A/M177I. The AF2 model suggested that the K174Q substitution may lead to the creation of new H-bonds between Gln174, Gln152 and Gln19 (Supplementary Figure S3). According to the prediction, substitutions K174Q and E173I may result in a flip of the 171–173 side chains, affecting the Cα backbone trace of the linker.

For the RDM8-15 variant with the E173L/K174P/K176E/M177K mutations, the AF2 model suggested that significant conformational changes may be introduced in the linker by the presence of Glu176, H-bonded to Arg149 and Gln152, and by Lys177, H-bonded to Ser274 (Figure 2F), as these interactions are absent in the AF2 model of the WT protein. According to the AF2 model, the substitution K174P of RDM8-15 also contributes to the conformational changes of the linker. The conformational changes in the linker region analyzed in this section may potentially reduce autoproteolysis rate by hampering proper orientation of the Gly178-Thr179 scissile bond for nucleophilic attack.

The results of mutagenesis in the linker region show that by modifying this part of the EcAIII sequence one can tune the efficiency of autoproteolysis without "touching" the active site. This might be important for designing new EcAIII variants with controlled maturation process. Also, designing EcAIII mutants with impaired autoproteolytic activity might be useful for crystallographic modeling of the intact linker structure, as an important step towards the elucidation of the mechanism of autoproteolytic activation.

Conclusion

This report describes a comprehensive approach to random mutagenesis of EcAIII and is a sequel to a previously published work (Loch et al., 2022). Our studies reveled that most of the new EcAIII variants had abolished or significantly reduced rate of autoprocessing, and were in consequence devoid of L-asparaginase activity. In this respect, we have demonstrated that local random mutagenesis of the EcAIII sequence is rather ineffective for designing better enzymes with increased substrate affinity. The problem lies not in the randomization itself, but is rooted in the biochemistry of Ntn-amidohydrolases. These enzymes are produced as inactive precursors and it is usually difficult to predict if the introduced mutations will affect the maturation process only, or L-Asn hydrolysis as well. Even if a given substitution could be beneficial for the ultimate substrate hydrolysis, this effect may not be observed if the same mutation is fatal to enzyme maturation. The only way to avoid such problems is to use circularly permutated genes for Ntn-amidohydrolase mutagenesis. This approach has been used only once, for the human HsAIII enzyme (Li et al., 2012).

We also predicted the role of several residues in the proper orientation of the linker and the scissile bond for autoprocessing. Moreover, we generated genes of several new active and inactive EcAIII variants that enrich the available library of EcAIII mutants (Michalska et al., 2008; Loch et al., 2022; Janicki et al., 2023). We believe that our randomization studies will help to better understand the catalytic properties of Class 2 L-asparaginases and will guide further engineering experiments with other Ntn-amidohydrolases as well as mechanistic studies (Andjelkovic et al., 2023) of the new Ntn-hydrolases.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding author.

Ethics statement

The studies conducted with the use of Genetically Modified Microorganism (GMM) were reviewed and approved by commission on GMM at the Ministry of Climate and Environment (Poland).

Author contributions

JIL designed experiments and coordinated the experimental work, carried out mutagenesis, clone screening (RDM3,

RDM7), structure modelling, data analysis and wrote the manuscript. AS performed large scale protein expression and activity tests for purified enzymes. MK performed mutagenesis and clone screening of the RDM8 series, carried out structure modelling and participated in manuscript preparation. IP performed clone screening of the RDM2, RDM3 and RDM9 series. WL performed clone screening of the RDM2 series and analyzed the data. KZ performed clone screening of the RDM4, RDM5 and RDM6. MJ analyzed the results and wrote the manuscript. All authors contributed to the article and approved the submitted version.

Stability in biosensors derived from domain map analysis of bibliometric data

Aleksandra Klos-Witkowska* and Vasyl Martsenyuk

Department of Computer Science and Automatics, University of Bielsko-Biala, Bielsko-Biala, Poland

In the presented work, advanced methods of analysis and visualization were used to compile trends and patterns in the scientific literature. The most relevant information for the stability of biosensors was selected on the basis of clusters constructed on the basis of keywords. The most significant publications in the clusters appearing over time were analyzed. The most explosive publications were identified, i.e., those that have had the greatest impact on science in the area of the subject under study. The scientific trend in the development of biosensor stability was determined on the basis of the most frequently cited words in recent publications. A map of cooperation and networking between countries in the field of interest of the above topic was presented. Leaders were identified by country of origin.

Systematic Review Registration: https://ubb.edu.pl.

Introduction

The number of scientific publications increases every year with the development of technology and the progress of civilization. Therefore, the need for a fast and accurate analysis of the literature to keep track of the development of existing research topics and emerging news in the world of science was naturally born. Previously used scientific analysis based on web reviews or studying scientific databases such as Web of Science, Scopus, PubMed allowed only retrospective analysis, i.e., chronological, recollective analysis without the ability to trace connections. Domain map analysis means the use of graph network representations of the source analysis, including the analysis of the relationships between data with the help of the choice and appropriate distance measure, clustering, mapping the relationships into graph nodes and edges. It allows us to determine the most significant resources analyzed temporal development of the area determined tendencies (Liu et al., 2020; Geng et al., 2023).

One of the most popular tools for bibliometric analysis of domain maps is CiteSpace, which is based on data mining, a process involving data extraction, pattern analysis and sorting. It is a process that can be compared to mineral processing, where the mineral must first be extracted, then cleaned and finally sorted. Data mining enables rapid predictions and classifications to be made and facilitates decision making.

CiteSpace is a Java based application designed to analyze and visualize trends and patterns in the scientific literature to present the structure and distribution of scientific

knowledge. It focuses on finding critical points in the development of a field or region, especially intellectual turning points (Xu et al., 2022; Gao et al., 2023; Zhao et al., 2023). In presented papers we used CiteSpace to group keywords and highlight results related to biosensors stability.

The analysis is based on the theoretical trend (intellectual) and the experimental trend. The intellectual trend is based on articles presenting research findings or a scientific point of view, while the experiential trend [as conceptualized by Price (1965)] is based on collections of cited articles.

The functions of the CiteSpace application are based on three central concepts:

1. The Kaliberg crack detection algorithm (Kleinberg, 2002), which is used to identify test concepts.
2. The Freman intercentricity matrix, used to highlight potential key points
3. The Heterogeneous Network, used to map between the intellectual base and the experimental front.

Mapping can be used to identify the nature of the research front, highlight specializations and identify emerging trends over time.

The CiteSpace analysis are based on select single words or phrases of up to four keywords from titles, abstracts and article descriptions based on articles by the method LSI (Latent Semantic Indexing) related to biosensors stability.

The research is based on a surge in citation frequency. Analysis by cluster view and by temporal variation is possible. The CiteSpace tool makes it possible to follow in real time the development of new fields of knowledge and the links in the existing field of knowledge (between institutions and countries), it also gives the possibility to see the history of the emergence of a scientific question and the impact of the main discoveries on the final view. The present article analyses the stability of biosensors on the basis of experimental studies. The analysis was carried out using the CiteSpace 6.2. R4 tool, which selects the most important articles that cause the scientific development of the topic, based on the keywords that appear most frequently in the titles and abstracts. The novelty of the article is: 1) the presentation of the latest trends, the indication of the direction of research in the field of stability of biosensors, based on an advanced analysis using the CiteSpace tool, 2) the identification of the scientific leaders dealing with the studied issue, and 3) the presentation of the mutual network of scientific links between research groups coming from different countries.

Methods

Sources of data

In this paper we used the Web of Science (WoS) database as a data source and through advanced search (TS= biosensor) we obtained 86,814 papers in the range time (01.01.1974–01.07.2023).

Figure 1 shows the number of publications in the field of biosensors from 1974 to 2022. We have chosen 2022 as the upper limit of the time frame because this is the last full calendar year in the WoS database (2023—not yet over). The graph shows a clear increase in publications over time, indicating a growing interest in biosensors, most likely related to the increase in environmental pollution (Pohrebennyk et al., 2018) and the widening range of biosensor applications [medicine (Grabowska et al., 2014), environmental protection (Klos-Witkowska, 2016), food industry (Dirpan et al., 2023) and the drive to improve existing devices to achieve even better detection quality (Laad and Ghule, 2022)]. It is worth noting the slight decrease in the number of papers published in 2020 (5,875 papers) compared to 2019 (5,902 papers), perhaps due to the impact of the COVID-19 pandemic, which was felt all over the world.

Current research is carried out in two parallel streams: experimental and theoretical.

In the experimental stream, work focuses on improving the quality of detection and the stability of the device (Klos-Witkowska and Kajstura, 2020), while the theoretical stream revolves around the development of mathematical models (Martsenyuk et al., 2021b), often using already existing solutions for this purpose (Martsenyuk et al., 2021a), also recently, the interest of scientists in combining biosensors with artificial intelligence has been noted. An extremely interesting issue is the problem of stability in biosensors, which is a very important problem not only from a scientific point of view, but also from a commercial point of view. The stability of biosensors directly translates into the longevity of use and the ability to operate the device. Therefore, following the latest scientific trends, the issue of biosensor stability was chosen to be analysed in biosensor development based on advanced analytics using CiteSpace 6.2.R4;

(1) Identifying the most important (so called "explosive articles") that generated the most interest among researchers based on their citability.
(2) The most relevant keywords (most cited) in the titles and abstracts were identified and clustered, i.e., grouped according to their relevance.
(3) The most important clusters were described.
(4) The keywords with the highest number of citations on a time scale were visualised.
(5) Identified scientific leaders working on stability issues in the field of biosensors and showed the network of scientific links between research groups from different countries.

Analytical method characteristics

We conducted a literature search using the following search strategy using Web of Science Advanced Search: Publication

FIGURE 1
Number of publication in the biosensor field from 1974 to 2022.

dates were from 01.01.1974 to 01.07.2023 and search criteria were: for biosensor stability (experimental research): [TS=(biosensor)] AND [TS=(stability)] AND [TS=(empirical)] OR [TS=(experimental)] in the Web of Science Core Collection.

We created visual graphs of keyword co-occurrence, keyword clustering and scientific collaboration using CiteSpace 6.2 R4 software. We investigated the current status and trends in the stability of biosensors.

Results

Biosensor stability

Biosensors are devices that are susceptible to ageing; this phenomenon can be characterised as a decrease in signal over time.

Stability of biosensors is critical for commercial success as biosensors are now used in an increasing number of different applications. Characterisation of stability in terms of shelf life, reusability and the ability to be used continuously is inadequate, although much work has been done in this area. Stability is very important as it is a major factor affecting the operation of the device.

The mechanisms of biosensor ageing are complex and still poorly understood. However, it is known that the loss of stability of a biosensor is the sum of all changes affecting both the biological material used: for example: enzymes (Fernandez-Lopez et al., 2017), antibodies (Oyetayo et al., 2017), as well as the signal mediator (Ricci et al., 2003; Malinauskas et al., 2004) and the binding material of complexes in the matrix (Panjan et al., 2017).

The analysis presented below illustrates the current state of knowledge and trends in biosensor stability research. As shown in Figure 2, the efforts of researchers have focused on chemically modified electrodes, reduced graphene oxide, direct electron transfer, magnetic microspheres, FFT cyclic voltammetry,

poly(o-phenylenediamine), LECTIMS and optimization. The analysis presented was carried out on the basis of the most frequently occurring keywords. These were used to create the clusters shown in Figure 2.

The larger the cluster area, the more frequent the occurrence of the keyword. In the analysis carried out, the keywords are also the names of each of the most relevant clusters, those shown in Figure 2.

Thus, it can be seen that the keyword for cluster #1 (#1) is chemically modified electrode, similarly for the others: #0 reduced graphene oxide, #2 direct electron transfer, #6 magnetic microspheres, #8 fft cyclic voltameters, #10 poly(o-phenylenediamine), #11 lectins, #12 optimisation.

The dots in each cluster represent publications; the names of the most prominent can also be seen in the diagram.

The CiteSpace analysis allows us to select the most significant sentences from the publications contained in the clusters.

Thus, cluster: #0 "reduced graphene oxide" was formed on the basis of 495 publications, of which the publications (Bai et al., 2012; Dong et al., 2012; Wei et al., 2012; Xu et al., 2012; Bai et al., 2013; Wang et al., 2013; Nalini et al., 2014; Zhou et al., 2014; Li et al., 2021) are considered to be the most significant, where one can find information on the application of gold nanoparticles and the development of an amperometric biosensor based on gold nanoparticles decorated with graphene nanoparticles for the detection of clenbuterol. Also of interest are electrochemical biosensors based on hemin-modified graphene nanoplatelets for the determination of l-tyrosine levels. Au nanoparticles were used as a stabilizer.

In cluster #1 "chemically modified electrode"; among the 243 publications forming it, the publications (Arkhypova et al., 2003; Gamella et al., 2006; Mu, 2006; Rahman et al., 2006; Wang and Zhang, 2006; Du et al., 2007; Fan et al., 2007; Fanjul-Bolado et al., 2007; Di Fusco et al., 2010; Chalikian, 2016) are highlighted. The main information in this cluster concerns: the optimization of the biosensor design, as well as the influence of experimental variables such as pH, working potential and temperature on the sensor response. The research also focused on improving the analytical characteristics of the fabricated biosensor, studies of direct electron transfer reactions, optimisation of experimental conditions and substrate affinity based on the Michaelis-Menten constant. pH, working potential and temperature are known as stabilizing factors.

Cluster #2 "direct electron transfer" consists of 460 publications. The ten most important publications are Lai et al. (2008), Zhang et al. (2008), Hsu et al. (2009), Kong et al. (2009), Nenkova et al. (2009), Zhang et al. (2009), Zhu et al. (2009), Liu et al. (2010), Lu et al. (2010), and Garay (2015). They contain information on factors influencing electron transfer. These include the results of studies describing the effect of pH, the preparation of new magnetic microspheres coated with chitosan by modifying magnetic carbon-coated iron nanoparticles. The effect of gold nanoparticles on electron transfer was also investigated.

FIGURE 2
Keyword clustering analysis network.

Cluster #6 "magnetic microspheres" consists of 215 papers. The most important of these are papers (Liu et al., 2005; Tan et al., 2005; Shan et al., 2006; Fan et al., 2007; Tong et al., 2007; Liu et al., 2010; Zhen et al., 2011; Heli and Yadegari, 2014; Ltaïef et al., 2017; Villani et al., 2018) devoted to the preparation of new magnetic microspheres, control of sensor potential, detection limits and response speed from the point of view of biosensor stability.

There are 62 publications in cluster #8 "fft cyclic voltameters." The most important are (Norouzi et al., 2010a; Norouzi et al., 2010b; Norouzi et al., 2010c; Marinov et al., 2010; Bohnenberger and Schmid, 2014; Cheraghi et al., 2017; Narwal et al., 2017; Stepashkin et al., 2018; de Oliveira et al., 2023; Kyomuhimbo et al., 2023). The key information is the application of this method to the study of: pyruvate oxidase, multiwalled carbon nanotubes immobilized on the surface of a glassy carbon electrode by means of a polymer layer of Nafion, the effect of individual components of an enzyme mixture containing gold nanoparticles, acetylcholinesterase, bovine serum albumin and glutaraldehyde on the current output of constructed acetylthiocholine biosensors. The research also included a biosensor for the detection and quantification of organophosphorus pesticides. fft cyclic voltameters allow us to investigate the stability of biosensors.

Cluster #10 "Poly(o-phenylenediamine)" was formed by 130 publications, of which the ten most important are publications (Ahammad et al., 2011; Devi et al., 2013; Zhang et al., 2014; Dervisevic et al., 2015a; Baytak et al., 2015; Dervisevic et al., 2015b; Chen et al., 2015; Tan et al., 2015; Wang et al., 2015), while clusters #11 "Lectins" and #12 "Optimization" were formed by 65 and 163 publications, respectively. The most important for cluster #11 are Bai and Shiu (2014), Gholivand et al. (2014), Oliveira et al. (2014), Ribeiro et al. (2014), Ghanbari et al. (2019), Bravo et al. (2022), Jalalvand (2022), Tvorynska et al. (2022), Zalpour et al. (2022), Ramesh et al. (2023), while for cluster 12 (Hsu et al., 2009; Kong et al., 2009; Liu et al., 2011a; Liu et al., 2011a; Liu et al., 2011b; Pasahan et al., 2011; Yang HC et al., 2011; Yang WY et al., 2011; Makhmudiyarova et al., 2015; Rakhi et al., 2016) with information on operational stability as well as sensitivity, conductivity, detection limits, response speed, detection range, calculation of the Michaelis-Menten constant, response gain.

Diagram 3 (Figure 3) shows an analysis of the most important publications in the cluster that emerged over time. The red circles indicate the most explosive publications, i.e., those that have had the greatest impact on science. These publications were selected based on the highest number of citations of words (extracted from titles, abstracts, descriptors, and identifiers of bibliographic records) found in these publications in the presented time scale.

The time scale in the graph makes it possible to determine when the explosive publication appeared. A detailed analysis is shown in Figure 4.

Thus, in the context of the stability of biosensors, it can be seen that in 2003 there was a publication (Wang et al., 2003,

FIGURE 3
Keyword clustering analysis network in timescale.

267 citations) dedicated to the amperometric biosensor of hydrogen peroxide with a sol-gel/chitosan layer as immobilization matrix, which the authors describe as the development of a new hybrid sol-gel/organic composite material based on the cross-linking of the natural polymer chitosan with (3-aoryloxypropyl) dimethoxymethylsilane. This material was used to fabricate biosensors for H_2O_2 amperometry.

A composite membrane was used to immobilize horseradish peroxidase (HRP) on a gold disc electrode. The properties of the sol-gel/chitosan and sol-gel/chitosan-HRP layers were thoroughly characterized by atomic force and Fourier transform infrared microscopy. Using fluorescent tracers, the protein density in the sol-gel/chitosan was calculated to be 3.14×10^{12} molecules cm^{-2}. The developed biosensor had a fast response in less than 2 s with a linear range of 5.0×10^{-9}–1.0×10^{-7} mol L^{-1} and a detection limit of 2×10^{-9} mol. L^{-1}. The reaction showed a typical Michaelis-Menten mechanism. The activation energy of the enzymatic reaction was calculated to be 8.22 kJ mol^{-1}. The biosensor retained about 75% of its initial activity after about 60 days of storage in phosphate buffer at $4°C$.

This was followed in 2004 by another publication (Wang and Wang, 2004, 415 citations) on a novel hydrogen peroxide sensor based on horseradish peroxidase immobilized on a colloidal Au-modified ITO electrode. The authors described the development of a novel method to fabricate a hydrogen peroxide sensor by immobilizing horseradish peroxidase (HRP) on a colloidal Au-modified conductive ITO glass substrate. The purified glass

substrate was first modified with (3-aminopropyl) trimethoxysilane (APTMS) to provide an interface for the deposition of colloidal Au. Next, 15 nm colloidal Au particles were chemisorbed onto the amine groups of APTMS. Finally, HRP was adsorbed onto the surface of colloidal Au. The immobilized HRP showed an excellent electrocatalytic response to hydrogen peroxide reduction. The performance and factors affecting the obtained biosensor were investigated in detail. The obtained biosensor showed a fast amperometric response (within 5 s) to H_2O_2. The detection limit of the biosensor was 8.0 µmol L^{-1} and the linear range was from 20.0 µmol L^{-1} to 8.0 mmol L^{-1}. In addition, the obtained biosensor showed high sensitivity, good reproducibility and long-term stability.

This is an article that is particularly important for the development of the issue related to the stability of biosensors. Despite the fact that the topic of biosensor stability is developing rapidly. An analysis conducted with the help of CiteSpace showed that no explosive articles have appeared in the last 5 years, which formed the basis for further scientific issues related to the topic of stability.

The next landmark publication was a paper (Qian and Yang, 2006, 284 citations) describing a composite layer of carbon nanotubes and chitosan for the fabrication of an amperometric hydrogen peroxide biosensor. The paper described the development of a novel amperometric hydrogen peroxide biosensor based on the cross-linking of horseradish

peroxidase (HRP) with glutaraldehyde with multi-walled carbon nanotubes/chitosan (MWNTs/chitosan) coated in a composite layer on a glassy carbon electrode. The MWNTs were first dissolved in a chitosan solution. The morphology of the MWNT/chitosan composite layer was then characterised by field emission scanning electron microscopy. The results showed that the MWNTs were well soluble in chitosan and that robust layers could be formed on their surface. HRP was cross-linked with MWNTs/chitosan by glutaraldehyde to prepare a hydrogen peroxide biosensor. The enzyme electrode showed excellent electrocatalytic activity and fast response for H_2O_2 in the absence of mediator. The linear detection range of H_2O_2 (applied potential: -0.2 V) was from 1.67×10^{-5} to 7.40×10^{-4} M with a correction factor of 0.998. The biosensor showed good reproducibility and stability in the determination of H_2O_2. There was no interference from ascorbic acid, glucose, citric acid and lactic acid.

The last of the four most explosive scientific publications was a paper (Zhou et al., 2010, 441 citations) on a novel hydrogen peroxide biosensor based on Au-graphene-HRP-chitosan biocomposites. The paper used graphene very effectively to construct an H_2O_2 biosensor. Graphene and horseradish peroxidase (HRP) were co-immobilised in a biocompatible chitosan (CS) polymer, and then a glassy carbon electrode (GCE) was modified with the biocomposite, followed by electrodeposition of Au nanoparticles on the surface to form an Au/Graphene/HRP/CS/GCE layer. Cyclic voltammetry showed that direct electron transfer of HRP was realized, and the biosensor had excellent performance in terms of electrocatalytic reduction towards H_2O_2. The biosensor exhibited high sensitivity and speed. In addition, the biosensor showed good reproducibility and long-term stability.

As can be seen from the most explosive publications, the stability of biosensors is primarily related to the generation of optimal substrates (i.e., receptor layers).

The range of words considered to be the most explosive, i.e., those that appear most frequently in citations, is shown in Figure 5.

CiteSpace 6.2 R.4 software was used to highlight keywords. The tool used performed a keyword analysis, i.e., it extracted the most frequently cited words. The graph shows a time scale indicating the period of the highest citation of a given keyword. It can be seen that although the analysis covered works from 01.01.1974 to 01.07.2023, the graph shows the period from 1991 to 2023. It can be seen that the dominant keyword is "glucose oxidase," this term has also been cited the longest, as can be seen in the figure. A similar reasoning can be applied to the other words in Figure 5.

Analyzing the entries below, the terms that deserve special attention are those that remain in quotation marks to this day. Among them we can distinguish: " Graphene oxide," "high-performance nanocomposite," "nanocomposites," "electrochemical sensor," "platform," "sensitive detection," "surface plasmon resonance," "amplification" and "immunosensor."

It can be seen that these words refer both to the substances or materials tested, e.g., non-composite, and to the test methods, e.g., "surface plasmon resonance," but also to the type of biosensors, e.g., "immunosensor," "electrochemical biosensor," or to research questions, e.g., "sensitive biosensor," "platform."

Based on the most recent citations of keywords (the above terms are related to the stability of biosensors), we can identify scientific trends and directions of development of a given scientific issue. From the point of view of stability of biosensors, it can be seen that research is growing in the direction of electrochemical biosensors and immunosensors in search of materials that are optimal in terms of durability. The experiments mainly use surface plasmon resonance as a leading research method.

From the point of view of scientific development, international cooperation in the area of development of a

44	India
40	Italy
33	South Korea
28	Taiwan
25	Spain
25	France
24	Turkey

working on biosensor stability. The areas marked with circles show the citation rate of representatives of a country (the detailed number of citations of representatives of a country is presented in Table 1). In Figure 6 you can see that the larger the marked area, the higher the citation rate (the graph does not show all countries, but only those whose representatives

turned out to be the most active in terms of cited works). Thus, based on the figure below, it can be seen that the most cited works devoted to the stability of biosensors were published by representatives of China (437 citations), but also among the leaders can be distinguished representatives of: Iran (70 citations), United States (57 citations), India (44 citations), Italy (40 citations), South Korea (33 citations), Taiwan (28 citations), Spain (25 citations), France (25 citations), Turkey (24 citations). In 2012, the work of scientists from Poland was also cited.

In the diagram shown in red is the publication of the French representative (as first author) and co-authors (from the United States and Hungary), which generated the widest cooperation in the area of biosensor stability issues. This publication (Theavenot et al., 1999) is extremely important not only in terms of international cooperation, but also in terms of citations and content. The paper is dedicated to the recommendation, classification and definition of electrochemical biosensors. It contains a detailed description of guidelines for reporting biosensor response and calibration characteristics: sensitivity, working and linear concentration ranges, limits of detection and limits of quantification. You will also find information on biosensor selectivity and reliability, response time, reproducibility, stability and device lifetime.

TABLE 2 List of journals in which the most articles related to biosensors have been published.

Citation counts	References
711	Ibiosens Bioelectron

553	Anal Chim Acta
466	Talanta
372	J Electroanal Chem
361	Electrochim Acta
359	Electroanal
344	J Am Chem Soc
304	Analyst

Table 2 presents list of journals in which the most articles related to biosensors have been published. It shows that the highest ranked item in terms of number of citations are the journals: Biosensors and Bioelectronics, Analytical Chemistry, Sensors and Actuators B: Chemical, Analytica Chimica Acta, Talanta and so forward as presented in Table 2.

Comparing the journals in which the most significant articles were published (Figure 4) with the list in which the largest number of articles related to biosensors are found (Table 2), it can be seen that the most cited articles were published in journals: Biosensors and Bioelectronics, Electrochimical Communication, Talanta and Electrochimica Acta. In the table presented (Table 2), the journal Biosensors and Bioelectronics is in the number 1 position, Talanta is in the number 5 position, Electrochimica Acta is in the number 7 position, while Electrochimical Communication is not among the top ten most cited journals.

Thus, it can be seen that there is a kind of correlation between highly cited articles and their impact on the journal's citability, while the publications with the highest citations do not fully reflect the journal's cutability.

Conclusion

This article presents an analysis of the stability of biosensors. This study provides a basic understanding and appreciation of biosensor stability research and shows the direction of scientific development of this topic.

Based on the CiteSpace, v.6.2.R4 tool, an analysis of trends and patterns in the scientific literature was performed. Based on the compilation of keywords, it was shown that the most frequent keywords in the analysed topic are: chemically modified electrode, reduced graphene oxide, direct electron transfer, magnetic microspheres, fft cyclic voltammetry, poly(o-phenylenediamine), lectims, optimization.

This study identified the most important publications in the development of biosensor stability. The 42 most frequently cited words were extracted. Among them, we can distinguish: "graphene oxide," "high-performance nanocomposite," "nanocomposites," "electrochemical sensor," "platform," "sensitive detection," "surface plasmon resonance," "amplification" and "immunosensor." From these it can be seen that research is increasing towards electrochemical biosensors and immunosensors. Optimal materials in terms of durability are being sought. The experiments mainly use surface plasmon resonance and fft cyclic voltammetry as leading research methods.

A map of collaborations and transnational networks in biosensor stability showed that researchers from 69 countries were working on biosensor stability. The leaders in citability by country of origin were found to be from China.

Although the Citespace tool has significant potential and greatly facilitates analysis it has certain limitations, inconsistencies and irrelevancies.

CiteSpace analyzes the citations received through the publication of the co-citation network found in the Web of Science bibliographic database.

Web of Science indexes only part of scientific literature. Thus, all analyses, regardless of the methods and tools used, exclude many journals and books.

In the second case, the influence of a specific publication concerns studies whose results are described in publications linked by a parallel citation network, i.e., with smaller or larger thematic links. In addition, it should also be noted that keyword analysis on the basis of titles, abstracts, article descriptions based on articles related to biosensors omits important information contained in books as subsections.

However, despite the limitations of the database, which is the basis of the analysis, CiteSpace remains a very important tool for rapid retrospective and predictive analysis.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Author contributions

Study conception and design: AK-W and VM; data collection: AK-W and VM; analysis: AK-W and VM; interpretation of results: AK-W and VM; draft manuscript: AK-W and VM; preparation: AK-W and VM. All authors contributed to the article and approved the submitted version.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgments

Box 2455, Riyadh 11451, Saudi Arabia

Mercury is a major pollutant in the environment due to its high concentration in the soil. In this study, a mercuric reductase was extracted from *Pseudomonas aeruginosa*. The sequence of the enzyme was retrieved from the literature and structural homologs were identified. The protein bonded with Mercuric compounds and their interaction was briefly studied. Autodock Vina was used to perform a molecular docking with the target protein. Results showed that the sequence consists of most of the random coil 44.74% followed by α-helix and B-turns. Moreover, the protein was predicted to have a FAD/NAD(P)-binding domain. The virulence factor prediction using different approaches of Virulentpred and VICMpred suggested that P00392 is non-toxic. Next, the mutational analyses were performed to predict the active site residues in the resulting models and to determine mutants. The results show that the enzyme is involved in the bioremediation of mercury by using in-silico techniques. Finally, molecular docking studies were conducted on the best-selected model to find the active site residues and to generate a pattern of interaction to understand the mode of action of the substrate and its catalytic activity which refers to the binding with mercury.

INTRODUCTION

The proliferation of industrial waste into the environment has led to the grave predicament of heavy metal contamination which has proved to be a peril to both the biosphere and humankind. These heavy metals can accumulate in the environment from various sources (Gworek *et al.*, 2020). Soil, water and especially air can get contaminated with these heavy metal compounds and hence, it is causing disastrous impacts on our environment and health. Even at low concentrations, heavy metals including mercury, cadmium, copper, lead and chromium are cytotoxic, carcinogenic and mutagenic in nature. The main cause of the release of such heavy metals into the environment is the utilization of non-biodegradable materials which directly affect the biosphere (Mandal & Mishra, 2023). The World Health Organization has classified four of the ten heavy metals as being of significant public health concern which includes: cadmium, arsenic, lead, and mercury (Budnik & Casteleyn, 2019).

Mercury can be produced in the atmosphere due to natural eruptions i.e., volcanoes, forest fires and weathering of rocks. Mercury can be found in a variety of forms in the inorganic state; metallic mercury, mercury vapor, mercuric salts, and mercury dioxide (Xu *et al.*, 2022). The organic state includes the mercuric compounds in which the mercury is bonded to a structure containing carbon atoms, and inorganic mercury in the form of compounds like methyl, ethyl, phenyl, or similar groups. Although the concentration of mercuric compounds in the air is less concerning, it is causing more damage to the soil. Human mercury exposure has adverse health consequences, such as headaches, insomnia, neuromuscular effects, difficulty in breathing, irritability, chest pain, stomachaches and cognitive or motor dysfunction. Mercury poisoning may also occur if the blood mercury levels exceed 100 ng/mL which will result in the malfunctioning of muscles (Duan *et al.*, 2020).

There are several conventional methods to decontaminate an environment containing mercuric compounds. An alternative method to distinctively remove this heavy metal is by utilizing a biological technique based on the use of a biological enzyme *mercuric reductase*, extracted from *Pseudomonas stutzeri* with an ecofriendly approach (Al-Ansari, 2022). Bioremediation is a safe approach that can be utilized to decontaminate our environment from these heavy metal pollutants by the use of microorganisms. Microorganisms are considered best for these types of mechanisms as they are well-known for their resistance against heavy metals. They have the potential to adopt various detoxifying mechanisms which include biomineralization, bioaccumulation and biosorption (Al-Ansari, 2022). Therefore, the aim behind opting for this topic is to use a mercury-resistant bacterium thriving in a mercuric environment and study the enzyme which is involved in the bioremediation of mercury by using in-silico techniques. Mercury-resistant *Pseudomonas stutzeri* is found in highly contaminated soil enriched with mercuric compounds. It is a gram-negative, rod-shaped, motile bacterium with greater metabolic diversity in the nature (Wan *et al.*, 2020).

In this study, *mercuric reductase* from *P. stutzeri* was selected as a candidate for further investigations (Zheng *et al.*, 2018). The sequence of mercuric reductase retrieved from literature and structural homologs was identified. Structural analysis via using bioinformatic tools was performed and validated to get good-quality protein structures and models. The protein bonded with mercuric compounds and their interaction was briefly studied. The models obtained from these strategies were further refined to remove steric clashes with other compounds. The main residue which is involved in ligand binding was determined based on the active sites and binding pockets identified in the structural homology (Bianchi *et al.*, 2012). Finally, docking studies were conducted on the best-selected model to find the active site residues and generate a pattern of interaction to understand the mode of action of the substrate and its catalytic activity which refers to the binding with mercury. Lastly, the mutational analyses were performed to predict the active site residues in the resulting models and to determine mutants. According to the study conducted, *P. stutzeri* mercuric reductase is a non-virulent protein that may be used for cheap and environmentally acceptable bioremediation of mercury (Sodhi *et al.*, 2019).

MATERIALS AND METHODS

Sequence Analysis

Sequence Retrieval

The FASTA sequence of Mercuric Reductase protein was retrieved from UniProt KB (https://www.uniprot.org) with the specifically allocated UniProt ID: P00392. The sequence contained a total of 561 amino acids and the annotation score 5/5 which confirmed it as a sequence of good quality and useful for all kinds of bioinformatics analysis.

Sequence Characterization

The sequence characterization was done by the prediction of Physiochemical Parameters. The computing for the physiochemical parameters of the Mercuric Reductase protein under study was performed by ExPASy-ProtParam Tool (https://web.expasy.org/protparam) which is an open-access online server by the Swiss Bioinformatics Resource Portal. The sequence was submitted in the FASTA format and various Physiochemical annotations like Molecular Weight, Theoretical pI, Aliphatic Index and GRAVY were calculated.

Sequence Comparison & Multiple Sequence Alignment

MSA or multiple sequence alignment is a crucial tool in understanding the interrelationships among sequences and identifying functionally important conserved regions. To detect conserved regions in the sequences, the ClustalW and MEGA version X MSA tools were utilized. Furthermore, to determine sequence homology and infer evolutionary relationships, phylogenetic analysis was performed using MEGA version X with the neighbor-joining algorithm and Poisson substitution method.

Function Prediction

The role of protein domains in protein function is essential as they often determine the protein's overall function, specificity, and interaction with other molecules. Protein domains can carry out various functions, such as binding to DNA, RNA, or other proteins, catalyzing chemical reactions, and transporting molecules across cell membranes. By containing specific sequence motifs, domains can also be responsible for post-translational modifications such as phosphorylation, glycosylation or ubiquitination, which can alter protein activity, stability or localization. Therefore, the protein domain prediction was performed by CATH DB (http://www.cathdb.info) which is an online bioinformatics tool for protein domain prediction. The protein sequence was inputted in FASTA format, and the domains were predicted.

Virulence Factors Identification

Keeping in view that the protein is planned to be used as a Bioremediator, it is necessary to make sure that the protein should not be toxic or virulent (Muhammad Naveed *et al.*, 2023). Therefore, the identification of virulence factors was performed with VirulentPred (http://bioinfo.icgeb.res.in/virulent), that is an online server for virulent factors identification. The protein sequence was used as input and the results were obtained.

Secondary structure prediction

Secondary structure prediction was performed by PSI-PRED (http://bioinf.cs.ucl.ac.uk/psipred) which uses position-specific matrices score that is produced by PSI-BLAST to employ neural network methods (M Naveed, I Ali, *et al.*, 2023). It predicts the secondary structure of the protein sequence. In addition to identifying protein characteristics and recognizing folds, secondary structure prediction is an intermediate step in predicting three-dimensional structures (Mohamadi *et al.*, 2022).

The analysis of the secondary structure sequence was also performed by the SOPMA online tool (https://npsa.lyon.inserm.fr/cgi-bin/secpred_sopma.pl) which analyzes the number of features of secondary structure such as b-turns, a-helix and coil etc. In addition to analyzing the amino acid sequence of a given protein, this tool offers information about protein secondary structures (Buchan & Jones, 2019).

Structure Prediction

Template Recognition

The PSI-BLAST program was used to carry out a sequence similarity search against the PDB database to provide a list of results that were most similar to the query sequence to identify the template. The sequence with the highest sequence identity, the largest query coverage, and the score with the lowest e-value was chosen as the reference template. Based on the outcomes returned by BLAST, the coordinates of the template structure were obtained from the Protein Data Bank (Bekker *et al.*, 2022). The motif and domain analysis were identified by Pfam and InterProScan. InterProScan (https://www.ebi.ac.uk/interpro/search/sequence-search) is an online tool used to obtain the functional analysis and classify the protein sequences into the families and domains as well as binding sites (Blum *et al.*, 2021). The Pfam (https://pfam.xfam.org/) is a database that contains a large collection of families of proteins each represented by specific Markov models (HMMs) and modeling by multiple sequence alignment (Mistry *et al.*, 2021).

Model Generation

The homology modeling for the three-dimensional structure was performed by SWISS-MODEL (https://

swissmodel.expasy.org/templates/) which is a tool for automatic homology modeling and Phyre2 (http://www.sbg.bio.ic.ac.uk/phyre2/) which is a tool that creates 3D structures and remote homology service as well as finds binding sites in the query structure to predict the 3D structure of the mercury reductase protein (Naveed et al., 2023). The best-predicted structure from each tool was chosen and was further validated for experimental analysis (Komari et al., 2020; Pasaribu et al., 2021).

Model Validation

The predicted structure from the two tools was further validated by performing Ramachandran plot analysis by using the PROCHECK (http://services.mbi.ucla.edu/PROCHECK/) via the platform of SAVES v5.0 (http://servicesn.mbi.ucla.edu/SAVES/) (M Naveed, N Ain, et al., 2023), which outlines the stereochemical characteristics of the structures (Reddy & Rao, 2020).

Docking Studies

Interaction Analysis

Autodock Vina, a free docking engine, allows for molecular docking. This is a collection of automated docking technologies that are integrated for the prediction of the interaction of small molecules with the protein (Eberhardt et al., 2021). The docking analysis of a chosen Mercuric compound was presented by Autodock Vina. Protein and ligand were first prepared, then active sites were identified, and finally a grid box was set up (by default) (Naveed et al., 2023). The mercurial compound with the lowest binding energies was chosen for docking with the target protein.

Site Directed Mutagenesis

Mutant Identification

For mutation identification, four different tools were used. The I-Mutant (http://gpcr.biocomp.unibo.it/cgi/predictors/I-Mutant3.0) online tool was used to observe the impact of single nucleotide polymorphisms on the stability of the protein. It predicts the effect of SNPs on the tertiary structure of the protein value based on the free energy change. PHD-SNP (http://snps.biofold.org/phd-snp/phd-snp.html) is based on support vector machines that predict whether point mutation links with a genetic disorder or is a neutral polymorphism. It predicts the human deleterious SNPs (Mustafa et al., 2020). The other mutation identification tool is SIFT (Sorting Intolerant from Tolerant) (https://sift.bii.a-star.edu.sg/), which employs sequence homology to predict the impact of amino acid substitution and whether it has a damaging impact on protein structure or not. It gives the probability score less than or equal to 0.05 if it is deleterious or a prediction value greater than 0.05 when it is tolerant. Another tool MuPro (http://mupro.proteomics.ics.uci.edu/) predicts the stability of protein decreases or increases and its effect on the protein structure (Naveed et al., 2019).

Model Generation

The 3D structure of mutant mercury reductase protein was generated by using SWISS-MODEL (https://swissmodel.expasy.org). It is an automated tool that predicts the 3D structure of protein and generates the model based on the homology modeling (Pasaribu et al., 2021; Komari et al., 2020).

Model Validation

The tertiary structure was validated by the PROCHECK through which Ramachandran Plot was created for Mercuric Reductase P00391. PROCHECK checks the stereochemical property of protein and analyzes the geometry of the residues present in the protein structure. The Ramachandran Plot was analyzed based on Rama favored regions present in the plots (Reddy & Rao, 2020).

Mutant Docking Studies

Prediction Of Binding Sites

Computed Atlas of Surface Topography of proteins (CASTp) (http://cast.engr.uic.edu) is an online bioinformatic tool that locates, measures and delineates concave surface regions on the 3D structure of the protein. It finds out the binding pockets of protein that locate or void buried in the internal of the protein surface. It includes a flexible interactive, interface, visualization as well as on the fly calculations for the input structure (Chandran et al., 2022).

Molecular Docking of the Mutants

After validating the best 3D mutant model, Autodock Vina was run to perform docking upon the protein receptor. The selective structures as ligand were taken from PubChem and were accounted for docking studies with Mercuric (Hg) compounds and complexes. Through this, the intramolecular interactions were evaluated in the final docked complex. To put it simply, PubChem is a repository for information about chemical compounds and their performance in various biological experiments (Eberhardt et al., 2021; Chandran et al., 2022).

RESULTS

Sequence Analysis

The protein sequence of Mercuric Reductase from *Pseudomonas aeruginosa* was obtained from UniProtKB with the UniProt ID P00392. Analysis of protein domains and motifs revealed that its function is in the

Table 1. Physiochemical characterization of the Mercuric reductase protein P00392

Number of amino acids	561
Molecular weight	58728.03
Theoretical pI	5.60
Negatively charged residues	60
Positively charged residues	48
Formula	$C_{2571}H_{4171}N_{733}O_{796}S_{20}$

reduction of mercury and that the protein family is predicted to have a FAD/NAD(P)-binding domain. Physio-chemical properties of the sequence were computed and are presented in Table 1. The instability index for P00392 was found to be 30.67, indicating its higher stability in the test tube compared to the other protein, which had a slightly higher instability index. Virulence factor prediction using different approaches of Virulentpred and VICMpred suggested that P00392 is non-toxic. Homologous sequences for P00392 were identified using BLASTp, and 10 sequences were retrieved. These sequences were suitable for multiple sequence alignment (MSA) to determine conserved regions and phylogenetic analysis to infer the evolutionary relationship. The phylogenetic tree constructed by Neighborhood-Joining Method is given below in Fig. 1. A sequence similarity search was performed to search for crystal structures of the closest homologs available in the Protein Data Bank (PDB).

35.29	19.96	0.0	44.74

Structure Predication

Secondary structure prediction

As shown in Fig. 2, the predicted secondary structure of mercury reductase protein consists of a majority of the coils as viewed by using PSI-PRED followed by a-helix. The secondary structure of a protein plays an important role in determining its stability, function, and interactions with other molecules. In the case of mercury reductase, the predominance of coils in its secondary structure suggests that it is a flexible protein that can undergo conformational changes to interact with its substrate and catalyze the reduction of mercury. The presence of alpha helices in the secondary structure also indicates that the protein may have structural stability and rigidity in certain regions. It is important to note that the predicted secondary structure is based on computational methods and may not precisely reflect the actual structure of the protein. Further experimental studies such as X-ray crystallography or NMR spectroscopy would be needed to confirm the actual secondary structure of mercuric reductase. The analysis of secondary structure by SOPMA is given in Table 2.

Secondary structure analysis was performed by SOPMA. Results show that the mercury reductase sequence

consists of most of the random coil 44.74% followed by α-helix and B-turns as shown in Table 2.

Generation of 3D Structure

The best model generated by Swiss-Model with the highest scoring was selected for further analysis. The generated 3D structure is given below in Fig. 3. The predicted 3D structure was further validated, and the Ramachandran assessment predicted the validation score of the predicted protein model. The Ramafavoured regions were observed to be 92.6% that possess the protein model as stable and having good quality. Therefore, the model was valid enough to be used for various kind of bioinformatic analysis.

Site Directed Mutagenesis

The FASTA sequence of the Mercuric Reductase protein was analyzed by aligning it with the sequences of other species. The local alignment was performed by BlastP tool by NCBI, and the alignments tab accessed all the present mutations. Top 10 mutations were select-ed, and their effects were studied by I-Mutant, MuPro, PHD-SNP and SIFT tolls. The mutants having negative effects on the structure and function of protein were further selected for the mutagenesis into the actual structure of protein so the effects could be accessed. The selected SNPs are given below in Table 3.

SNPs with negative effects were selected and using the PyMol mutagenesis was introduced into the protein structure. The mutated structure of the Mercuric Reductase protein is given below in Fig. 4. It was further utilized for interaction studies to analyze the effects of the mutated structure of protein.

Docking Studies

Interaction Analysis

Autodock Vina was used to perform molecular docking between the chosen mercuric compound and the target protein. The docked model which was selected based on the lowest binding energy retained the binding energy of -7.9 kcal/mol, predicting the more efficient binding

Figure 4. Mutated protein structure with the highlighted mutant areas.

Figure 5. A docked complex of Bis[tris(p-dimethylaminophenyl) phosphine] mercuric chloride complex with targeted protein

Figure 6. Interaction complex of the Mercuric reductase with Mercury compound.

with the protein. The docked Complex of Bis[tris(p-di-methylaminophenyl) phosphine] mercuric chloride complex compound with targeted protein is shown in Fig. 5.

Validation of docked complex:

Protein-ligand interaction profiler (PLIP) provided interpretation of the interaction data by estimating the bond length. As the range of hydrogen bond is between 2.7-3.3 angstroms, the three hydrogen bonds detected as 2.73, 3.19, 2.91 angstroms. Due to the slightly greater distance of bond length of van der Waals forces (3.3-4.0 angstroms) it was predicted that two van der Waals or hydrophobic bonds were present, with a length of 3.69 and 3.54 angstroms, respectively. The interaction predicted by PLIP (Protein-ligand interaction profiler) is shown in Fig. 6.

Prediction of binding sites

The analysis of active sites was performed by using CASTp online tool. This tool analyzes the proteins surface topography and measures the available surface area of the protein as a potential active site. The 3D model highlights the active sites as seen in Fig. 7.

Interaction Studies of the Mutated Mercuric Reductase

Autodock Vina was utilized to produce a mutant protein docked complex, among which the best one was chosen to make a docking complex with the maximum binding affinity of -6.6. After this, a visualizer is used to study the interactions among the ligand (*S-Mercuric-N-dansylcysteine*) and the protein (Studio, 2008). For exam-

Figure 8. The docked complex of S-Mercuric-N-dansylcysteine with the targeted mutant protein.

ple; hydrogen bonds, hydrophobicity, aromaticity, charge distribution and ionizability etc., which confirmed the stability of the complex as shown in Fig. 8.

Validation of mutated docked complex:

Protein-ligand interaction profiler (PLIP) was used for the further interpretation of the interaction between the mutant protein and the ligand by measuring the bond length. According to the range, two hydrogen bonds were detected with bond length of 2.53 and 2.48 angstroms between the protein and the ligand, respectively. Moreover, one van der wall force was detected between them with value falling in between the range; 3.99 angstroms. The interaction predicted by PLIP (Protein-ligand interaction profiler) is shown in Fig. 9.

DISCUSSION

Mercury toxicity (Hg) mainly depends on the route of exposure and the chemical form of Hg. Its most toxic form is Hg^{+2} and its non-toxic form is Hg^0. Its accumulation in the food chain causes deleterious effects on human health (Gworek *et al.*, 2020). Lohren *et al.*, revealed the toxic effect of Hg accumulation on the central nervous system that harms the blood-brain barrier and facilitates the entrance of other toxicants to penetrate into

Figure 7. The 3-D structure and its active site.
The red area depicts the active site, while the grey area depicts the rest of the structure as represented in cartoon style.

Figure 9. Interaction complex of the mutated Mercuric reductase with Mercury compound

the brain (Gworek et al., 2020; Al-Ansari, 2022; Singh & Kumar, 2020).

Nowadays, the prime focus of different industries is to abolish the effect of Hg toxicity by remediation of Hg-polluted soil or water. Bacteria harbor an extensively studied Hg-detoxification mechanism, Mer operon which encodes the functional proteins for transportation (merT, merP and/or merC, merF), lysis of organomercurial compounds (merB), reduction of mercuric ion reductase (merA) and a secondary regulatory protein (merD) to modify toxic Hg (II) to nontoxic elemental state Hg (0) (Paria et al., 2022; Nivetha et al., 2023). Structural studies determined a unique fold of protein, MerB, which is a significant conformational transformation that occurred on the binding of the substrates as organomercurial compounds. Structural as well as computational studies revealed that aspartic acid and two cysteine residues in the active site are responsible for cleaving the carbon–mercury bond. The second enzyme, mercuric reductase (MerA) encoded by the merA gene is directly involved in the reduction of the reactive ionic form Hg (II) to the volatile form Hg (0) (Rahayu et al., 2021; Somayaji et al., 2022). MerT, a membrane-bound protein is responsible for the uptake of Hg (II) and is arranged on the mer operon under the control of MerR, a unique responsive regulator of metal. Silver and Hobman et al., reveal the mercury reduction process by mercury reductase (Naguib et al., 2019). The binding of Hg^{+2} to the carboxyl-terminal subunit part of Cys 557- Cys 558 of mercury reductase then quickly move towards the thiol-thiol exchange to the monomer pain of Cys 135-Cys 140. The Cys 135-Cys 140 pair is the active site that causes the reduction of Hg^{+2} into Hg^0 by the FAD cofactor that helps in the electron transport (Meyer et al., 2023).

Conventional methods such as bioreactors have been used for the mercury cleanup of wastewater by up to 90%. Mercury-resistant bacteria have a major advantage as conventional practices produce a large amount of mercury load biomass (Duan et al., 2020). A recent study on a non-pathogenic bacterial isolate of Pseudomonas putida SP-1, which volatilizes mercury by 89%, has shown the efficiency of mercury-resistant bacteria in the bioremediation process. However, case studies act as a bridge to some extent to fill the gap between field application and laboratory research. In-silico studies identify the efficacy and potential of mercury-resistant bacteria in the bioremediation of mercury toxication. The current study shows that mercury reductase is the best candidate as a bio-remediator and mercury accumulator (Gupta et al., 2022; Priyadarshanee et al., 2022).

In a recent study, the screening of the mercury reductase calcium complex compound that results in highly competent attachment to the target protein of mercury reductase isolated from the bacteria source was done through computational analysis. Protein stability depends on the instability index. The instability index of the protein was less than 40 as shown in Table 1. Our results are consistent with the statement given by Mirzaei et al. where protein having a stability index of less than 40 is stable and when greater than 40 shows that protein may be unstable (Gamage et al., 2019). The aliphatic index was predicted to be where a higher value of the aliphatic index shows the thermal stability of the protein. This is in line with the statement given by Sahay et al., that the aliphatic index is considered a positive factor for the increase of thermostability of globular proteins. The GRAVY score was found to be positive with a 0.092 value, which indicated that mercury reductase is generally a hydrophobic protein. The reason for hydrophobicity may be due to the presence of large numbers of non-polar amino acids. Another study conducted by Zhou and Pang supported our results by showing that protein folding stability was mainly attributed to the hydrophobic interactions among non-polar amino acid residues. Thus, based on a few parameters of the Expasy ProtParam, the mercury reductase could be considered a stable protein (Sharma et al., 2022; Naveed et al., 2022).

The mutational analysis revealed that it affects the binding sites of mercury reductase protein. The mutations identified from five tools as shown in Table 3. Docking studies have been found helpful to understand the protein-ligand interactions (Eberhardt et al., 2021). The model was then generated and docking analysis of both the non-mutated protein and mutant protein shows that binding affinity energy reduces from –7.9 to 6.6 KJ/mol. The 3D structure of the mutant model generated from SWISS-MODEL shows the removal of two ligands of FAD (Flavin Adenine Dinucleotide) that were present in the non-mutated protein. As mutation T240A was introduced it acts as an active binding site as shown in the active site prediction Figure 7. The binding sites and motifs for NADPH and FAD in different MerA proteins vary among residues ALA, CYS, TYR, LEU, THR, PRO, SER, ASN, VAL, GLY, ALA, ASP, LYS, PHE, GLU and ARG. As the distance among binding residues of FAD and NADPH varies in microorganisms, no such correlation was observed between the protein-ligand binding affinity and binding residues (Chandran et al., 2022). As a result of folding into a specific three-dimensional structure, the amino acids undergo conformational changes to perform the function they are designed to perform. Thus, the binding affinity of mutant protein reduces due to the conformational change of amino acid residues and binding active sites (Afroz et al., 2023).

Engineered proteins, particularly enzymes, are being used more frequently in various industries due to their selective ligand binding, capabilities and catalytic ability as food additives. The urge to engineer or generate proteins with higher specificity, activity and stability has increased along with the number of possible applications for engineered proteins (Gupta et al., 2022). As the application of protein technology develops, exploiting the potential advantages of modulating remote regions will become imperative. The present study reveals that the mutation affects the binding pockets of mercury reductase, and it acts as a mercury accumulator and candidate for bioremediation of mercury in the field of application. It is a stable protein with an applicable Ramachandran plot which validates its stability, and virulent predictions show that it is non-virulent and causes no toxicity. Protein engineering bacterial mercury reductases can produce enzymes that reduce mercury more efficiently with no toxicity, and that will function with additional contaminants (Wan et al., 2020; Meyer et al., 2023).

CONCLUSIONS

In conclusion, this study provides insights into the molecular and structural features of mercuric reductase. The results suggest that the protein has a stable structure and a specific function of reducing mercury. The information obtained from this study could be useful in developing strategies to bioremediate mercury-contaminated sites. Additionally, the methodology used in this study, such as homology modeling, molecular docking, and virulence factor prediction, could be applied to other proteins and enzymes to further understand their

properties and functions. Overall, this study contributes to our understanding of the biochemical and molecular mechanisms involved in the bioremediation of mercury pollution in the environment.

Abstract: Extensive pesticides (herbicides) use is negatively disturbing the environment and humans. Pesticide bioremediation with eco-friendly techniques bears prime importance. This study aimed to isolate and characterize three different herbicides (metribuzin, clodinafop- propargyl, MCPA (2-methyl, 4 chlorophenoxyacetic acids) and Bromoxynil) degrading bacterial strains from agricultural fields of Punjab University, Pakistan. Among the 12 bacterial isolates, 5 were metribuzin degrading, 3 were clodinafop propargyl degrading and, 4 were MCPA and Bromoxynil degrading bacteria. Morphological, microscopic, and molecular characterization revealed that the majority of these bacterial strains were gram-negative and belonged to *Bacillus* and *Pseudomonas* genera. The isolates A6, B3, and C1 were subjected to respective herbicide degradation and the data was confirmed through GC-MS analysis. The effect of herbicide concentrations, pH, and temperature on bacterial growth was determined at OD_{600}. The strain A6 degraded 14.8% metribuzin out of the provided concentration of 50 ppm by following the deamination pathway. While the isolates B3 and C1 degraded 23.2% and 33.9% clodinafop, MCPA and bromoxynil, respectively, at a spiking concentration of 50ppm. The clodinafop, MCPA & Bromoxynil were metabolized into less toxic products i.e., dicarboxylic acids and 2-methyl phenol respectively, and metabolized *via* decarboxylation and dehalogenation mechanism. The present study evaluates the herbicides degrading bacterial strains that could potentially be used for bioremediation of agricultural contaminated sites.

INTRODUCTION

Different varieties of chemicals used to repel or destroy pests including animals, insects, plants, bacteria, fungi, or other microbes; that are harmful to cultivated crops and animals are known as Pesticides (Alam *et al.*, 2018; Nawab *et al.*, 2015). They are classified according to their chemical formulation and targeted organism, but the latter is more common. Based on target organisms, these are grouped as insecticide, weedicide and fungicide, rodenticide, bactericide, etc. (Richardson *et al.*, 2019).

Pakistan is an agricultural country, and its economy greatly depends upon this sector in terms of labor participation; provision of food to the whole nation, and a primary source of foreign exchange earnings (Khan *et al.*, 2021). The share of agriculture in Gross Domestic Product (GDP) is 19.3% for the FY2020and it is gradually shrinking in the last few decades. Different challenges like global warming, insect/pest attack, and water shortage hinder the overall potential of this sector (GOP 2020; Koondhar *et al.*, 2021). Weeds are unwanted plants that are not grown intentionally at a place and negatively impede human activities. Almost, there are 250 000 species of plants in the world; out of which approximately 8 000 species i.e., 3% are considered weeds. Weeds are problematic because of their rapid growth, long-term survival, and competition with normal plant growth for sunlight, air, water, space, and soil minerals (Storkey *et al.*, 2021).

To control the growth of weeds the most extensively used form of pesticide is herbicide. Herbicides are a chemical used to eradicate or kill unwanted vegetation (weeds) that interferes with normal plant growth and restrain the overall yield of several crops (Clapp 2021; Okieimen *et al.*, 2020). Although the global use of pesticides ensures high production yield, on the other hand, it also produces high levels of environmental contamination because of their excessive use (Bakshi *et al.*, 2020). These deadly pollutants are directly exposing the trophic food web and enter into the ecosystem either by direct application, spillage, and disposal (Khan *et al.*, 2020; Lone *et al.*, 2014).

Physicochemical methods are mostly used as an alternative to chemical pesticides, which are costly because these techniques require the excavation of polluted soil

from the site of contamination and transferring it to another place for treatment. As pesticides can accumulate in food and water supplies, it is need of the time to design environmentally friendly and cost-effective technologies to replace hazardous pesticides.

Enormous biological techniques have been designed in which toxic organic pollutants are degraded by microbes (Bakshi *et al.,* 2020; Oladipo *et al.,* 2020). Bioremediation is one such technique in which naturally occurring microbes such as bacteria and fungi are used for the breakdown and removal of pollutants (Huang *et al.,* 2018). This method is relatively cheaper in comparison to physicochemical methods. Without excavating the material from the contaminated site, they have the potential to treat the polluted soil and groundwater because of this reason it requires very less energy input and preserves the soil structure which otherwise can either be disturbed by excavation (Pertile *et al.,* 2020). The present study is to focus on environment-friendly techniques for the minimization and elimination of persistent herbicide levels via biodegradation by using locally isolated bacterial strains.

MATERIALS AND METHODS

Soil Sampling

Total 9 soil samples were randomly collected at the depth of 0–12 inches from wheat fields of Punjab University located near the fishponds; where the soil had a previous history of clodinafop and MCPA & Bromoxynil applications but had never been treated with metribuzin over the last few years. The samples were taken to the laboratory, air dried at room temperature, sieved through 2 mm mesh size to remove stones and debris, and mixed thoroughly to make a composite soil sample and stored at 4°C.

Isolation and Screening of Bacterial Isolates

Four grams of soil samples were placed in 250 mL Erlenmeyer flasks containing 100 mL of mineral salt medium (Glucose 5, KH_2PO_4 0.5, K_2HPO_4 0.5, $MgSO_4.7H_2O$ 0.2, NaCl 0.2 g/L). The stock solutions of three herbicides (metribuzin, clodinafop, and MCPA & Bromoxynil) were prepared in distilled water. Then, 100 µL of each respective herbicide stock solution providing the final concentration of 5ppm was inoculated into the above sample medium. The samples were incubated for one week in the dark at 30°C and 160 rpm shaking. Afterwards, 10 mL of each culture medium was transferred into 90 mL of fresh mineral salt medium fortified with each of the herbicides at 10, 20, and 50 ppm by adding 200 µL, 400 µL and 1 mL of each herbicide stock solution, respectively. The samples were again incubated for 7 days at 30°C at 160 rpm in dark. After 7 days, 200 µL from each subculture was spread on L.B plates fortified with each respective herbicide at a concentration of 20 ppm. The plates were incubated for 4 days at 30°C and different bacterial colonies were observed after 4 days.

Purification of Bacterial Colonies

Morphologically different bacterial colonies were picked and streaked on L.B plates aseptically and incubated at 30°C for 24 hours to obtain pure bacterial colonies. The purified colonies were maintained on L.B slants and stored at 40°C for further use.

Identification of Bacterial Isolates

The isolated bacterial strains were identified by performing morphological analysis, gram staining technique, and 16S rRNA gene sequencing analysis.

Morphological analysis

Bacterial isolates were morphologically analyzed based on color, shape, texture, and size. Morphological analysis was carried out visually.

Gram staining

Bacterial isolates were analyzed microscopically by gram staining technique and their cell shape, size, and arrangement were determined.

Molecular identification of herbicides degrading bacterial strains

Extraction of bacterial genomic DNA. Almost 2–3 bacterial colonies from freshly grown cultures were scratched and mixed well in DNase or RNase-free water or elution buffer in sterilized Eppendorf tubes. Thermo fFisher Scientific catalogue no AM9923. The bacterial suspension was provided heat shock in boiling water for about 10 min. The tubes were then ice-cooled and centrifuged at 12 000 rpm for 10 minutes. The supernatant containing the template DNA was taken carefully; its quality was observed by electrophoresis ion a 1% agarose gel at 100 V and visualized under a UV-light illuminator. (Daihan Scientific Model no. Wuv-L50).

Amplification of 16S rRNA Gene and Sequencing reaction. 1.5 kb DNA fragment of 16S rRNA gene was amplified using the following set of ribotyping universal primers: forward primer 27F (5'-AGAGTTTGATCCTGGCTCAG-3') and reverse primer 1522R (5'-AAGGAGGTGATCCA(AG)CCGCA-3') (Hasnain *et al.,* 1994; Johnson *et al.,* 1994). Reaction was carried out in 20 µL containing template DNA 5 µL, 10XPCR buffer 2 µL, 25 mM MgCl2 2 µL, 2.5 mM dNTPs 2 µL, Primer-forward 2 µL, Primer-reverse 2 µL, 5 units/µL 1 µL and ddH$_2$O (nuclease free) 4 µL. The template DNA was initially denatured at94°Cfor 5 minutes followed by 35 cycles of denaturation at 94°C for 30 seconds, annealing of primers at 54°C for 30 seconds, and elongation at 72°C for 1 minute and 40 seconds. The PCR reaction was finally extended for 10 minutes at 72°C. The PCR was then separated on 1% agarose gel observed under a UV light illuminator. Required DNA bands were precisely cut with a sterilized surgical blade and purified from gel and sent to Korea for sequencing analysis. The sequencing analysis was performed by the dideoxy chain termination method (Sanger *et al.,* 1977).

Biodegradation of Herbicides by Soil Bacteria

Preparation of samples for GC-MS

L.B. broth (250 mL) was taken in each 1 litter flask and amended with each of the herbicide 50 ppm by adding 2 mL of each respective herbicide stock solution. The herbicides (metribuzin, clodinafop, and Bromoxynil+MCPA) fortified media were then inoculated with bacterial isolates A6, B3, and C1, respectively, aseptically and incubated for 4 days at 30°C and 160 rpm in dark. The controls contained the same herbicide concentration without bacterial culture. After 4 days, 50 mL of each sample was transferred in sterilized 50 mL falcon tubes. Samples were centrifuged at 12 000 rpm for 10 minutes. The respective supernatants were collected carefully, transferred into new sterile falcon

tubes, labeled, and underwent the liquid-liquid extraction technique. For this 50 mL of each sample was placed in a glass separating funnel with equal volume (50 mL) of dichloromethane. The samples with dichloromethane were vortexed well to thoroughly mix both solvents and allowed for separation until the two distinct layers were formed. The components moved from the media phase to the dichloromethane layer. The upper layer consisting of the medium was discarded and the lower dichloromethane layer containing the components was collected from each sample carefully without any mixing with the above layer. Dichloromethane was evaporated and the final volume of each sample was adjusted with n-hexane. Final samples were then transferred in screw cap glass sterile vials and stored at 40°C until preceded for gas chromatography-mass spectrometry (GC-MS) analysis. Statistical analysis was performed to determine Pearson's correlation test between herbicide response factors and the peak areas of herbicide residues in the sample by using SPSS 16.0.

Effect of different parameters on herbicides degradation and bacterial growth

Effect of herbicides concentrations on herbicides degradation. L.B. broth (50 mL) was taken in each of the 250 mL flasks amended with different concentrations (20, 50, 80, and 100 ppm) of each of the three herbicides and inoculated with respective bacterial isolates A6, B3, and C1 under aseptic conditions. The flasks were incubated at 300°C and 160 rpm in a shaker incubator. After every 24, 48, 72, and 96 hours, the OD_{600} of each treatment was measured with a mass spectrophotometer and biodegradation in terms of bacterial growth (OD_{600}) was noted. It is recommended to monitor the bacterial growth at 600 nm.

Effect of pH on herbicides degradation. L.B. broth (50 mL) was taken in each of the 250 mL flasks with pH values maintained at 5.0, 6.0, 7.0, and 8.0 and fortified with herbicides at a concentration of 20 ppm. The media were inoculated with respective isolates A6, B3, and C1 and incubated in dark at 300°C and 160 rpm in a shaker incubator. The OD_{600} was measured every 24, 48, 72, and 96 hours with a mass spectrophotometer.

Effect of temperature on herbicides degradation. L.B. broth (50 mL) was taken in each of 250 mL Erlenmeyer flasks with each of the three herbicides at a concentration of 20 ppm and inoculated with respective bacterial isolates. These culture media were incubated at different temperatures i.e., 30, 35, and 400°C and 160 rpm in a shaker incubator. The OD_{600} was measured every 24, 48, 72, and 96 hours and the biodegradation in terms of bacterial growth (OD_{600}) was noted.

Statistical Analysis

Statistical analysis was performed to determine the effect of different parameters on herbicide degradation with the help of a three-way Analysis of Variance (ANOVA) by using SPSS 16.0 (Wahla et al., 2019; Pacciani et al., 2020).

RESULTS

Isolation and Screening of Herbicides Degrading Bacteria

Bacteria were isolated by inoculating an aliquot of soil sample into the mineral salt medium amended with three

Figure 1. Morphological characteristics herbicide degrading bacteria (A, Metribuzin; B, Clodinafop; C, Bromoxynil)

different herbicides and incubated for 7 days at 30°C and 160 rpm in dark. 10mL of this cell suspension was transferred into a fresh mineral salt medium containing each of the three herbicides at 10, 20 and 50 ppm and incubated again under the same conditions as above. Morphologically different bacterial colonies were purified and stored at 4°C. A total of 14 herbicides degrading bacterial colonies were isolated from soil samples. Among these, 6 colonies (A1–A6) were found effective in degrading metribuzin; 3 colonies (B1–B3) degraded clodinafop and 5 of these bacterial colonies (C1–C6) metabolized MCPA & Bromoxynil as shown in Fig. 1 (A–C).

Identification of Herbicides Degrading Bacteria

Morphological characteristics of bacterial colonies

The morphological characters (color, shape and texture) of herbicide-degrading bacteria were observed visually. The bacterial isolates were also gram stained and their properties were observed under a light microscope.

Molecular characterization of herbicides degrading bacteria

The 16SrRNA gene of 12 herbicides degrading bacterial strains was amplified by PCR. The amplified products of the 1.5 kb fragment were purified and sequenced for further conformation (Fig. 2).

Determination of Herbicides Degradation by GC-MS Analysis

Herbicides degrading bacterial isolates were inoculated in 250 mL LB broth supplemented with 50 ppm of each herbicide to assess their biodegradation potetial. Af-

MCPA & Bromoxynil	20651611	624497.74	33.9%

Pearson's correlation at α=0.01(2-tailed test) was used to identify the relationship between the response factor and % degradation for studied herbicides.

Table 2. Pearson correlations through SPSS

		Response factor	Degradation %
response factor	Pearson Correlation	1	−.748**
	Sig. (2-tailed)		.462
	N	3	3
% degradation	Pearson Correlation	-.748**	1
	Sig. (2-tailed)	.462	
	N	3	3

**Correlation is significant at the 0.01 level of significance (2-tailed)

Table 3. Variation in metribuzin concentration and optical density as a result of herbicide degradation by bacterial strain A6

Time period	Metribuzin concentration			
	20 ppm	50 ppm	80 ppm	100 ppm
Day 1	0.882	0.813	0.885	0.818
Day 2	1.804	1.78	1.77	1.705
Day 3	1.722	1.774	1.716	1.753
Day 4	1.712	1.701	1.708	1.675

Table 4. Variation in Clodinafop concentration and optical density as a result of herbicide degradation by bacterium B3

Time period	Clodinafop propargyl concentration			
	20 ppm	50 ppm	80 ppm	100 ppm
Day 1	0.405	0.447	0.491	0.147
Day 2	1.708	1.69	1.665	1.705
Day 3	1.726	1.792	1.767	1.806
Day 4	1.667	1.635	1.71	1.725

ter four days, the bacterial samples were further analyzed through gas chromatography-mass spectroscopy (GC-MS) to study possible degradative products after herbicide degradation. The results showed that metribuzin was metabolized into deaminated metribuzin by *Bacillus* sp. A6. Clodinafop propargyl, MCPA, and Bromoxynil degraded into corresponding dicarboxylic acid and 2-methyl phenol by strain and C1, respectively. Pearson correlation between different herbicide response factors and the peak areas of herbicide residues in each sample was identified using SPSS 16.0 (Table 1 and 2).

Table 2 shows the resulting matrix of Pearson's correlation test which revealed that the co-efficient r is equal to −0.748 which is statistically significant at $p<0.01$. It confirmed a strong negative correlation between the response factor and percentage degradation of all herbicides. The more the response factor; the less will be the percentage degradation.

Effect of Different Parameters on Biodegradation of Herbicide and Bacterial Growth

Effect of herbicides concentration

The herbicide biodegradation at different concentrations (20, 50, 80, and 100 ppm) was determined by measuring the optical density (OD) at 600nm (Table 3, 4, 5 and Figs 3, 4, and 5).

The metribuzin-degrading bacterium A6 showed the highest growth rate on the second and third days (48–72 h) at concentrations of 20 ppm and 50 ppm. The isolate was able to degrade metribuzin at concentrations of 20 and 50 ppm. Strain A6 showed a moderate growth pattern at (80–100 ppm) concentrations of herbicide. Whereas clodinafop degrading bacteria B3 showed almost similar growth rates at all the concentrations but the maximum clodinafop propargyl biodegradation was observed on 2nd and 3rd day with peak metabolism at the concentrations ranging from 50–100 ppm on the 3rd day. The MCPA & Bromoxynil degradation behav-

ior by strain C1 was a little bit different than the two herbicides i.e., the maximum degradation of MCPA & Bromoxynil was noticed on the fourth day (96 hours) at 50 ppm.

Effect of pH

The biodegradation of herbicides at different pH levels (5.0, 6.0, 7.0, and 8.0) was also studied (Tables 6, 7, 8 and Figs 6, 7, and 8). Results revealed that maximum degradation activities in terms of bacterial growth were

observed at the end of day 1 and day 2 at pH 7.0–8.0 and minimum at pH 5.0. There was more biotic degradation in alkaline ranges of pH than in acidic.

Effect of Temperatures

The biodegradation of herbicides at different temperatures (30°C, 35°C and 40°C) was determined and the results are summarized in (Tables 9, 10, 11, and Figs 9, 10, 11). The results depicted that the optimized temperature for bacterial growth was observed at a temperature range of 35–37°C. The metribuzin degrading bacterium A6 showed maximum growth on day 2nd at 35°C and 40°C, while at 30°C maximum growth was recorded on the 3rd day. On day 4th a slight decline in bacterial growth rate was noticed at all temperatures. Almost similar trends were observed for clodinafop degrading

Statistical Analysis of the Effect of Different Parameters on Bacterial Growth

A three-way ANOVA with $\alpha=0.05$ (level of significance) was used to determine the statistically significant effect of herbicides, concentrations, and time intervals on bacterial growth. Table 12 illustrates that there is a significant effect of the three-way interaction of herbicides, concentration, and time on bacterial growth at $p<0.05$. Similarly, the effect of herbicides, pH, and time intervals on the bacterial growth also showed significant interaction at a 95% significance level i.e. $p<0.05$ as shown in Table 13. The three-way interaction of herbicides, temperature, and time intervals on bacterial growth was also statically significant at $p<0.05$ (Table 14).

DISCUSSION

The use of chemical pesticides to reduce the pest attack on crops and to improve the yield has become routine in recent times. These hazardous chemicals are responsible for soil and groundwater contamination as they have a long persistence time and can percolate through the soil to the groundwater table and pose a serious threat to human health. There is an increasing need to identify different bioremediation approaches to degrade and detoxify these toxic pesticides. Several studies have demonstrated the use of bacteria, which can effectively degrade herbicides (Huang *et al.*, 2018). Because of its effectiveness and low cost, bioremediation appeared as the most favorable alternative treatment for the removal of agrochemicals (Arora, 2018).

In the current study, three herbicides (metribuzin, clodinafop propargyl, 2-methyl, 4-chlorophenoxyacetic acid and Bromoxynil) degrading bacterial strains were isolated and characterized. All the herbicide-degrading bacterial isolates were rod=shaped and belonged to the *Bacillus* genera. In a previous study conducted by Sehrawat and others (Sehrawat *et al.,* 2021), it was examined that pesticides in the environment are mostly mineralized and detoxified by bacterial genera like "*Bacillus* and *Pseudomonas*"

because these bacteria possess a variety of enzymes that are helpful in the degradation of toxic compounds.

Out of fourteen bacterial isolates, six were able to metabolize metribuzin. The bacterial isolate A6 was further used to study the metabolism of metribuzin herbicide and results were confirmed by GC-MS analysis. Bacterial isolate metabolized the metribuzin into the deaminated metribuzin. The results showed that the bacteria adopted the deamination pathway for sensor metribuzin degradation. The metribuzin herbicide was broken down into degradative products by the release of an amino group from the parental herbicide compound and converting it into a less toxic product i.e., deaminometribuzin. The bacterial strain A6 degraded 14.8% metribuzin out of the provided concentration of 50 ppm. In a similar study Wahla and others (Wahla *et al.,* 2019) investigated the biodegradation of two pesticides metribuzin and profenofos by three bacterial isolates "*Pseudomonas aeruginosa, Staphylococcus aureus,* and *Bacillus subtilis*" and determined the effect of pH, temperature, and various carbon and nitrogen sources on degradation. The strains exhibited excellent growth at pH 6, 30°C in minimal salt broth amended with 25 mg/L pesticides containing dextrose as carbon and malt extract as nitrogen source. *Bacillus subtilis* was found active in degrading the pesticides after that *Staphylococcus aureus* and *Pseudomonas aeruginosa.*

In this study, three Bacillus sp. were found efficient in the metabolism of clodinafop propargyl and the bacterium B3 was further selected for biodegradation study through GC-MS analysis. The bacterial strain B3 degraded 23.2% clodinafop propargyl out of the provided concentration of 50 ppm. The isolate B3 degraded the clodinafop into corresponding acids and adopted a dehalogenation pathway for the breakdown of herbicide. The bacterium released the chloride ions from the compound, due to which the pyridyl ring underwent further degradation and broken down into the corresponding dicarboxylic acids which is an allosteric activator of acetyl co-enzyme-A decarboxylase (Singh *et al.,* 2013). *Aeromonas* sp. isolated from the crop field degraded 81.3% of clodinafop propargyl with a concentration of 80 ppm as the bacteria consumed it as a sole carbon and nitrogen source (Dong *et al.,* 2017). The formation of 4-(4-chloro-2-fluorophenoxy) phenol as a main degradative metabolite was reported. In another study conducted by Singh and others (Singh *et al.,* 2013) the degradation efficiency of clodinafop by *Pseudomonas* sp. was determined which consumed about 87.14% of herbicide out of the initial concentration of 80 ppm. The breakdown of clodinafop propargyl released chloride ion and confirmed the breakdown of CF into 4-(4-chloro-2-fluorophenoxy) phenol and clodinafop acid. The production of phenol as the metabolic product reveals the presence of esterase activity (Yuan *et al.,* 2015).

Were found to metabolize the MCPA & Bromoxynil. The strain C1 was efficient in degrading MCPA through the decarboxylation mechanism and forming 2-methyl phenol as a major degradative metabolite. (Mierzejewska *et al.,* 2016) reported three bacterial strains *Xanthomonas maltophilia*, *Pseudomonas* sp., and *Rhodococcus globerulus* that degraded 99% MCPA in non-contaminated soil and up to 61% in the contaminated soil by *Xanthomonas maltophilia*.

CONCLUSIONS

Bioremediation has become a popular environment-friendly approach for the decontamination of a heavy buildup of toxic recalcitrant compounds from the environment. Microbial degradation plays a pivotal role to endorse a clean and sustainable environment. In this study three bacterial isolates namely, A6, B3, and C1 were found efficient for degrading metribuzin, clodinafop, and Bromoxynil & MCPA herbicides respectively, and their respective degradation capacities recorded as 14.8% for metribuzin, 23.2% for clodinafop and 33.9% MCPA & Bromoxynil. The optimum temperature and pH for the biodegradation of herbicides was 35°C and pH ranging from 7.0–8.0. These bacterial strains were found efficient in the metabolism of herbicides and can be utilized for the bioremediation of polluted sites in the future.

Declarations

Supplementary Materials. The following supporting information can be downloaded: Table S1: Morphological characterization of herbicides degrading bacteria at https://ojs.ptbioch.edu.pl/index.php/abp/

Ethical approval. This article does not contain any studies with animals performed by any of the authors.

Data availability. All major data generated and analyzed in this study are included in this manuscript and its supplementary information files.

Conflict of interest. The authors declare no conflict of interest.

The relationship between EMG high frequency and low frequency band amplitude changes correlates with tissue inorganic phosphate levels

Assessing inorganic phosphate levels seems crucial in deciphering the biochemical state of organisms or tissues. The concentration of inorganic phosphate in blood is an order of magnitude smaller than in tissues and, on top of that, it is dynamically used to fill temporary gaps in tissues. This is the reason blood inorganic phosphate level is considered a poor proxy for tissue levels. Therefore, tissue biopsy seems to be the dominant method when assessing inorganic phosphate levels for instance in muscles. In this study, we attempted to derive a non-invasive biomarker for phosphate tissue levels. We analyzed surface electromyography signals taken during 31P spectroscopy of leg muscles in five adult pigs. We induced hypophosphatemia *via* 20 minutes-long hyperventilation. It turned out that the proportion of the amplitude of the low frequency band and the high frequency band is significantly (p=0.002) correlated with the relative phosphate levels. The electromyographic signal did not correlate significantly with pCO2 levels in the blood, suggesting that the changes in the signal are a result of inorganic phosphate levels, not hyperventilation. The results might lead to the development of a real-time phosphate fluctuations measurement procedure.

INTRODUCTION

Disturbance in phosphate levels is an electrolyte disorder associated with many diseases, but hypophosphatemia is more common than hyperphosphatemia. Hypophosphatemia is typically diagnosed when serum phosphate levels drop below 2.0 mg/dl. The most common causes of hypophosphatemia are infection, refeeding, and Fanconi syndrome (Saito *et al.*, 2014). It also manifests as a complication in critically ill patients in the postoperative phase, hypothermia, or trauma (Geerse *et al.*, 2010). Symptoms of hypophosphatemia are potentially life-threatening but at the same time nonspecific - it includes muscle weakness, arrhythmias, respiratory failure, hypercalciuria, and others (Assadi, 2010). The disturbance in phosphate levels is associated with increased morbidity (Felsenfeld & Levine, 2012; Sin *et al.*, 2021).

The relationship between phosphate levels in compartments is tightly regulated and complicated. As only 1% of total phosphate in the body is in the extracellular compartment, the changes of concentration in serum are dynamic and a poor indicator of total-body phosphorus level (Felsenfeld & Levine, 2012). Routine phosphate monitoring is uncommon in patients admitted to intensive care units (ICU), and hypophosphatemia is often not corrected (Berger *et al.*, 2021). 31P spectroscopy is rarely a viable solution due to equipment requirements.

As hypophosphatemia is associated with disturbances in muscle function and ATP synthesis (Pesta *et al.*, 2016), the aim of this study was to determine if muscle activity could be a non-invasive, real-time indicator of phosphate level. The studies performed on cows showed that phosphate deprivation could induce abnormalities in muscle activity that can be detected by electromyography, but there is no data about transient and immediate effects, which could have clinical implications in human studies (Pesta *et al.*, 2016; Grünberg *et al.*, 2019, 2015). The approach of combining 31P with surface EMG for studying muscle disorders and fatigue has been used many times since 1993 (Roy, 1993; Giannesini *et al.*, 2003; Rzanny *et al.*, 2006). But again, experiments using this approach did not investigate fast fluctuations of inorganic phosphate in healthy and unfatigued muscle. Our study fills this gap and might lead to the development of a novel phosphate biomarker.

MATERIALS AND METHODS

Major protocol

The experiments were approved by the II Local Ethical Committee on Animal Testing in Warsaw, Poland (permit number: 20/2015 from 23 April 2015) on behalf of the National Ethical Committees on Animal Testing. Three preliminary experiments were conducted: two animals under normo- and hyperventilation were performed outside the MRI scanner chamber and one in the MRI chamber under normoventylation (animal 0). In the main part of this study, four female healthy piglets (animals 1–4) with an average body weight of 20 kg and an average age of 2 months were first sedated with azaperone

Figure 1. Schematic of the main experiment - dashed and filled rectangles indicate which fragments of data were taken into further analysis.
Additionally, the range of hyperventilation and moments of blood gasometry were shown as vertical lines and circles respectively. Each spectroscopy measurement lasted 4 min 26 seconds. The time between measurements slightly varied but the mean time between blood tests was 5 min.

(Stresnil, 3 mg/kg body weight (b.wt.), Janssen Pharmaceutica, Turnhoutseweg, Belgium). Each animal was then orotracheally intubated with an endotracheal tube and mechanically ventilated with room air. The respiration rate was set to zero (free respiration) during normoventylation and 20/min during hyperventilation. To evaluate muscle activity, the surface EMG electrodes were placed on the trapezius and triceps (front leg), and biceps femoris (rear leg) muscles. During the experiment, a swine was placed inside the MRI scanner. Each measurement lasted 4 min 26 seconds. In four cases, between the measurements, the pig's blood was drawn to evaluate gasometry. After the first two control scans, the next four were made in a hyperventilated state, followed by another seven scans under normoventylation. A schematic of the main experiment is shown in Fig. 1. The well-being of animals was closely monitored by an anesthesiologist and in case of suspected risk to animal health, the experiment was terminated. In addition to experiments with ^{31}P spectroscopy, EMG measurements for two other animals upon normo- and hyperventilation were performed outside of the MRI scanner chamber.

^{31}P MRS data analysis

^{31}P-MRS data was acquired using an MR750w 3T MRI scanner (GE Healthcare, USA) with ^{31}P/^{1}H surface coil (Rapid Biomedical, Germany). Data was acquired with parameters: TR 1s, Navg 256, spectral bandwidth 5kHz, acquisition time 102.4 ms, slice thickness 40 mm. No shimming was applied for the ^{31}P-MRS acquisition. Data were acquired before, during, and after hyperventilation. Localization was done through coil sensitivity. The coil was located on the biceps femoris. Raw data were quantified with jMRUI software (Naressi *et al.*, 2001; Stefan *et al.*, 2009) using the AMARES algorithm (Vanhamme *et al.*, 1997) according to published procedures and parametrization (de Graaf, 2019). Signal location and assignment were done for each spectrum individually to account for pH-induced changes in the spectra.

Electromyography data analysis

The electromyography record was running continuously throughout the whole experiment. Because between spectroscopy measurements the pigs were touched by a technician for blood extraction, the analysis of electromyography measurements has been made only on fragments of record that were recorded during spectroscopy. The first part of the analysis was made using the "signal" library from Python 3. The "spectrogram" function was used to create a signal spectrogram which then has been converted into dB. To extract the spectroscopy parts of the signal the sum of signal power in the 210 dB – 249 dB range has been taken and then the frag-

ments where the summed signal power went above the average for the known spectroscopy time – 4 minutes and 26 seconds – were chosen. Further signal analysis has been done using the R language "psd" library. The signal was further cleaned up, a spectrogram was created, and then the relation between high and low frequency bands was calculated according to the equation:

This approach to the analysis of EMG signals was al-

$$EMG_{score} = \Sigma_{150-400Hz}(amplitude)/\Sigma_{1-49Hz}(amplitude)$$

ready used in clinical research (Allison & Fujiwara, 2002; Badier *et al.*, 1993; Krogh-Lund & Jørgensen, 1993).

Gasometry data analysis

Between ^{31}P-MRS measurements, blood samples were collected and further using a critical points analyzer RAPIDPoint 500 (Siemens, Erlangen, Germany). The measured parameters were: pH, pCO_2 (mmHg), pO_2 (mmHg), $cHCO_3^-$(mmol/L), BE (ecf) (mmol/L), cSO_2 (%), Na^+ (mmol/L), K^+ (mmol/L), Ca^{++}(mmol/L), Cl^- (mmol/L), $cTCO_2$ (mmol/L), Anion gap (mmol/L), Anion gap K^+ (mmol/L), Hct (%), cHgb (g/dL), BE (b) (mmol/L), Glucose (mg/dL), Lactate (mmol/L), Creatinine (mg/dL) (Supplementary Table 1 at https://ojs.pt-bioch.edu.pl/index.php/abp/).

RESULTS

Hyperventilation induces hypophosphatemia in most animals

Four hyperventilated animals were put in an MRI chamber. Two measurements were done with normoventilation and then animals were hyperventilated for 4 consecutive scans (see Materials and Methods for exact protocol). Analysis of the ^{31}P-MRS signal indicates that inorganic phosphate content in muscles drops by as much as 30% after 5 steps of the experiment (about 20 minutes of hyperventilation) (Fig. 2). Not all cases had a drop in phosphate levels following hyperventilation, but when blood gasometry analysis was performed, hyperventilation robustly induces a drop in pCO2 levels (Supplementary Fig. 1 at https://ojs.ptbioch.edu.pl/index.php/abp/).

Figure 2. Inorganic phosphate levels in muscles before, during and after hyperventilation.
The total number of points per animal depended on its condition – some experiments were decided to finish earlier. Phosphate levels are normalized against the first measurement.

A

B

Figure 3. Correlation between EMG score (see Materials and Methods) and phosphate levels (panel A) and pCO2 (panel B). Values on all axes were normalized against the first measurement per animal.

EMG signal correlates with inorganic phosphate but not with pCO₂ levels

The distribution of the collected EMG signal was symmetrical, and values ranged typically between -100mV and 100mV (Supplementary Fig. 2 at https://ojs.ptbioch.edu.pl/index.php/abp/). The ratio of the power spectrum between high and low frequencies was calculated for a window spanning 4 minutes during MRI acquisition (4 min 26 seconds). The window for EMG analysis was taken slightly smaller to remove artifacts caused by switching on/off of MRI scanning. Pearson correlation between this calculated ratio (called "normalized score") and normalized phosphate levels is negative and significant: R is –0.45, and the p-value is 0.002 (Fig. 3A). We made the same comparison between the score and normalized pCO₂ levels, and the Pearson test indicated an insignificant correlation (Fig. 3B). Detailed trajectories for each animal are in Supplemental Fig. 3 at https://ojs.ptbioch.edu.pl/index.php/abp/.

Figure 4. Experiment with hyperventilation repeated outside of the MRI chamber. The start and end of hyperventilation are denoted as vertical lines. Dots are the EMG score calculated every 1s.

Fast reaction to hyperventilation seen in EMG

The EMG signal collected during MRI scans is, despite shielding and usage of carbon electrodes, quite noisy. We repeated the hyperventilation experiment outside of the MRI chamber. Phosphate measurement wasn't possible but the goal was to obtain a clear picture of changes in EMG following hyperventilation. It turned out that the reaction of EMG to hyperventilation is pretty fast - the changes in the EMG spectrum can be observed tens of seconds after hyperventilation is started (Fig. 4). To remove the possibility that the interaction with a ventilating machine was the cause of EMG response, another animal was put on ventilator but with respiration rate set to 12 breaths. No significant changes in EMG score (other than artifacts from body movement) were detected (Supplemental Fig. 4 at at https://ojs.ptbioch.edu.pl/index.php/abp/).

DISCUSSION

In this study, we presented the results of an attempt to derive a non-invasive biomarker of hypophosphatemia. We showed that hyperventilation induces hypophosphatemia and that the level of inorganic phosphate in muscles correlates with changes in the power spectrum density of a surface electromyographic signal. The observed correlation is significant despite the limited number of animals used for the research.

Animals appeared healthy, but we cannot rule out pre-existing conditions (one animal needed a longer recovery time after the experiment was concluded). This could potentially explain why, not in all cases, we were able to notice hypophosphatemia.

An interesting aspect of EMG response to hyperventilation is the time needed to elicit it. MRI scans affect the EMG signal, so we could not see when exactly the EMG started to drift. Experiments outside of the MRI chamber showed that a response is faster than 30 seconds. Existing hypotheses about how hyperventilation influences phosphate levels (O'Brien & Coberly, 2003) support a fast response rate. O'Brien and Coberly proposed a model where an increased rate of glycolysis and ATP production in response to respiratory alkalosis is responsible for a sudden drop in inorganic phosphate levels. However, this study doesn't provide evidence if that is the mechanism that occurs.

The role of TGF-β in the electrotactic reaction of mouse 3T3 fibroblasts *in vitro*

Patrycja Ciesielska[†], Slawomir Lasota*[†], Sylwia Bobis-Wozowicz and Zbigniew Madeja*

Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Kraków, Poland

Endogenous electric fields (EFs) serve as a crucial signal to guide cell movement in processes such as wound healing, embryonic development, and cancer metastasis. However, the mechanism underlying cell electrotaxis remains poorly understood. A plausible hypothesis suggests that electrophoretic or electroosmotic forces may rearrange charged components of the cell membrane, including receptors for chemoattractants which induce asymmetric signaling and directional motility. This study aimed to explore the role of Transforming Growth Factor Beta (TGFβ) signaling in the electrotactic reaction of 3T3 fibroblasts. Our findings indicate that inhibiting canonical and several non-canonical signaling pathways originating from the activated TGF-β receptor does not hinder the directed migration of 3T3 cells to the cathode. Furthermore, suppression of TGF-β receptor expression does not eliminate the directional migration effect of 3T3 cells in the electric field. Additionally, there is no observed redistribution of the TGF-β receptor in the electric field. However, our studies affirm the significant involvement of Phosphoinositide 3-Kinase (PI3K) in electrotaxis, suggesting that in our model, its activation is likely associated with factors independent of TGFβ action.

electric field, electrotaxis, cell migration, TGFβ signaling, 3T3 fibroblasts

Introduction

The existence of endogenous electric fields in diverse anatomical locations within living organisms has been extensively documented across various research accounts [for a comprehensive overview, refer to the work of McCaig et al.(2005)]. These electric fields emerge from polarized ion transport across epithelial tissues, resulting in the formation of a transepithelial potential. Following the disruption of the epithelial layer, such as by injury, this potential collapses at the center of the wound, while remaining stable in distal regions where ion transport is unaffected. This creates a voltage gradient, forming a direct current electric field (dcEF) with a vector parallel to the epithelial surface, and the wound center acting as the cathode (McCaig et al., 2009). Evidence increasingly highlights the pivotal role of electric signals in guiding cell migration during processes such as wound

healing, embryonic development, and the metastasis of cancer (Djamgoz et al., 2001; McCaig et al., 2005; Zhao, 2009). This phenomenon is referred to as electrotaxis and is defined as an active directional movement toward the cathode or anode.

While electrotaxis is well-documented in various cell types, the molecular mechanisms employed by cells to sense electric fields remain largely elusive. It is hypothesized that electrophoretic or electroosmotic forces redistribute the charged components of the cell membrane, including receptors for chemoattractants. This redistribution could lead to a higher concentration of these receptors on the side of the cell facing the cathode (or anode), potentially driving asymmetric signaling that underlies directional movement (McCaig et al., 2005; Allen et al., 2013).

The role of chemoattractant receptor redistribution on the cell membrane during electrotaxis is critically important. In particular, the Epidermal Growth Factor (EGF) receptor has been identified as a key player in the electrotactic responses of various cell types, including corneal epithelial cells, keratinocytes, and breast cancer cells (Fang et al., 1999; Zhao et al., 2002; Pu et al., 2007). Small direct current electric fields not only upregulate the expression of EGF receptors but also induce their asymmetrical distribution within the cell membrane. Nevertheless, it has been proposed that the electrotaxis process depends on the redistribution of receptors specific to additional chemotactic factors such as Basic Fibroblast Growth Factor (bFGF), acetylcholine, Vascular Endothelial Growth Factor (VEGF), and Transforming Growth Factor Beta (TGF-β) (Orida and Poo, 1978; Zhao et al., 1996; Zhao et al., 1999; Zhao et al., 2012). However, the mechanism of receptor translocation does not sufficiently explain the nature of the first rapid reactions of cells to dcEF (Korohoda et al., 2000; Djamgoz et al., 2001; Zimolag et al., 2017). Another significant hypothesis posits that the mechanism underlying electrotaxis could stem from uneven activation of different ion channels within the cell membrane. Several ion channels have been implicated in the electrotactic responses of diverse cell types. These include calcium channels (Mycielska and Djamgoz, 2004), voltage-gated sodium channels (Djamgoz et al., 2001), voltage-gated potassium Kv1.2 channels (Zhang et al., 2016), inwardly rectifying potassium channels (Kir4.2) (Nakajima et al., 2015), and ion transporters such as Na, K-ATPase (NaKA) and Na+/H+ exchanger isoforms (NHE1 and 3) (Özkucur et al., 2011). Additionally, Liu et al. documented the activation of Na+ and K+ pumping modes of (Na,K)-ATPase by an oscillating electric field (Liu et al., 1990). Furthermore, large-scale screening methods identified several ion channel genes as potential key players in electrotaxis (Nakajima et al., 2015; Lasota et al., 2024).

In our previous investigation (Lasota et al., 2024), we demonstrated that in slowly migrating 3T3 cells, the response to a direct current electric field (dcEF) occurs quite swiftly, with initial signs becoming apparent after just 1 min of exposure. This strongly suggests that the primary mechanism governing the electrotactic response is linked to the activation of ion channels rather than the translocation of cell membrane receptors. Indeed, through comprehensive screening, we identified several ion channel genes as potentially involved in 3T3-cell electrotaxis. Notably, the electrotactic response of 3T3 cells was significantly reliant on inwardly rectifying potassium channels (Kir4.2). Since inhibiting the Kir4.2 channel only diminishes the directional movement of 3T3 cells for approximately 1–2 h, followed by the reappearance of electrotaxis, we proposed a biphasic mechanism for the electrotaxis of mouse 3T3 fibroblasts. According to this model, the activation of ion channels triggers the initial rapid cellular response to an electric field, while the redistribution of membrane receptors is responsible for the sustained directionality of cell movement over the long term. Our preliminary findings indicated that the prolonged response might be attributed to the relocation of the EGF receptor in the membrane of 3T3 cells. On the other hand, we have proven the involvement of TGFβ signaling in the electrotaxis of another cell type – human bronchial fibroblasts (Pavlenko et al., 2023). Building on these findings, the current study delves into the role of TGFβ signaling in the long-term reaction of 3T3 fibroblasts to an electric field.

Materials and methods

Cell culture

Mouse 3T3 fibroblasts (ATCC CRL-1658) were cultured in DMEM HG (Dulbecco's Modified Eagle's Medium High Glucose) medium (Sigma–Aldrich, St. Louis, MO, United States), supplemented with 10% FBS (Fetal Bovine Serum) (Gibco, Waltham, MA, United States), penicillin (100 IU/mL), and streptomycin (100 µg/mL) (herein referred to as the 'complete culture medium') under standard conditions at 37°C and 5% CO_2. Cells were passaged using 0.25% trypsin/EDTA (Gibco, Waltham, MA, United States) approximately every third day to maintain confluency below 80%.

Cell seeding and application of electric field

To apply a direct current electric field (dcEF) to the cells, we used a custom electrotactic chamber based on a previously described protocol with minor modifications (Sroka et al., 2018). The scheme depicting the methodology of electrotaxis examination is presented in Supplementary Figure S1. We seeded $1×10^4$ cells onto a sterile 60 × 35 × 0.2 mm cover glass using 400 µL of complete culture medium, achieving a final cell density of approximately $2.5×10^3$ cells/cm². Before the experiment, the second part of the observation chamber was assembled using another cover glass and two additional 60 × 10 × 0.2 mm glass

pieces, connected with double-sided adhesive tape (tesa SE, Hamburg, Germany). This assembly, once completed, was filled with fresh complete culture medium or serum-free medium and inserted into an external electrotactic chamber made of PVC. Ag|AgCl electrodes (each 6 cm²) immersed in PBS were connected to a power supply. These electrodes were linked to the observation chamber using salt bridges made of glass pipes filled with agar (2% in 0.5 M KCl). Applying a dcEF with an intensity of 3 V/cm completed the setup. In the case of experiments without a dcEF, cells were seeded onto 24-well plates with glass bottoms (Eppendorf, Hamburg, Germany) in the quantity of 5×10^3 per well.

Registration and analysis of cell migration

Time-lapse imaging was conducted using integrated modulation contrast (IMC). For electrotaxis studies, a Leica DM IL LED microscope (Leica, Wetzlar, Germany) equipped with a Moticam 3.0 camera controlled by Motic Images Plus 3.0 software (both Motic, Xiamen, China) was used. For the registration in isotropic conditions (w/o dcEF), we employed a Leica DMI6000B motorized microscope with a Leica DFC360FX camera operated via LAS X 3.4 software (all Leica, Wetzlar, Germany). A temperature of 37°C was maintained inside the observation chamber using an environmental chamber and a heating unit. To offset the lack of CO_2 control, HEPES buffer (15 mM) was added to the complete culture medium before each recording session. The images were captured every 5 min for 4 h (with the cathode on the right-hand side).

Analysis of single-cell migration was performed using Hiro 1.0.0.4 software (Krecioch et al., 2015; Sroka et al., 2016; Sroka et al., 2018), where cell migration trajectories were constructed from manually identified cell centroids. To obtain circular diagrams, the initial point of each trajectory was placed in the origin of the coordinate system. The following quantitative parameters were calculated: (a) the speed of cell migration (μm/min)—the total length of the cell trajectory divided by the time of recording; (b) cell displacement (μm)—the length of the line segment from the first to the last position of a cell; (c) average directional cosine γ—γ is the angle formed by the line that connected the initial point of trajectory to subsequent cell positions and the X-axis (parallel to the vector of EF); (d) CME (Coefficient of Movement Efficiency)—representing the ratio of displacement to the total length of the cell trajectory. It approaches 1 when cell migration is persistent and decreases toward 0 when the direction of movement changes frequently.

Pharmacological modification of signaling pathways

To investigate the role of TGFβ signaling in the electrotaxis of 3T3 fibroblasts, we utilized inhibitors targeting both the canonical and noncanonical TGF-β pathways. Specifically, to block the canonical Smad-dependent signaling pathway, SB431542 (10 μM) was introduced into the complete culture medium during the preparation of the chamber. This inhibitor was applied 30 min prior to recording cell migration and was present throughout the duration of the experiment. To inhibit the noncanonical signaling pathways, the following inhibitors were added: U0126 (10 μM) for MEK1/2, SB203580 (10 μM) for p38, Y-27632 (10 μM) for ROCK, and LY-294002 (20 μM) for PI3K, following the protocol for the SB431542 inhibitor (all inhibitors from Sigma-Aldrich, St. Louis, MO, United States). In experiments without the presence of serum, the serum-free medium was additionally supplemented with TGF-β1 at a concentration of 5 ng/mL.

Knockdown of the TGF-β receptor gene

To verify the involvement of Tgfbr2 in the electrotaxis of 3T3 fibroblasts, the receptor was knocked down with a specific siRNA. Briefly, 5×10^4 cells/well were seeded into a 12-well plate the day before. Cells were transfected with 25 nM siRNA targeting mouse Tgfbr2 (#AM16708, siRNA ID: 64894, Ambion, Austin, TX, United States) or non-targeting control (#AM4611, Ambion) using DharmaFECT 1 (Dharmacon, Lafayette, CO, United States) as the transfection reagent. The procedure was performed according to the manufacturer's instructions. Approximately 24 h after transfection, cells were harvested and seeded into an electrotactic chamber to allow for adherence. Electrotaxis was analyzed 24 h later as described above.

Western Blot analysis

Cells transfected with siRNA were harvested 48 h after transfection and lysed with RIPA lysis buffer (Sigma-Aldrich) supplemented with protease and phosphatase inhibitors (Thermo Fisher Scientific, Waltham, MA, United States). The lysates were then sonicated (3 × 10 s) with intermediate incubations on ice and centrifuged at 16.000 g for 10 min at 4°C to isolate the protein fraction. Protein concentration was measured using a BCA assay (Thermo Fisher Scientific) according to the manufacturer's instructions. Samples were then mixed with 4x Loading Protein Buffer Plus (Eurx, Gdańsk, Poland) and boiled at 95°C for 5 min 10 μg protein samples were separated by SDS-PAGE using Miniprotean TGX Gel, 4%–15% (Bio-Rad, Hercules, CA, United States) and transferred onto a polyvinylidene fluoride (PVDF) membrane using a Trans-Blot Turbo Transfer Pack Midi Format 0. 2 μM PVDF (Bio-Rad) in a semi-dry transfer at 25 V, 1.3 A for 7 min in the Trans-Blot Turbo Transfer System (Bio-Rad). Membranes were incubated in 3% BSA in TBST (0.05% (v/v) Tween 20 in

Tris-buffered saline) for 90 min to block nonspecific binding sites. The membranes were then incubated with primary antibodies against TGFBR2 (#GTX55814, GeneTex, Irvine, CA, United States) or GAPHD (#MA5-15738, Invitrogen/ Thermo Fisher Scientific) as a loading control overnight at 4°C with gentle shaking. The next day, the membranes were washed three times with TBST and incubated with horseradish peroxidase (HRP)-conjugated secondary antibodies: goat anti-rabbit IgG, horse anti-mouse IgG (#7074 and #7076, respectively, both from Cell Signaling Technology, Danvers, MA, United States) in 3% BSA in TBST for 50 min at room temperature. After washing the membranes 3 times with TBST, the signal was detected with the chemiluminescent HRP substrate (Merck, Rahway, NJ, United States) in a ChemiDoc XRS + imager (BioRad). Densitometric analysis was performed using Quantity One software (Bio-Rad).

TGF-β receptor distribution

3T3 fibroblasts were seeded into a 24-well plate at a density of 2.5×10^4 cells per well and incubated overnight under standard conditions. The next day, cells were transfected in accordance with the manufacturer's protocol (Thermo Fisher Scientific, Waltham, MA, United States) using 0.75 μL of Lipofectamine 3000 reagent and 0.5 μg of a plasmid vector encoding the TGFBR1 (ALK5) receptor fused to an mEmerald Green fluorescent protein (Addgene, Watertown, MA, United States, #62751) for each well. Twenty-four hours post-transfection, cells were reseeded onto 60 × 35 × 0.2 mm glass slides for the electrotaxis chamber as outlined in the preceding section. Given the rapid reduction in the expression of the protein, transient transfection was scheduled 48 h before the planned imaging of the receptor redistribution. Imaging was done utilizing a Leica DMI8 inverted fluorescence microscope equipped with a DFC7000 GT monochromatic CCD camera, dry HCX APO U-V-I 40x/0.75 DRY UV objective, a GFP-optimized filter set (all Leica, Wetzlar, Germany), and a CoolLED pE-4000 LED illuminator (CoolLED Ltd., Andover, Great Britain). Following the application of the electric field, as previously described, images of fluorescent cells across various fields of view were recorded. These images were then processed with ImageJ Fiji software (National Institute of Health, Bethesda, MD, United States) (Schindelin et al., 2012), i.e., the images were shading corrected and used for designation of plot profiles along lines with a thickness of 5 pixels, with the intention of reducing noise.

Statistical analysis

The statistical significance of variances in cell migration speed, cell displacement, and CME was evaluated using the

FIGURE 1
Movement of 3T3 fibroblasts in an isotropic environment and under the influence of a direct-current electric field (dcEF) of physiological strength. Circular diagrams depict the combined trajectories of individual cell migration **(A)** in the absence of dcEF and **(B)** with a dcEF of 3 V/cm. The starting point for each trajectory (formed by tracking 48 consecutive positions of the cell centroid, recorded every 5 min) was repositioned to the origin of the coordinate system. The dcEF cathode, when applicable, is situated to the right in the illustration. Scale is provided in micrometers (μm). The directional cos γ values below (referring to the directionality of the cell migration), are provided as the mean (for the cell population; $n = 30$ and 60, respectively) $\pm$ the standard error of the mean (SEM). *Statistically significant difference between compared conditions (dcEF 3 V/cm vs. w/o dcEF) ($p < 0.05$).

Student's t-test. In contrast, for directionality, these differences were examined using a non-parametric U–Mann–Whitney test due to the nature of this parameter and its inherent lack of a normal distribution (confirmed by the Shapiro-Wilk test). All

statistical analyses were conducted using GraphPad Prism version 8.0.1 (GraphPad Software, Boston, MA, United States), with a threshold for statistical significance set at $p < 0.05$.

Results

The impact of inhibiting canonical and non-canonical TGF-β signaling pathways on 3T3 cell electrotaxis in the presence of a serum

As previously communicated, 3T3 fibroblasts in a medium with 10% FBS exhibit robust electrotactic activity (Lasota et al., 2024). Indeed, as shown in Figure 1A, in the absence of an electric field, the 3T3 cells displayed random movements (cos γ = 0.018 ± 0.109). However, following the application of an electric field (3 V/cm), the cell migration became distinctly directional, with cells moving toward the cathode (cos γ = 0.799 ± 0.029) (Figure 1B).

To determine the role of TGFβ in directing the migration of 3T3 cells in an electric field, we assessed the effects of inhibiting both canonical and non-canonical signaling pathways activated by TGFβ, using specific pharmacological inhibitors at concentrations validated in our previous studies (Paw et al., 2021; Pavlenko et al., 2023). As presented in Figure 2 and Figure 3D, inhibition of the canonical Smad-dependent pathway with SB431542 did not alter the electrotaxis of 3T3 cells. Similarly, inhibitors of noncanonical TGFβ signaling pathways, specifically MEK1/2 (U0126), p38 (SB203580), and ROCK (Y-27632), did not affect the directional migration of 3T3 cells in the electric field. However, the PI3K signaling pathway stood out as its inhibition with LY-294002 significantly reduced the directional cosine from 0.799 ± 0.029 under the control conditions to 0.347 ± 0.092 with the inhibitor present (Figure 3D; Table 1), pointing to a critical role of PI3K in migration directionality. Notably, while U0126 (MEK1/2 inhibitor) and Y-27632 (ROCK inhibitor) significantly influenced the speed of migration and cell displacement, suggesting the importance of these signaling pathways for motile activity, they did not affect the directionality of cell movement (Figure 3; Table 1). A similar effect of these inhibitors on the migration of 3T3 cells was found under control conditions without the application of an electric field (Supplementary Figure S2).

[a]Statistically significant differences relative to control (serum, direct current electric field 3 V/cm) ($p < 0.05$).

The presented results underscore that among the TGFβ-activated signaling pathways we explored, only the PI3K-dependent pathway is crucial for electrotaxis. Nonetheless, given that this pathway can also be activated by additional factors within the FBS (e.g., EGF), we conducted additional experiments to investigate the impact of the tested inhibitors on the electrotaxis of 3T3 cells in a serum-free medium, supplemented with exogenously added TGFβ.

The impact of inhibiting canonical and non-canonical TGF-β signaling pathways on 3T3 cell electrotaxis in a serum-free media

In serum-free conditions, 3T3 cells demonstrated a distinct electrotactic response, migrating toward the cathode in an electric field of 3V/cm (Figures 4A,C). The directional cosine in these conditions was only marginally lower than in the presence of 10% FBS (0.636 ± 0.050 and 0.799 ± 0.029, respectively). However, both the speed of cell migration and their final displacement were reduced in the absence of serum compared to conditions with 10% serum (0.169 ± 0.006* μm/min vs. 0.233 ± 0.017 μm/min and 20.098 ± 1.364* μm vs. 42.879 ± 3.391 μm, respectively). Notably, adding exogenous TGFβ (5 ng/mL) did not alter the directionality of cell movement (Figure 4F), yet significantly enhanced their migration speed and final displacement (Figure 4E; Table 2).

As depicted in Figure 5 and Figure 6, in serum-free media at the presence of TGFβ (5 ng/mL), SB431542, an inhibitor targeting the canonical Smad-dependent signaling pathway, did not impact the electrotaxis of 3T3 cells. Similarly, inhibitors of noncanonical TGFβ signaling pathways such as p38 (SB203580) and ROCK (Y-27632) exhibited no discernible

FIGURE 4
The impact of TGF-β1 on the electrotaxis of 3T3 fibroblasts in serum-free media. **(A–D)** Circular diagrams illustrate the combined trajectories of individual cell migrations **(A,B)** without dcEF and **(C,D)** in the presence of a dcEF of 3 V/cm. All experiments were performed in serum-free conditions, with the culture media in **(B,D)** further enriched with TGF-β1 (5 ng/mL). The approach for chart creation and presentation is consistent with that described previously (see Figure 1). **(E,F)** Graphs showing quantitative parameters summarizing the effect of TGF- β1 (5 ng/mL) addition to the culture medium. **(E)** Speed of cell migration normalized to corresponding control (-TGFβ1) and **(F)** directionality of cell migration (shown as the average directional cosine γ), presented as the mean (for the cell population) ± the standard error of the mean (SEM). The number of cells (n) is 30, 30, 60, and 30, respectively. *Statistically significant differences compared to the corresponding control (serum-free, w/o TGF-β1) ($p < 0.05$).

effect on the directional migration of 3T3 cells in the electric field. Intriguingly, even the inhibition of the PI3K signaling pathway did not significantly diminish electrotaxis under these experimental conditions. It is worth emphasizing that the inhibitor of MEK1/2 (U0126) completely halted the migration

of 3T3 cells (Figure 5C). It is important to note that data from non-migrating cells were excluded from further analysis, as movement parameters could not be determined. The effects of all these inhibitors on the migration of 3T3 cells in the absence of an electric field are detailed in Supplementary Figure S3.

FIGURE 5
The role of TGF-β signaling in the electrotaxis of 3T3 fibroblasts examined in the serum-free medium containing TGF-β$_1$. Circular diagrams illustrating composite cell trajectories under various conditions: **(A)** control conditions (dcEF 3 V/cm, serum-free, TGF-β$_1$ (5 ng/mL)), and in the presence of **(B)** Smad inhibitor - SB-431542 (10 μM), **(C)** MEK1/2 inhibitor - U0126 (10 μM), **(D)** p38 inhibitor - SB-203580 (10 μM), **(E)** ROCK inhibitor - Y-27632 (10 μM), and **(F)** PI3K inhibitor - LY-294002 (20 μM). The methodology for constructing and displaying these diagrams follows that of Figure 1.

FIGURE 6
The impact of TGF-β signaling inhibition on the electrotaxis of 3T3 fibroblasts in the serum-free medium containing TGF-β$_1$ − quantitative analysis. **(A)** Speed of cell migration, **(B)** displacement, **(C)** coefficient of movement efficiency (CME) and **(D)** directionality of cell migration (presented as the average directional cosine γ), presented as the mean (for the cell population) $\pm$ the standard error of the mean (SEM). The number of cells (n) is detailed in Table 2. *Statistically significant differences compared to the control (dcEF 3 V/cm, serum-free, TGF-β$_1$ (5 ng/mL)) ($p < 0.05$).

The obtained results suggest that although the PI3K pathway emerges as a crucial component in the response of 3T3 cells to an electric field, its activation in this context does not appear to be directly related to TGFβ. Instead, it is likely associated with other factors present in the serum that stimulate this pathway.

Given that our findings do not affirm a substantial role of TGFβ in driving electrotaxis, we endeavoured in subsequent experiments to validate the hypothesis concerning the translocation of the TGFβ receptor within the cell membrane under the influence of an applied electric field.

FIGURE 7
The distribution and role of TGF receptors during the electrotaxis of 3T3 fibroblasts. **(A,B)** Fluorescence images of cells expressing TGFBR1 (ALK5) fused to a fluorescent protein (green) both in the absence of an electric field **(A)** and following a defined period of stimulation by a dcEF of 3 V/cm **(B)**. The scale bar in **(A)**, representing 50 μm, applies to all images. When applicable, the dcEF's cathode is positioned on the right side of the field of view. Each image is accompanied by a corresponding plot profile that illustrates the normalized intensity of green fluorescence along the indicated white line. **(C)** Western blot analysis demonstrates reduced levels of TGFBR2 protein in cells transfected with specific siRNA compared to wild-type cells and those transfected with non-targeting siRNA. **(D)** A circular diagram shows the combined migration trajectories of individual cells (with Tgfrb2 silenced) in a dcEF of 3 V/cm. The approach for diagram creation and presentation is consistent with that described in a prior figure (see Figure 1). Quantitative parameters: V - speed of cell migration, D — displacement and directional cos γ (referring to the directionality of cell migration), are provided as the mean (for the cell population $n = 30$) $\pm$ the standard error of the mean (SEM). *Statistically significant differences compared to the control (dcEF 3 V/cm, 10% FBS) ($p < 0.05$).

TGFβ receptor redistribution in an electric field and its implication in 3T3 fibroblast electrotaxis

To test this hypothesis, we investigated the kinetics of TGFβR redistribution within the cell membrane of the 3T3 cells exposed to a direct current electric field (dcEF) of 3 V/cm, focusing on potential receptor displacement within a specified time frame. The results, illustrated in Figures 7A,B, reveal that after 15–60 min of exposure to a 3 V/cm dcEF, there was no detectable accumulation of TGFβ receptors on the cathode- or anode-facing side of the cell.

As this result aligned with our earlier observations, we proceeded to investigate the impact of TGFβ receptor silencing (Figure 7C) on the electrotaxis of 3T3 fibroblasts in a medium containing 10% FBS. As depicted in Figure 7D, the silencing of the receptor led to only a minor reduction in the

average directional cosine, with values slightly lower than the control (cos γ = 0.616 ± 0.058* compared to 0.799 ± 0.029).

Discussion

The understanding of the intricacies of electrotaxis remains incomplete, with two main hypotheses competing to explain this phenomenon. The first hypothesis predominantly concentrates on the asymmetrical activation of ion channels within the cell membrane, triggered by hyperpolarization of the cell membrane at the anodal side and depolarization at the cathodal side of the cell in response to an external electric field, or induced by mechanical effects from dcEF (Mycielska and Djamgoz, 2004; Gao et al., 2011; Allen et al., 2013). Although effective in elucidating the initial rapid responses of cells to dcEF (Korohoda et al., 2000; Djamgoz et al., 2001), this hypothesis

does not effectively explain the unclear mechanism responsible for the asymmetrical activation of these ion channels by the electric field (Mycielska and Djamgoz, 2004).

On the other hand, the second plausible hypothesis posits that electrophoretic or electroosmotic forces alter the distribution of charged components on the cell membrane, including receptors for chemoattractants. It is proposed that an increased concentration of these receptors on the side of the cell facing the cathode (or anode) triggers asymmetric signaling and directional motility (McCaig et al., 2005; Allen et al., 2013). However, this hypothesis does not fully explain the swift initial reactions of cells to dcEF (Korohoda et al., 2000; Djamgoz et al., 2001). Nevertheless, it should be acknowledged that both mechanisms, whether activation of the ion channel or receptor redistribution, are not mutually exclusive and may synergistically contribute to the process of electrotactic migration.

In our previous study (Lasota et al., 2024), we demonstrated the rapid response of 3T3 cells to a direct current electric field (dcEF), manifesting within the first minute of exposure. This response was notably reliant on inwardly rectifying potassium channels, particularly Kir4.2. Inhibiting these channels led to a transient reduction in the directional movement of 3T3 cells lasting approximately 1–2 h, followed by a reappearance of electrotaxis. We proposed a biphasic mechanism for the electrotaxis of mouse 3T3 fibroblasts, suggesting that ion channel activation underlies the initial rapid cellular response to an electric field, while the long-term maintenance of directional movement is facilitated by the redistribution of membrane receptors. Notably, we observed a distinct accumulation of EGF receptors on the side of the cell facing the cathode after 30–60 min in a dcEF (3 V/cm). Moreover, inhibition of the EGF receptor signaling pathway partially impeded the electrotaxis of 3T3 fibroblasts. Given that the relocation of EGF receptors has been established as a crucial factor in electrotaxis for various cell types (Fang et al., 1999; Zhao et al., 1999; Zhao et al., 2002), we postulated that the EGF pathway may underlie the sustained electrotactic response in 3T3 cells.

However, beyond the EGF receptor, the importance of receptor redistribution in the electrotaxis process has been suggested for additional chemotactic factors (Orida and Poo, 1978; Zhao et al., 1996; Zhao et al., 1999; Zhao et al., 2012), including Transforming Growth Factor β (TGFβ). Zhao et al. (1996), Zhao et al. (1999) reported that TGFβ restored cathodal-directed migration of corneal epithelial cells (CECs) under serum-free conditions. However, these studies did not examine how the inhibition of TGFβ-activated signaling pathways might affect CEC electrotaxis.

Nevertheless, our research (Pavlenko et al., 2023) has shown that adult human bronchial fibroblasts respond to external electric fields by orienting themselves perpendicular to the field lines and exhibit efficient electrotaxis toward the anode.

These processes depended on both canonical and non-canonical TGF-β pathways. This observation suggested the possibility that the electrotaxis of 3T3 fibroblasts might also be dependent on TGFβ.

Transforming growth factor beta (TGF-β) is a cytokine known to activate a variety of signaling pathways, leading to diverse biological effects including the stimulation of cell migration (Hao et al., 2019; Tie et al., 2022; Massagué and Sheppard, 2023). Within TGF-β-induced migratory signaling, two main types of pathways are recognized: canonical and noncanonical. The canonical pathways are Smad-dependent, where TGF-β receptor activation leads to phosphorylation and activation of Smad2 and Smad3 proteins. These phosphorylated Smad proteins then form a complex with Smad4 to move into the cell nucleus, regulating the expression of genes associated with cell migration (Costanza et al., 2017; Tie et al., 2022). On the other hand, the noncanonical MAPK pathway, comprising ERK, JNK, and p38 MAPK, can be activated by TGF-β, affecting cytoskeletal dynamics, cell adhesion, and migration. Additionally, noncanonical pathways include the Rho GTPase pathway (involving RhoA, Rac1, and Cdc42) and the PI3K/Akt pathway, each playing a role in cell migration regulation (Ridley et al., 2003; Costanza et al., 2017; Tie et al., 2022). Nevertheless, there is a lack of genetic evidence and a structural foundation supporting the notion that MAPKs and PI3K directly act as mediators in TGF-β receptor signaling. Moreover, these pathways already have established agonists which are commonly present in the microenvironment of TGF-β target cells *in vivo*, prompting inquiries into the significance of TGF-β as an activator of these pathways (Tie et al., 2022).

Unexpectedly, in our hands, inhibiting both the canonical and several non-canonical signaling pathways from the activated TGF-β receptor did not hinder the directional migration of 3T3 cells toward the cathode. Notably, the only statistically significant reduction in electrotaxis occurred with the inhibition of PI3K kinase (Figure 2; Figure 3).

This observation aligns with previous reports highlighting the essential role of PI3K activity in electrotaxis. For instance, Zhao et al. (2006) found that the genetic disruption of phosphatidylinositol-3-OH kinase-γ (PI(3)K γ) diminished electric-field-induced signaling and abolished electrotaxis of healing epithelium in response to electric signals. Similarly, Meng et al. (2011) demonstrated the significance of the PI3K pathway in the electrotaxis of neural progenitor cells (NPCs) driven by electric fields in the presence of growth factors.

However, given that PI3K activity can also be induced by additional factors in FBS (such as EGF) (Zhao et al., 2006; Meng et al., 2011), subsequent experiments were conducted to examine the influence of the tested inhibitors on the electrotaxis of 3T3 cells in a serum-free medium,

supplemented with exogenously added TGFβ. This approach aimed to minimize the influence of PI3K-activating chemoattractants other than TGFβ. In this simplified model, none of the inhibitors used, including LY-294002 (PI3K inhibitor), affected electrotaxis. This suggests that while PI3K plays a crucial role in the induction of directional migration of 3T3 cells in an electric field (as evidenced by the inhibition of electrotaxis in the presence of FBS after the addition of LY-294002), its activation in our experiments was probably related to the action of factors other than TGFβ present in the serum. Literature reports, including our own (Zhao et al., 1996; Zhao et al., 1999; Meng et al., 2011; Lasota et al., 2024), suggest EGF as a possible activator.

The negligible effect of TGF signaling on the electrotaxis of 3T3 fibroblasts is further confirmed by the observation that the addition of TGFβ in serum-free conditions does not substantially influence the directionality of cell movement (Figure 4). However, it is important to note that the presence of TGFβ does induce a significant increase in the velocity of 3T3 cell movement (Figure 4E).

Our findings of TGFβ's limited role in the regulation of electrotaxis in 3T3 cells were further supported by experiments investigating the redistribution of TGFβ receptors in an electric field. After 60 min in a dcEF of 3 V/cm, we did not observe any discernible accumulation of TGFβ receptors on the cathode-facing side of the cells (Figure 7B). This is in line with Zhao et al. (1999), who also reported no clear asymmetry in TGFβ receptor distribution under a 1.5 V/cm electric field, even after 3 h. Substantial accumulation was only noticeable after 12–16 h in the electric field. Although TGFβ partially restored cathodal-directed migration of corneal epithelial cells (CECs) in a serum-free medium over a 5-h period, the mechanism responsible for the observed electrotaxis remained unclear (Zhao et al., 1999). Interestingly, the relatively low electroosmotic mobilities of the TGFβ receptor also align with the theoretical model proposed by Sarkar et al. (2019). The non-involvement of TGFβ in the regulation of electrotaxis in 3T3 fibroblasts was further validated through experiments where the silencing of TGFβ receptors in 3T3 cells led to only a marginal reduction in the average directional cosine (Figure 7D).

By systematically inhibiting both canonical and non-canonical TGF-β signaling pathways, we demonstrated that TGF-β signaling does not play a major role in the directional migration of 3T3 fibroblasts in an electric field. The use of both serum-free and FBS-supplemented conditions further strengthens the reliability of our findings. Simultaneously, our study highlights significant insights into the role of PI3K kinase in the electrotaxis of 3T3 fibroblasts. However, our *in vitro* model has limitations, as it may not fully replicate the complex *in vivo* environment. Moreover, the findings, based on the 3T3 fibroblast cell line, may not represent the behavior of all fibroblast types. Notably, as mentioned before, we previously found that human

bronchial fibroblasts, which exhibit electrotaxis towards the anode, contrasting with the cathodal migration observed in 3T3 cells, rely on the TGF-β signaling pathways (Pavlenko et al., 2023).

While we focused on TGF-β and PI3K pathways, alternative signaling mechanisms such as ion channels and other growth factor receptors require further exploration. Our recent publication on ionic mechanisms and EGFR involvement in 3T3 electrotaxis has begun to explore these additional pathways (Lasota et al., 2024). Further investigations will focus on the dynamics of membrane receptors redistribution, aiming to validate the biphasic model proposed in our work.

Although specific *in vivo* experiments concerning the detailed cellular mechanisms of electrotaxis may be challenging, the application of electrostimulation in treating hard-to-heal wounds underscores the clinical relevance of understanding these mechanisms (Martin-Granados and McCaig, 2013). A deeper comprehension of electrotaxis could significantly enhance the efficacy of combining electrostimulation with pharmacological interventions in wound care. This integrated approach could lead to more targeted and effective treatments, paving the way for innovative therapeutic strategies in wound management.

Conclusion

Our study has shown that inhibition of both canonical and several non-canonical signaling pathways associated with the activated TGF-β receptor did not impede the directional migration of 3T3 cells to the cathode. Furthermore, silencing the expression of the TGF-β receptor failed to eliminate the directional migration of 3T3 cells in the electric field. Additionally, there was no redistribution of the TGFβ receptor under electric field conditions. Nonetheless, our research confirms an important role for PI3K kinase in electrotaxis, but its activation in our model was probably related to the action of factors other than TGFβ.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Ethics statement

Ethical approval was not required for the studies on animals in accordance with the local legislation and institutional requirements because only commercially available established cell lines were used.

Background: Postoperative delirium (POD) is a common complication after anesthesia and surgery, especially in the elderly. RNF146 has neuroprotective effects in cerebral ischemia, hypoxia, and chronic neurological diseases. However, whether RNF146 expression is related to the occurrence and development of POD remains unclear. Therefore, in this study, we aimed to determine whether RNF146 is involved in the occurrence of POD. **Methods:** (Sprague-Dawley) male rats (18 months old) were splenectomized under sevoflurane anesthesia. The cognitive function of rats at 1, 3, and 7 d after anesthesia and surgery was evaluated. Changes in the expression of neuroinflammatory cytokines, IL-6 and IL-10, and RNF146 were measured in the hippocampus in both control group (con) and anesthesia (AS) group. We examined cognitive outcomes and expression of inflammatory factors and RNF146 in con and AS mice using cluster analysis. **Results:** The cognitive ability and mobility of rats after anesthesia and surgery at day 1, 3, and 7 decreased, especially at day 3. Similarly, the expression of neuroinflammatory factors and RNF146 increased after anesthesia and surgery at day 1, 3, and 7, and the increase was highest at day 3. The clustering and correlation analysis of RNF146 expression in the hippocampi of elderly rats revealed a correlation between POD and neuroinflammation resulting from anesthesia and surgery. **Conclusion:** Anesthesia and surgery can lead to POD and neuroinflammation. The expression of RNF146 correlates with delirium and neuroinflammation caused by anesthesia and surgery.

INTRODUCTION

With the progress of modern medicine and the aging of the population, the number of elderly patients under-going surgery and anesthesia is increasing (H *et al.*, 2017; Lin *et al.*, 2020). Postoperative delirium (POD) is a common complication of anesthesia and surgery in elderly patients. POD is characterized by mild cognitive impairment, impaired memory, decreased ability to process information, and reduced attention accompanied by a series of negative outcomes, including changes in mood, personality, and loss of labor ability (Evered *et al.*, 2018). Having POD may result in increased morbidity and mortality, deteriorating quality of life, and causing other physical and psychological diseases, which negatively affect social stability (Carr *et al.*, 2018; Deiner *et al.*, 2017). A study reported that patients with POD were nearly twice as likely to die within 1 year within 3 months of surgery compared with patients without POD (Fodale *et al.*, 2010). According to the International Postoperative Delirium Study, the incidence of POD in elderly patients (>60 years old) is approximately 25.8% within 7 days of surgery and 10% within 3 months of surgery (Moller *et al.*, 1998). The incidence of POD within 3 months and 1 year after surgery is approximately 29% and 33.6%, respectively (Deiner *et al.*, 2017; Liu *et al.*, 2022). However, the mechanism of POD is unclear. POD occurs due to the combined action of susceptibility and predisposing factors, and aging is the only independent risk factor for the occurrence of POD (Evered *et al.*, 2018). The pathogenesis of POD is believed to be mainly caused by central nervous system inflammation (Feng *et al.*, 2017), oxidative stress (Chen *et al.*, 2020), dysregulations of the cholinergic system (Zuo *et al.*, 2018), increased neuronal apoptosis (Zhang *et al.*, 2020), and decreased neuronal regeneration and synaptic plasticity caused by amyloid deposition (Evered *et al.*, 2018). However, neuroinflammation is an important pathological basis for the occurrence of POD (Li *et al.*, 2022).

The E3 ubiquitin ligase RNF146 is present in the brain, spleen, heart, kidney, and testis (Matsumoto *et al.*, 2017). Neuronal cytoplasm mainly expresses RNF146 at a relatively high level in the cortex and hippocampus (Yang *et al.*, 2017). Studies have confirmed that RNF146 has a neuroprotective effect in cerebral ischemia, hypoxia, and chronic nervous system diseases (Kim *et al.*, 2017; Mu *et al.*, 2020) and mediates DNA damage repair through PAR-dependent ubiquitination to degrade PAR-mediated proteins (Andrabi *et al.*, 2011; Koo *et al.*, 2018). Cells overexpressing RNF146 exhibited higher survival rates after γ-irradiation (Andrabi *et al.*, 2011; Bensih et al., 2023). *In vitro* and *in vivo* experiments have revealed

that RNF146 expression in nerve cells is significantly increased after exposure to low-dose *n*-methyl-d-aspartic acid (NMDA) receptor and sublethal glucose-oxygen deprivation or transient bilateral common carotid artery occlusion in mice, protecting nerve cells from injury (Belayev *et al.*, 2017; Mu *et al.*, 2020). The presence of higher RNF146 expression in the brains of patients with early Alzheimer's disease supports a neuroprotective role for RNF146 (von Rotz *et al.*, 2005). The occurrence and clinical manifestations of POD are similar to neuroinflammation-related degenerative diseases, such as Alzheimer's disease (Belayev *et al.*, 2017; Evered *et al.*, 2018). However, whether RNF146 is involved in the occurrence and development of POD is unknown. In this study, elderly rats were used to induce delirium-like behavior during anesthesia and surgery to evaluate changes in RNF146 expression in the occurrence of POD. The purpose of this paper is to investigate the changes of RNF146 expression during POD development, whether RNF146 can be a biomarker of POD development, and to improve new insights for studying the pathogenesis, treatment, and prevention of POD.

MATERIALS AND METHODS

The animal program was approved by the Animal Care and Use Committee of Ningxia Medical University Medical Center. All animal experiments were conducted following the National Institutes of Health Guidelines for the Care and Utilization of Laboratory Animals (No. 2016-124), revised in 2016.

Animals

A total of 72 healthy male SPF (Specific pathogen Free) SD rats, aged 18–20 months and weighing 450–600 g, were provided by the Laboratory Animal Center of Ningxia Medical University (IACUC Animal Use License number: SCXK (Ning) 2020-0001). The rats were randomly divided into six groups (12 animals in each group): con group 1, 3, and 7 d without exposure to anesthesia and AS group 1, 3, and 7 d after anesthesia and surgical intervention. Each cage, measuring 27.94 cm×15.24 cm×11.43 cm, contained 3–4 animals under a 12-h light–dark cycle. The rats were provided free access to food and water.

Anesthesia and Surgery

Splenectomy was performed under anesthesia with sevoflurane in the AS group. In brief, rats were anesthetized in an airtight chamber prefilled with 3% sevoflurane in 100% O_2. Anesthesia was induced by continuous inhalation of 3% sevoflurane in 100% O_2 at a rate of 1.5 L/min. As soon as the correct reflex disappeared, the rats breathed spontaneously after being fixed on the operating table. In order to maintain the depth of anesthesia, rats were given 100% pure oxygen mixed with 3% sevoflurane. Splenectomy was performed in the AS group according to the methods described in the literature (Kong *et al.*, 2017; Wang *et al.*, 2017). The operation was performed on a heating table and the temperature was maintained at 37°C. Skin disinfection was performed routinely. First, an incision of 1cm was made, and a surgical field was created. The spleen was bluntly separated from the surrounding tissue. Then the blood vessel was ligated with 6-0 thread, and the distal blood vessel was cut after the spleen was taken out. Abdominal muscles and skin were sutured with 4-0 silk thread. The incision was locally infiltrated with ropivacaine (1%, 1 mL), and erythromycin ointment was applied to the incision. The rats were kept at 37°C±0.5°C from anesthesia until they woke up. The entire operation was completed in 30 min, and a sine individual performed all the surgical operations. The rats in the con group were placed in the air-containing induction chamber for 30 min.

Morris water maze test

The Morris water maze (MWM) test of spatial memory and cognitive ability was performed in splenectomized rats. The MWM consists of a circular pool of 120 cm in diameter and 50 cm in height. The pool was divided into four quadrants. A circular platform with a diameter of 15 cm was fixed in the middle of the second quadrant. The platform was immersed 1 cm underwater, with a water temperature of 22°C±2°C. A camera was placed above the maze to record the rats' movements. The test included the following: (1) Positioning navigation experiment: The experiment was conducted at the same time every day, once a day for 5 consecutive days. The time for rats to find the platform was recorded as escape latency. The automatic camera system and computer analysis and processing system recorded escape latency. If the rat could not find the platform within 60 s after entering the water, it was led to the platform and allowed to stay on it for 15 s to guide its spatial learning and memory. In such cases, the escape incubation period was recorded as 100 s; (2) Space exploration experiment: The platform was removed on the second day after the positioning navigation experiment, and the rat was placed into the water facing the pool wall at the entry point of 1/2 arc in the fourth quadrant. The computer recorded the time it took the rat to reach the original platform position, the number of times it crossed the platform position, and the total swimming distance within 60 s. The samples were collected after the behavioral experiment.

IntelliCage test (automated IntelliCage testing)

The IntelliCage test (TSE Systems GmbH, Germany; http://www.newbehavior.com) assessed spontaneous behavior and spatial learning in rats raised in groups. After surgery, the rats in each experimental group were put in the IntelliCage box before adding water and feed and changing the padding regularly. A miniature signal transceiver was injected into the neck of the rats (used to record activity) (Wu *et al.*, 2017). The labels of each group of rats injected were input in the IntelliCage test software (IntelliCage plus). The experimental test could detect when the rats entered the corner, and the system recorded it as a "visit". Two water bottles were placed in each corner, and the system records a "nose-poke" when rats touch their noses. When a rat licks a water bottle for a drink, the system records it as a lick. The IntelliCage test was designed in four stages: (1) Free exploration: The number of corner visits and nose contacts of each rat was recorded to assess the ability of the rat to adapt to the new environment for 3 d. (2) Nose-poke learning: The times of corner visits and a nasal touch of each rat were recorded to evaluate the learning and memory ability of the rat for 5 d. POD modeling was performed after nose contact learning. (3) Position learning: The correct access ratio of each rat was recorded to evaluate the spatial position learning ability for 3 d. After the end of the learning behavior, all rats had access to all corners and vial vents. (4) Position reversal learning: the diagonal corner of the "correct" area in the previous spatial position learning stage was defined as "correct"

and the rest as "wrong." The number of times each rat visited the correct corner was recorded to evaluate the learning ability of spatial position for 3 d.

Nesting test

The nesting experiment is used to evaluate the behavior and habits of rats. Before the experiment, each rat was placed in a new sterilized cage, facial tissue was added (the thickness of the cage was ~1.5 cm), and 10 pieces of clean, unscented tissue paper were placed in the cage (close to the side wall of the cage, and not right below the water bottle). The rectangular paper measured 10×6 cm. After the rats were put in, the cage was covered, and the room lights were turned off. The experiment generally started from 16:00 to 18:00, and all rats were placed within 1 h to reduce experimental errors. The nesting situation of the rats was scored at 24 h.

Score with reference to the literature: 1 = no obvious bite marks on the paper; 2 = partial shredding of the paper; 3 = scrap most of the paper; 4 points = flat nest can be identified; 5 = perfect nest. The experiment was double-blind, scored by more than three trained experimenters, and each experimenter's rating of a rat was evenly divided into the rat's nesting score.

Western blotting

After MWM, six animals in each group were injected with cold PBS (phosphate buffered saline) and normal saline through the cardiac vein under deep anesthesia, and their brains were quickly removed. Brain tissue was homogenized in a mixture of RIPA lysis buffers, phosphatase, and protease inhibitors and incubated in ice for 30 min. The lysates were then ultrasonicated and centrifuged at $13\,000\times g$ at 4°C for 30 min. Protein samples were quantified using a BCA protein determination kit (Thermo Scientific, Waltham, MA, USA) and concentrations were determined using a spectrophotometer (MULTISKAN MK3, Thermo Scientific). Subsequently, the samples were mixed with 5× sample buffer, balanced with double distilled water, and heated at 100°C for 5 min. An equal amount of protein in each sample was separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis on a 10% gel and then electrophoretically transferred to a polyvinylidene fluoride membrane (Bio-Rad, Hercules, CA, USA). Blocking was performed with 10% skim milk in Tris-buffered saline and Tween-20 (0.1%) (TBST) for 2 h. Then the membranes were immunoblotted with primary antibodies (RNF146, 1:1000, ab2736529, Invitrogen, USA; IL-6, 1:1000, ab9324, Abcam, USA; IL-10, 1:1000, DF6894, Affinity Biosciences, China) overnight. After being incubated with secondary antibody (1:5000, anti-rabbit antibody, ab150077, Abcam), signal detection was performed by Odyssey infrared laser imaging system, followed by gray intensity analysis.

RT-PCR

Total RNA of the hippocampus was extracted using TRIzol reagent according to the manufacturer's protocol (TransGen Biotech). The reaction system was configured with a real-time quantitative PCR kit using 2 µL DNA as a template, and the reaction was amplified *in vitro* by quantitative PCR. The expression level of miR-RNF146 (internal reference GAPDH) was analyzed using the $2^{-\Delta\Delta CT}$ method. The primers used for real-time fluorescent quantitative PCR are shown in Table 1. The primers and sequencing reactions were sent to Shanghai Sangong Bioengineering Co., Ltd.

ELISA

The hippocampus was homogenized with an extraction buffer containing 5 mol/L guanidine hydrochloride in 50 mmol/L Tris-HCl and a protease inhibitor cocktail containing a serine protease inhibitor AEBSF, according to the manufacturer's instructions (Jiang Lai, China). In brief, the samples were centrifuged at $16\,000\times g$ for 20 min at 4°C and the supernatant was diluted from 1:2 to 1:10, added to ELISA plates coated with anti-mouse IL-6 or IL-10 antibody, respectively, and then incubated for 2 h at RT. After the samples were washed, they were incubated with 100 µL of IL-6 or IL-10 detection antibody for 1 h at RT, washed, and incubated with 100 µL of horseradish peroxidase labeled anti-rabbit antibody for 30 min at RT. Then the stop solution was added, and absorbance was measured at 450 nm with a spectrophotometer (Nanodrop2000C, ThermoScientific). The protein samples were quantified using an ELISA assay kit (Jiang Lai, China) and the concentration was determined with a spectrophotometer. The concentration of IL-6 and IL-10 was expressed in pg/mg tissues.

Immunofluorescence

All six animals in each group were deeply anesthetized with 5% chloral hydrate, infused with normal saline through the cardiac vein, and bled simultaneously in the right atrium. The animals were given 4% paraformaldehyde in 0.1 mol/L phosphate buffer (pH of 7.4) 24 h after MWM. The brain was removed and stored overnight in 4% paraformaldehyde at 4°C. Continuous 30-µm coronal sections were cut from the frozen samples using a cryoslicer (Thermo Scientific HM430, Microm, Germany). The frozen sections were warmed at RT for 30 min and washed three times with TBS for 5 min each. The sections were blocked with 5% BSA and incubated with antibodies overnight at 4°C (RNF146, 1:200, ab2736529 Invitrogen, USA; IL-6, 1:200, ab9324, Abcam, USA; IL-10, 1:200, DF6894, Affinity Biosciences, China). Then the samples were washed three times with TBS, incubated with CY3-labeled goat anti-rat IgG (H+L) (1<500) at RT for 3 h, and washed with TBS three times for 10 min each. The tablets were sealed with anti-fluorescence quenching tablets containing DAPI (4',6-diamidino-2-phenylindole) and photographed using a fluorescence microscope (The Chongqing Optical Instrument Factory). Average fluorescence intensity was analyzed using the image analysis software ImageJ1.48. The coronal plane of brain tissue in the hippocampus was included in the samples of three rats in each group for observation and analysis. The middle piece was selected to be photographed, and the average fluorescence intensity of CA1 in the hippocampus of each sample was calculated to compare differences between groups.

Statistical analysis

Data were analyzed using the SPSS21.0 software (SPSS Inc., Chicago, IL, USA). Measurement data were expressed as mean ± standard deviation (mean ± S.D.).

Table 1. Primers used for real-time fluorescent quantitative PCR

Primer name	Primer sequence (5′–3′)
RNF146-sense	ATAAGAAGGCGAGTGAGACC
RNF146-anti	AGGGCAGACTGACTGGATGA
GAPDH-sense	ACAACTTTGGCATTGTGGAA
GAPDH-anti	GATGCAGGGATGATGTTCTG

Figure 1. Behavioral changes in aged rats after anesthesia and surgery

One-way analysis of variance (ANOVA) was used to compare means between groups, SNK-q test (Student-Newman-Keuls) was used for pairwise comparison, and repeated measures analysis of variance was used for the water maze test. *P*<0.05 was considered statistically significant, and the test level of homogeneity of variance was 0.1.

RESULTS

Learning and memory ability before anesthesia and surgery

The water maze and IntelliCage experiments were conducted to evaluate the learning and spatial memory ability of rats before anesthesia and surgery. The repre-sentative tracking's of rats' movement in the test session were shown in Fig. 1A. During the positioning naviga-tion stage of the water maze experiment, no statistical-ly significant differences were observed in the learning abilities of the rats in the AS and con groups (Fig. 1B, 1C). During the free exploration and nose-poke learning stage in the IntelliCage system, no statistically significant differences were observed in the total number of cor-ner visits and lickings between the AS and con groups (Fig. 1G, 1H). The results showed that the two groups' cognitive learning ability was the same under normal conditions. The test was performed at the end of spatial learning on day 5. The learning ability level of the two groups was the same, with no statistically significant dif-ference (Fig. 1B). The influence of individual differences and groups on the experiment was excluded.

Figure 2. Neuroinflammatory response was induced in aged rats after anesthesia and surgery

Anesthesia and surgery induced decrease in learning and memory and decreased purposeful behavior.

The rats underwent behavioral evaluation after anesthesia and surgery. In the water maze experiment, compared with the con group, the escape latency of rats 1, 3, and 7 d after surgery in the AS group was longer (Fig. 1D) and the number of platform crossings was smaller (Fig. 1E). In the AS group, the escape latency time was the longest (Fig. 1D) and the number of platform crossings was the lowest (Fig. 1E) on day 3 after surgery compared with days 1 and 7 after surgery, whereas the parameters in the con group were not statistically different (Fig. 1F). During the spatial learning exploration in the IntelliCage experiment, the number of correct accesses and licks was significantly lower in the AS group than the con group (Fig. 1I), suggesting that learning and spatial memory decreased within 3 d after

the operation. In the inverse spatial learning exploration stage, the correct visits and licks of the AS group were significantly lower than those of the con group (Fig. 1J), suggesting that the learning and spatial memory ability of rats decreased within 7 d after anesthesia and operation. At the end of the experiment, the three groups of rats did not lose weight, excluding the interference of postoperative pain.

The nesting experiment was performed at the end of the water maze experiment 3 d after surgery. The con group rats tore most of the pieces of paper and the pieces were orderly stacked to build a complete nest, resulting in high nesting scores. Rats in the AS group tore a few pieces of paper, stacked a few pieces of paper or did not stack to build nests, with only embryonic nests or no nests, and the nesting scores decreased significantly (Fig. 1K). Compared with the con group, the difference

Figure 3 Expression of RNF146 in aged rats after anesthesia and surgery

was statistically significant (Fig. 1L). The results indicated that the executive function and daily activity ability of rats undergoing anesthesia and operation decreased.

Anesthesia and surgery induced changes in the levels of neuroinflammatory factors

To evaluate central nervous system inflammation in rats after anesthesia and surgery, we tested the expression of IL6 and IL-10 in the CA1 region of the hippocampus (Fig. 2A, 2E). Results from western blot analysis and immunofluorescence showed that the expression and fluorescence intensity of IL6 and IL-10 in the hippocampus of the AS group increased at 1, 3, and 7 d after surgery compared with those of the con group (Fig. 2B, 2D, 2F, 2H). In the AS group, the protein content and fluorescence intensity of IL-6 and IL-10 at 3 d after surgery were higher than those at 1 and 7 d after surgery (Fig. 2B, 2D, 2F, 2H). ELISA results were consistent with western blot and immunofluorescence tests (Fig. 2C, 2G).

Anesthesia and surgery induced changes in RNF146 expression

We detected changes in the expression of RNF146 in CA1 region after anesthesia and surgery (Fig. 3A). It shows that compared with the con group, the protein expression and fluorescence intensity of RNF146 in the hippocampus of the AS group increased 1, 3, and 7 d after surgery (Fig. 3B, 3D). Compared within the AS group, the protein expression and fluorescence intensity of RNF146 in the hippocampus of the AS group at 3 d after surgery were higher than those at 1 and 7 d after surgery. These results confirmed the high expression of RNF146 protein content and fluorescence intensity in neurons induced by anesthesia

and surgical stimulation in aged rats. The results of RT-PCR experiment showed that compared with the con group, the expression of miR-RNF146 in the hippocampus of the AS group was higher at days 1, 3, and 7 (Fig. 3C). In the AS group, miR-RNF146 in the hippocampi of rats 1 day after surgery was lower than that in rats 3 d after surgery ($p < 0.05$), and miR-RNF146 in the hippocampal region of rats 3 d after surgery was lower than that in rats 7 d after surgery (Fig. 3C).

Correlation analysis of RNF146 with behavioral and neuroinflammatory factors

Experimental data parameters were analyzed by hierarchical clustering and correlation testing. Figure 4 shows the correlation between RNF146, inflammatory cytokines IL-6, IL-10, and behavioral data. The relative expression of RNF146 was positively correlated with the relative expression of inflammatory factors IL-6 and IL-10 (Fig. 4) and was negatively correlated with the escape latency in the water maze experiment, which showed significant correlation ($p<0.05$). It is indicating that after anesthesia/surgery, the expression of endogenous brain protective protein RNF146 is associated with hippocampus-dependent cognitive impairment and central nervous system inflammation. The expression of RNF146 was negatively correlated with the number of times that rats crossed the platform in the water maze, again demonstrating its correlation with hippocampus-dependent cognition. In addition, the correlation coefficients between RNF146 expression and cognition-related indicators in the IntelliCage system were concentrated between 0.1 and 0.4, but the correlation was not significant.

Figure 4. Heat maps of RNF146 and parameters of anesthesia and surgical induction in rats

DISCUSSION

The study investigated the involvement of RNF146 induced by anesthesia and surgery in aged rats and dissected the molecular mechanism underlying this regulation. Ho Chul Kang stated that RNF146 regulates cell survival and DNA repair by ubiquitinating PAR and blocking AIF nuclear translocation to inhibit parthanatos cell death (Kang et al., 2011). In the oxygen and glucose deprivation/reoxygenation (OGD/R) model, NPD1 induces activation of the Wnt/β-catenin pathway through upregulation of RNF146, enhanced cell survival, decreased oxidative stress markers, and a lower level of autophagy (Mu et al., 2020). With reference to Ismail Nurul Iman and others (Iman et al., 2021), this study combined the IntelliCage experiment and the traditional water maze experiment and nesting evaluation of elderly rats to assess learning and memory and ability to care for themselves. The findings revealed that learning and memory and ability for daily living of aged rats after anesthesia decreased on days 1, 3, and 7 after surgery, and the abnormal neurobehavioral function recovered on day 7 after surgery. Clinical evidence also shows that POD occurs mostly within 24–72 h after surgery. Most patients heal within 1 week, but some patients may develop long-term cognitive dysfunction. Animal experiment studies have shown that the appropriate time period for observing delirium-like behavior changes in rodents after anesthesia is 24–48 h, and neurobehavioral changes are the most obvious at this time. These results are consistent with our findings. Neuroinflammation causes delirium after general anesthesia in rodents (Cao et al., 2010; Dong et al., 2016). In animal models, the synthesis and release of proinflammatory factors can damage nerve formation and synaptic plasticity and nerve repair function (Belarbi et al., 2012; Liu et al., 2018). Studies have shown that anesthesia and surgery increase the level of IL-6 in the hippocampi of aged wild-type mice, resulting in cognitive dysfunction in aged mice. The use of the IL-6 antibody can improve cognitive dysfunction after peripheral trauma in aged wild-type mice. In addition, anesthesia did not affect the level of IL-6 in the hippocampi of IL-6 gene knockout rats, nor did it lead to cognitive impairment in aged IL-6 gene knockout rats, suggesting that the increase of IL-6 may be involved in the cognitive dysfunction caused by anesthesia surgery (Dong et al., 2016; Naveed et al., 2022; Muhammad AS et al., 2023; Waseem et al., 2023). After anesthesia surgery, aged rats exhibited impaired spatial memory and significantly higher expression of inflammatory factor IL-6 within 1 and 3 d after surgery. Spatial memory is improved, and the expression of inflammatory factors is downregulated 7 d after surgery (Cao et al., 2010). Studies have indicated that IL-10 is not only closely related to autoimmune diseases and infectious diseases, but also has neuroprotective effects in cerebral ischemia, hypoxia, and chronic nervous system diseases (Morris et al., 2018; Sudheimer et al., 2014; Wang et al., 2019). Furthermore, in in vitro experiments, M2-type microglia produced IL-10 and TGF-β to reduce the neuronal cell damage caused by OGD, and this response was downregulated when the damage or pathogen was removed (Ahmad et al., 2023; Zhao et al., 2017). Li et al. reported that in the rat model of acute cerebral ischemia, IL-10 increased sharply 6 h after surgery, suggesting the activation of the anti-inflammatory system (Li et al., 2001). In clinical studies, IL-10 in acute cerebral infarction began to rise at 24 h after surgery, reached a peak at 3 d after surgery, and then gradually decreased (van Exel et al., 2002) IL-10 has similar biological activities in humans and mice (Moore et al., 2001). In our study, the expressions of IL-6 and IL-10 in the hippocampi of aged rats at 1, 3, and 7 d after anesthesia were higher than that in the control group, and the expressions increased most significantly on day 3 after anesthesia. Our findings coincide with the results of other studies, suggesting that inflammatory and anti-inflammatory effects exist simultaneously in the nervous system after anesthesia and surgery.

RNF146, also known as Iduna, has two important functional regions in its N terminus: E3 ubiquitin ligase active region and PAR binding region, and the C3HC4 RING finger domain in amino acids 35–77 showed E3 ubiquitin ligase activity (Belayev et al., 2017; Koo et al., 2018). When glutamate excitatory toxicity, oxygen glucose deprivation, and other sublethal stimuli caused neuronal damage, RNF146 could recognize PARP1 to ubiquitinate and degrade axin/tankyrase through WWE domain-mediated PARP1, positively regulate Wnt/β-catenin signaling pathway, and inhibit autophagy-induced death. It can reduce the excitatory toxicity of glutamate and damage of neurons induced by oxygen and sugar deprivation, and play a role in protecting neurons from damage (Mu et al., 2020). In addition, RNF146 binds to apoptosis-inducing factor, a key death molecule in the parthanatos death pathway, and prevents the nuclear translocation of apoptosis-inducing factor in the mitochondria (Andrabi et al., 2011). Thus, glutamate and NMDA receptor excitotoxicity-mediated cell parthanatos death is inhibited and brain protective effect is generated (Yang et al., 2017). The Wnt signaling pathway plays an important role in POD. A study showed that treatment with 3.6% sevoflurane for 6 h inhibited the Wnt/b-catenin signaling pathway, thereby increasing GSK-3 β- and decreasing β-catenin. By inhibiting this pathway, sevoflurane downregulates annexin A1, thereby breaching the blood–brain barrier and inducing POD. However, it is unclear whether increasing the expression of RNF146 can activate the Wnt/β-catenin pathway and increase the concentration of β-catenin, thus inhibiting the occurrence of POD (Hu et al., 2016). However, our findings revealed that the expression of RNF146 in the hippocampi of aged rats increased 1, 3, and 7 d after surgical anesthesia, especially on day 3, when the increase was the most obvious. This change was consistent with

neurobehavioral changes and expression of neuroinflammatory factors IL-6 and IL-10 in the brain. Correlation analysis showed that the relative expression of RNF146 was positively correlated with the relative expression of inflammatory factors IL-6 and IL-10, as well as the escape latency in the water maze experiment, with the correlation coefficients being 0.90 and 0.99, respectively, and the correlation was significant.

RNF146 is an endogenous protective protein. When the body receives injury, RNF146 increases its reactivity and defends against external injury. Studies have confirmed this phenomenon. After exposure to low-dose NMDA and sublethal OGD or transient bilateral common carotid artery occlusion, the expression of RNF146 in mice nerve cells significantly increased to protect the nerve cells from injury. RNF146 may play the same role as anti-inflammatory factors such as IL-10 in the occurrence of POD.

CONCLUSION

Our findings reveal that after anesthesia and surgery, rat spatial learning and memory ability decreases and RNF146 expression increases and the level of IL-6 and IL-10 increases. Hierarchical cluster analysis showed that the expression of RNF146 was related to the degree of central nervous system inflammation and spatial learning and memory impairment. RNF146 may play a neuroprotective role similar to that of the anti-inflammatory factor IL-10. However, the mechanisms involved need to be investigated. In addition, the limitation of this study is that RNF146 was not knocked down or overexpressed in rats to verify the mechanism of action of RNF146 in POD. This will be a topic of research for the future.

Understanding mitochondrial potassium channels: 33 years after discovery

Adam Szewczyk*

Laboratory of Intracellular Ion Channels, Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warsaw, Poland

Mitochondrial investigations have extended beyond their traditional functions, covering areas such as ATP synthesis and metabolism. Mitochondria are now implicated in new functional areas such as cytoprotection, cellular senescence, tumor function and inflammation. The basis of these new areas still relies on fundamental biochemical/biophysical mitochondrial functions such as synthesis of reactive oxygen species, mitochondrial membrane potential, and the integrity of the inner mitochondrial membrane i.e., the passage of various molecules through the mitochondrial membranes. In this view transport of potassium cations, known as the potassium cycle, plays an important role. It is believed that K^+ influx is mediated by various potassium channels present in the inner mitochondrial membrane. In this article, we present an overview of the key findings and characteristics of mitochondrial potassium channels derived from research of many groups conducted over the past 33 years. We propose a list of six fundamental observations and most important ideas dealing with mitochondrial potassium channels. We also discuss the contemporary challenges and future prospects associated with research on mitochondrial potassium channels.

KEYWORDS

mitochondria, potassium channels, reactive oxygen species, cytoprotection, potassium channel openers

Introduction

When investigating the fundamentals of mitochondrial function within cells, we can identify several simple cations that form the basis of many processes (Szabo and Zoratti, 2014). It is well known that the proton gradient serves as the driving force for ATP synthesis in mitochondria. The Ca^{2+} cations entering the mitochondria not only buffer the cytosolic pool of these ions but can also contribute to some physiological situations such as the mitochondrial mega-channel activation (Carraro and Bernardi, 2023; Zoratti et al., 2024). The effects of Mg^{2+} on mitochondrial functions such as energy metabolism, mitochondrial Ca^{2+} handling, and apoptosis are well established (Liu and Dudley, 2020). Mitochondrial Na^+ have been discovered as a new second messenger regulating inner mitochondrial membrane (IMM) fluidity and reactive oxygen species (ROS) generation by respiratory chain complex III (Hernansanz-Agustín and Enríquez, 2022). In this study, we will focus on the properties and the role of K^+ transport, via potassium channels

FIGURE 1
Potassium channels identified in the inner mitochondrial membrane. All these types of channels were described in the manuscript. Additionally, the biophysical role in mitochondria and physiological role within the cell is summarized. VDAC, voltage dependent anion channel (porin).

(mitoK channels) present in IMM (Szewczyk, 1996; Kicinska et al., 2000; Debska et al., 2001; O'Rourke, 2007; Singh et al., 2012; Szabo and Szewczyk, 2023) (Figure 1).

In general, proper mitochondrial function is based on the integrity of mitochondrial membranes. Peter Mitchell in his Nobel Lecture delivered in 1978 underlined the importance of the low permeability of the IMM to ions (Mitchell, 1985). Consequently, the discovery of multiple potassium channels in the IMM was for many years considered to be an experimental artifact. Nowadays, mitoK channels present in the IMM are recognized as crucial players for regulating some mitochondrial function (Kravenska et al., 2021; Szabo and Szewczyk, 2023). The mitoK channels have attracted attention for many years, especially in the context of the regulation of life/death processes in the various cell types (Garlid, 2000). For example, the activation of mitoK channels may induce cytoprotective phenomena in cardiac tissue and in neurons (O'Rourke, 2007). On the contrary, inhibition of mitoK channels may cause cell death (Checchetto et al., 2021).

In this paper, we will present what we consider to be the most significant discoveries/ideas in the field of mitoK channels over the past 33 years. These subjective, proposed by author, list of six the most important observations are as follows: 1). Discovery of mitoK channels in various tissues and identification of their molecular identity; 2). Cytoprotection (cardioprotection, neuroprotection) induced by mitoK channels activation; 3). Cancer cell death by mitoK channels inhibition; 4). Role of mitoK channels in aging/senescence/life span; 5). Interactions of mitoK channels with respiratory chain; 6). Druggability of the mitoK channels.

Mitochondrial potassium channel discovery

In 1991, an ion channel selective for K^+ was discovered in the IMM of rat liver mitochondria (Inoue et al., 1991), confirming previous findings on channels in mitochondria by Catia Sorgato (Sorgato et al., 1987). However, what significantly altered the interpretation of this experimental data was the revelation that the channel exhibited not only K^+ selectivity but also susceptibility to inhibition by ATP and the antidiabetic sulfonylurea, glibenclamide (Inoue et al., 1991). This discovery situated mitoK channels within a similar family to ATP-regulated potassium channels found in the plasma membrane of pancreatic beta-cells, cardiomyocytes, neurons, and others (Szewczyk, 1996; O'Rourke, 2007). Undoubtedly, this observation served as a pivotal starting point for numerous experiments identifying ATP-regulated mitochondrial potassium (mitoK$_{ATP}$) channels across various tissues, notably cardiomyocytes (Szewczyk et al., 2009; Szabo and Szewczyk, 2023). Following several years of intensive investigation across multiple laboratories into the functional role of these channels, it was demonstrated that the activation of mitoK$_{ATP}$ channels (by potassium channel openers) induces a cardioprotective phenomenon (Liu et al., 1999; Garlid, 2000; Szteyn and Singh, 2020; Lukowski et al., 2022). Subsequently, similar findings in neural tissue suggested the involvement of these channels in neuroprotection (Busija et al., 2004; Bednarczyk, 2009). In summary, the association of mitoK$_{ATP}$ channels with cytoprotection marked a significant milestone in the rapid development of the mitochondrial potassium channel field. Moreover, other mitoK channels

(such as large conductance calcium-activated potassium—mitoBK$_{Ca}$ channels) were later implicated in cytoprotection across various cell types (Xu et al., 2002). Despite a plethora of observations, however, the biochemical mechanisms underlying these events remain unclear. It is probable that the indirect modulation of ROS generation by mitoK channels (via depolarization of mitochondria) contributes to this phenomenon.

In recent years, researchers have demonstrated that the family of mitoK channels constitutes one of the most numerous classes of mitochondrial channel proteins. They are also present in plants and in simple organisms (Koszela-Piotrowska et al., 2009; Matkovic et al., 2011; Laskowski et al., 2015). It includes not only mitoK$_{ATP}$ and mitoBK$_{Ca}$ channels but also intermediate conductance (mitoIK$_{Ca}$), and small conductance (mitoSK$_{Ca}$), voltage-regulated potassium (mitoKv1.3, mitoKv7.4) channels, mitochondrial hyperpolarization-activated cyclic nucleotide-gated (mitoHCN) channels, mitochondrial sodium-activated potassium (mitoSlo2) channel and two-pore domain potassium (mitoTASK-3) channel (Szabo and Szewczyk, 2023). The activity of potassium channels are regulated by various stimuli, such as pH, Ca^{2+} and ROS (Szabo and Szewczyk, 2023). The mitoK channels have been identified in many tissues but at the same time their number of molecules in mitochondrial membranes is relatively small compared to other mitochondrial transport proteins. Probably low density of mitoK channels and channel run down phenomenon were reasons for questioning in the 90's the presence of these channels at all.

Another issue regarding mitoK channels is the following: why is such a simple process, like K$^+$ influx into a matrix, facilitated by a wide variety of potassium channels? For example, in cardiac mitochondria, six mitoK channels have been identified: mitoK$_{ATP}$, mitoBK$_{Ca}$, mitoSK$_{Ca}$, mitoSlo2, mitoHCN channels and mitoKv7.4 channels (Szabo and Szewczyk, 2023). What is the physiological benefit of using many different ligands and factors to regulate these channels? Probably, potassium channels present in cardiomyocyte mitochondria are activated under specific physiological circumstances (Kulawiak et al., 2021). An early event during cardiac ischemia is ATP depletion. This is followed by mitochondrial membrane depolarization. Moreover, because of ATP depletion, ion pumps cannot function, leading to an increase in the cellular Ca^{2+} concentration. The rise in Ca^{2+} during ischemia and reperfusion leads to an overload of mitochondrial Ca^{2+}, during reperfusion when oxygen is reintroduced. The decrease in intracellular pH during severe ischemia promotes the imbalance of other cations and leading to cellular Na$^+$ overload (Kulawiak et al., 2021). These complex changes may lead to channel activation/inhibition possibly explains why there are few potassium channels in cardiac mitochondria. Most likely, the timing of ATP, pH, Ca^{2+}, and Na$^+$ concentration changes is

critical to control K$^+$ flux in mitochondria stabilizing structure of mitochondria.

Molecular identity of mitoK channels for many years was a mystery. Lack of molecular mitoK identity was an argument questioning the presence of potassium channels in mitochondria. Let's summarize this long way of channel molecular identity recognition. Today we believe that mitoBK$_{Ca}$ channel is one of the splice variants of KCNMA1 (Slo1) gene (Singh et al., 2013; Galecka et al., 2021). Properties of mitoBK$_{Ca}$ suggest that the pore-forming subunit is encoded by the same gene coding for plasma membrane BK$_{Ca}$. Several studies suggested that the VEDEC BK$_{Ca}$ isoform is located in the IMM. With the mitoK$_{ATP}$ channel there is a more complex situation. It can not be excluded that K$^+$ influx is catalyzed by 2-3 various proteins in various tissues. Recently, it was shown that the pore-forming subunit of the mitoK$_{ATP}$ channel is a product of the CCDC51 gene (Paggio et al., 2019). The mitoK$_{ATP}$ is inhibited by the antidiabetic sulfonylurea glibenclamide. Therefore, it was speculated that the glibenclamide receptor (product of ABC8/MITOSUR gene) is an integral part of the mitoK channel. Indeed the mitoK$_{ATP}$ channel formed by these two proteins has the established pharmacological properties of the mitoK$_{ATP}$ channel (Paggio et al., 2019). Previous studies showed that also the ROMK2 potassium channel isoform of the renal outer medullary potassium channel could be the component of the mitoK$_{ATP}$ channel (Bednarczyk et al., 2018; Laskowski et al., 2019). Detailed discussion on mitochondrial potassium channel molecular identity was recently reviewed (Szabo and Szewczyk, 2023).

The presence of various auxiliary β subunits in mitoBK$_{Ca}$ channels and sulfonylurea receptors in the mitoK$_{ATP}$ channel causes that, despite undoubted progress in the identification of channel proteins, the problem of their detailed identification is still a challenge for the future (Piwonska et al., 2008).

From cytoprotection to cell death

The mitoK channels have been described as an important player in cellular pro-life and death signaling. The activation of mitoK channels (by potassium channel openers), such as ATP-regulated or calcium-activated large conductance potassium channels, may have cytoprotective effects in cardiac or neuronal tissue (Liu et al., 1999; Busija et al., 2004). This concept was a strong driving force of studies in many laboratories. Potassium channel opener induced cytoprotection is also induced by endogenous signaling via protein kinases (Frankenreiter et al., 2017).

It has also been shown that inhibition with channel blockers of the mitochondrial Kv1.3 channel may lead to pancreatic cancer cell death (Leanza et al., 2014). But still there is an open question to what extent mitoK channels are promising drug targets in various organs and tissues? Future prospects of

the druggability concept of mitoK channels was evaluated recently (Wrzosek et al., 2020).

Searching for new functions of mitochondrial potassium channels

The putative functional roles of these channels involve alterations in mitochondrial matrix volume, mitochondrial respiration, and protonmotive force (membrane potential) (Czyz et al., 1995). Furthermore, the activity of these channels influences the generation of ROS by mitochondria (Kulawiak et al., 2008; Kulawiak et al., 2023). The activity of mitochondrial potassium channels is subject to modulation by various intrinsic signals, including Ca^{2+} concentration, membrane potential, phosphorylation, and membrane stretching (Szabo and Szewczyk, 2023).

It was demonstrated that BK_{Ca} channels are present in *Drosophila melanogaster* mitochondria, and channel mutants induce structural and functional defects in mitochondria leading to an increase in ROS (Gururaja Rao et al., 2019). It was found that the absence of BK_{Ca} channels reduced the lifespan of *Drosophila*, and overexpression of human BK_{Ca} channels in flies extends their life. This suggested a potential role of mitoK channels and ROS in regulating mitochondrial functional integrity, and lifespan (Gururaja Rao et al., 2019). Probably mitoBK$_{Ca}$ play a role in cellular senescence induced by oxidative stress (Gluchowska et al., 2023).

Mitochondrial context of potassium channel regulation

The mitochondrial respiratory chain comprises a series of complex organized redox reactions generating a protonmotive force and, consequently, ATP synthesis. Certain redox centers, such as complexes I and III of the mitochondrial respiratory chain are sources of ROS. Mitochondrial generated ROS can influence remotely the activity of mitoK channels. But there are some indications proposing an alternative, a direct mechanism for the regulation of mitoK channels by the respiratory chain.

It is well-known that mitoK channels interact with various mitochondrial proteins, some of which are involved in the respiratory chain. These observations were recently summarized (Lewandowska et al., 2024). For instance, it has been suggested that mitoK$_{ATP}$ channels interact with succinate dehydrogenase. In cardiac mitochondria, it was found that the β1 subunit of the mitoBK$_{Ca}$ channels interacts with Cytochrome c Oxidase (COX) subunit I. Furthermore, studies have demonstrated that other respiratory chain protein complexes interact with mitoBK$_{Ca}$ channels in both cardiac and brain mitochondria. Additionally, mitochondrial tandem pore domain K^+ channels TASK-3 interact also with the respiratory

chain. A recent report revealed a similar interaction between the mitoKv1.3 channel and respiratory chain complex I (for review see Lewandowska et al., 2024).

We found that the activity of mitoBK$_{Ca}$ channels in glioblastoma cells is regulated by substrates and inhibitors of the respiratory chain (Bednarczyk et al., 2013). This study suggested that COX is a key element of this kind of channel regulation (Bednarczyk et al., 2013). Moreover, given that COX is the primary infrared-absorbing protein, it raises questions about the potential light regulation of mitoK channels (Szewczyk and Bednarczyk, 2018).

Further research will be important to clarify the functional consequences of these interactions. Undoubtedly, this form of regulation may prove to be unique for mitoK channels. The exact nature and functional implications of these interactions remain unclear. This kind of direct functional coupling between the energy generating system (respiratory chain) with the energy dissipation system (potassium channels) may lead to an interesting putative regulatory mechanism in mitochondria.

Recently other functional/structural coupling within the mitochondrial potassium channel was observed. It was found that mitochondrial potassium channel ROMK2 may interact with two lipid kinases: acylglycerol kinase (AGK) and diacylglycerol kinase ε (DGKE), which are localized in mitochondria (Krajewska et al., 2024). Additionally, it was found that the products of AGK and DGKE, lysophosphatidic acid (LPA) and phosphatidic acid (PA), stimulated the activity of ROMK2 potassium channels reconstituted in planar lipid bilayers (Krajewska et al., 2024).

The structure/function interplay of mitoK channels alongside other mitochondrial proteins suggests a new dimension in mitoK channels regulation. The exceptionally high membrane potential of the IMM and its potential for ROS generation may characterize significant signaling pathways within cells.

The troublesome pharmacology of mitochondrial potassium channels

In order to influence activity of various mitoK channels, numerous research groups continually explore novel compounds hoping to find molecules with high specificity for mitoK channels (Szewczyk and Marban, 1999; Augustynek et al., 2017; Leanza et al., 2019). The existing literature already reports positive protective effects on ischemia/reperfusion processes through the activation of mitoK$_{ATP}$ channels by the potassium channel opener - diazoxide, and the mitoBK$_{Ca}$ channels by potassium channel opener NS1619 and its follower NS11021 (Szewczyk et al., 2006). Nevertheless, it is noteworthy that these compounds exhibit limited specificity towards mitoK channels. Application of these substances in the micromolar concentration range unmasks a variety of side effects (Wrzosek et al., 2022). It is

important to remember that molecules with some hydrophobicity of positive charge (in physiological pH) will be accumulated by mitochondria. It is due to very high membrane potential (up to—180 mV) on the IMM, with negative polarization of the mitochondrial matrix. For example, a 10 nM drug present in cytosol could accumulate up to 10 µM concentration in a matrix (Kowaltowski and Adbulkader, 2024). At this concentration range the probability of nonspecific interaction with some of ~1,500 mitochondrial proteins is very high. In contrast, toxins isolated from the venom of various scorpion species such as iberiotoxin specifically (at low concentration) inhibit the activity of mitoBK$_{Ca}$ channels (Augustynek et al., 2017). But application of this peptide to block mitoBK$_{Ca}$ channels on intact cells is practically impossible.

Developing very selective channel blockers and potassium channel openers targeting mitoK channels is a significant challenge in this field. Recently it was shown that selective targeting of mitoIK$_{Ca}$ channel (Bachmann et al., 2022), mitoTASK channel (Bachmann et al., 2021) and mitoKv channel (Severin et al., 2022) is possible.

Discussion

Over the past 33 years since the identification of the first potassium channel in the IMM, research in this field has made significant progress (Kulawiak and Szewczyk, 2022). This pathway started from identification of the mitoK channels that met with skepticism by the bioenergetics community to current research placing these channels in the phenomena of cytoprotection, cellular senescence, and neoplastic cell death. What limits further development of this field?

First, access to good pharmacology is the "dark side" of this field (Szewczyk et al., 2010; Olszewska and Szewczyk, 2013; Leanza et al., 2019). Because mitoK channels are similar to those located in plasma membranes, it is very difficult to identify pharmacological modulators specific only for mitoK channels (Szewczyk and Wojtczak, 2002; Citi et al., 2018). The unique high membrane potential of mitochondria may help to discriminate targeting of some drugs to mitoK channels (Testai et al., 2015; Wrzosek et al., 2020).

The second limiting factor for further progress is the development of new techniques to measure channel activity *in situ*, that is, within an intact cell. Majority of techniques currently applied in the studies are based on cell fractionation and mitochondria isolation (Walewska et al., 2022). By definition in this process we lose a network of signaling pathways where mitoK channels are potentially involved

(Walewska et al., 2018). Probably progress in synthesis of potassium specific fluorescent probes may solve this problem. Unfortunately, there are other potassium transport proteins in mitochondria.

The third challenge for the future involves further identifying the molecular identity of various mitoK channels. This aim will not only expand our understanding of the system but also will start new avenues of research, such as *in vitro* translation with lipid nanodiscs and the application of various biophysical techniques. Additionally, it will aid in the identification of protein neighborhoods, clarification of the import machinery, and more.

In summary, mitoK channels, considered the "younger siblings" of the potassium channels found in plasma membranes, play a crucial role in some cellular signaling pathways. The mitoK location within mitochondria, which serve as hubs for fundamental metabolic and signaling functions, highlight their significance. The author believes that the future of this field holds exciting prospects.

PELP1 and SRC kinase as important molecules in the estrogen-mediated pathway in human testis and epididymis

Izabela Skibińska[1]✉, Mirosław Andrusiewicz[1], Magdalena Jendraszak[1], Aleksandra Żbikowska[1], Czesław Żaba[2] and Małgorzata Kotwicka[1]

[1]Chair and Department of Cell Biology, Poznan University of Medical Sciences, Poznań, Poland; [2]Chair and Department of Forensic Sciences, Poznan University of Medical Sciences, Poznań, Poland

Background: Estrogens have pleiotropic mechanisms of action, and their cellular transduction pathways can modulate various proteins with differential tissue expression. Proline-, glutamic acid-, and leucine-rich protein 1 (PELP1) is one such protein whose role seems important. However, very little is known about the expression of modulators involved in the estrogen-mediated pathways in the tissues of the male reproductive tract. **Methods:** In this study, we obtained autopsy specimens of testis and epididymis from 13 men of Caucasian descent. Expression levels were analyzed for both estrogen receptors (*ESR1* and *ESR2*) and their co-regulators, including *PELP1* and kinase c-Src (*SRC*). **Results:** Protein expression was confirmed with western blot and immunocytochemistry techniques. The expression of both *SRC* and *PELP1* was significantly higher in the testis compared to the epididymis (*p*=0.040 and *p*=0.002, respectively). Furthermore, a significant, positive correlation was observed between *SRC* and *PELP1*, regardless of tissue type (*p*<0.0001, R=0.78). In the testis, *PELP1* expression positively correlated with *ESR1* expression (*p*=0.0367, R=0.6). **Conclusions:** Our study suggests a possible relationship between PELP1, SRC, and ESR1 in the human testis and epididymis. This study makes a valuable contribution to the field of estrogen-mediated pathways in the male reproductive tract and describes trends of analyzed genes' expression and presence. We think our results may open some new research directions in the study of estrogen signaling in the male reproductive system.

Keywords: estrogen receptors (ESR1 and ESR2); proline-, glutamic acid-, and leucine-rich protein 1 (PELP1); proto-oncogene tyrosine-protein kinase c-SRC (SRC); steroid hormones; human testis; human epididymis

Abbreviations: BC, basal cells; CC, ciliated cells; Cr, concentration ratio; ESR1, estrogen receptor 1; ESR2, estrogen receptor 2; GPER, GPR30, G protein-coupled estrogen receptors; HPRT1, hypoxanthine-guanine phosphoribosyltransferase; IT, interstitial tissue; LC, Leydig Cells; MNAR, modulator of non-genomic action of estrogen receptor; nCC, non-ciliated cells; PELP1, proline-, glutamic acid-, and leucine-rich protein 1; Psp, primary spermatocytes; S, spermatozoa; SC, Sertoli cells; SEC, seminiferous epithelium cells; Sd, spermatids; Sg, spermatogonia; SRC, proto-oncogene tyrosine-protein kinase c-SRC

INTRODUCTION

The predominant paradigm concerning the influence of steroid hormones in the regulation of the male reproductive tract's functions was primarily focused on androgens such as testosterone. However, in 1990 knock-out animal models began to be extensively used and demonstrated that estrogens play an important role in male reproductive health (Carreau *et al.*, 2011a; Akingbemi, 2005; Carreau *et al.*, 2011b; Chimento *et al.*, 2020; Hess & Cooke, 2018). These commonly considered female hormones are indispensable for the proper development of certain structures within the male reproductive tract, such as the prostate, epididymis, and efferent ductules. Estrogens are synthesized in the testis, and 17β-estradiol is highly expressed in the rete testis fluid. Studies have shown that the male reproductive tract has extensive expression of both estrogen receptors (ESRs), namely ESR1 and ESR2, starting from the neonatal period through puberty to adulthood. However, expression level differs with regard to tissue type and age (Cooke *et al.*, 2017; Cunha *et al.*, 2021; Hess & Cooke, 2018). Several findings also confirmed an association between estradiol and a handful of physiological events such as erectile function, spermatogenesis, Leydig cell self-regulation, testosterone production control, and auto- and paracrine effects on germ cells (Hess & Cooke, 2018; Solakidi *et al.*, 2005; Carreau *et al.*, 2011a; Cooke *et al.*, 2017; Hammes & Levin, 2019; Lazari *et al.*, 2009). Furthermore, the identification of an aromatase function has been a tremendous breakthrough in defining the role of estrogens in males (Carreau *et al.*, 2006; Otto *et al.*, 2009; Akingbemi, 2005; Rago *et al.*, 2007; Carreau *et al.*, 2010; Aquila *et al.*, 2003) and has directed the attention of many researchers around the world to the influence on the male reproductive tract of estrogen-like compounds present in the environment (referred to as "xenoestrogens"). Previously, the idea of the potential negative influence of estrogens and their role in disrupting the function of the male reproductive system has become widespread (Rahman *et al.*, 2015; Mohamed *et al.*, 2011; Sikka & Wang, 2008; Hess *et al.*, 2011; Bertolla, 2020).

The commonly identified pathways that control the functional influence of estrogens on the tissues/cells of interest (including those in the male reproductive tract) classically involve either ESR or G protein-coupled estrogen receptors (GPER, GPR30). It cannot be excluded that recently discovered novel proteins, referred to as putative ESRs (estrogen-related receptor, saxiphilin-binding protein, ER-X, and ER-x), may play a similar role in mediating estrogen signals in males (Barut *et al.*, 2020; Li *et al.*, 2015; Eyster, 2016; Micevych & Dewing,

2011; Toran-Allerand et al., 2002; Cooke et al., 2017; Akingbemi, 2005). It is also essential to highlight the role of certain co-regulators in mediating estrogen signals in tissues/cells of interest. One of them is the scaffold protein proline-, glutamic acid-, and leucine-rich protein 1 (PELP1), also known as MNAR (modulator of nongenomic action of estrogen receptor). PELP1 was shown to interact not only with nuclear receptors and transcription factors (such as activator protein 1, specificity protein 1, or nuclear factor kappa B) but also with several key modulators of cell cycle progression, such as protooncogene tyrosine-protein, epidermal growth factor receptor, phosphoinositide-3 or c-SRC kinases (Vadlamudi & Kumar, 2007; Sareddy & Vadlamudi, 2016; Vadlamudi et al., 2001). This previous literature has shown PELP1 to be an important mediator of steroid hormone regulation of cell or tissue functions. Moreover, our previous studies demonstrated that the percentage of PELP1+ sperm cells is correlated with decreasing sperm quality (Skibińska et al., 2018). Also, our investigation revealed weak, negative ESR2/PELP1 correlations in patients with abnormal sperm values. Interestingly, SRC/PELP1 was moderately and positively correlated with all parameters within the WHO reference range in the subgroup of patients (Skibińska et al., 2022). The literature has identified that SRC-mediated signaling is coordinated by binding PELP1 and ESR to SRCs SH3 and SH2 domains, which is then stabilized by the ESR-PELP1 interaction through PELP1's LXXLL motifs (Xiao et al., 2019; Shupe et al., 2011; Barletta et al., 2004). SRC has been characterized as the downstream protein kinase of the non-classical testosterone signaling pathway involved in the release of sperm at spermiation. It cannot be excluded that close interactions between these two proteins have implications for estrogen signaling in males.

Despite the broad availability of animal models for research purposes, this is not the case for human tissues. Therefore, data regarding estrogens and estrogen-mediated pathways in humans do not currently provide clear answers concerning the presence, localization, and interactions between proteins involved in estrogen-mediated signaling. It appears crucial in determining the potential clinical repercussions of estrogens in the male reproductive tract, also in the context of impaired male fertility. Where and when estrogen and/or an estrogen/androgen balance might play a role in the development and function of the male reproductive tract needs to be determined. It is expected that with recent advances in molecular and cell biology techniques, many questions about estrogen-mediated signaling in men will be answered within the next decade. The aim of this study was to analyze the potential links between ESRs, PELP1, and SRC in human testis and epididymis, as these proteins are considered important factors involved in estrogen-mediated signaling in the male reproductive system.

MATERIALS AND METHODS

Testes tissue samples

Autopsy specimens of testis and epididymis were obtained from 13 men of Caucasian descent at the Chair and Department of Forensic Medicine of PUMS. The mean age of participants was 45±15 years (range: 23–76) with a 45% coefficient of variation. Tissues qualified for the study came from men with no significant spermatogenesis disorders. The assessment of tissues stained with the standard hematoxylin and eosin method was based on the microscopic evaluation, accordingly to Cerilli et al. (Cerilli et al., 2010). Each testis and epididymal caput sample was split into three fragments (equal in mass). For RT-qPCR analyses, the tissues were immersed in RNA protective medium (Englert-Golon et al., 2021; Camacho-Sanchez et al., 2013), and for protein isolation were placed in phosphate-buffered saline (PBS, Chempur; Piekary Śląskie, Poland). In both cases, the tissues were stored at –80°C until further procedures. The third portion, intended for immunohistochemistry, was fixed in 4% paraformaldehyde (Chempur; Piekary Śląskie, Poland) and processed for standard formalin-fixed paraffin-embedding.

METHODS

Nucleic acid isolation and validation

Before nucleic acid isolation, the samples were thawed to room temperature. The RNA protective medium was removed, and testis and epididymis tissue samples were patted dry with a paper towel. The tissues were immediately placed in a chilled mortar and pulverized with a pestle. Aliquots of 25 mg of tissue were immersed in 800 μL fenozol reagent to deactivate endogenous RNases (A&A Biotechnology, Gdynia, Poland). The samples were dissolved by vortexing (15 sec, 1200 rpm, room temperature) and incubated in a thermal mixer to permit complete dissociation of the nucleoproteins (5 min, 300 rpm, 56°C). Then, 200 μL of chloroform (Avantor Performance Materials Poland S.A., Gliwice, Poland) was added to each aliquot, mixed by inversion, incubated (3 min, room temperature), and centrifuged (15 min, $12\,000{\times}g$, 4°C). The aqueous upper phase containing total cellular RNA was carefully transferred to a new tube, avoiding transferring the interphase.

The aqueous phases were subjected to high molecular weight RNA extraction, without microRNA fractionation, using the double-column system for microRNA and RNA isolation according to the manufacturer's protocol (A&A Biotechnology, Gdynia, Poland) as described previously (Englert-Golon et al., 2021). The quality, quantity, and purity of extracted RNA were analyzed as described previously (Andrusiewicz et al., 2016) with the use of NanoPhotometer NP-80 (IMPLEN, München, Germany), and the integrity was evaluated by electrophoretic separation under denaturing conditions (Andrusiewicz et al., 2016).

Reverse transcription and quantitative polymerase chain reaction

Three-step reverse-transcription reactions were performed as described previously (Andrusiewicz et al., 2016). In brief, a mixture of 0.5 M universal oligo(d)T_{10} primer, 1 mM random hexamer primer (Genomed; Warsaw, Poland), 1 μg RNA, and water (Thermo Fisher Scientific; Waltham, MA, USA) were incubated for 10 mins at 65°C, and samples chilled on ice. Then, 10 U transcriptor reverse transcriptase, 5 U RNasin ribonuclease inhibitor, 1× reaction buffer (Roche; Manheim, Germany), 0.1 U/μL E. coli poly(A) polymerase, 100 nM adenosine triphosphate (New England BioLabs; Ipswich, MA, USA), and 100 mM deoxyribonucleotide triphosphates (Novayzm; Poznan, Poland) were added with water to a final reaction volume of 20 μL. The subsequent steps of cDNA synthesis were followed as described previously (Englert-Golon et al., 2021). The cDNA was synthesized in duplicate for

each sample and subsequently served as a template for qPCR reactions. The threshold cycles mean values derived from replicated samples were used for further analysis.

To determine primer sequences and hydrolysis Universal Probe positions for *ESR1*, *PELP1*, and *SRC*, the UPL Assay Design Center was used (http://qpcr.probefinder.com, last accessed on September 28, 2017, product discontinued on December 30, 2020) (Skibińska *et al.*, 2018). Probe numbers and primers' sequences are as follows: *ESR1* F: CCTTCTTCAAGAGAAGTATTCAAGG; R: ATTCCCACTTCGTAGCATTTG; probe #69 (Roche cat. no.: 04688686001; GenBank AC: NM_001122740.2, NM_001122741.2, NM_001385571.1, NM_001291241.2, NM_001385568.1, NM_001385572.1, NM_001385570.1, NM_001385569.1, NM_000125.4, NM_001328100.2, NM_001291230.2), *PELP1* F: CAAGGAGGAGACTCACAGGAG; R: CAAGGAGGAGACTCACAGGAG; probe #24 (Roche cat. no.: 04686985001; NM_014389.3, NM_001278241.2), and *SRC* F: GCCATGTTCACTCCGGTTT; R: CAGCGTCCTCATCTGGTTTC; probe #21 (Roche cat. no.: 04686942001; NM_005417.5). Either the forward or the reverse primers were designed for the exon-exon junction of the analyzed mRNAs. The amplicon lengths were similar. With regards to *ESR2*, we applied a ready-to-use assay (PrimePCR, qHsaCEP0052206, BioRad; Hercules, CA, USA). The hypoxanthine-guanine phosphoribosyltransferase (*HPRT1*) gene assay (UPL102079, Roche; Manheim, Germany) was used as a reference gene.

The quantitative PCR reactions were carried out according to the MIQE guidelines (Bustin *et al.*, 2009) (Supplementary Materials: MIQE checklist and data set). All qPCR reactions were made in a total volume of 20 µL. Standard cycling and acquisition steps were performed with adjusted and standardized reaction mixtures for Roche UPL probes in the LightCycler 2.0 glass-capillary thermal cycler (Roche Diagnostics International AG; Rotkreuz, Switzerland) (Englert-Golon *et al.*, 2021; Andrusiewicz *et al.*, 2016). The expression level of each gene, expressed as concentration ratios (Cr), was derived from reaction efficiencies (obtained from the relevant standard curves) compared with the appropriate mean of two-reaction threshold values and normalized to reference gene expression (Englert-Golon *et al.*, 2021; Skibińska *et al.*, 2018).

Western blot analysis

Tissue samples immersed in PBS were used for protein isolation, followed by western blot. After mechanical pulverization in liquid nitrogen, tissue samples were suspended by pipetting in RIPA Lysis Buffer (Merck Millipore, Darmstadt, Germany). Then, total sample extracts were shaken in an orbital shaker (1 600 rpm, 60 min, 4°C) and centrifuged (14 000×*g*, 20 min, 4°C). The supernatant was transferred into a fresh tube and centrifuged again (3 000×*g*, 10 min, 4°C), and then the supernatant containing purified proteins was used in further analyses.

Western blot analyses were conducted as described previously (Englert-Golon *et al.*, 2021). In short, protein concentration was measured colorimetrically with QuickStart Bradford 1 × Dye Reagent (BioRad, Hercules, CA, USA). Protein lysates (20 µg) diluted with Laemmli buffer (BioRad, Hercules, CA, USA) were denatured at 70°C for 10 min, loaded onto a 10% SDS-polyacrylamide gel (TGX FastCast Acrylamide Kit 10%, BioRad, Hercules, CA, USA), and separated by electrophoresis. After wet-transfer, PVDF membranes (Merck Millipore, Darmstadt,

Germany) were incubated on an orbital shaker at 200 rpm for 60 min at room temperature in TBS-T blocking buffer (TBS with 0.1% Tween-20 and 5% bovine serum albumin, pH 7.5; LabEmpire; Rzeszow, Poland). After blocking, the membranes were incubated with primary antibodies on an orbital shaker at 200 rpm overnight at 4°C. The antibodies used are as follows: anti-ESR1 (1:1000, LS-C88420, Lifespan Biosciences, Seattle, WA, USA), ESR2 (1:1000, ab3576, Abcam, Cambridge, UK), PELP1/MNAR (1:1000, A300-180A, Bethyl, Montgomery, TX, USA), SRC (1:1000 orb379229, Biorbyt, Cambridge, UK), pSRC (1:500, orb14869, Biorbyt, Cambridge, UK), and GAPDH (1:2500, sc-25778, Santa Cruz Biotechnology, Dallas, TX, USA). Subsequent visualization processing steps were performed as described previously (Englert-Golon *et al.*, 2021). Immunoreactive bands were compared with the mass standard (3-Colour Prestained Protein Marker; Blirt, Gdansk, Poland). For protein density analysis ImageJ Software version 1.53r was used (https://imagej.nih.gov/ij/download.html, accession date 22.04.2022). The high-resolution TIFF images obtained with G:BOX (Syngen, Cambridge, UK) from chemiluminescent-visualized western blots were converted into JEPG 255 grayscale format. A defined frame size was used to measure the optical density of analyzed proteins, the background, and the GAPDH protein as the reference. The pixel density for all data was inverted and expressed as 255 − recorded by ImageJ value. Next, the net values for analyzed proteins and controls were calculated (by subtracting the value obtained for the background). Finally, the ratios of net band values for analyzed proteins and corresponding references were obtained and expressed as optical density in arbitrary units.

Immunohistochemical protein localization

The protein localization in tissue samples was assessed using immunohistochemistry as described previously (Waligórska-Stachura *et al.*, 2017; Englert-Golon *et al.*, 2021). In brief, 3 µm thick tissue sections were immersed in antigen retrieval solution (0.1 mM citric acid and 0.1 mM sodium citrate; pH 6.0; Avantor Performance Materials Poland S.A., Gliwice, Poland) and then microwaved, and this process repeated. Endogenous peroxidase activity was blocked in a 3% hydroperoxide solution (Avantor Performance Materials Poland S.A., Gliwice, Poland). The slides were blocked in a TBS-T blocking buffer for 60 min at room temperature. Immunohistochemical reactions were performed using the primary antibodies specified in the western blot analysis description at a 1:100 dilution in TBS-T buffer and visualized and assessed as described previously (Englert-Golon *et al.*, 2021). The specificity, dilutions and immunohistochemical reactions' conditions for positive controls were also adopted from the methodology referred above. The primary antibodies were substituted with a blocking buffer in the appropriate negative controls.

Statistical analyses

Results were evaluated using Statistica version 13.5.0 software for Windows (TIBCO Software Inc., Palo Alto, CA, USA). All continuous variables were checked for outliers. Min-Max normalization was used to describe and present the final data. All genes were analyzed for not only normalized C_r values but also gene-to-gene C_r values. Results were described by the median [interquartile range] (Me [IR]) values. The Shapiro-Wilk test was applied for the normality of continuous variables distribution assessment. The non-parametric two-tailed

Figure 1. Normalized expression of *SRC* and *PELP1* in testis and epididymis.
*$p<0.05$, **$p<0.01$ (two-tailed Mann-Whitney *U* test).

Mann-Whitney *U* test was used for statistical analyses. The Spearman rank correlation test was applied to evaluate the strength of the correlation coefficient (R). The strength of the correlation coefficient was assessed according to Guilford's classification. Data were considered statistically significant when $p<0.05$.

RESULTS

ESRs, *PELP1* and *SRC* mRNA expression

The normalized expression level of both *SRC* and *PELP1* differ significantly between testis and epididymal tissue ($p=0.040$ and $p=0.002$, respectively), with both genes having higher expression levels in the testis (Fig. 1). We did not observe significant differences in the expression level of *ESR1* and *ESR2* in either testis or epididymal tissue in any of the analyzed samples ($p>0.05$) (not shown).

With respect to the tissue of origin, both *SRC* and *PELP1* expression was significant and very strongly positively correlated in both testis and epididymis (R=0.66, $p=0.014$, and R=0.80, $p=0.0019$, respectively). Additionally, *PELP1* expression was strongly positively corre-

lated with the expression of *ESR1* in the testis (R=0.6; $p=0.0367$) (Fig. 2). We did not observe this correlation in the case of the epididymis ($p>0.05$).

We observed a moderate positive correlation between the tissue donors' age and *ESR1* normalized expression in the testis (R=0.59; $p=0.0322$) and a moderate negative correlation of the age and *PELP1* expression in the epididymis (R=-0.61; $p=0.0354$) (Fig. 3). The expression levels of other genes were not correlated with age ($p>0.05$).

Considering the expression ratio of analyzed genes, the *ESR2/PELP1* ratio differed significantly between the testis and epididymis ($p=0.0068$). The expression ratio was lower in the testis (Fig. 4). There was no significant difference in the expression ratios of other genes between the tissue types.

Considering tissue-origin-dependent division, *ESR1/ESR2*, *ESR1/SRC*, and *ESR1/PELP1* expression ratios were moderately and positively correlated in the testis. *ESR2/SRC* was moderately positively correlated with *ESR2/PELP1*, and strongly negatively correlated with *SRC/PELP1*. We observed very strong positive correlations of *ESR1/ESR2* with *ESR1/SRC*, *ESR1/SRC* with *ESR1/PELP1*, and *ESR2/SRC* with *ESR2/PELP1* in the epididymis. Additionally, a moderately positive

correlation was established for the expression ratios of *ESR1/ESR2* and *ESR1/PELP1*. *ESR2/SRC* and *SRC/PELP1* in the epididymis were not correlated (Table 1).

Protein presence and localization

The presence of the analyzed proteins in the testis and epididymis was confirmed by western blotting to identify the presence of immunoreactive bands at the expected sizes (ESR1: 36 kDa; ESR2: 55 kDa; PELP1: 170 kDa; SRC: 60 kDa and pSRC: 61 kDa). The GAPDH reference protein bands (37 kDa) were present in all samples (Fig. 5).

The protein density of both pSRC and PELP1 differ significantly between testis and epididymal tissue ($p=0.015$ and $p<0.001$, respectively), with both proteins having a higher density in the testis (Fig. 6).

Table 1. Spearman rank order correlations of the analyzed gene ratios in testis and epididymis.

Pair of Variables	Testis			Epididymis		
	N	R	*p*-value	N	R	*p*-value

Figure 7. Immunohistochemical localization of PELP1 (A), SRC (C), pSRC (phospho-Tyr529) (E) in testis, and PELP1 (B), SRC (D), and pSRC (phospho-Tyr529) (F) in the epididymis.
Legend: BC, basal cells; CC, ciliated cells; nCC, non-ciliated cells; IT, interstitial tissue; LC, Leydig Cells; Psp, primary spermatocytes; S, spermatozoa; SC, Sertoli cells; SEC, seminiferous epithelium cells; Sd, spermatids; Sg, spermatogonia. (+), positive immunostaining; (–), negative immunostaining. Scale bar: 200 μm.

Immunohistochemical staining enabled the identification of all studied proteins in tissues of interest. The ESR1 and ESR2 expression showed similar localization as observed by other authors (Fietz *et al.*, 2014; Rago *et al.*, 2018). In the testis, ESR1 was observed in some primary spermatocytes and spermatids but not in the spermatogonia, Sertoli, or interstitial cells. The ESR2 was localized in spermatogonia, primary spermatocytes, spermatids, and Sertoli cells but not in the interstitial compartment. On the other hand, in the epididymis, ESR1 was expressed in non-ciliated cells and ESR2 in the ciliated and non-ciliated cells of the epithelium and the basal cells (Supplementary Fig. S1 at https://ojs.ptbioch.edu.pl/index.php/abp). We observed PELP1 localization in the Sertoli cells, primary spermatocytes, and single spermatogonia in the testis. We did not observe positive staining in Leydig cells or spermatids (Fig. 7A). In the magnification of Fig. 7A, positive immunostaining was indicated in primary spermatocytes and spermatogonia. On the other hand, SRC was extensively expressed in the cytoplasm of Sertoli cells and the cells of the seminiferous epithelium. SRC was also weakly expressed in the cytoplasm of Leydig cells (Fig. 7C). A similar but weaker reaction was observed for the cells of the seminiferous epithelium for pSRC (Fig. 7E). In the epididymis, a strong PELP1 expression was demonstrated in the nuclei of the ciliated and non-ciliated cells of the epididymal ductal epithelium. Weak cytoplasmic staining was also observed in these cells. The vast majority of basal cells were PELP1 negative. There was no expression of PELP1 in smooth muscle cells of the ductal wall or interstitial tissue cells. In the magnification, the ciliated and non-ciliated cells were indicated (Fig. 7B). SRC was expressed in the basal cells' nuclei, spermatozoa, and the ciliated and non-ciliated cells of the epididymal ductal epithelium. In the magnification, the non-ciliated and ciliated cells and spermatozoa were indicated (Fig. 7D). A similar but slightly weaker reaction was observed in the case of pSRC (Fig. 7F).

DISCUSSION

There are distinct roles of ESRs throughout the entire reproductive tract in males. However, there is a lack of consensus on their detection and localization in the published literature (Hess *et al.*, 2021; Fietz *et al.*, 2014; Cooke *et al.*, 2017; Li *et al.*, 2015). There are several studies indicating that estrogen signaling may use a variety of different pathways where, for example, gene transcription may be induced by either direct binding of certain receptors to estrogen response elements (ERE) in the promotors of target genes or can involve transcription factor complexes that are able to activate transcription in the promoter regions of genes directly and without the use of EREs (Klinge, 2001). Conversely, an alternative non-genomic mechanism was also described. It uses other signaling pathways, such as growth factors, kinases, or associated co-regulators, which may activate ESRs in the absence of a ligand (Hess & Cooke, 2018). It was established that aromatase is expressed in human epithelial cells of ductuli efferentes and proximal caput of the epididymis. It suggests a putative role of estrogens produced locally in the epididymal function. Moreover, epididymal caput and cauda differed in ESR1 and ESR2 presence in humans and animals. Additionally, the possible involvement of ESR2 in estrogen modulation of the epididymal function is suggested, as ESR2 expression was confirmed in the epithelial cells of human epididymis indicates (Bilińska *et al.*, 2006; Carpino *et al.*, 2004a; Carpino *et al.*, 2004b; Kolasa *et al.*, 2003). Our study suggests that the specific ESR-mediated pathway in the male reproductive system might result from the different local interactions of estrogens with estrogen receptors and their co-regulators. Even though the tissues

are of the same type, we observed significant differences in the expression levels of the studied genes, especially PELP1 and SRC kinase in both mRNA and protein levels. This paper confirmed the presence of ESR1, ESR2, and their co-regulators, including PELP1 and SRC kinase, in human testis and epididymis. Furthermore, we analyzed potential links between them, as their interactions may have a particular impact on physiological phenomena in these tissues. However, further analyses exploring estrogen-mediated signaling supported by colocalization studies are essential to determine the nature of these interactions and the potential clinical repercussions of estrogens in the male reproductive tract.

Our study suggests that there may be a dependence between PELP1 and SRC in human testis. Our study established the significant differences in normalized expression levels of both SRC and PELP1 in the testis and epididymis, with significantly higher expression and protein density in the testis. Furthermore, our study indicated that *SRC* and *PELP1* expression levels were moderately positively correlated in the testis (R=0.66, p=0.014). Moreover, *PELP1* expression was positively correlated with the expression of *ESR1* (R=0.6; p=0.0367). It may imply the role of ESR1 in testis, as well as the involvement of PELP1 and SRC in estrogen-mediated signaling (e.g., ligand-independent signaling to induce specific effects via ESR1). As we observed PELP1 being localized in Sertoli cells and spermatocytes, it could not be excluded that PELP1 may be involved in certain stages of spermatogenesis or may somehow modulate Sertoli cells' function in this regard.

It has been confirmed that *ESR1* expression is different through certain stages of development (Hess *et al.*, 2011). In 1994, the first man lacking a functional ESR1 was reported, and subsequently, other men lacking aromatase were identified, with 13 reported cases of loss of function mutations in CYP19A1 (Cooke *et al.*, 2017). Regardless of species or investigators, *ESR1* has been shown to be highly expressed in the efferent ductule epithelium, which suggests its contribution to fluid reabsorption (Fietz *et al.*, 2014). Interestingly, the most severe histopathological changes following the disruption of ESR1 function occur in the testis and efferent ductules, likely due to its high expression, which is approximately 3.5-fold greater than in the female uterus or any other organ independent of biological sex (Fietz *et al.*, 2014). Furthermore, ESRs involvement was suggested in the development of sperm cells (Hess, 2014). We observed age-related increasing *ESR1* and decreasing *PELP1* expression. Due to the limited number of published papers on the topic of PELP1 expression in the male reproductive tract, and because the *ESR1* and *ESR2* expression alters with age (in different tissues, not only in the male reproductive tract), it would be challenging to propose strong conclusions. Considering that we analyzed the specimens from males not only of reproductive age, further studies need to be conducted to elaborate on this topic. Moreover, a recent report confirmed the ESR1 and PELP1 presence in the human reproductive tract, including in the nuclei of ciliated and non-ciliated cells for ESR1 and principal cells of proximal epididymis for PELP1 (Rago *et al.*, 2018). As our results highlight the *SRC/PELP1* correlation in testis, it cannot be ruled out that these proteins may potentially be involved in ESR1-mediated processes surrounding rete fluid resorption in the testis, influence the composition of seminal fluids, or anyhow in the regulation of spermatogenesis. Interactions between PELP1-SRC-ESR1 seem feasible in the above-mentioned processes, especially due to the fact that the binding of PELP1 and ESR coordinates SRC-mediated signaling to SRC's SH3 and SH2 domains. It is known that the SRC family kinases (SFKs), including SRC (but also Yes, Fyn, and Lck among others) play a role in cell polarity, in the testis spermatogonial stem cell proliferation, cell adhesion or to influence the dynamics of the blood-testis barrier in the seminiferous epithelium. Even though the effects of c-SRC and c-Yes kinases may considerably overlap, and their action is thought to be limited to the cell matrix at the focal contacts, their role in the testis cannot be denied (Xiao *et al.*, 2013; Xiao *et al.*, 2019; Rago *et al.*, 2018). It is also suggested that SRC plays a crucial role in the 17β-estradiol-induced translocation of estrogen receptors from the nucleus to the cell membrane (Lucas *et al.*, 2008). Furthermore, the ability of ESRs to simultaneously bind SRC and PELP1 results in the activation of a non-genomic pathway such as cSRC/MAPK-pathway, which leads to enhanced, phosphorylation-dependent ESR1 transcriptional activity (Nieto *et al.*, 2015; Barletta *et al.*, 2004).

Figure 8. Map of interactions in PELP1 modulation of estrogen receptor activity (cpb.molgen.de/CPDB/cyVis).

The PELP1 biochemical interactions with other proteins are complex and involve other kinases, such as ATM, ATR, CDK2, CDK4, and PRKDC, in addition to SRC (Fig. 8). The biochemical/enzymatic reactions with these proteins directly influence PELP1 and, other protein complexes involved in estrogen signal transduction. It seems that ESR1, but not ESR2 plays a crucial role in the PELP1-mediated pathway.

Upon phosphorylation by SRC, certain cellular events may be influenced by the specific cellular localization of PELP1, SRC, and ESR1. Furthermore, it is important to mention that the extent of SRC-PELP1-ESR1 interactions in human testis may influence the availability of another estrogen receptor GPER. However, it was not analyzed in this study. These dependencies could modulate the microenvironment for spermatozoa maturation in different sites of the male reproductive tract, depending on the availability of certain receptors and their co-regulators in the tissue area of interest. It was shown that SRC phosphorylation at Tyr529 deactivates the protein function (Gonfloni *et al.*, 2000). The Tyr529 phosphorylation status is closely related to the autophosphorylation of Tyr418, which determines the SRC activity (Xiao *et al.*, 2017), leading to complex conformational changes (Gonfloni *et al.*, 2000). As a consequence SH3 domain of SRC ceases to be strongly associated with the linker of the SH2 domain and the catalytic domain and becomes more accessible to other ligands (Xiao *et al.*, 2017). Consistent with this idea would be the fact that we observed differences in the SRC and pSRC expression pattern, as this protein works bidirectionally upon phosphorylation status (Gonfloni *et al.*, 2000). Differentiated expression patterns of SRC and pSRC in testis and epididymis, observed in our study, could be reflected in the modulation of cell events, such as cell maturation and migration, mediated by other signaling pathways (Xiao *et al.*, 2017). Therefore, investigations of the molecular consequences and the role of these phenomena in the male reproductive tract should be further conducted.

Regarding *ESR2* expression in the testis, *ESR2/SRC* correlated positively with *ESR2/PELP1*. Moreover, *ESR2/SRC* had a strongly negative correlation with *SRC/PELP1*. Until 2018, common knowledge regarding *ESR2* indicated its ubiquitous expression in the male reproductive tract. However, more recent investigations have questioned antibody specificity for immunohistochemical localization of the receptor (Hess & Cooke, 2018), and therefore data concerning ESR2 distribution needs to be re-evaluated. Furthermore, it is worth pointing out that ESR2 knock-out animal models are more limited than ESR1 ones. Recent studies confirmed *ESR2* expression only in ciliated cell nuclei of the efferent ductules and in a few epithelial layer cells in proximal epididymis (Rago *et al.*, 2018).

Additionally, it cannot be excluded that PELP1, SRC, and ESR2 also take part in maintaining the function of the efferent ductule epithelium, especially as it was reported that some of the expressed genes contain both EREs. The PELP1 function may depend on other proteins' tissue-specific availability, including ESR1, ESR2, and SRC. The expression level of these proteins may be one of the limiting elements of the entire PELP1-mediated signal transduction pathway. As shown in Figure 8, some more proteins, enzymes, and factors influence this signaling network. Our results showed a differentiated expression ratio of analyzed genes, which could result from tissue-specific availability of, e.g., transcription factors. However, since androgen response elements were also identified in this location, it is clear that a hormonal milieu (estrogens vs. androgens) is likely required for maintaining the proper epithelial function. For example, the testosterone metabolite 5α-androstane-3β-17β-diol (3β-diol) was shown not to bind the androgen receptor but bind ESR2 with higher affinity than it does for ESR1. Therefore it could mediate ESR2 activity in the testis and maintain epithelial function (Hess *et al.*, 2021). We speculate that SRC and PELP1 could be somehow involved in this phenomenon.

In the epididymis, we noted very strong positive correlation ratios of *ESR1/ESR2* with *ESR1/SRC* and *ESR1/SRC* with *ESR1/PELP1*. These observations could suggest SRC kinase and PELP1's more intense involvement in ESR1 function in the epididymis. Immunohistochemical staining in our study indicates strong PELP1 expression in the nuclei of the principal cells of the efferent ductules epithelium. Other studies have shown that acute morphological changes, such as epithelial degeneration, may occur due to disrupting ESR1 function in the efferent ductules. As SRC and PELP1 seem to play an important role in modulating epididymal epithelial function, it cannot be excluded that impaired SRC-PELP1 interaction caused by, for example antiestrogens, may lead to a blockage of ESR activity in the efferent ductules, and consequently to the inhibition of fluid reabsorption (Hess *et al.*, 2021). PELP1 is a scaffolding protein that enhances transcriptional activity by assembling crucial protein partners. We localized its presence in the principal cells of proximal epididymis. Thus, its function may depend on the availability of co-occurring factors in the local environment. That being said, the activity of PELP1 and other estrogen pathway-related proteins should be considered holistically (Rago *et al.*, 2018). It is worth pointing out that previous literature focuses on the exploration of *ESR1* expression patterns in the epididymis.

On the other hand, difficulties in establishing *ESR2* expression are most likely caused by methodological obstacles concerning the ESR2 distribution in the male reproductive tract, and a literature review examining the expression of both *ESRs* in the epididymis has brought contradictory results (Cunha *et al.*, 2021; Davis & Pearl, 2019; Aprea *et al.*, 2021; Hess, 2014; Hess *et al.*, 2021). Most studies in mammals report that ESR1 distribution is species-dependent, while ESR2 expression can be found the entire length of the efferent ductules (Hess *et al.*, 2021; Hess & Cooke, 2018). Animal models have shown that ESR1 may play a prominent role in the specific cell types of the epididymis, likely during fetal development. However, the epididymal epithelium is reported to have a much lower expression of *ESR1*, which would likely have more significant direct estrogen and dual estrogen/androgen regulation in efferent ductules (Joseph *et al.*, 2011). Several studies suggest that estrogens play a very important role in maintaining fluid resorption by the epithelium of the efferent ductules, mostly *via* ESR1 (Joseph *et al.*, 2011; Hess *et al.*, 2011; Hess, 2014). However, recent studies have not confirmed the presence of ESR1 in the human epididymis, stating that it is ESR2 that is more prominent in this tissue (Rago *et al.*, 2018). It appears doubtful, considering several studies that have confirmed the presence of ESR1 in this tissue. There are also papers indicating that the loss of ESR2 in knock-out mice demonstrates no major effects on the development of testes, efferent ductules, and epididymis. Interestingly, important long-term effects were seen in the prostate and an increase in neonatal gonocytes, but not in the adult testis (Cunha *et al.*, 2021; Davis & Pearl, 2019; Hess, 2014; Aprea *et al.*, 2021; Hess *et al.*, 2021).

Despite the contradictory findings regarding the expression of *ESRs* in the testis and epididymis, and considering our results, we suggest that an ESR-SRC-PELP1 relationship may be anywise important in controlling some functions of these tissues. However, our study proved the abundance of these proteins only and not their interactions. It seems that not only the level of gene expression and post-translational events influencing protein expression in a specific tissue compartment are important, but also the locally determined interaction between certain proteins and their expression ratios.

Finally, we acknowledge that our study also had some limitations. Firstly, our investigation was limited by the sample size. However, we did not find comparable data in the literature investigating the expression of modulators involved in the ESR-mediated pathways in the tissues of the male reproductive tract. This study was limited by sample size, so conclusions should be interpreted with caution. It is important to establish the proteins' presence, localization, and interplay with other proteins involved in estrogen-mediated signaling in a larger group. However, since these proteins have many different partners and functions, further analyses exploring estrogen-mediated signaling and/or estrogen signaling stimulation/inhibition analyses supported by colocalization studies are essential to determine the nature of these interactions and the potential clinical repercussions of estrogens in the male reproductive tract in the context of impaired male fertility.

[4]Medical University of Gdansk, Gdańsk, Poland

Various high-efficiency hemodialysis techniques exist, including different online high- volume hemodiafiltration (HDF) modes and expanded hemodialysis (HDx) utilizing dialyzers with medium cut-off (MCO) membranes. This study aimed to evaluate the efficacy of uremic toxin removal among four modalities: (I) HDx, (II) pre-dilution HDF (PRE-HDF), (III) mixed-dilution HDF (MIX-HDF), and (IV) post-dilution HDF (POST-HDF), each applied for 1 week in a randomized order. This research was a single-center, prospective, open-label, exploratory crossover study. The reduction ratio (RR) for small molecular toxins (urea and phosphate), a middle molecular toxin (beta-2-microglobulin, β2M), a large-middle molecular toxin (Chitinase-3-like protein 1, YKL-40), and a protein- bound uremic toxin (indoxyl sulfate, IS) was evaluated during a single mid-week dialysis session. Twelve patients were included, with an average age of 52.5 $\pm$ 15.47 years and an average dialysis duration of 42.05 $\pm$ 31.04 months. The dialysis parameters, including; post-dialysis weight, session duration, dialysate composition, blood and dialysate flow; rates, dialysate temperature, and anticoagulation dosage, were maintained consistently across all modalities. No significant differences in RR for urea, phosphate, β2M, YKL-40, and IS were observed between the treatments. Although the highest IS clearance, though not statistically significant, was observed with POST-HDF and HDx, the differences were not substantial enough to favor any particular modality as the most effective.

GRAPHICAL ABSTRACT

Introduction

Hemodialysis has seen substantial advancements, evolving from low-flux to high-flux membranes, which are now standard in chronic dialysis therapies (Palmer et al., 2012; Himmelfarb et al., 2020). These technological improvements have led to the development of advanced dialysis methods, such as hemodiafiltration (HDF) in pre-dilution (PRE-HDF), post-dilution (POST-HDF), and mixed-dilution (MIX-HDF) modes, as well as expanded hemodialysis (HDx) employing MCO membranes. These new methods have enhanced clearance profiles, significantly improving the removal of a wider range of uremic toxins, especially larger middle molecules, which traditional high-flux dialysis failed to eliminate effectively (Pedreros-Rosales et al., 2023; Zhang et al., 2022). The CONVINCE trial demonstrated that high-volume POST- HDF, delivering at least 23 Liters per session, was associated with a reduced risk of all-cause mortality compared to conventional high-flux hemodialysis, especially among older, non-diabetic patients with arteriovenous fistulas and no history of cardiovascular disease (Blankestijn et al., 2023). In Asian countries, PRE-HDF has also shown a potential for improved survival rates over conventional high-flux hemodialysis. A Japanese cohort study involving 5,000 patient pairs treated with either standard hemodialysis or pre-dilution HDF indicated that PRE-HDF might offer better overall and cardiovascular survival, particularly with high substitution volumes (>40.0 L per session) (Kikuchi et al., 2019).

Smaller studies have suggested HDx might improve patient quality of life and reduce symptoms such as restless leg syndrome and pruritus (Zhang et al., 2022). However, a randomized controlled trial by Lee et al. found no significant cardiovascular differences between HDx and POST-HDF (Lee et al., 2021). HDx remains technically simple, similar to conventional hemodialysis, which makes it increasingly popular, especially in patients with high comorbidity, long dialysis duration, or who are not candidates for kidney transplantation. Although numerous studies have compared different HDF techniques or HDx with individual HDF modes, comprehensive comparisons among all high-efficiency dialysis methods are scarce (Mitchell et al., 2023; Zakrzewska et al., 2024). This study aimed to evaluate the efficacy of all available high-efficiency dialysis techniques at our center in terms of solute clearance across a broad spectrum of uremic toxins.

Materials and methods

Study design

This study was a single-center, prospective, exploratory, open-label, crossover trial. The objective was to compare the removal of uremic toxins across four high-efficiency dialysis methods: (I) HDx, (II) online pre-dilution HDF (PRE-HDF), (III) online mixed-dilution HDF (MIX-HDF), and (IV) online post-dilution HDF (POST-HDF). Patients underwent each modality for a week in a randomized sequence. The effectiveness of toxin removal was determined by calculating the reduction ratio (RR) for small molecular toxins such as urea (MW 60 Da) and phosphate (MW 95 Da); a middle molecular toxin, beta-2-microglobulin (β2M, MW 11,800 Da); a large

middle molecular toxin, Chitinase-3-like protein 1 (YKL-40, MW 40,000 Da); and a protein-bound uremic toxin (PBUT), indoxyl sulfate (IS, MW 213 Da). Toxin reduction was evaluated during a single mid-week dialysis session. The study followed the Declaration of Helsinki's guidelines and was approved by the Medical University of Gdansk's Ethical Committee (NKBBN/479-759/2022; 18 November 2022).

Patients

Participants included adult patients with end-stage renal disease (ESRD) who had been receiving standard high-flux hemodialysis or online HDF (either pre- or postdilution) three times per week for a minimum of 6 months. Eligible patients had a single-pool Kt/V for urea (spKt/Vurea) greater than 1.2, weighed between 60 and 89 kg, and had a dialysis blood flow of at least 350 mL/min through a fistula or arteriovenous catheter. Exclusion criteria included single-needle dialysis, the use of temporary non-tunneled catheters, poor compliance with dialysis procedures, hemodynamic instability during dialysis sessions, life expectancy of less than 6 months, hospitalization within the last 30 days, active inflammation or cancer, liver cirrhosis, and hypoalbuminemia (albumin <30 g/L).

Dialysis prescription and equipment

All dialysis treatments were performed using the Fresenius 5008 machine with the AutoSub Plus system (Fresenius Medical Care, Bad Homburg, Germany). Online HDF sessions were carried out with FX 100 high-flux dialyzers (surface area: 2.2 m^2; UF coefficient: 73 mL/h × mmHg; Fresenius Medical Care). HDx treatments utilized Terranova 400 MCO dialyzers (surface area: 1.7 m^2; UF coefficient: 48 mL/h × mmHg; Baxter, Alliston, ON, Canada). Each dialysis session lasted 4 h, with a dialysate temperature of 36.5°C. Blood flow and dialysate flow rates were set to 350 and 500 mL/min, respectively. Dry weight was verified using bioimpedance spectroscopy prior to the study. Ultrafiltration for each session was adjusted based on the patient's interdialytic weight gain and fluid intake, along with bloodline priming volume. Neither ultrafiltration nor sodium profiling was employed. The dialysate composition was: Na 138–140 mmol/L; K 2.0–3.0 mmol/L; HCO$_3$ 32 mmol/L; Ca 1.25–1.5 mmol/L; Mg 0.5 mmol/L; Cl 110 mmol/L; glucose 1.0 g/L. Most patients (83.3%) used a potassium concentration of 2.0 mmol/L, and 91.7% used a calcium concentration of 1.25 mmol/L. Heparin was administered as a bolus and a continuous infusion according to current practices. Sterile, non-pyrogenic substitution fluid was generated online via ultrapure dialysate filtration. The AutoSub Plus system automatically adjusted the substitution and convection rates based on pressure pulse attenuation and transmembrane pressure, optimizing ultrafiltration while preventing excessive hemoconcentration. Dialysis settings, such as post-dialysis weight, session length, dialysate composition, and anticoagulation, were kept consistent across all modalities. Medications remained unchanged throughout the study.

Monitoring of uremic toxins concentration

Blood samples for assessing toxin RR were collected before and after mid-week dialysis session. Post-dialysis sample collection was done at the dialysis session end from the arterial needle after decreasing the blood flow rate to 50 mL/min for 15s to avoid recirculation. RR of toxins was calculated by the following equation:

$$RR\ (\%) = \left[1 - \left(\frac{cCpost}{Cpre} \right) \right] \times 100$$

Cpre and *Cpost* refer to toxin concentration of pre- and post-dialysis session, respectively while *BWpost* is the body weight at the end of the session. *Cpost* was corrected for hemoconcentration as follows:

$$cCpost = \frac{cCpost}{\left[1 + \left(\frac{BW}{0.2 \left(BWpost \right)} \right) \right]}$$

Laboratory measurements

Urea and phosphate in serum were quantified using routine colometric methods (Abbott GmbH and Co. Wiesbaden, Germany).

Serum beta-2-microglobulin levels were determined with a reagent kit (Abbott GmbH and Co. Wiesbaden, Germany). The Alinity c β2-microglobulin reagent utilizes latex particles coated with IgG antibodies specific to human β2M, and agglutination is measured via a turbidimetric method. The detection limit was 0.110 mg/L, with an inter-assay CV of 4.1% and an intra-assay CV of 4.2%. The measurement range was 0.97–2.64 mg/L.

Serum YKL-40 (CHI3L1) was quantified using the YKL-40 Human Sandwich ELISA Kit (Thermo Fisher Scientific Inc.). This assay involves an anti-human YKL-40 antibody that binds to YKL-40 in the sample, followed by the addition of a biotin-conjugated detection antibody. The sensitivity was 10.83 pg/mL, with an assay range of 78–5,000 pg/mL, an inter-assay CV of 7.2%, and an intra-assay CV of 2.3%. Serum YKL-40 (CHI3L1) was quantified using the YKL-40 Human Sandwich ELISA Kit

TABLE 1 Characteristics of the study group.

Gender (Men/Women)	11/1
Causes of ESRD (n/%)	
Autosomal Dominant Polycystic Kidney Disease	4/33
Glomerulonephritis (primary or secondary)	3/25
Hypertensive nephropathy	2/17
Renal malformation	1/8
Interstitial nephropathy	1/8
Other	1/8
Age (years)	52.5 (15.5)
AACI (points)	4.5 (2.2)
Dialysis vintage (months)	42.5 (31.0)
Body Mass Index (kg/m^2)	23.8 (3.6)
Weight (kg)	73.7 (14.2)
spKt/V urea	1.5 (0.3)
Hemoglobin (g/dL)	10.9 (0.9)
Albumin (g/L)	33.1 (4.9)

ESRD, end-stage renal disease; AACI, Age Adjusted Charlson Comorbidity Index. Data are presents as mean (SD) or number (%).

(Thermo Fisher Scientific Inc.). This assay involves an anti-human YKL-40 antibody that binds to YKL-40 in the sample, followed by the addition of a biotin- conjugated detection antibody. The sensitivity was 10.83 pg/mL, with an assay range of 78–5000 pg/mL, an inter-assay CV of 7.2%, and an intra-assay CV of 2.3%.

Serum indoxyl sulfate (IS) levels were determined using a competitive ELISA kit (Fine Test[1]). In this method, IS in the sample competes with the IS coated on the microtiter plate for the binding sites of a biotinylated detection antibody. The resulting colorimetric reaction was measured at 450 nm. The detection range for the assay was 1.563–100 ng/mL, with an intra- assay precision of 5.1% (low concentration: 3.16 ± 0.16) and inter-assay precision of 5.4%.

Statistical analysis

Continuous variables were expressed as means with standard deviations (SD), while categorical data were represented as percentages. The Shapiro–Wilk test was used to evaluate the normality of continuous variables. The Wilcoxon signed-rank test or ANOVA was utilized for repeated measures comparisons. Statistical significance was considered at $p < 0.05$. All analyses were performed using Statistica 13.3 (TIBCO Software Inc.; Palo Alto, CA, United States).

Results

Characteristics of patients

12 patients met inclusion criteria and were enrolled to the study, 11 men (92%) and 1 woman, in mean age of 52.5 ± 15.47 years. Hypertension was diagnosed in 10 (83%) patients. A description of the study group is presented in Table 1.

Dialysis parameters

Dialysis session time, blood flow rate, and dialysate flow rate were constant during all modalities. All patients achieved the minimum level of convection for high volume online HDF. Mean (standard deviation) total convection for post-HDF, pre-HDF and mix-HDF were 25.6 (3.8), 61.5 (7.2) and 47.1 (11.4) L, respectively. The arterial and venous dialysis pressure did not differ between tested treatments. Detailed delivered dialysis parameters are presented in Table 2. All patients in all sessions have achieved high-volume convection defined as ≥23 L of substitution fluid.

Effectiveness in the removal of toxins

No difference was seen in RR between treatments for small middle and large molecules, neither for the protein bound uremic molecule (Table 3). The best degree of IS clearance, although statistically insignificant, was obtained during POST-HD and HDX.

The impact of studied blood purification modalities on the removal of the toxins is displayed on Figure 1.

Figure 2 compares each treatment modality's capacity to remove a whole profile of molecules. Again, there was no difference between modalities.

Discussion

The main purpose of all blood purification techniques is to remove uremic toxins from the patient's blood. Our study showed no significant differences in uremic toxin removal between the compared methods of high-efficiency dialysis. Ensuring high-volume convection, i.e., 23 Liters (POST-HDF), 60 Liters (PRE) and 45 Liters (MIX-HDF) on average, these methods do not differ from each other in the clearance efficiency, nor do they differ from hemodialysis using MCO membranes.

We analyzed a broad spectrum of uremic toxins, including small-molecule toxins (urea), medium-molecule toxins (β2M), large medium-molecule toxins (YKL-40), and toxins bound to and proteins (IS). The proposed cross-over design study excluded the influence of patient-related variability on the obtained results and ensured the same technical parameters of dialysis, including

TABLE 2 Delivered dialysis parameters during the study treatments.

	PRE-HDF	MIX-HDF	POST-HDF	HDX
Real Time min	240	240	240	240
Blood flow mL/min	350	350	350	350
Dialysate flow mL/min	500	500	500	500
Ultrafiltration L/session (SD)	2.45 (0.8)	2.29 (0.74)	2.19 (0.52)	2.33 (0.62)
Total convection L	61.5 (7.2)	47.1 (11.4)	25.6 (3.8)	NA

Note: Ultrafiltration refers to the fluid removed from the patient during the dialysis session. Total convection is the total volume of fluid moved by convection during the session, which includes both the patient's dehydration volume and the volume of replacement fluid administered.

TABLE 3 Molecules reduction ratio, according to size and treatment modality, Data expressed as means (SD).

Molecule	Size (Da)	HDF-pre	HDF-mix	HDF-post	HDx	P-value
Urea	60	0.73 (0.1)	0.72 (0.06)	0.75 (0.07)	0.72 (0.06)	0.67
Phosphate	95	0.54 (0.16)	0.56 (0.08)	0.59 (0.11)	0.56 (0.12)	0.86
Beta-2-microglobulin	11.000	0.62 (0.15)	0.69 (0.13)	0.7 (0.1)	0.67 (0.06)	0.41
YKL-40	40.000	0.31 (0.12)	0.32 (0.12)	0.32 (0.14)	0.36 (0.19)	0.92
Indoxyl sulfate	213	0.36 (0.23)	0.40 (0.17)	0.40 (0.17)	0.49 (0.17)	0.51

its time, blood and dialysis fluid flow rate limited bias in this regard.

The technical development of dialysis mainly resulting from the introduction of high-flux dialyzers, dialyzers with MCO membranes and dialysis methods based on high-volume convection has led to very effective removal of most uremic toxins. This is especially true for small water-soluble compounds with low molecular mass (<500 Da) whose reduction ratio during

FIGURE 2
Comparative efficacy profiles of dialysis methods against specific toxins. This figure illustrates mean reduction ratio of uremic toxins during the study treatments.

the dialysis is very high for most commonly used methods. The ability to remove larger uremic toxins relies largely on the convection amount. The high-flux dialyzer, when applied in the standard hemodialysis, has a molecular mass cutoff of 25 kDa, being boosted up to 30 kDa in HDF mode. In our study, we did not show significant differences between studied treatments in the removal of urea, phosphate and β2M. The degree of purification was high, exceeding 70% for urea. Previous studies have shown slightly better clearance rate for small molecules during POST-HDF compared to PRE-HDF, which was explained by the smaller concentration gradient of these toxins across the dialysis membrane in the later mode. These toxins are removed during dialysis primarily by the diffusion mechanism. In some studies, slightly better clearance was observed during POST-HDF compared to PRE-HDF also for medium size toxins (500–25,000 D) such as β2M or alfa-1 microglobulin (Duval-Sabatier et al., 2023; Meert et al., 2008). The purification potential of MIX-HDF has been investigated only in few studies, indicating that the removal of β2M is also slightly better than in PRE-HDF and similar to POST-HDF (Park et al., 2021; de Sequera et al., 2013). In our study, β2M removal during PRE-HDF was the lowest among the tested methods, but the differences did not reach statistical significance. In previous studies, HDF patients in the highest β2M tertile tended to have

lower replacement fluid volume than patients in the middle and lowest tertiles (Kanda et al., 2021). This points to an important advantage of our protocol in which all techniques were applied to the same patient. Careful selection of the study group allowed for optimal convection in each applied method. Therefore we were able to control important clinical confounders and our conclusions on comparability between single sessions of all used modalities are more reliable.

Large-middle uremic toxins (25–58 kDa) are important molecules, the accumulation of which is associated with numerous complications of chronic kidney disease and an increased risk of cardiovascular complications. They are poorly removed during hemodialysis using high-flux dialyzers; some but unsatisfactory improvement has been achieved in online HDF methods with high-volume convection (Rosner et al., 2021). The new class of MCO membranes with a large pore radius of 5 nm and high internal convection using in so called extended hemodialysis were intended to provide more efficient clearance for these toxins. Clinical studies in this area to date has yielded inconclusive results. Some studies showed better removal of large molecules involving λ free light chains and YKL-40 as compared to PRE-HDF (Kim et al., 2019), MIX-HDF (Eiamcharoenying et al., 2022), and POST-HDF (Kirsch

et al., 2017; Hadad-Arrascue et al., 2022). On the other hand, other studies do not show differences between HDx and POST-HDF in this regard (Garcia-Prieto et al., 2018; Maduell et al., 2019a). Moreover, Maduell et al. showed no differences in removal efficacy between HDx and POST-HDF analyzing the global removal score, taking into account 6 different uremic toxins (Maduell et al., 2019b). In our study, HDx showed slightly better removal of YKL-40 compared to other methods, achieving a clearance rate of 36%, though the differences were not statistically significant.

Protein-bound uremic toxins (PBUTs) like indoxyl sulfate (IS) and p-cresol sulfate are crucial prognostic markers. Elevated serum levels of these toxins are linked to cardiovascular events and contribute to vascular diseases such as arteriosclerosis, endothelial inflammation, oxidative stress, and vascular calcification (Lin et al., 2015; Opdebeeck et al., 2019). Despite their relatively small molecular weight, PBUTs are poorly cleared during conventional hemodialysis, even with high-flux dialyzers. Their removal is hindered by their strong binding to plasma albumin, as only the unbound fraction can pass through the dialysis membrane. In the kidneys, PBUTs are primarily eliminated via tubular secretion (Masereeuw et al., 2014). The efficiency of PBUT removal during hemodialysis may depend on several factors, including dialyzer size, protein loss, dialysis duration, dialysate flow rate, protein adsorption to the dialysis membrane, and the extent of PBUT-albumin dissociation during contact with the membrane (Sanchez-Ospina et al., 2024; Huang et al., 2009). There was initial hope that high-volume HDF and HDx might improve PBUT removal. However, prior studies have produced mixed results regarding whether high- volume HDF is superior to conventional HD (Abad et al., 2016; Panichi et al., 2017; Krieter et al., 2010; Snauwaert et al., 2020; van Gelder et al., 2020), and no substantial evidence has shown that HDx increases PBUT clearance (Deltombe et al., 2015; Ronco et al., 2017). No comparative studies exist that assess PBUT removal across all high-efficiency modalities. In our research, the highest IS clearance was observed with POST-HD and HDx, although the difference was not statistically significant.

The novelty of our study lies in the fact that no previous research has compared the efficacy of all forms of online HDF and HDx in a single analysis. Our study also has several strengths: 1) the crossover design was chosen to mitigate interpatient variability; 2) basic dialysis parameters were standardized across all treatment methods; 3) all HDF modalities were performed at high volumes, which is known to offer the best long-term outcomes; 4) the removal rate was adjusted for hemoconcentration during dialysis. Our findings have practical implications, suggesting that treatment selection should consider the characteristics of uremic toxins. However, we acknowledge the limitations of our study. The study population may not reflect a typical European dialysis cohort, as we only included one woman, potentially affecting the homogeneity of the group, though the crossover design should minimize this issue. Another limitation is the small sample size, which may have prevented some differences from reaching statistical significance. Additionally, we analyzed the reduction ratio during only a single dialysis session. Future research could benefit from assessing the long-term effects of these modalities on toxin concentrations. A valuable complement to the analysis would be a comparison of the treatment effectiveness of the tested high-efficiency methods to the results obtained during standard hemodialysis. The influence of hemoconcentration on the concentration of all toxins and their reduction ration was taken into account in the study. For this purpose, toxin concentrations were corrected taking into account the change in the patient's weight during dialysis but an important limitation of the analysis is the lack of hematocrit-based hemoconcentration calculations. Considering these limitations, the findings should be viewed as exploratory.

In conclusion, this study found no significant differences in the clearance of a broad range of uremic toxins across four high-efficiency dialysis methods—PRE-HDF, MIX-HDF, POST-HDF, and HDx. While some trends were observed, particularly in PBUT removal, these differences were not substantial enough to recommend any one modality as the most effective.

Criteria analysis for kinetics curves of initiated blood serum chemiluminescence

Iryna Oliynyk[1,2]✉

[1]Department of Physical and Chemical Disciplines, Lviv Medical University, Lviv, 79018, Ukraine; [2]Institute of Animal Biology of NAAS, Lviv, 79034, Ukraine

The chemiluminescence (CL) methods unlike the other methods of determining free radicals (FR) allow investigating the kinetics of the derivation and recombination of radicals/antioxidants, and thus the development and attenuation of the process/processes after excitation in time. However, these methods are of limited application because the knowledge of the explored parameters is insufficient (maximum intensity and integrated area under the kinetics plot). The kinetics is studied by the CL methods and a new parameter (IR-criterion) of analysis of damping of the initiated CL dynamics has been introduced. The IR-criterion parameter: identifies the relationship between the rates of initiation and recombination of peroxide radicals in blood-serum samples; allows the full straightening of the CL curves; provides new information in the considered pathological processes; can serve as an additional universal characteristic of FR activity of blood serum in pathological processes.

INTRODUCTION

Causal connectivity between pathological states and lipid peroxidation has been analyzed in the scientific literature for a long time and serves as the subject of research by many scientists.

The studies are performed in several directions. Some of them are quantitative content analysis of oxidation products such as diene conjugates and malondialdehyde (Varesi *et al.*, 2022; Eggen *et al.*, 2022; Chen *et al.*, 2022). Other methods include spectral (Rubio *et al.*, 2021) and photometric analysis (Reidy *et al.*, 2023). In this case, one cannot ignore the research methods of the antioxidant status (Bojarczuk *et al.*, 2022), because antioxidants inhibit oxidation processes. All the above-mentioned methods are methods for testing the end-products of oxidation. Only the chemiluminescence methods provide opportunities to study the oxidation dynamics and branching of the oxidation chain (Mas-Bargues *et al.*, 2022). The recombination of radicals R˙, R˙₂, leads to light (Damle *et al.*, 2022). The electrons of these substances are in an excited energy level during the transition to the basic state and the substance is emitting the excess energy as a photon. Exactly this emission is called CL (Li *et al.*, 2022). Studying this process can provide much information about the processes occurring in the body (Oliynyk 2022).

Considering the benefits of the CL method highlights the following aspects

The first aspect is sensitivity. The recombination of radicals is responsible for the intensity of CL (Romodin 2022; Colowick *et al.*, 1986). Therefore recombination of radicals will determine the intensity of the glow of the process and the presence of oxidative stress (OS) in the body (Colowick *et al.*, 1986) and the CL methods are sensitive. They reveal the influence of drugs on the body and the quality of screening and monitoring therapeutic manipulation (Kohno *et al.*, 2008).

The second aspect is equally important; it is the speed of analysis. CL analyzers provide information for three minutes, and do not require expensive and specific reagents. In this case, bioliquids analysis as an estimation of the oxidative status of the whole organism is meant, not the surface CL methods of studies of a surface and local detection of problems and areas of defeat (Teruyama *et al.*, 2022; Syed *et al.*, 2021; Deepa *et al.*, 2022).

The usage of luminol and metals of variable valence greatly enhances the potential for utilizing and implementing CL methods in laboratory research. One of the applications is the investigation of the kinetics of initiated CL. The CL kinetics are initiated by adding hydrogen peroxide to the bioliquid, followed by the occurrence of glow kinetics. As with any typical laboratory analysis, such studies should have quantitative characteristics (Freyer *et al.*, 2008). There are several such characteristics identified:

– the intensity of the maximum peak I_{max} – defines the maximum concentration of peroxide radicals formed in the sample after the introduction of hydrogen peroxide;
– the area under the plot S – determines the total number of radicals formed during peroxidation processes.

These are two main features of the study. Also, there are two additional numerical characteristics of kinetics: the maximum angles of the increase and the glow recession. They characterize the maximum rates of formation and recombination of radicals (Oldham *et al.*, 2000; Rizzo *et al.*, 2022; Kaczmarek, 2011; Wang *et al.*, 2016). Yet, all these quantitative characteristics do not allow conducting a qualitative analysis without studying the kinetics curves.

The initial use of the methods of investigation of initiated CL kinetics for the analysis of lipid peroxidation was promising. However, they have not been widely introduced into diagnostic laboratory practice due to some issues:

– the variability of curves of initiated CL
– these parameters (Imax, S) do not allow a quantitative diagnosis of pathology (Muller *et al.*, 2013)
– at pathological stages, these parameters often overlap
– deviation of one of them does not always indicate pathology
– getting two or more parameters in normal limits does not ensure the absence of a pathological condition.

The present article is devoted to the finding of such an additional quantitative clinical diagnostic criterion for analyzing initiated CL kinetics.

MATERIALS AND METHODS

The method of initiated CL requires using $FeSO_4$ to study blood serum. Ions of variable valence make it possible to increase the intensity of CL by oxidation chain branching. The temperature of the experiment was 38°C.

In experiments, we used fibrinogen-free *BS* of healthy people and also patients with different pathological processes. Blood samples for the experiments were taken in the morning on an empty stomach. The initiated H_2O_2 (2%) CL BS in the solution ($BS + FeSO_4$) (0.02 mM) + phosphate buffer) was investigated. We did not utilize any additional radiation to initiate the luminescence. The glow resulting from the chemical reaction was captured using an FEU-79 photomultiplier. The electrical signal obtained was then amplified and processed by a PC (refer to Fig. 1).

More details on the experiment methodology and equipment are available below in this article (Oliynyk, 2016; Chaichi *et al.*, 2016).

Free radical oxidation involves three stages: initiation with speed w_i, propagation, and termination (free radicals combine to form stable molecules (with radiation of excess energy) and prevent their further reaction with other molecules (without light emission).

Overall, free radical oxidation can cause damage to cells and tissues in the body, leading to various diseases and conditions such as cancer, cardiovascular disease, and aging. Antioxidants can help to prevent or reduce the damage caused by free radicals by neutralizing them and breaking the chain reaction.

The most significant influence on the CL process with a lack of branching is introduced by the recombination of radicals. Consequently, the emission intensity is proportionate to the speed of that recombination:

$$I=\eta k[\text{rdicals}]^2 \tag{1}$$

where:
η – the CL quantum efficiency
k – the constant of the speed of the peroxy radicals recombination
[rdicals] – the radicals concentration.

Since the recombination of FR mainly leads to radiation. Initiation is characterized by a sharp flash, and transition into the stationary condition is characterized by a decrease in the CL intensity.

In Non-Stationary mode:

$$-\frac{d[\text{radicals}]}{dt} = w_i - \eta k\,[\text{radicals}]^2 \tag{2}$$

where w_i is the constant of the rate of the radicals formation.
t – time moment.

We ignored all the intermediate reactions of peroxidation therefore in the future we will use the above definition.

Integration of the given formula leads to the following result:

$$\frac{1}{2\sqrt{w_i k}} ln \frac{[\text{radicals}]\sqrt{k}+\sqrt{w_i}}{[\text{radicals}]\sqrt{k}-\sqrt{w_i}} = t \tag{3}$$

In Stationary mode, when our system stabilizes $\frac{d[\text{radicals}]}{dt} = 0$, so:

$$[\text{radicals}]_\infty = \sqrt{\frac{w_i}{k}} \tag{4}$$

then we get

$$ln \frac{[\text{radicals}]+[\text{radicals}]_\infty}{[\text{radicals}]-[\text{radicals}]_\infty} = 2t\sqrt{w_i k} \tag{5}$$

substitute into (see Eqn 5):

$$\frac{I_\infty}{I} = \frac{[\text{radicals}]_\infty^2}{[\text{radicals}]^2} \tag{6}$$

the final result:

$$ln \frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}} = 2t\sqrt{w_i k} \tag{7}$$

where:
– the time from the moment when hydrogen peroxide was introduced
I – the emission intensity for the t time moment
I_∞ – the emission intensity at the moment when intensity becomes stationary (in our case after 70 seconds).

So in $\left(t, ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}\right)$, rectification of the initiated CL kinetics coordinates should take place.

BS is a complex heterogeneous environment and therefore the process of oxidation and recombination will be much more difficult for several reasons. Primarily, the heterogeneity and presence processes of radical hydration radicals. This will be shown in forthcoming studies on spectrum analysis during the reaction of recombination of peroxide radicals.

Note that the kinetics of fluorescence and phosphorescence spectra often exhibit similar kinetic curves. However, in the case of chemiluminescence, the glow occurs due to the recombination of free radicals, such as peroxides, which are formed as a result of a chemical reaction. The subsequent process involves relaxation to the ground state of the recombination products. In contrast, in fluorescence and phosphorescence kinetics (without observing a

Figure 1. Chemiluminometer.
1: Suvette with the sample; 2: Parabolic mirror; 3: Collective lens; 4: Photodetector device, which includes a system of detection, amplification, conversion, analysis and signal output.

chemical reaction), only relaxation to the ground state occurs, as the molecule is excited during light irradiation of the sample. If fluorescence and phosphorescence are utilized to enhance the glow in the chemiluminescence reaction, the proposed approach carries the same significance.

All the samples of BS at pathological conditions were taken before medical treatment. The main task of this study is to refute or confirm the theory that chemiluminograms will be straightened in the specified coordinates. That the tangent of the straightening angle (IR-criterion) may vary depending on the pathology.

More than 774 chemiluminograms were analyzed, but only a few pathological conditions were selected. The criterion for choosing pathological conditions to be analyzed was an attempt to combine viral, bacterial, and fungal infections, and diseases of unknown etiology – sarcoidosis. We did not include cancer – they will be the subject of a forthcoming study.

Note: On each BS sample, we conducted a minimum of three independent parallel experiments and made an interesting discovery. When it came to Imax and S, we had to discard results that deviated by more than 5% to avoid false-positive outcomes. However, for the angle tangent, such exclusion was unnecessary as the results did not differ by more than 5%. Thus, the relationship between the rates of initiation and recombination of peroxide radicals in the samples appears to be a more stable characteristic than the area under the plot and the maximum intensity of ICL. This suggests that in the analysis of $2\sqrt{w_i k}$, we have a more reliable parameter than Imax and S. Nonetheless, chemiluminograms displaying a deviation of more than 5% across all these parameters were rejected since we also analyzed the average values for Imax and S. Please refer to Fig. 2 for the calculation scheme.

Below we describe the division of patients suffering from different forms and diseases into six groups:

1. Active forms of pulmonary tuberculosis 14 (fourteen) people, the tuberculosis was diagnosed for the first time (disseminated forms of tuberculosis).

2. Sarcoidosis 8 (eight) people.

3. Hepatitis 21 (twenty-one) people. Viral hepatitis is not divided into subgroups. The group includes viral hepatitis of the group A, B, C.

4. Influenza 20 (twenty) people. The blood sampling was done after hospitalizing, the strain was not classified.

5. Asperhiloma 5 (five) people. Asperhiloma of the lungs was investigated against the background of pulmonary tuberculosis.

6. The control group of 51 (fifty-one) people.

RESULTS AND DISCUSSION

The differences in the results for I_{max} and S between the control group and pathological conditions were not

Figure 2. Scheme of conducting experiments and calculations in each group.

Figure 3. Typical view of a chemiluminogram of one of the samples of the control group.

always clear although these parameters were well correlated between themselves within a group.

The group correlation coefficients:
1. Active forms of pulmonary tuberculosis – 0.944
2. Sarcoidosis – 0.88
3. Hepatitis – 0.84
4. Influenza – 0.95
5. Asperhiloma – 0.76
6. Control – 0.93.

This means that within a group the parameters Imax and S are interrelated. The weakest correlation between I_{max} and S values was observed in aspergilloma. This could be due to the fungal infection and its stage, which can cause changes in the ratio between primary and secondary radicals in the middle of the group. Similar deviations were also observed in the middle of the group with sarcoidosis and hepatitis. Chemiluminescence is a highly sensitive parameter, and even the phase of the lesion can affect the relationship between I_{max} and S values, and thus the correlation between them.

Figure 3 shows a typical view of a chemiluminogram of one of the samples of the control group. The first maximum appeared at 0.6–1 sec after the introduction of H_2O_2. After this, the intensity of luminescence sharply decreased.

In the control group and in all pathological processes, there was no difference in the chemiluminogram view (except the group of chemiluminograms for certain types of cancer). All the chemiluminograms have an exponential character.

The confidence intervals of the main parameters for each pathology (the maximum intensity and the area under the plot) overlap with the confidence intervals of the parameters for the control group. This indicates selective sensitivity to the disease and low specificity of the corresponding criteria (see Table 1).

The analysis of chemiluminograms as to the coordinates $\left(t; \ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}\right)$ (see Fig. 4) showed the straightening of chemiluminograms for the control group and in all pathological conditions in coordinates $\left(t; \ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}\right)$.

Let's write the equation $\ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}} = 2t\sqrt{w_i k}$ in the form $y = at$, where $y = \ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}$. The coefficient for the variable (angle coefficient) $a = 2\sqrt{w_i k}$, is nothing but the tangent of the angle of inclination of the straight line to the abscissa axis. The $2\sqrt{w_i k}$ (IR-criterion) differs from the control group under pathological conditions. Note that we have not analyzed chemiluminograms of other biological fluids; the obtained results we can design only for the blood serum tests (Table 1).

Table 1. Average measured values for different groups.

Pathological conditions	$I_{max} \pm m$ (mV)	$S \pm m$ (mV*sec)	IR-criterion$\pm m$
Control group	1.76±0.07	18.91±1.21	0.081±0.021
Pulmonary tuberculosis	3.10±0.59	38.42±4.69	0.099±0.021

Figure 5. The confidence intervals of parameter $2\sqrt{w_i k_6}$.

A significant increase in the parameters Imax and S relative to the control group was observed only in groups **1** (tuberculosis) (I_{max} at 76.14% ($p<0.05$), S at 103.17% ($p<0.01$)) and **2** (sarcoidosis) (I_{max} at 54.55% ($p<0.05$), S at 147.17% ($p<0.01$)). Such an increase indicates a significant increase of FR in the organism. We know that a quick flash is responsible for the number of primary FR formed in the organism. The primary radicals include semihions, superoxides, and nitroxides. The FR formed during the oxidation are consumed by recombination with emissions of light. Note that under the introduction of hydrogen peroxide into the samples, in the control group and in all pathologies, it was observed a significant level of CL 0.05–0.08 mV. When we came to the plateau of chemiluminograms (in the simulation, we considered this level as a steady state), this level was higher than the original level – 0.1–0.7 mV. The secondary oxidation processes that occur in the system correspond to this level. The high level of the plateau at tuberculosis and sarcoidosis indicates the significant number of secondary radicals formed in the serum samples. These radicals include hypochloride, hydroxyl radicals, and lipid radicals. The parameter S which indicates

the total number of recombinant radicals in the sample by eliminating the quanta of light is also much higher than the norm.

A large number of primary radicals is also observed with diseases such as hepatitis and influenza. I_{max}=2.154 mV – at hepatitis and 1.946 mV – at influenza, however, the situation changes when we consider the total number of radicals recombinated by light emission («Hepatitis» S =28.45 mV×sec, «Influence» S=23.84 mV×sec). At the same time, under these pathologies we sometimes observed results falling into the normal range on these parameters.

A totally different case was with tuberculosis complicated by asperhiloma. In this case, both the number of primary radicals and secondary radicals recombined by light emission was below the norm. These effects can be caused by the four ways of reaction evolution in the sample:
1. the low level of radicals;
2. the high level of antioxidants;
3. non-radiative recombination of radicals;
4. the luminescence quenching molecules' environment.

All these four ways and mechanisms are equally possible and require further study.

The results for the angles tangents of straightening are not homogeneous. In particular – in the IR-criterion, no significant increase in tuberculosis and sarcoidosis was observed. Also, there is an overlapping of the confidence intervals in these diseases (Fig. 5).

A significant overlap of the confidence intervals is observed between tuberculosis and control groups ($p>0.75$), and between the sarcoidosis and control groups ($p>0.75$). At the same time, no overlapping of confidence intervals at hepatitis ($p<0.01$), influenza ($p<0.01$), and asperhiloma ($p<0.01$) were found.

A significant and sustained increase of IR-criteria at influenza, hepatitis, and asperhiloma was observed, which indicates that in these diseases deviations towards the initiation/recombination of peroxide radicals occur. So, we can confidently apply this parameter as an additional criterion to improve chemiluminogram analysis in various pathological conditions, as well as the investigation of processes of free radical oxidation (FRO) and OS.

In modern biology, the activation of lipid peroxidation is considered a universal response of living systems to extreme factors. In general, the proxidant-antioxidant status of the organism reflects the balance between the two opposite actions, namely the antioxidant properties (defence) and the formation of FR (damage). The influence of extreme factors (viruses, bacteria, xenobiotics, radiation, etc.) leads to the rejection of their balance in the prooxidant direction and the development of the so-called OS (Paulsen *et al.*, 2013). On the one hand, FRO at all stages of the course forms a series of products re-

sulting from the interaction of FR with each other and with biological macromolecules (Rahman, 2013). On the other hand, the analysis of the kinetic profile has not appeared as a universal factor in the process progress analysis. Important is the fact that the results of our investigation comply with the data published in literary sources. For example, the authors in (Wilson *et al.*, 2009) point to the fact that the FR play a significant role in the formation of lung fibrosis in pulmonary tuberculosis. This is confirmed by our results, in particular, we observed the increased levels of FR which caused an increase in both CL intensity maximum and S parameter.

For tuberculosis, the rate constants of initiation-recombination reactions are slightly different from the norm. Pulmonary tuberculosis is a serious and contagious illness that results from infection with Mycobacterium tuberculosis. It was studied in research the levels of free radicals, antioxidant capacity, and lipid profile in individuals who are afflicted with pulmonary tuberculosis (Vidhya *et al.*, 2019). When macrophages engulf Mycobacterium tuberculosis, the bacterium prevents the phagosome from maturing and fusing with lysosomes. This allows the pathogen to survive and multiply inside the phagocytic vacuoles, despite the hostile environment created by reactive oxygen and nitrogen intermediates produced by the macrophages. These highly toxic molecules, which include hydrogen peroxide, nitric oxide, and peroxynitrite, are normally produced at low levels during metabolic processes and are neutralized by antioxidant systems in the cell. However, during infection, their concentrations increase and cause damage to the cell's lipids, nucleic acids, proteins, and metal cofactors, leading to mutagenesis, necrosis, and apoptosis (Dalvi *et al.*, 2013) This may be due to a proportional increase in both the primary and secondary FR (Meulmeester *et al.*, 2022) in the body.

Sarcoidosis also causes the OS. Our results reflect an increase of the same parameters (I_{max} and S), therefore the content of FR. Other authors (Boots *et al.*, 2009) point to the reduction of the blood serum antioxidant status. The dependence of the rate of initiation of oxidation and recombination of radicals in this case has not changed, therefore the ratio of primary and secondary radicals in this case corresponds to the norm.

Hepatitis has slightly different parameters. The significantly increased level ($2\sqrt{w_i k}$) of primary radicals against the background of reducing the secondary oxidation processes reveals the fact that the virus itself induces reactive forms of oxygen (Farinati *et al.*, 2007). So, we can predict an increase in oxidation rate constants of oxidation initiation. Furthermore, the mitochondrial dysfunction, observed in work (Moezzi *et al.*, 2022), is induced by the hepatitis C virus and decreases the oxidation of fat acids and accelerates the formation of reactive oxygen forms causing fat accumulation in the liver. This indicates that the number of secondary radicals is reduced, as well as the total number of FR, which fully confirms our results.

Influenza is also characterized by increasing of primary radicals against the background of reducing the total number of radicals in the organism. The indicator IR-criterion increased at this pathological state to which we also find the confirmation in the literature. In particular, in (Andrés *et al.*, 2022), the increase in reactive oxygen forms under this pathological condition was emphasized.

Asperhiloma was the last interesting subject of our study. Again, we observed a decrease in both primary and secondary radicals. Literature source (Ryoo *et al.*, 2009) provides an interesting fact concerning the synthe-

sis of connections based on the fermentation broth of Aspergillus sp. FN070449 (KCTC 26428) with antioxidant properties. So, the aspergillus infection as a complication of tuberculosis may lead to a reduction of the total number of FR. But at the same time, it increases relative to the control group, that is the ratio of primary and secondary radicals increases. The above considerations prove, that the introduced criterion, quantitatively and informatively shows the evolution of oxidative processes in the organism and can serve as an additional clinical diagnostic criterion for the quantitative analysis of chemiluminograms.

Although the analysis of chemiluminograms did not demonstrate selective specificity and sensitivity towards pathologies, it is still a useful and relevant method for evaluating the level of free radical processes in patients and monitoring their dynamics (for the purpose of assessing treatment effectiveness). Additional justification is required for the analysis of fluorescence and phosphorescence kinetics. However, preliminary analysis suggests that the fluorescence and phosphorescence kinetic curves also align within these coordinates.

CONCLUSIONS

As a result of the analysis of chemiluminograms, we introduced an additional quantitative criterion (IR-criteria/ $2\sqrt{w_i k}$). The parameter introduced displays the angle tangent of straightening chemiluminograms in the coordinates $\left(t;\ ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}\right)$. This straightening was observed in chemiluminograms under normal conditions and in pathological processes, with the exception of with the exception of chemiluminograms characterized by two peaks. The basic assumption in the simulation was the absence of a degenerate chain FRO.

Through a comparative analysis of available publications, we found significant consistency between the data of peroxide oxidation/free radicals and obtained by us the new parameter. This suggests that this criterion can be considered a complementary and independent parameter for estimating FRO.

Therefore, the investigation of the straightening of chemiluminograms in the coordinates $\left(t;\ ln\frac{\sqrt{I}+\sqrt{I_\infty}}{\sqrt{I}-\sqrt{I_\infty}}\right)$ reveals promising perspectives for comparative monitoring of pathological states and creates a new paradigm in the study of the kinetics of initiated CL. This analysis will enable the combination of parameters such as intensity and area under the graph, providing an additional description of the rapid chemical transformations accompanied by light emission.

Candida glabrata is an important opportunistic human pathogen well known to develop resistance to antifungal drugs. Due to their numerous desirable qualities, antimicrobial lipopeptides have gained significant attention as promising candidates for antifungal drugs. In the present study, two bioactive lipopeptides (AF_4 and AF_5 m/z 1071.5 and 1085.5, respectively), coproduced and purified from *Bacillus subtilis* RLID12.1, consist of seven amino acid residues with lipid moieties. In our previous studies, the reversed phased-HPLC purified lipopeptides demonstrated broad-spectrum of antifungal activities against over 110 *Candida albicans, Candida* non-*albicans* and mycelial fungi. Two lipopeptides triggered membrane permeabilization of *C. glabrata* cells, as confirmed by propidium iodide-based flow cytometry, with PI uptake up to 99% demonstrating fungicidal effects. Metabolic inactivation in treated cells was confirmed by FUN-1-based confocal microscopy. Together, the results indicate that these lipopeptides have potentials to be developed into a new set of antifungals for combating fungal infections.

KEYWORDS

antifungal, bioactive, *Bacillus subtilis*, *Candida glabrata*, lipopeptides, membrane permeabilization

Introduction

After *Candida albicans*, the most prevalent yeast species reported to have been isolated from humans is *Candida glabrata* (*C. glabrata*). The past two and a half decades have witnessed *C. glabrata* becoming one of the most predominant *Candida* species, causing fungal infections (Chakrabarti et al., 2009; Lockhart et al., 2012; Benaducci et al., 2014; Cleveland et al., 2015; Pappas et al., 2018; Naicker et., 2023). The reason behind this steep upward trend of *C. glabrata* infections may be associated with geographical variation and the rampant overuse of azoles (Richardson and Lass-Flörl, 2008). Given the prevalence of *C. glabrata* as the second leading cause of candidiasis infections,

including oral candidiasis, candidemia, invasive candidiasis, and urinary candidiasis (Esfandiary et al., 2012; Nash et al., 2016), it is essential to understand the alarming 40% mortality rate associated with *C. glabrata* infection underscores the seriousness of this opportunistic human pathogen, especially in immunocompromised hosts (Rodrigues et al., 2014; Mota et al., 2015; Nagayoshi et al., 2017). It has been recently reported that *C. glabrata* has developed several strategies to survive and thrive in its host cells and found ways to overcome antifungal resistance to commonly used antifungals, which also contribute to increased virulence (Pappas et al., 2018; Salazar et al., 2018). Flow cytometry (FCM) has been one of the major techniques that has successfully demonstrated its utility in determining the effect of antimycotics on yeast cells, cell membranes, or mechanisms of action when used with appropriate dye or fluorescent probes and experimental conditions (Pore, 1994). In our previous study (Ramachandran et al., 2018b), the antifungal susceptibility test (AFST) analyses of the two lipopeptides were done according to the CLSI guidelines. In this current investigation, the two lipopeptide fractions (AF$_4$ and AF$_5$) coproduced by *Bacillus subtilis* RLID 12.1 were purified, and the main objective of the study was to determine their membrane-permeabilizing effects on the yeast cell membrane and metabolic activity at two different peptide concentrations using the membrane-impermeant propidium iodide (PI) dye and two-colour FUN-1 stain.

Materials and methods

Microorganisms

The test strain *C. glabrata* ATCC 2001 was obtained from the National Culture Collection of Pathogenic Fungi (NCCPF), Post Graduate Institute of Medical Education and Research (PGIMER) Chandigarh, India and maintained as 20% glycerol stock at −80°C. The producer strain was also maintained as glycerol stock at −80°C.

Extraction and purification of antifungal compounds

For the purification of antifungal lipopeptides, cell-free supernatant (CFS) was obtained after 60 h at 30°C of incubation under stirring conditions of cells of the strain *B. subtilis* RLID 12.1. The CFS was subjected to a three-step purification that included HCl precipitation, solvent extraction using n-butanol, and silica gel (mesh size 230–400) based adsorption chromatography using proper ratios of methanol and chloroform. After the adsorption chromatography, all the collected fractions were tested for antifungal activity by spot-on-lawn assay against freshly grown *C. glabrata* cells spreading on Sabourad dextrose agar (SDA) plates. The 5 μL

aliquots of fractions which showed the clear zones of inhibition after 24 h of incubation were considered as bioactive fractions. These bioactive fractions AF$_4$ and AF$_5$ were fractionated using the reversed phased-HPLC system (Agilent Technologies, United States) at a semi-preparative scale equipped with a variable wavelength detector and an Agilent C18 column (10 mm × 250 mm, 5 μm) (Ramachandran et al., 2018a; Ramachandran et al., 2018b). The analytical scale HPLC profiles of AF$_4$ and AF$_5$ and their m/z values are shown in Supplementary Figure S1.

Antifungal susceptibility testing (AFST) against *Candida glabrata*

The minimum inhibitory concentrations (MICs) of the purified antifungal lipopeptides AF$_4$ and AF$_5$ were tested against *C. glabrata* ATCC 2001, according to CLSI guidelines (M27-A2) (Clinical and Laboratory Standards Institute, 2008). For antifungal assays, two-fold serial dilutions of each drug were prepared in RPMI-1640 (pH 7.0 ± 0.1) (with L-glutamine and phenol red without sodium bicarbonate) was buffered with 0.165 M MOPS (morpholinepropanesulfonic acid) (Himedia) and supplemented with 0.2% glucose. As reference yeast strain for the AFST, *C. albicans* ATCC 24433 and the positive control amphotericin B (AMB) (HiMedia, India) were used.

PI uptake assay by flow cytometry (FCM)

To study the impact of novel antifungal lipopeptides on membrane integrity, lipopeptides AF$_4$ and AF$_5$ (8 and 16 mg/L), and AMB (×1 and ×2 MIC) were added to *Candida* cell suspension (1 × 10^6 CFU/mL) in RPMI 1640 and incubated at 37°C for 18 and 5 h, respectively, in shaking conditions (Gokahmetoglu et al., 2003; Seyedjavadi et al., 2020). Two types of controls were used in the study: negative controls consisting of untreated cells, and PI positive controls, treated with 70% ethanol for 30 min. Post-incubation, the cells were harvested, washed with 1× phosphate buffered saline (PBS), and stained with PI at a concentration of 7.5 μg/mL for 20 min. Unstained and untreated cells were sampled and analysed in the beginning. Flow cytometry analysis was performed on 30,000 events using a FACSMelody flow cytometer with a 488 nm laser line and a 586 nm filter with PI detection.

Viability (CFU) assays

Prior PI staining, aliquots of yeast cultures (both untreated and treated) were collected, serially diluted in sterile 1×PBS, and plated in duplicate on SDA plates (Chaturvedi et al., 2004; Ramesh et al., 2023). The plates were incubated for 24 h at 37°C, colonies were

FIGURE 1
The effect of the lipopeptide AF$_4$ on the cell membrane permeability of *C. glabrata* 2001, measured by PI uptake. Experiments recorded forward scatter, side scatter, and the percentage of PI-stained cells, and the data was analyzed using the software FlowJo version 10.8.1. The histograms related to PI fluorescence intensity were split into two quadrants, i.e., one with PI negative cells (viable cells), and another with PI-positive cells (membrane compromised cells). **(A)** Flow cytometry analysis of membrane permeabilization assay by PI uptake. **(B)** The side scatter versus PI plot shows the shift of population of PI-positive cells along the x-axis. **(C,D)** Confocal images of *C. glabrata* cell membrane integrity treated with AF$_4$, AF$_5$ and AMB monitored by PI uptake (Left panel, magnification 60 × 2 and, right panel 100 × 2, respectively). A few cells in the field as indicated by white arrows are non-viable.

counted, and findings were represented as the percentage reduction in CFU/mL compared to the growth in the untreated sample.

Confocal laser scanning microscopy (CLSM)

The CLSM analysis was performed using PI (ThermoFisher, United States) and [2-chloro-4-(2, 3-dihydro-3-methyl-(benzol-1, 3-thiazol-2-yl)-methylidene)-1-phenylquinolininum iodide] FUN-1 (ThermoFisher, United States) (Chan et al., 2011; Zhang et al., 2018). Cells were treated with AF$_4$/AF$_5$ (8 and 16 mg/L) for 18 h, AMB (1 mg/L) for 5 h, and untreated cells were used as control. Post-treatments, cells were harvested and resuspended in 1×PBS, following which staining with PI (7.0 μg/mL) for 20 min in the dark and washing with 1×PBS were done. FUN-1 at a final concentration of 5 μM was prepared in 10 mM glucose-HEPES (GH) buffer, and cells were incubated in (GH)

FIGURE 2

Cells were treated with AF$_5$ (8) and (16) mg/L compared with the control (untreated). **(B)** The side scatter versus PI plot shows the shift of population of PI-positive cells along the x-axis. Density plot of PI uptake by *C. glabrata* cell populations of a) unstained, b) control, and c) and d) AF$_5$ (8) and (16) mg/L treated cells, respectively, along with e) 70% ethanol. Ethanol-treated cells exhibited a high permeability to PI (99.99% cells stained). **(C)** Confocal image (×200 magnification) showing cells stained with FUN-1, the AF$_4$, AF$_5$ and AMB treated cells are without discernible and red fluorescent CIVS and show yellow-green fluorescence in the merged channel, representing metabolically inactive cells compared to untreated cells. The inset images show non-viable cells from another field.

buffer with FUN-1 stain for 30 min (Pina-Vaz et al., 2001; Kwolek-Mirek and Zadrag-Tecza, 2014; Yan et al., 2019). Treated and untreated cells were imaged with an Olympus FV3000 (Japan) microscope at 60 × 2 and 100 × 2 magnifications for PI-stained cells and 100 × 2 for FUN-1 stained cells.

Statistical analysis

Experiments were performed in three individual times with two technical replicates. Data are presented as the means ±SD values and, One-way ANOVA statistical analysis was done in the Graph-pad prism Software version 9.3.1.

Results and discussion

The MICs of two lipopeptides and AMB (used as the standard antifungal) against *C. glabrata* were determined to be 4 mg/L and 1 mg/L, respectively. The results agree with the previously determined MIC values (Ramachandran et al., 2018b; Ramchandran et al., 2020). To gain more insights into lipopeptides' membrane permeabilizing potential, we performed PI uptake assays using 8 mg/L (×2) and 16 mg/L (×4) MICs as determined by the AFST for *C. glabrata* ATCC 2001. FC results were expressed as the fluorescence intensity (FI) of PI-stained yeasts. AF_4 and AF_5 treatments caused cell membrane disruption in *C. glabrata* cells, as seen by the enhanced fluorescence that resulted from PI uptake. In cells treated with AMB, AF_4, AF_5, and 70% ethanol, the increase in PI-fluorescence is manifested as a distinct shift of the peak along the x-axis (Figures 1A, B) and (Figures 2A, B). The histograms pertaining to all flow cytometry assays where *C. glabrata* ATCC 2001 cells were stained with PI after being exposed to AMB for 5 h (Gokahmetoglu et al., 2003) at 1 and 2 mg/L and AF_4/AF_5 (8 and 16 mg/L) for 18 h have been shown in Figures 1A, 2A. All the events of FC population density plots have been shown in Figures 1B, 2B.

Significant congruence was found when comparing the proportion of PI uptake with the drop in CFU/mL among AF_4 treatments. A substantial association was observed between the percentage PI uptake estimated in flow cytometry and the percentage reduction in plate counts, presented in tabular form (Table 1) to summarize the findings. Cells unexposed to lipopeptides showed very negligible fluorescence, as evidenced by the PI uptake percentage graph (Figure 3). At 8 mg/L, the AF_4-treated *C. glabrata* showed an average of 81.92% PI-positive cells and 99.90% CFU reduction, better was the observation in AF_4-(16 mg/L)-treated *C. glabrata* cells, where 99.51% PI-positive cells were noted and a CFU reduction of 99.97% recorded (Figure 3; Table 1). At 8 mg/L, the AF_5-treated *C. glabrata* showed an average of 92.14% PI-positive cells and 99.4% CFU reduction. However, AF_5-(16 mg/L)-treated *C. glabrata* cells showed 81.35% PI-positive cells, and the CFU reduction of 99.92% was recorded, indicating that AF_5 even at a 2-fold concentration, did not show more membrane permeabilization and increased fungicidal effects. This may be due to the hydrophobic aggregation of AF_5 lipopeptide at higher concentrations (Ramchandran et al., 2020). In AMB (1 and 2 mg/L)-treated cells for 5 h, only 20.02% and 26.06% PI-positive cells were detected, respectively. The increase in the fluorescence intensity percentage observed in yeast cells treated with higher AF_4 and AF_5 (8 mg/L) concentrations agreed with the positive control values, indicating potential antifungal activity. In comparison, untreated cells showed negligible fluorescence.

Candida cells exposed to AF_4/AF_5 (8 mg/L) displayed PI uptake as evident from red fluorescence, indicating cell membrane damage and hence permeabilization [Figure 1C (×120) and Figure 1D (×200)] magnifications. Since the formation of cylindrical intravacuolar structures (CIVS) needs metabolically active cells with undamaged plasma membrane, the presence of yellow-green fluorescence (Figure 2C) in FUN-1 stained cells instead of red

TABLE 1 Correlation between PI uptake percentage from flow cytometry and plate count.

Drug (concentration)	PI uptake (%)	Plate count	
		Log reduction	Reduction (%)
AF_4 (8 mg/L)	81.92 ± 8.7 SD	3.03	99.90 ± 0.79 SD
AF_4 (16 mg/L)	99.51 ± 0.07 SD	3.64	99.97 ± 0.59 SD
AF_5 (8 mg/L)	92.14 ± 6.8 SD	2.25	99.44 ± 0.82 SD
AF_5 (16 mg/L)	81.35 ± 12.8 SD	3.10	99.92 ± 2.1 SD
AMB (1 mg/L)	20.02 ± 6.7 SD	4.12	99.99 ± 0.53 SD
AMB (2 mg/L)	26.06 ± 6.02 SD	4.43	99.99 ± 0.56 SD

FIGURE 3
The histogram analysis in the graph shows the percentage of PI-positive *C. glabrata* cells upon (AF$_4$/AF$_5$) antifungal treatments. Ethanol-treated yeast cells exhibited a high permeability to PI (99.99% of cells stained). P-values (****$p < 0.0001$) indicate statistically significant differences from the effects of AF$_4$ and AF$_5$-treatments and control (untreated). Statistically significant observations were made between AMB-treated cells and control used during AMB-treatments.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Author contributions

MM was exclusively involved in the experimental works and preparing the preliminary draft. SMR oversaw the progress of the work and has been the co-principal investigator of the project. UR was involved in the logistics part, designing the experiments and revising the manuscript. All authors contributed to the article and approved the submitted version.

fluorescence in lipopeptide-treated cells clearly indicates the loss of membrane integrity, metabolic activity, and cell death (Millard et al., 1997). The cell deaths are quite evident from the log reductions of 3.03 and 3.64 CFU/mL by AF$_4$ (8 and 16 mg/L). In the lipopeptide-treated and AMB-treated cells CIVS were not observed. Collectively, it may be surmised that the prime targets of AF$_4$ and AF$_5$ might be the components of the cell membrane (Ramesh et al., 2023). The presence of a long acyl chain in antifungal cyclic lipopeptides such as iturin and fenzycin enables oligomer formation and subsequent insertion into the plasma membrane (Malina and Shai, 2005) and the organisation of aggregates in biological membranes triggering early membrane damage and membrane disintegration was also reported by Horn et al. (2013). The preliminary mechanism of action on the yeast cell membrane has been schematically depicted in the Supplementary Figure S2. Taken together, the results revealed that two lipopeptides demonstrated remarkable fungicidal effects on *C. glabrata* cells with enhanced cell membrane permeability, and damage. Consequently, the findings positively indicate that the lipopeptides AF$_4$ and AF$_5$ hold considerable promise as prospective antifungal agents.

Intrauterine development is a key period in human life. The foetal progress largely depends on the function of the placenta, whose responsibility is transportation and biosynthesis of fatty acids. Desaturation enzymes play a key role in placental fatty acid metabolism. Expression of genes coding for desaturases may be associated with pregnancy abnormalities. The objective of this study was to determine the transcriptional activity of the placental genes Fatty Acid Desaturases 1, 2 and 3 (FADS 1, 2 and 3) in women who gave birth to the infants appropriate for gestational age, large for gestational age, small for gestational age, with intrauterine growth restriction and born preterm. 34 pregnant women aged 21–37 years old participated in the study. The placental samples were taken from a site located 2–3 cm away from the umbilical cord attachment. The collected tissue sections were stored in RNAlater according to the manufacturer's protocol, until required for molecular analysis. The expression profiles of *FADS1*, *FADS2* and *FADS3* were determined with RT-qPCR. There was no difference in *FADS1* and *FADS2* expression between the groups. However, the differences in the expression of the *FADS3* were found. Analysis of the *FADS1*, *FADS2* and *FADS3* transcription showed significant differences between most of the examined groups. Our findings suggest that the transcriptional activity of *FADS* genes changes with the severity of intrauterine disorders and is associated with foetal lipid disorders linked to a greater accumulation of fat in the foetal tissues.

Keywords: placenta, foetal development, desaturases, fatty acids, gene expression

INTRODUCTION

Intrauterine foetal development is a critical period in human development. Subsequent health, susceptibility to diseases, intelligence, and many other factors are dependent on this foetal stage (Bobiński & Mikulska, 2015). The placenta plays a key role during pregnancy. It controls metabolic processes on the hormonal pathway between the organisms of the mother and child – including oxygenation and supplying the foetus with building and energy substrates (Bobiński *et al.*, 2013; Bobiński & Mikulska, 2015). Placental abnormalities lead to premature births with varying degrees of foetus malnutrition (e.g., intrauterine growth restriction, IUGR), as well as the birth of small for gestational age (SGA) or large for gestational age (LGA) babies. Fatty acids (FA) are one of the most important ingredients that determine proper intrauterine development. They are responsible for the structure of the child's nervous system, development of cell membranes, structure and function of the retina as well as fulfilling many other metabolic and structural functions (Helland *et al.*, 2003; Gale *et al.*, 2008). The diversity of FA functions results from the high heterogeneity of their structure, determined by the number of carbon atoms and the number and location of unsaturated bonds in the carbon chain. The source of FAs for the developing foetus is the mother's diet (Herrera, 2002; Cetin *et al.*, 2009a), the release of FA from deposits in maternal tissue (Prentice & Golberg, 2000), the endogenous biosynthesis of FA by the mother and later – foetal FA synthesis (Clandinin *et al.*, 1981). The placenta is primarily responsible for the maternal-foetal metabolism of FA; this includes transportation of the FA from mother to foetus, as well as placental FA biosynthesis and modification. Placental transfer is determined by numerous factors, such as the mother's health, condition of the foetus, transport efficiency of the placenta and diet during pregnancy (Cetin *et al.*, 2002; Haggarty 2002; Cetin *et al.*, 2009a). Some placental disorders can impair FA metabolism, and this may lead to intrauterine foetal developmental disorders and a predisposition to numerous diseases after birth. Changes in the activity of the enzymes responsible for the desaturation of essential fatty acids (EFAs) seem to be particularly important in the maternal-foetal homeostasis. The first of these is delta-5 desaturase (D5D) [EC 1.14.19.44], encoded by the fatty acid desaturase 1 (FADS1) gene.

This gene is clustered with its family members at 11q12-q13.1 (Lattka *et al.*, 2010). This desaturase plays one of the key roles in the biosynthesis of long-chain polyunsaturated fatty acids (L-CPUFA) of both the n-3 and n-6 families. D5D introduces a cis double bond at carbon 5 into dihomo-gamma-linoleate (DGLA) (20: 3n-6) and eicosatetraenoate (ETA) (20: 4n-3) to generate arachidonate (AA) (20: 4n-6) and eicosapentaenoate (EPA) (20: 5n-3), respectively. The second important enzyme in the biosynthesis pathway of L-CPUFA is delta-6-desaturase [EC 1.14.19.3]. It introduces a double cis bond at carbon 6 in linoleic acid (LA) (18: 2n-6) and alpha-linolenic acid (ALA) (18: 3n-3). As a result of this reaction, gamma-linoleate (GLA) (18: 3n-6) and stearidonate (18: 4n-3) are formed, respectively (GeneCards The Human Gene Database, Weizmann Institute of Science, Israel., 2020a). The third representative of desaturases is the delta (13) desaturase (D13D) enzyme (EC 1.14.19.-) encoded by the FADS3 gene. D13D introduces a cis double bond in (11E)-octadecenoate (trans-vaccenoate) at carbon 13 to generate (11E, 13Z)-octadecadienoate, likely participating in the biohydrogenation pathway of LA (GeneCards The Human Gene Database, Weizmann Institute of Science, Israel., 2020b). Under normal conditions, the activity of these enzymes remains in a delicate dynamic balance, maintaining the biosynthesis of L-CPUFA n-3 and n-6 at the appropriate level. Disturbance of enzymatic activity, which may be caused by altered transcriptional activity of FADS genes, may contribute to the loss of control over the biosynthesis of the membrane phospholipids and DHA – the key lipids for the development of the foetal nervous system (Otto *et al*, 1997), as well as the loss of control over the metabolism of inflammatory lipids, such as prostaglandin E2 ,which is critical for acute inflammatory response, maintenance of epithelial homeostasis (Challis *et al.*, 2002) and metabolic disorders, such as diabetes, lipid disorders, cardiovascular diseases, etc. (Cetin *et al.*, 2002). The processes controlled by these desaturases are extremely important for the intrauterine development of the foetus, especially for the structure of its nervous system. Therefore, the aim of the study was to analyse the expression (at transcription level) of the FADS1, fatty acid desaturase 2 (FADS2), and fatty acid desaturase 3 (FADS3) genes.

MATERIALS AND METHODS

Study population

The research was conducted with the approval of the Ethics Committee in Bielsko-Biala under approval no:

2016/02/11/4. All relevant guidelines and regulations were adhered to, and informed consent was obtained in writing from all the participants. The study population consisted of 34 women who gave birth at the Provincial Specialist Hospital No. 1 in Tychy, Poland. The pregnant women were recruited for the study during their first visit to the hospital. The women were between 21 and 37 years of age. A description of the study population is provided in Table 1.

To obtain a homogeneous group of women, the following inclusion criteria were applied (Bobiński *et al.*, 2013; Waksmańska *et al.*, 2017):

– Polish nationality (excluding naturalised Polish citizens); single pregnancy; pregnancy I-III (parity considered);

– Stable socioeconomic status; married, secondary level or higher education; living in a highly industrialised urban region, both the women and their husbands having a steady job;

– Consenting to participate in the study.

The following exclusion criteria were applied (Bobiński *et al.*, 2013; Waksmańska *et al.*, 2017):

– Chronic diseases occurring before pregnancy, such as pre-gestational diabetes; pathologies during the course of pregnancy such as infections during pregnancy (any kind of infection in the perinatal period, such as fever, respiratory infections, urinary infections, etc.); miscarriages and/or premature birth resulting in the death of the child or developmental anomalies in the foetus;

– AIDS and sexually transmitted diseases;

– Adherence to a vegetarian diet, Mediterranean diet, or any other special diet;

– Lack of consent by the mother to take part in the research programme or withdrawal of consent during the study.

Women who participated in the research programme were classified into five groups according to the following criteria:

– AGA Group (AGA – appropriate for gestational age, n=9): healthy mothers, routine and uneventful pregnancy, full-term delivery neonates (bw 10–90th percentile). Age (y) 27.5±4.3; BMI (kg/m²) 22.6±4.2; delivery (week) 39.6±1.1; neonatal weight (g) 3542.1±387.7; placental weight (g) 503.4±108; mode of delivery 8n/1cs; Apgar score 9–10. AGA served as the control group.

– LGA Group (LGA – large for gestational age, n=10): healthy mothers who gave birth to large for gestational age neonates (bw>90th percentile). Age (y) 29.2±5.2; BMI (kg/m²) 35.6±4.5; delivery (week) 41.8±1.3; neonatal weight (g) 4056.8±411.2; placental weight (g) 693.3±124.9; mode of delivery 1n/8cs; Apgar score 8–9.

Table 1. Characteristics of the study population.

	AGA	LGA	SGA	IUGR	PTB
Age (Y)	27.5±4.3	29.2±5.2	29.1±5.1	25.6±5.7	27.8±4.1
BMI (kg/m2)	22.6±4.2	35.6±4.5	23.8±4.7	37.3±7.2	23.3±4.4
Delivery (week)	39.6±1.1	41.8±1.3	38.2±1.1	34.5±1.9	36.8±1.0
Neonatal weight (g)	3542.1±387.7	4056.8±411.2	2297.5±149.9	1975.6±258.9	2398±432.8
Placental weight (g)	503.4±108	693.3±124.9	356.4±108	423.4±88.8	323.8±102
Mode of delivery	8n/1cs	1n/8cs	6n	6cs	3n
Apgar Score	9/10	8/9	9/10	6/7/8	9/10

n=natural delivery, cs=caesarean section. Apgar Score measured after 1, 3 and 5 minutes.

– SGA Group (SGA – small for gestational age, n=6): healthy mothers who gave birth to full-term, but small for gestational age, neonates (neonatal weight <10th percentile). Age (y) 29.1±5.1; BMI (kg/m²) 23.8±4.7; delivery (week) 38.2±1.1; neonatal weight (g) 2297.5±149.9; placental weight (g) 356.4±108; mode of delivery 6n; Apgar score 9–10.

– IUGR Group (IUGR – intrauterine growth restriction, n=6): mothers who gave birth to babies showing characteristics of intrauterine growth restriction. In this group, all ultrasound studies showed foetal growth restriction (bw <10th percentile). Age (y) 25.6±5.7; BMI (kg/m²) 37.3±7.2; delivery (week) 34.5±1.9: neonatal weight (g) 1975.6±258.9; placental weight (g) 423.4±88.8; mode of delivery 6cs; Apgar score 6–8.

– PTB Group (PTB – preterm birth age, n=3): mothers who gave birth prematurely at 32–36 weeks' gestation to neonates whose weight fell in the 10–90th percentile. Age (y) 27.8±4.1; BMI (kg/m²) 23.3±4.4; delivery (week) 36.8±1.0; neonatal weight (g) 2398±432.8; placental weight (g) 323.8±102; mode of delivery 3n; Apgar score 9–10.

Women eligible for the study underwent three ultrasound examinations. The first ultrasound test was performed between the 12th and 14th weeks of gestation, the second between the 20th and 22nd weeks of gestation and the third one between the 32nd and 33rd weeks of gestation.

Using ultrasound scans, the foetal weight and length were determined primarily according to the gestational age. The dimensions obtained at the 27th gestational week were crucial and determined the appropriate way to proceed with the delivery. Although usually the results of Doppler flow are not considered significant for foetuses younger than 30-weeks, this test was performed too on the foetuses at the 27th week. The foetal dimensions were taken every 6–7 days and marked on a growth chart. If the foetus was between the 10th and 3rd percentile and its gestational age was above 27 weeks further ultrasound scans were conducted to assess hypotrophy or intrauterine foetal growth inhibition (IUGR) according to the radiological criteria. The ultrasound was used to measure the standard parameters of so-called basic foetal biometry, including the bi-parietal diameter (BPD), head circumference (HC), abdomen circumference (AC), and femur length (FL). The ultrasound estimation of foetal weight and length were converted into a growth chart.

Collection of the placentas

The placental samples were collected from a site approximately 2–3 cm away from the umbilical cord attachment. For the research, we wanted to standardise the site of collection to the place where blood supply to the placenta was the highest, ensuring the highest metabolic activity and a strong RNA expression. In our opinion, taking samples from a different site would not give a full picture of the expression of the genes tested. The samples were collected immediately after birth and transported on ice to the laboratory. The transport time did not exceed one hour. The samples were then weighed, immersed in 1 ml RNAlater for 48 hours at 4°C and then snap frozen.

RT-qPCR

Collected tissue sections were stored in RNAlater according to the manufacturer's protocol (Sigma-Aldrich, St Louis, MO, USA) until required for molecular analysis. Total RNA was extracted using TRIzol reagent (Invitrogen Life Technologies, Carlsbad, CA, USA) according to the manufacturer's instructions. The concentration and purity of the obtained extracts were assessed using a MaestroNano MN-913 nano-spectrophotometer (MaestroGen, Inc., USA). The expression profiles of *FADS1*, *FADS2* and *FADS3* were determined in the presence of β-actin as an endogenous control by RT-qPCR using SensiFAST SYBR No-ROX One-Step kit (Meridian Life Science Inc., Memphis, TN, USA) and Opticon DNA Engine Sequence Detector (MJ Research Inc., Watertown, MA, USA) according to the manufacturer's instructions. The reaction was carried out using primer pairs specific for the sequence of each gene tested: *FADS1* (forward: 5' ATGATTACCTTCTACGTCCG 3', reverse: 5' TCAATGTGCATGGGAATATG 3', amplicon length – 149 bp), *FADS2* (forward: 5' GATGAATCACATCGTCATGG 3', reverse: 5' GTGCTCAATCTGGAAGTTAAG 3', amplicon length – 139 bp), *FADS3* (forward: 5' CAACATCTTCCACAAAGACC 3', reverse: 5' CTGGTTGTAGGGTAGGTATC 3', amplicon length – 109 bp), *ACTB* (forward: 5' TCACCCACACTGTGCCCATCTACGA 3', reverse: 5' CAGCGGAACCGCTCATTGCCAATGG 3', amplicon length – 295bp) purchased in Sigma-Aldrich (St Louis, MO, USA). The thermal profile of the RT-qPCR reaction included the following steps: reverse transcription (45°C for 10 minutes), activation of the polymerase (95°C for 2 minutes), 41 cycles consisting of denaturation (95°C for 5 seconds), annealing (60°C for 10 seconds), and elongation (72°C for 5 seconds). A standard curve was plotted for every run, based on which the Opticon DNA Engine Sequence Detector (MJ Research Inc., Watertown, MA, USA) calculated the mRNA copy numbers of studied genes in each sample. The curves were drawn based on the quantitative standard – β-actin (TaqMan DNA Template Reagent kit, Applied Biosystems, Foster City, CA, USA) at five different concentrations (400, 800, 2000, 4000, 8000 copies of *ACTB* cDNA). Each run included positive and negative controls and was completed by melting curve analysis of each sample to confirm the specificity of the reaction. The endogenous control assessment together with the melting curve analysis were the basis for including the results of the studied genes in the comparative analysis. The results are presented as the number of mRNA copies per 1 μg of total RNA.

The calculations were made in the statistical environment R ver.3.6.0, PSPP program and MS Office 2019. Parametric tests (analysis of variance ANOVA) or their non-parametric equivalents (Kruskal-Wallis test) were used to analyse the quantitative variables broken down into groups. The *T*-test and Wilcoxon pairs test were also used. The selection of tests was based on the distribution of variables, which was verified by the Shapiro-Wilk test.

There were no significant differences in β-actin mRNA copy number between the control and study groups, which indicates that β-actin can be used as an endogenous control in this experiment.

RESULTS

FADS1 and *FADS2*

After checking the assumptions of normality, a non-parametric Kruskal-Wallis test was performed to compare the median in individual groups. In terms of the *FADS1* and *FADS2* genes, the groups did not differ

Figure 1. Box plot for *FADS3* expression.
The y-axis represents the number of mRNA copies/1 µg RNA.

significantly (*p*>0.05). The AGA, LGA, SGA, IUGR and PTB groups were therefore similar in terms of the distribution of *FADS1* and *FADS2*.

FADS3

After checking the assumptions of normality of the distribution, it turned out to be possible to use the parametric analysis of variance ANOVA, to compare the average of the dependent variable in the individual groups. In the *FADS3* range, the groups significantly differed statistically (*p*<0.05). Tukey's post hoc test was performed to determine the groups whose means differed significantly.

Significant statistical differences (*p*<0.05) were observed between the following groups: AGA and IUGR, AGA and PTB, LGA and PTB, SGA and PTB, and IUGR and PTB (shown in Fig. 1). In the AGA group, the average values of FADS3 M were: 9149.67 in the AGA group; 4713.50 for IUGR; 967.33 for PTB, 8487.60 for LGA; and 8580.83 for SGA.

In the next part of the analysis, the transcription levels of the *FADS1*, *FADS2* and *FADS3* genes were analysed within each of the research groups (AGA, LGA, SGA, IUGR, PTB) using Friedman's test and Bonferroni's post hoc test.

AGA Group

Friedman's test showed statistically significant differences (*p*<0.05) between *FADS1*, *FADS2* and *FADS3* expression levels within the AGA group. The mean mRNA levels were M=2640.8 mRNA copies/1 µg RNA for *FADS1*, M=494.9 mRNA copies/1 µg RNA for *FADS2*, and M=9149.7 mRNA copies/1 µg RNA for *FADS3* (shown in Fig. 2).

Bonferroni's post hoc test was conducted to determine which of the comparisons between groups were statistically significant (*p*<0.05). Such differences were detected between FADS1 and FADS3 and between FADS2 and FADS3 groups.

LGA Group

Friedman's test showed statistically significant differences (*p*<0.05) between *FADS1*, *FADS2* and *FADS3* expression levels within the LGA group.

The mean mRNA level for *FADS1* was M=2663.2 copies/1 µg, for *FADS2* 8090.9 copies/1 µg RNA, and for *FADS3* M=8487.6 copies/1 µg RNA (shown in Fig. 3).

The Bonferroni test identified that statistically significant (*p*<0.05) comparisons were between FADS1 and FADS2, and between FADS1 and FADS3 groups.

SGA Group

Friedman's test showed statistically significant differences (*p*<0.05) between *FADS1*, *FADS2* and *FADS3* expression levels within the SGA group. Tukey's post hoc test was performed to determine which of the comparisons between groups were statistically significant (*p*<0.05). Such differences were detected between FADS1 and FADS3.

The mean mRNA level for FADS1 was M=2587.2 copies/1 µg, and M=8580.8 copies/1 µg RNA for FADS3 (shown in Fig. 4).

IUGR Group

Friedman's test showed statistically significant differences (*p*<0.05) between *FADS1*, *FADS2* and *FADS3* expression levels within the IUGR group.

The mean mRNA levels were M=671.8 copies/1 µg for *FADS1*, 2123 copies/1 µg RNA for *FADS2*, and

b)

Figure 5. Expression of FADS1, FADS2 and FADS3 in the IUGR group presented as:
(**a**) a box plot where the y-axis represents the number of mRNA copies/1 µgRNA and (**b**) a line graph of the average expression values, where the y-axis represents the number of mRNA copies/1 µg RNA

for M=4713.5 copies/1 μg RNA for *FADS3* (shown in Fig. 5).

The Tukey's post hoc test identified that statistically significant ($p < 0.05$) comparisons were between FADS1 and FADS3, and between FADS2 and FADS3.

PTB Group

The Friedman's test showed no statistically significant differences ($p < 0.05$) between *FADS1*, *FADS2* and *FADS3* expression in the PTB group. Tukey's post hoc test confirmed there were no differences.

DISCUSSION

Fat is one of the key ingredients necessary for proper foetal development. During pregnancy, a mother's body deposits fat in an amount which corresponds approximately to the baby's weight (3500 g) (Hytten & Chamberlain, 1974). These processes occur most vigorously in the first and second trimester and will happen even if the mother is malnourished (Prentice & Golberg, 2000; Herrera, 2002; Herrera *et al.*, 2006). In the second trimester (the anabolic period), the concentration of phospholipids, non-esterified FAs and triglycerides increases in the mother's circulation. This mechanism is associated with an insulin-dependent decrease in lipoprotein lipase activity in adipose tissue and subsequent insulin resistance. As a result of these processes, part of the accumulated fat is transferred to the foetus via the placenta. In contrast, the third trimester is a catabolic period for the mother. Increased lipolysis in the mother's adipose tissue is associated with decreased sensitivity of insulin receptors, which are hormonally controlled by progesterone, cortisol, prolactin and leptin (Cousins, 1991; Herrera *et al.*, 2006; Catov *et al.*, 2007). As a result, in comparison to the anabolic period, even greater amounts of fat, including FAs, reach the placenta. The dynamics of changes in fat content in the foetus is different from that found in the mother. First, there is no catabolic period in the foetus, and second, the anabolic period begins much later than the mother's – between 20 and 22 weeks of pregnancy. Complicated maternal-placental-foetal fat metabolism, especially of FAs and their derivatives, continues to be controlled by numerous factors, including enzymes whose expression is regulated, *inter alia*, at the level of transcription. This paper presents the analysis of expression of three genes encoding the strategic desaturases, which control the formation of n-3 and n-6 FA. In the AGA, LGA, SGA, PTB and IUGR groups that were studied, no significant differences in mRNA levels of the *FADS1* and *FADS2* were observed. This could imply that LC-PUFA biosynthesis and the function of pro- and anti-inflammatory cytokines are unaffected in neither group. However, since we have not studied the polymorphism of the *FADS1* and *FADS2* genes as a factor that could influence foetal development, this conclusion is not irrefutable. Our studies have shown differences in the placental mRNA expression level of the *FADS3*. Women who gave birth to healthy children in due time (AGA) and women who gave birth to children with only minor problems (SGA and LGA), had higher *FADS3* mRNA expression levels in the placenta than women in the PTB and IUGR (higher level of problems) groups. This result is difficult to interpret because *FADS3* and the desaturase encoded by it have not yet been sufficiently researched. It is known that *FADS3* transcriptional activity in tissues is significantly different between male and female mice and rats. *FADS3* encod-

ed desaturase can introduce a double bond into the FA chain like any other desaturase but other potential functions of the enzyme should be considered as well. Desaturases are known to perform hydroxylation (Mizutani *et al.*, 2004; Blanchard *et al.*, 2011), acetylenation and epoxidation (Lee *et al.*, 1998). Substances such as etherlipid (Paltauf & Holasek, 1973), sphingolipid (Mizutani *et al.*, 2004) and cholesterol (Nusblat *et al.*, 2005) can also be substrates for desaturases. Therefore, FADH3 potential physiological role can be broad, especially considering that D13D exists in at least three isoforms (Blanchard *et al.*, 2011). One concept that could explain the lower transcription activity of *FADS3* in the PTB and IUGR groups is the specific structure of the gene promoter. It contains target sites for NF-ϰB (Szczesna-Skorupa *et al.*, 2004; Yan *et al.*, 2007), MYCN (Alaminos *et al.*, 2003) and p63 protein (Blanchard *et al.*, 2011), suggesting that *FADS3* expression can be regulated by these factors. It is known that NF-ϰB, MYCN and p63 are the components of intracellular pathways associated with proliferation and apoptosis. Several studies have demonstrated the relatedness of IUGR and these pathways. For example, in IUGR, the NF-ϰB-regulated proangiogenic targets in foetal pulmonary artery endothelial cells are disrupted, which leads to the abnormal metabolism of extracellular matrix components and, as a result, interferes with pulmonary angiogenesis (Dodson *et al.*, 2018). In pregnancies complicated with IUGR, the processes of apoptosis in placenta are stronger than in a healthy placenta (Erel *et al.*, 2001) and a significantly higher NF-ϰB expression can be observed (Aban *et al.*, 2004). It is not known why the increase in NF-ϰB expression does not cause an increase in the expression of *FADS3* in the IUGR placenta; in fact, exactly the opposite is observed. Higher NF-ϰB expression is accompanied by lower *FADS3* transcriptional activity. It is possible that NF-ϰB inhibitors increase during IUGR, or the chromatin is remodelled in such a way that the *FADS3* promoter becomes inaccessible for NF-ϰB. Changes in FADS 3 activity in the course of IUGR may also be related to the functioning of the membrane transport system, which is responsible for maintaining the correct FA ratio in the maternal (M) and foetal (F) circulation. Changes in the F/M ratio were observed in IUGR, SGA and PTB children (Cetin *et al.*, 2002; Bobiński *et al.*, 2013).

This work also analyses *FADS* genes expression within the AGA, LGA, SGA, PTB, and IUGR groups. Except for the PTB group, which had the lowest number of samples, and in which no differences in *FADS* gene expression were observed, there were differences in expression between *FADS1, FADS2* and *FADS3* in the remaining groups. In the LGA group there were no differences between *FADS2* and *FADS3* transcript levels Comparing the average *FADS* mRNA expression between the AGAs and LGAs, it can be assumed that the lack of differences in the LGA group was due to an increased *FADS2* and slightly reduced *FADS3* transcript levels. LGAs are a group of children who, in addition to the increased body weight (>90 percentile), have also increased body fat. Both are involved in fat metabolism, so with the increased fat mass of the child, changes in D6D and D13D activity are highly likely, although the case of the *FADS3* gene product is surprising. It has been previously shown that the increased expression of *FADS3* in adipose tissue is characteristic of hyperlipidemia (Plaisier *et al.*, 2009). Our research shows that this is the opposite for the placenta. Perhaps, the reduced placental expression of *FADS3* in LGA pregnancies is a type of compensatory mechanism that regulates foetal fat

metabolism. From a clinical point of view, however, it would be more interesting to see a significant increase in the transcriptional activity of the *FADS2* gene encoding desaturase 6, catalysing the reactions of the n-3 and n-6 main biosynthesis pathway. One of the factors (although not studied in this research) that could affect *FADS2* expression is the pregnant woman's diet. With an ample supply of plant oils, which contain high proportion of LA, such as sunflower seed oil, safflower oil or corn oil, less DHA is produced from ALA as a result of n-6 desaturase inhibition leading to a decreased EPA biosynthesis. The n-6 FA pool then increases, which could be a risk factor for the development of LGA (Llanos *et al.*, 2005; Bobiński & Mikulska, 2015). Furthermore, it may have an influence on the metabolism of medium-chain fatty acids (MCFA), especially myristic acid (C14: 0) and lauric acid (C12: 0), which have a significant impact on the conversion of EPA to DHA (Legrand *et al.*, 2020). This, in turn, in addition to placental biosynthesis of LC-PUFA, can disturb the specified hierarchy DHA>AA>LA>ALA defining the order of transport of the acids across the placental barrier (Cetin *et al.*, 2009a; Cetin and Alvino, 2009b).

CONCLUSION

The placenta fulfils hormonal, nutritional and metabolic roles. Its task is to control the development of the foetus, but the hormonal-metabolic placental processes affect, to a large extent, also the body of a pregnant woman. Fatty acids play a key role in these mechanisms. Some of them are transported through the placental barrier, others undergo biosynthesis in the placenta. Often, placental biosynthesis involves the elongation and desaturation processes of the pre-existing FAs with shorter carbon chains, which either lack or have fewer double bonds. Desaturases are involved in these processes. This important group of enzymes maintain the balance of n-3 and n-6 FAs levels, has a significant role in the development of the nervous system and cell membranes, and affect general maternal-placental-foetal homeostasis. Our studies have shown that the transcriptional activity of the *FADS1* and *FADS2* genes remain at similar levels in the pregnancy groups we examined. It was only in the *FADS3* gene expression that the differences were discovered. *FADS3* lowest mRNA levels were observed in the placenta of women who gave birth to premature babies. In this group, also no differences were observed in the *FADS1*, *FADS2* and *FADS3* mRNA levels. In the SGA group, expression differences were observed between the *FADS3* and *FADS1* genes only. The AGA, LGA and IUGR groups had a similar expression profile, in which the *FADS3* gene had the highest and the *FADS1* gene had the lowest expression except for the difference between *FADS2* and *FADS3* expression, which was observed in AGA and IUGR, but not LGA. . The IUGR group had the lowest expression of all tested genes, while maintaining differences between their expression. The largest number of differences in *FADS* mRNA levels were observed in the placenta of women who gave birth to children with a mild degree of disorder, i.e., PTB and SGA.

Considering the number of FAs undergoing maternal-placental-foetal transformation and the complexity of their metabolism, it is difficult to unequivocally interpret changes in the transcriptional activity of genes encoding desaturases in selected pregnancy pathologies. Many factors regulate these processes and one of the most im-

portant is - not studied in this work - the expression of genetic variants of the *FADS1*, *FADS2* and *FADS3*. Their analysis would provide further data for the assessment of maternal-placental-foetal FA changes, crucial for the proper development of the foetus, the emergence of metabolic or genetic risk factors and an improvement in the profile of prevention and treatment of foetal developmental abnormalities.

Synergistic effect of Dactolisib/Lys05 combination on autophagy in A549 cells

Mohammad M. Abdelwahab[1], Hesham Saeed[1]✉, Nefertiti El-Nikhely[1] and Hisham A. Nematalla[2]

[1]Department of Biotechnology, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt; [2]Department of Pharmacology and Toxicology, Faculty of Pharmacy, Damanhour University, Damanhour, Egypt

Effective therapeutic strategies are urgently required to enhance the prognosis of patients suffering from KRAS mutations. Owing to the undruggable nature of KRAS, targeting downstream signaling pathways, namely PI3K/AKT/mTOR, shows antiproliferative and apoptotic effects. Unfortunately, targeting this pathway upregulates autophagy, contributing to reduced drug efficacy. Therefore, it was reasonable to use a combination of kinase inhibitors and autophagy inhibitors to achieve a higher therapeutic benefit. The impact of Dactolisib, a dual PI3K/mTOR inhibitor, and Lys05, a dimeric chloroquine, was tested on the survival of breast cancer MCF-7 and lung cancer A549 cells. The dose selection for the optimal effect of the Dactolisib/Lys05 combination was determined using CompuSyn software. This combinatorial effect was evaluated using various methodologies, such as expression profile analysis for autophagic, proliferative, and apoptotic markers. These effects were corroborated by ELISA, Western blot, and flow cytometry using the Annexin V-FITC apoptosis detection kit. A549 cells treated in a 2:1 ratio of Lys05 and Dactolisib demonstrated a synergistic effect on cell death, proliferation, and apoptotic gene markers, in addition to its effect on autophagic gene and protein markers, showing an enhanced effect compared to monotherapy. Therefore, the PI3K/AKT kinase inhibitor/autophagy inhibitor combination establishes higher therapeutic benefits on A549 cells compared to kinase inhibitor monotherapy.

INTRODUCTION

Epidemiologically, lung cancer represents the leading cause of cancer-related deaths among both men and women (Barta *et al.*, 2019; Sun *et al.*, 2021). Our increasing understanding of cancer biology has revealed numerous causes for therapeutic failures (Rizzo, 2008). Research on signaling pathways has uncovered a complex network of cross-regulatory interactions, connecting receptors, enzymes, transducing systems, and transcription factors that regulate cell fate (Sever & Brugge, 2015).

Resistance to apoptosis, continuous proliferation, evasion from cell cycle suppressors, angiogenesis, invasion, and metastasis are the five features that characterize carcinoma (Hanahan & Weinberg, 2011). Autophagy, a further level of adaptation, is known to increase under conditions of cellular stress, particularly in cancer (Haider *et al.*, 2020; White & DiPaola, 2009).

Currently, non-small cell lung cancer (NSCLC) accounts for up to 85% of all lung cancers (El Osta *et al.*, 2019). Kirsten Rat Sarcoma Viral Oncogene Homolog (KRAS) is a gene that codes for a protein involved in cell signaling pathways. It is a well-known oncogene, meaning that mutations in the KRAS gene can contribute to the development of cancer. These mutations result in constant activation of the KRAS protein, leading to abnormal cell growth and division. KRAS mutation is among the most predominant mutations in NSCLC and shows little variation between early-stage and metastatic NSCLC (Ghimessy *et al.*, 2020; Lohinai *et al.*, 2017). The undruggable nature of KRAS, attributed to the inability to develop direct inhibitors that can effectively compete with its high affinity for GTP, and the lack of selectivity with wild-type RAS resulting in toxicity, has hindered the design of selective inhibitors targeting mutant KRAS (Chen *et al.*, 2020; Luo *et al.*, 2022). Inhibition of post-translational modifications by farnesyltransferase inhibitors has also demonstrated minimal clinical activity (Adjei *et al.*, 2003; Heymach *et al.*, 2004).

A promising approach now is to target KRAS downstream signaling pathways, particularly PI3K/AKT/mTOR, as evidence suggests their upregulation in lung cancer, promoting cell survival, growth, proliferation, and migration (Huang *et al.*, 2021). The PI3K/Akt/mTOR pathway also plays a role in tumors with other activating mutations (Yu *et al.*, 2021), and increased PI3K or Akt activity regulates mTOR activity in lung cancer (Liang *et al.*, 2019). Treatment of NSCLC cells with mTOR inhibitors has been reported to significantly decrease cancer cell proliferation (Huang *et al.*, 2021). This signaling pathway plays a crucial role in the occurrence and progression of tumors by regulating autophagy and apoptosis of tumor cells (Lee *et al.*, 2021; Zou *et al.*, 2020).

Unfortunately, targeting the PI3K/Akt/mTOR pathway with various kinase inhibitors results in the upregulation of autophagy (Y. Liu *et al.*, 2021; Zhao *et al.*,

2015). Autophagy, as a cellular process in cancer, can both suppress and promote tumor growth, depending on the tissue and timing (Hanahan & Weinberg, 2011; Lim *et al.*, 2021). Furthermore, autophagy addiction characterizes KRAS-driven cancers, including NSCLC, as it replenishes mitochondria substrates required for acetyl-CoA synthesis (Eng *et al.*, 2016; White, 2012).

Given that the inhibition of the PI3K/Akt/mTOR pathway leads to the upregulation of autophagy, it was reasonable to consider a combination of kinase inhibitors and autophagy inhibitors to achieve a higher therapeutic benefit.

MATERIALS AND METHODS

Cell viability assay

Cancer cells MCF-7 and A549 were plated in 96-well plates at a density of 7000 cells/well in 100 μl of DMEM high glucose medium (4.5 g/L) supplemented with only 1% FBS overnight and 1% penicillin/streptomycin at 37°C and 5% CO$_2$. After serum starvation, cells were treated with Dactolisib (LC Laboratories, USA), and Lys05 (Sigma-Aldrich, China) at different concentrations for 48 h. For cytotoxicity assay using 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl- 2H-tetrazolium bromide (MTT), MTT (5 mg/mL in 1×PBS) was added to the cells and incubated for 3 h at 37°C in 5% CO$_2$. A volume of 100 μL of DMSO was added to the cells to solubilize the formed formazan crystals with shaking. Finally, the absorbance was measured at 490 nm and the percentage of cell viability was calculated compared to the control (Kumar *et al.*, 2018).

Identification of synergism and antagonism in drug combination

Drug concentrations used in combination studies were selected from the dose–response data for individual agents in 1% FBS starved A549 cells. Fraction affected (Fa) values were calculated as the percentage inhibition of cell viability, relative to control, as described by Chou (Chou, 2006). Synergism, additivity, or antagonism of drug combinations was identified using the Chou Talalay Combination Index (CI) method (Chou, 2006) and CompuSyn software (http://www.combosyn.com) based mainly on the following equation:

$$CI = (D)_1/(D_x)_1 + (D)_2/(D_x)_2$$

where $(D)_1$ and $(D)_2$ represent the concentrations of Drug 1 and Drug 2 in the combination that produce a Fa value of x. $(D_x)_1$ and $(D_x)_2$ represent the concentrations of Drug 1 and Drug 2 that produce the same effect (x) when applied as single agents. CI values <1, =1, and >1 indicate synergism, additivity, and antagonism, respectively.

Protein determination and analysis by Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) and western blotting

Protein concentration was determined according to Bradford using bovine serum albumin as a standard (Bradford, 1976). The total protein extract (50 μg) was mixed with a 5× sample application buffer, boiled for 5 min, and resolved on 14% SDS-PAGE. LC3B was detected through western blotting using anti-LC3B monoclonal antibody (Molecular weight 17.5 KDa) (Cell signaling, USA) at a dilution of 1:1000. The sec-

ondary antibody used was goat anti-mouse IgG labeled with horse radish peroxidase (Invitrogen, USA) at a 1:1000 dilution. The nitrocellulose membrane was developed using enhanced chemiluminescence (ECL, Sigma-Aldrich, China)(Liu *et al.*, 2014). Beta-actin (ACTB) (Molecular weight 42 KDa) was used as a loading control.

Apoptosis detection by flow cytometry

Apoptosis was analyzed using Annexin V-FITC apoptosis detection kit (Miltenyi Biotec.). A549 cells were treated with Lys05, Dactolisib and the synergistic combination dose for 48 h. After incubation, cells were harvested by centrifugation, re-suspended in binding buffer, and incubated with fluorescein isothiocyanate (FITC)-labeled with Annexin V for 15 min in the dark at room temperature. Cells were then washed twice with 1×PBS and resuspended in binding buffer, propidium iodide was added, and cells were incubated for 15 min in the dark at room temperature (Lakshmanan & Batra, 2013). The stained cells were analyzed using BD FACS flow cytometer (BD Biosciences) at the flow cytometry service core facility at the Center of Excellence for Research in Regenerative Medicine and its Applications (CERRMA), Faculty of Medicine, Alexandria University.

Quantitative RT-PCR

Total RNA was isolated and purified from the treated and untreated A549 cells using TRIzol reagent (Qiagen, Germany) following the manufacturer's protocol (Rio *et al.*, 2010). The concentration and purity of RNA were determined using Nanodrop. One microgram of the total RNA was reverse transcribed into the first strand cDNA using a High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems) using random hexamer primers according to the manufacturer's instructions. Quantitative real-time PCR was carried out in triplicates using Maxima SYBR Green qPCR Master Mix (ThermoFisher). Primers used were as follows: *HPRT* forward primer, 5'-TGACACTGGCAAAACAAT-3'; reverse, 5'-GGTCCTTTTCACCAGCAA-3'; *LC3A* forward primer, 5'-GGATTTTGAGGAGGGGGACTC-3'; reverse, 5'-CATCTGCAAAACTGAGACAGTG-3'; *ATG4B* forward primer, 5'-GCAAGTCAAAAAGCT-GTCTCT-3'; reverse, 5'-CAGTCGCTCTACATCA-GAAGAA-3'; *LC3B* forward primer, 5'-CGAGA-GCAGCATCCAACCAA-3'; reverse, 5'-GAGCTGTAA-GCGCCTTCTAA-3'; *KI67* forward primer, 5'-GAG-GTGTGCAGAAAATCCAAA-3'; reverse, 5'-CTGTCC-CTATGACTTCTGGTTGT-3'; *CASP3* forward primer, 5'-TTTTTCAGAGGGGGATCGTTG-3'; reverse, 5'-CG-GCCTCCACTGGTATTTTA-3'. Primers were added to the reaction mixture at a final concentration of 250 nM. The reaction was prepared in a final volume of 20 μL by mixing 5 μL of each cDNA sample (diluted 1:5), 12.5 μL of SYBR Green, 0.5 μL of each primer, and the final volume was adjusted through the addition of RNase/DNase free water. The reaction conditions used were as follows: 5 min at 95°C for 1 cycle followed by 40 cycles of 15 s at 95°C, 30 s at 58°C, and 30 s at 72°C. The specificity of each primer pair was verified by the presence of a single melting curve peak. Results were analyzed for the relative expression of mRNA normalized against hypoxanthine guanine phosphoribosyl transferase (HPRT) as a housekeeping gene. Finally, the results were analyzed, and expressed as fold change(Rao *et al.*, n.d.).

Figure 1. MTT cytotoxicity assay of Lys05 (L) and Dactolisib (D) on MCF-7.
Cells were treated with different concentrations of Lys05 and Dactoilsib for 48h. Data were normalized and IC50 values were 12.6 μM and 1.1 μM (n=5). The fraction affected "Fa" was calculated as 1 – (% Cell viability/100)

Figure 2. MTT cytotoxicity assay of Lys05 (L) and Dactolisib (D) on A549 cells.
A549 cells were treated with different concentrations of Lys05 and Dactolisib for 48h. Data were normalized and IC50 values on A549 for Lys05 was 11.8 μM and for dactolisib was 0.375 μM (n=5). The fraction affected (Fa) was calculated as 1 – (% Cell viability/100)

ELISA assay

Coated 96-well strip plate has been pre-coated with target-specific capture antibody LC3A (LifeSpan Bioscience, Inc.), LC3B (LifeSpan Bioscience, Inc.) and P62/SQSTM1 (MyBioSource, Inc.). A volume of 100 μL of the samples was added to the wells and incubated for 2 hours at 37°C. The liquid was aspirated and 100 μl of Biotin-labeled antibody working solution was added and incubated for 1 hour at 37°C. The liquid was aspirated then the wells were washed 3 times with wash buffer. The HRP-Streptavidin Conjugate working solution was added and incubated for 60 minutes at 37°C. The liquid was aspirated, and wells were washed 5 times with a wash buffer. The reaction was visualized by the addition of 90 μl of TMB Substrate solution and incubated for 15–30 minutes at 37°C. The reaction was stopped with 50 μl of sulfuric acid stop solution (1N H_2SO_4) to complete the color development reaction and then the ELISA plates were measured at a wavelength of 450 nm using a micro-plate Spectrophotometer.

Statistical analysis

Data were presented as mean ± standard deviation and were evaluated by a univariate analysis of variance (ANOVA) Tukey's multiple comparisons test at $p<0.05$ using GraphPad Prism version 7.00, GraphPad, Software, San Diego California, USA. The IC_{50} values and Combination analysis were conducted as described by Chou using CompuSyn software (http:// www. combo syn. com).

RESULTS

The effect of the individual administration of dactolisib and Lys05 on MCF-7 and A549 cells

To evaluate the cell growth inhibitory effect of Dactolisib and Lys05 individually, the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was performed. The impact of both drugs on the survival of MCF-7 and A549 cells was examined to determine the IC50 values using GraphPad Prism version 7.0 and CompuSyn software version 1.

Increasing concentrations of Dactolisib and Lys05, as well as a clear culture media (control), were administered to MCF-7 and A549 cells. Figure 1 illustrates the

dose-dependent reduction in cell viability caused by the individual administration of Dactolisib in MCF-7 cells compared to the control (untreated cells). The cytotoxic effect of Dactolisib was observed at a concentration of 1.1 μM (n=5) in MCF-7 cells.

Similarly, Fig. 2 shows the dose-dependent reduction in cell viability caused by the individual administration of Lys05 in A549 cells compared to the control. The cytotoxic effect of Lys05 was observed at a concentration of 0.375 μM (n=5) in A549 cells.

In summary, the individual administration of Dactolisib and Lys05 resulted in a dose-dependent reduction in cell viability in MCF-7 and A549 cells, respectively. Dactolisib exhibited cytotoxic effects at concentrations of 1.1 μM (n=5) in MCF-7 cells, while Lys05 showed cytotoxic effects at concentrations of 0.375 μM (n=5) in A549 cells.

A synergistic effect results from dactolisib/Lys05 combination on A549 cells

To investigate the combined cytotoxic effect of Dactolisib and Lys05, starved A549 cells were exposed to various combination ratios. The IC50 value of the 2:1 ratio (2L/1D) (0.05 μM Dactolisib + 3.19 μM Lys05)

Figure 3. Combination index plot.

was determined, and it showed a significant effect below the additive line, indicating a synergistic effect. The combination index (CI) for this ratio was calculated as 0.4.

This finding suggests that the combination of Dactolisib and Lys05 at the specified ratio has a stronger cytotoxic effect on A549 cells compared to what would be expected if the effects of the two drugs were merely

Figure 4. Expression levels of the autophagic markers.
(**a**) *ATG4B,* (**b**) *LC3A and* (**c**) *LC3B* genes in A549 control cells, Dactolisib-treated cells (0.375 μM), Lys05-treated cells (11.8 μM) and mix-treated cells (0.05 μM Dactolisib + 3.19 μM Lys05).

additive. The synergistic effect indicates that the combination is more effective than individual treatments alone.

Treatment of starved A549 cells with Lys05 plus dactolisib with various combination ratios, the IC$_{50}$ value of the 2:1 ratio (2L/1D) (0.05 μM Dactolisib + 3.19 μM Lys05) showed a significant effect below the additive line, indicating a synergistic effect with combination index "CI" 0.4.

Table 1. The combination index "CI" of IC50 values of various combination ratios.

	Ratio		
	(2L/1D)	L/D	(1L/2D)
Combination Index: "CI"	0.4	0.91	1.2

Dactolisib and Lys05 individually and in combination altered the expression of autophagic, proliferative, and apoptotic gene markers

Using quantitative real-time PCR, the gene expression levels of the autophagic markers *ATG4B, LC3A,* and *LC3B* were determined. In Dactolisib-treated cells, the levels of *ATG4B, LC3A,* and *LC3B* were found to be elevated compared to control cells. Conversely, in Lys05-treated cells, only *LC3A* showed a significant increase in expression compared to control cells (Fig. 4a).

Interestingly, in the mix-treated cells (combination of Dactolisib and Lys05), while *ATG4B* and *LC3B* were downregulated, *LC3A* exhibited a significant increase in expression compared to control cells (Fig. 4a).

These results indicate that Dactolisib treatment leads to the upregulation of *ATG4B, LC3A,* and *LC3B*, suggesting the induction of autophagy. In contrast, Lys05 treatment primarily upregulates the expression of *LC3A*. Notably, in the mix-treated cells, the combination of Dactolisib and Lys05 resulted in the downregulation of *ATG4B* and *LC3B*, but a significant increase in *LC3A* expression compared to control cells.

These findings suggest that the combination treatment may have a distinct effect on autophagic markers compared to individual treatments alone.

The expression levels of *CASP3* and *KI67* were examined in different treatment groups compared to control cells

Firstly, it was observed that *CASP3*, a marker of apoptosis, showed a considerable elevation in mix-treated cells compared to control cells (Fig. 5a). This suggests that the combination treatment of Dactolisib and Lys05 induced a higher level of *CASP3* expression, indicating an increased apoptotic response. Additionally, *CASP3* was also found to be upregulated in cells treated with Dactolisib alone and Lys05 alone, indicating that both individual treatments could induce apoptosis to some extent.

Secondly, the expression *KI67*, a marker of cellular proliferation, was significantly downregulated in cells treated with Dactolisib, Lys05, and the mix of Dactolisib and Lys05 (Fig. 5b).

This suggests that Dactolisib, Lys05, and the combination treatments inhibited cellular proliferation, as evidenced by the reduced expression of *KI67*.

Overall, these results indicate that the mix-treated cells had a notable elevation in *CASP3* expression, indicating an enhanced apoptotic response compared to control cells. Additionally, both Dactolisib, Lys05 and the mix of Dactolisib and Lys05 resulted in the downregulation of *KI67*, suggesting inhibition of cellular proliferation.

Figure 5. Expression levels of apoptotic and proliferative markers.
(**a**) *CASP3* and (**b**) *KI67* genes in A549 control cells, Dactolisib-treated cells (0.375 μM), Lys05-treated cells (11.8 μM) and mix-treated cells (0.05 μM Dactolisib + 3.19 μM Lys05).

Figure 6. Apoptosis detection through flow cytometry.
(**a**) A549 control cells, Dactolisib-treated cells (0.375 μM), Lys05-treated cells (11.8 μM) and mix-treated cells (0.05 μM Dactolisib + 3.19 μM Lys05). Apoptosis was analyzed through double staining with Propidium iodide and Annexin V-FITC. The lower left quadrant represents control cells, the lower right quadrant represents cells in early apoptosis, the upper right quadrant represents cells in late apoptosis and the upper left quadrant represent cells in necrosis. (**b**) Quantitative analysis of cell population in early, late apoptosis, and necrosis in control A549 cells, Dactolisib-treated cells, Lys05-treated cells and mix-treated cells.

Dactolisib/Lys05 combination enhances killing in A549 cells

Flow cytometry was employed to evaluate the induction of apoptosis in starved A549 cells following treatment with Dactolisib, Lys05, or a combination of both. The percentage of cells undergoing early apoptosis was determined for each treatment group.

The results showed that Dactolisib treatment led to an early apoptosis percentage of 16.9%. Lys05 treatment exhibited a significantly higher early apoptosis percentage of 82.6%. Notably, when the two drugs were combined (mix), the early apoptosis percentage dramatically increased to 96.3%. In comparison, the control group of untreated A549 cells had an early apoptosis percentage of 1.3% (Fig. 6).

These findings indicate that both Dactolisib and Lys05 treatments can induce apoptosis in starved A549 cells. However, the combination of Dactolisib and Lys05

(mix) resulted in a much higher early apoptosis percentage compared to either treatment alone or the control group. This suggests a synergistic effect between Dactolisib and Lys05 in promoting apoptosis in A549 cells.

Dactolisib and Lys05 individually and in combination alter the expression of autophagic protein markers on A549 cells

The expression levels of P62/SQSTM1, LC3A, and LC3B were assessed in different treatment groups compared to control cells.

Firstly, it was found that the expression of P62/SQSTM1, a protein involved in autophagy, was significantly increased in Lys05-treated cells and mix-treated cells compared to control cells (Fig. 7a). This suggests that both Lys05 treatment and the combination treatment led to an upregulation of P62/SQSTM1 expression, indicating a potential disruption in the autophagic process.

Figure 7. ELISA assay of autophagic protein markers.
(**a**) P62 protein, (**b**) LC3A protein and (**c**) LC3B protein on control A549 cells, Dactolisib-treated cells (0.375 μM), Lys05-treated cells (11.8 μM) and mix-treated cells (0.05 μM Dactolisib + 3.19 μM Lys05)

Secondly, the levels of LC3A, an autophagy-related protein, were significantly higher in mix-treated cells compared to control cells (Fig. 7b). This indicates that the combination treatment resulted in an increased expression of LC3A, suggesting the induction of autophagy. Similarly, LC3B showed a significant increase in expression in Lys05-treated cells (Fig. 7c). Interestingly, the same pattern was observed in cells treated with the combination of both drugs, indicating a consistent effect.

Overall, these results demonstrate that the Lys05 treatment and the combination treatment (mix) led to an upregulation of P62/SQSTM1 expression. Furthermore, the combination treatment resulted in higher levels of LC3A expression compared to control cells, while Lys05 treatment specifically increased LC3B expression. These findings suggest a potential modulation of autophagy-related proteins by the treatments, indicating a complex interplay between autophagy and the therapeutic effects of Lys05 and the combination treatment.

In the experiment, a semi-quantitative analysis of LC3B expression was conducted using Image J software. Figure 8 illustrates the results of this analysis, showing the upregulation of LC3B in Lys05-treated cells and mix-treated cells compared to the untreated control A549 cells.

The upregulation of LC3B in Lys05-treated cells and mix-treated cells suggests an increase in autophagy activity. LC3B is a well-known marker for autophagosomes, which are structures involved in the autophagy process. The upregulation of LC3B indicates an accumulation of autophagosomes, suggesting an enhancement of the autophagic response in the treated cells.

The semi-quantitative analysis performed using Image J software allows for the quantification and comparison of LC3B expression levels between different treatment groups. The results clearly demonstrate the higher expression of LC3B in Lys05-treated cells and mix-treated cells, highlighting the impact of these treatments on autophagy induction.

DISCUSSION:

Indeed, the PI3K/mTOR signaling pathway plays a crucial role in various aspects of cancer development

Figure 8. Western blot analysis of LC3B expression in A549 cells. After treatment with Dactolisib and Lys05 individually and in combination. (a) Lane 1 represents A549 control cells, lane 2 represents Dactolisib-treated cells (0.375 µM), lane 3 represents Lys05-treated cells (11.8 µM) and lane 4 represents mix-treated cells (0.05 µM Dactolisib + 3.19 µM Lys05). (b) Chart represents LC3B expression level.

and progression, including cell proliferation, angiogenesis, invasion, cell survival, and motility. Dysregulation of this pathway has been frequently observed in many types of cancer, making it an attractive target for developing novel anticancer agents (Samuels et al., 2004).

Targeting the PI3K/mTOR pathway has shown promise as a therapeutic approach in cancer treatment. By inhibiting specific components or key signaling molecules within this pathway, it is possible to disrupt the aberrant signaling cascade and potentially halt or slow down cancer progression (Herrera et al., 2011).

Several studies have investigated the development of novel anticancer agents that target the PI3K/mTOR pathway. These agents aim to selectively inhibit the activity of specific enzymes or molecules within the pathway, thereby modulating its downstream effects on cell proliferation, angiogenesis, invasion, and survival (Herrera et al., 2011).

Previously, it has been revealed that inhibition of the PI3K/mTOR pathway induces autophagy as a mechanism of cell death or drug resistance (Fujiwara et al., 2007; Yang et al., 2011). Therefore, the inhibition of autophagy in addition to targeting the PI3K/Akt/mTOR pathway may enhance cancer cell death.

In our study, we examined the cytotoxic effect of the two drugs on MCF-7 and A549 cells. The IC50 values for each cell line were determined and presented in Fig. 1 for MCF-7 cells and Figure 2 for A549 cells. The results revealed that A549 cells exhibited greater sensitivity to the two drugs compared to MCF-7 cells.

Additionally, we investigated the effect of combining Lys05 and Dactolisib on starved A549 cells using different ratios. Among the combination ratios tested, the 2:1 ratio (2 parts Lys05 to 1 part Dactolisib) demonstrated a significant effect below the additive line, indicating a synergistic effect. The combination index (CI) value of 0.4, as shown in Figure 3, further supports the synergistic interaction between the two drugs.

Furthermore, we investigated the gene expression levels of autophagic markers, namely ATG4B, LC3A, and LC3B, using quantitative real-time PCR. ATG4B is an autophagic cysteine protease responsible for cleaving the pre-protein ATG8, specifically LC3, resulting in the formation of the non-lipidated soluble form (LC3A). The cleaved LC3A can then interact with phosphatidylethanolamine to form the lipidated form (LC3B), which is anchored to the autophagic membrane (Xia et al., 2022).

Our gene expression analysis revealed significant upregulation of ATG4B, LC3A, and LC3B in Dactolisib-treated cells compared to the control cells, indicating autophagic induction (p values = 0.0009 for ATG4B, 0.0001 for LC3A, and 0.0003 for LC3B) (Fig. 4a, 4b, and 4c, respectively). Similarly, in Lys05-treated cells, we observed a significant upregulation of LC3A (p = 0.0001) (Fig. 4a) as a compensatory mechanism in response to Lys05-induced autophagic inhibition. However, ATG4B and LC3B showed obvious downregulation, suggesting autophagosome inhibition.

In mix-treated cells, we found that LC3A was significantly upregulated compared to the control cells (p = 0.0032) (Fig. 4a). However, both ATG4B and LC3B were downregulated, likely due to the combined effect of the two drugs. These findings indicate that the combination of Dactolisib and Lys05 exerted a significant effect on A549 cells, modulating autophagic processes through differential regulation of autophagic markers.

Furthermore, we examined the gene expression levels of a proliferative marker, KI67, and an apoptotic marker, CASP3. CASP3 is an executioner caspase involved

in apoptosis that coordinates the degradation of cellular structures (Ma *et al.*, 2021). KI67 is an antigen associated with nuclear proliferation and is expressed during the growth and synthesis phases of the cell cycle (G1, S, G2, and M), but not during the resting phase (G0) (Gerdes *et al.*, 1991).

Our results demonstrated that Ki-67 was significantly downregulated in Dactolisib-treated cells and mix-treated cells compared to control cells ($p=0.0244$ and 0.0001, respectively) (Fig. 5b). This suggests that the treatment with Dactolisib and the combination of the two drugs resulted in a suppression of proliferation in A549 cells.

In contrast, CASP3 was upregulated in Dactolisib-treated cells and Lys05-treated cells. Notably, it was significantly upregulated in mix-treated cells compared to control cells ($p=0.0007$) (Fig. 5a). These findings indicate that the combination of Dactolisib and Lys05 had a significant impact on promoting apoptosis in A549 cells.

Taken together, our results demonstrate the significant effects of the drug combination on both the proliferative and apoptotic levels in A549 cells, as evidenced by the downregulation of the proliferative marker KI67 and the upregulation of the apoptotic marker CASP3.

It is well-established that the evasion of regulated modes of cell death is a hallmark of cancer (Sharma *et al.*, 2019). In our study, we further supported our findings regarding apoptotic and proliferative levels using flow cytometry analysis. Annexin V/PI staining of A549 cells treated with dactolisib, Lys05, and the combination (Mix) revealed percentages of early apoptosis at 16.9%, 82.6%, and 96.3%, respectively (Fig. 6). In comparison, the control untreated A549 cells exhibited an early apoptosis rate of 1.3%. These results clearly demonstrate that our combination treatment has a significant effect on both proliferation and apoptosis in A549 cells.

Furthermore, to support our gene expression findings, we performed additional analyses using ELISA for p62/SQSTM1 and LC3s (MAP1-LC3A and B), and Western blot for LC3B. P62/SQSTM1 acts as a receptor for cargo destined to be degraded by autophagy, including ubiquitinated protein aggregates targeted for clearance. The p62 protein can bind to both ubiquitin and LC3, facilitating the targeting of cargo to autophagosomes for degradation (Berkamp *et al.*, 2021). LC3s (MAP1-LC3A and B) are structural proteins found in autophagosomal membranes and are widely used as biomarkers of autophagy (Koukourakis *et al.*, 2015).

Our results revealed that p62/SQSTM1 was significantly upregulated in both Lys05- and mix-treated cells ($p=0.0305$ and 0.0011, respectively) compared to the control (Fig. 7a). This upregulation indicates autophagic inhibition. Additionally, LC3A was significantly upregulated in mix-treated cells ($p=0.0044$) (Fig. 7b). On the other hand, LC3B was significantly upregulated in Lys05-treated cells ($p=0.0482$) (Fig. 7c) due to its accumulation resulting from autophagic inhibition. Similarly, mix-treated cells exhibited the same pattern of upregulation in LC3B due to the combined effect of the two drugs ($p=0.0017$). The semi-quantified Western blot analysis of LC3B aligned with the ELISA results (Fig. 8). These findings strongly support the efficacy of our drug combination.

Considering the comprehensive findings from our study, it is evident that the combination of kinase inhibitor and autophagy inhibitor led to increased cell killing, as demonstrated by enhanced annexin V/PI staining, upregulation of the apoptotic gene marker CASP3, and downregulation of the proliferative gene marker KI67. This combination exhibited a synergistic effect on A549

cells compared to each drug used alone. Therefore, we can confidently conclude that the kinase inhibitor/autophagy inhibitor combination provides greater therapeutic benefits for A549 cells compared to monotherapy with kinase inhibitors alone. This synergistic effect has also been observed in other studies involving glioma (Cerniglia *et al.*, 2012) and malignant peripheral nerve sheath tumors (Ghadimi *et al.*, 2012), further supporting the significance of our findings.

Tween 80™-induced changes in fatty acid profile of selected mesophilic lactobacilli

Dorota Zaręba[1] and Małgorzata Ziarno[2]*

[1]Professor E. Pijanowski Catering School Complex in Warsaw, Warsaw, Poland, [2]Institute of Food Science, Department of Food Technology and Assessment, Warsaw University of Life Sciences - SGGW (WULS-SGGW), Warsaw, Poland

Fatty acid profiles are crucial for the functionality and viability of lactobacilli used in food applications. Tween 80™, a common culture media additive, is known to influence bacterial growth and composition. This study investigated how Tween 80™ supplementation impacts the fatty acid profiles of six mesophilic lactobacilli strains (*Lacticaseibacillus* spp., *Limosilactobacillus* spp., *Lactiplantibacillus plantarum*). Analysis of eleven strains revealed 29 distinct fatty acids. Tween 80™ supplementation significantly altered their fatty acid composition. Notably, there was a shift towards saturated fatty acids and changes within the unsaturated fatty acid profile. While some unsaturated fatty acids decreased, there was a concurrent rise in cyclic derivatives like lactobacillic acid (derived from vaccenic acid) and dihydrosterculic acid (derived from oleic acid). This suggests that despite the presence of Tween 80™ as an oleic acid source, lactobacilli prioritize the synthesis of these cyclic derivatives from precursor unsaturated fatty acids. Myristic acid and dihydrosterculic acid levels varied across strains. Interestingly, palmitic acid content increased, potentially reflecting enhanced incorporation of oleic acid from Tween 80™ into membranes. Conversely, cis-vaccenic acid levels consistently decreased across all strains. The observed fatty acid profiles differed from previous studies, likely due to a combination of factors including strain-specific variations and growth condition differences (media type, temperature, harvesting point). However, this study highlights the consistent impact of Tween 80™ on the fatty acid composition of lactobacilli, regardless of these variations. In conclusion, Tween 80™ significantly alters fatty acid profiles, influencing saturation levels and specific fatty acid proportions. This work reveals key factors, including stimulated synthesis of lactobacillic acid, competition for oleic acid incorporation, and strain-specific responses to myristic and dihydrosterculic acids. The consistent reduction in cis-vaccenic acid and the presence of cyclic derivatives warrant further investigation to elucidate their roles in response to Tween 80™ supplementation.

KEYWORDS

lactic acid bacteria, lactobacilli, fatty acid profile, functionality, Tween 80™

Introduction

The fatty acid composition of bacterial cells of the lactobacilli determines their survival and depends on many environmental factors (Johnsson et al., 1995; Partanen et al., 2001; Corcoran et al., 2007; Montanari et al., 2010; Li et al., 2011; Tan et al., 2012; Terraf et al., 2012; Al-Naseri et al., 2013; Hansen et al., 2015; Reitermayer et al., 2018). Corcoran et al. (2007) proved this by showing that oleic acid (C18:1,*cis*-9) and *cis*-vaccenic acid (C18:1,*cis*-11) have a protective effect on *Lacticaseibacillus rhamnosus* GG cells suspended in artificial gastric juice. These researchers have shown that only in the case of these two fatty acids, the number of bacterial cells was greater than the number of cells in the control sample. Other tested fatty acids, including stearic (C18:0), elaidic (C18:1,*trans*-9), linoleic (C18:2,*cis*-9,*cis*-12), *cis*-9,*trans*-11-octadecadienoic, and *trans*-10,*cis*-12-octadecadienoic, caused a decrease in the number of viable cells (to a level of 3.89 log CFU/mL in case of *trans*-10,*cis*-12-octadecadienoic acid and to 4.75 log CFU/mL for stearic and elaidic acids). This phenomenon can be explained by the fact that oleic (C18:1,*cis*-9) and *cis*-vaccenic (C18:1,*cis*-11) acids are the substrates for the synthesis of fatty acid in various ways required for cell survival and modification of cell membrane fluidity. Lactic acid bacteria (LAB), lactobacilli including, are equipped with the mechanisms for transforming these fatty acids in their cyclic, polyunsaturated, or conjugated forms (Henderson and McNeill, 1966; Weeks and Wakil, 1970; Partanen et al., 2001; Corcoran et al., 2007; Tan et al., 2012). Transformation of linoleic (C18:2,*cis*-9,*cis*-12) or conjugated acids to oleic acid (C18:1,cis-9) requires the action of specific enzymes if LAB cells lack access to external sources of oleic acid. In the absence of external oleic acid, some LAB strains may resort to this conversion pathway to maintain a certain level of oleic acid, potentially leading to a decrease in the overall protective action of these polyunsaturated fatty acids.

One of the external sources of fatty acids for bacterial cells is their living environment, including culture media. A key example is oleic acid, a fatty acid found in many natural sources. However, bacteria can also utilize oleic acid provided in the form of Tween 80™. Tween 80™ is a nonionic surfactant, commonly used in the food industry as an emulsifier, dispersant, and stabilizer. It finds application in microbiology as a common additive to media for cultivating lactobacilli (Johnsson et al., 1995; Partanen et al., 2001; Montanari et al., 2010; Li et al., 2018). It could be also employed in food fermentation processes for its beneficial effects on microbial growth and product quality (Li et al., 2018). Chemically, Tween 80™ is a synthetic molecule derived from sorbitan (a cyclic polyol) and esterified with oleic acid (C18:1,*cis*-9). This combination results in a molecule with a hydrophilic head (sorbitan) and a hydrophobic tail (oleic acid), allowing Tween 80™ to act as a surface-active agent. Tween 80™ improves the solubility and bioavailability of nutrients, promoting microbial growth and fermentation efficiency. By facilitating

nutrient uptake and metabolism, Tween 80™ can lead to higher yields of fermented products (Li et al., 2018). The combination of oleic acid (C18:1,*cis*-9) with sorbitol permits the solubility of fatty acid in aqueous solution and a uniform dispersion of particles in growth medium, thereby making it more accessible to acid bacterial cells. Corcoran et al. (2007) compared the effect of adding Tween 80™ to the survival of four strains of lactobacilli suspended in artificial gastric juice: *Lacticaseibacillus rhamnosus* GG, *Lacticaseibacillus rhamnosus* E800, *Lacticaseibacillus paracasei* subsp. *paracasei* NFBC 338, and *Ligilactobacillus salivarius* UCC 500. In each case they confirmed the protective effect of Tween 80™ on cell viability. No Tween 80™ resulted in a decrease in the number of LAB viable cells in at least two logarithmic cycles after incubation in artificial gastric juice for 90 min. The cited studies are confirmed by other references (Johnsson et al., 1995; Broadbent et al., 2014).

The most widely used methods in study cellular fatty acid (as methyl esters) of Firmicutes (including lactobacilli) is matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF) based on the principle of ionization and mass analysis of molecules, and it is particularly well-suited for identifying bacteria because it can analyze intact bacterial cells rather than extracting and purifying specific molecules (Anderson et al., 2014; Foschi et al., 2017; Nacef et al., 2017). As a result of these advantages, MALDI-TOF is becoming the preferred method for the identification of lactobacilli in many laboratories. MALDI-TOF (matrix-assisted laser desorption ionization time-of-flight mass spectrometry) is another method that is increasingly being used for the study of bacterial cellular fatty acid. It is a rapid, sensitive, and easy-to-use technique that can provide accurate species identification. However, the Sherlock Microbial Identification System (by MIDI Inc.) is a reliable method for species identification, particularly for lactobacilli, and is often used in conjunction with other methods, such as sequencing, to provide a complete taxonomic profile (Brondz, 2002; Kunitsky et al., 2006; Alexander, 2012). The alternative method referred to in the statement is likely to be gas chromatography-mass spectrometry (GC-MS), which is a more sophisticated technique that can provide more detailed information about the composition of fatty acids. However, GC-MS is a more expensive and time-consuming method, so it is not always the most practical choice. MIDI is a faster and more cost-effective method, and it is often sufficient for routine identification of lactobacilli. In general, MIDI is a suitable choice for routine identification of lactobacilli when speed and cost are important, while MALDI-TOF is the more advanced method and is the best choice for routine identification and specialized applications. GC-MS is most appropriate for more detailed studies or when species identification is challenging.

This study investigates the influence of Tween 80™ (oleic acid source) supplementation in growth media on the FA profile of selected mesophilic lactobacilli strains. We aim to compare

their abilities to modulate FA synthesis and transformation upon incorporation of this external oleic acid (C18:1,*cis*-9) source.

Materials and methods

Materials

Eleven lactobacilli strains of the lactobacilli (Table 1) deposited in the laboratory collection in the form of monocultures freeze-dried or frozen were used in our research. Cultures of each bacterial strain were conducted in three independent experiments. First, the cultures were revived in the MRS (de Mann, Rogosa, and Sharpe) broth supplemented with Tween 80™ (Sigma-Aldrich) in portions of 50 mL (incubation at 37°C for approx. 12 h). Tween 80™ is known to influence membrane fluidity and potentially impact fatty acid synthesis in lactobacilli (Al-Naseri et al., 2013; Zotta et al., 2017b; Reitermayer et al., 2018). Subsequently, the cultures were inoculated onto the surface of three parallel MRS agar plates with Tween 80™ and three parallel MRS agar plates without Tween 80™ (in two independent replicates for each growth medium). Cultures were incubated at 37°C for 24 h under anaerobic conditions. Anaerocult™ A (Merck) was used to produce an anaerobic milieu in the anaerobic jar™ (Merck). Anaerocult™ A is recommended for the cultivation of obligatory and facultative anaerobes. To minimize growth phase variation, we carefully harvested cells for biomass collection from the defined center sector of each plate using the secondary inoculum. This ensured a representative sample of the cultured population for fatty acid analysis (Asadi et al., 2015).

The extraction of fatty acids: separating and detecting conditions of fatty acid methyl esters using GC-MS

The fatty acids were extracted from the entire bacterial biomass according to recommendations (Haack et al., 1994; Buyer, 2002; Kankaanpaa et al., 2004). Each bacterial biomass sample was prepared for analysis and analyzed in two replicates. The chromatographic separation of fatty acid methyl esters was carried out by gas chromatography coupled with mass spectrometer (GC-MS QP 2010 Shimadzu, Shimadzu Corporation, Japan) using polar column 007-23-30-0.2F (30 m × 0.25 mm × 0.20 μm; Quadrex, Quadrex Corporation, United States). The sample was injected under a split ratio of 1: 25 at the dispenser temperature equal to 230°C. The chromatographic separation was conducted in the following conditions: Initial temperature of column of 60°C, 2 min isotherm, the temperature increase of 4°C/min to 220°C, 10 min isotherm. The carrier gas was helium with a flow rate of 0.37 mL/min. The following detector conditions were used: Temperature of the ion source of 200°C, temperature of the line connecting GC with MS of 220°C, detector voltage of 1.45 kV, and quadrupole filter sweep in a range 50-400 m/z. The following standards were used for identifying fatty acids: oleic acid (Sigma Aldrich, United States), anteiso12-methyltetradecanoic acid (Sigma Aldrich, United States), 2-hydroxytetradecanoic acid (Sigma Aldrich, United States), nonadecanoic acid (Sigma Aldrich, United States), the BAME (bacterial acid methyl esters; Sigma Aldrich, United States), GLC-674 and GLC-617 (Nu-Chek-Prep., United States), and isomers of methyl esters of linoleic acid 18:2 (*cis*-9,*trans*-11 and *trans*-10,*cis*-12; Nu-Chek-Prep., United States). The composition of bacterial acid methyl

[a,b,c,d,e]–Means with different lowercase letters the same line indicate a significant difference at the significance level of 0.05 (Tukey HSD).

esters (BAMEs) is presented in Supplementary Table 1S. In other cases of fatty acids (including lactobacillic acid), the comparisons were made with the literature data (Brondz, 2002; Christie et al., 2007; Montanari et al., 2010). The data obtained from GC-MS was analyzed using GCMS Solution v.2.50 (Shimadzu Corporation).

Statistical analysis

The statistical analysis was carried out using the statistical program Statistica v.10. The analysis of variance (ANOVA) was employed. In this study, ANOVA was complemented by Tukey's test, conducted at a significance level of 0.05, to scrutinize the mutual influence of the factors and identify any statistically significant differences between them. Principal components analysis (PCA) was conducted to assess the relationship between fatty acid profiles and the presence or absence of Tween 80™ in the growth medium. In this case, PCA was used to identify the main components that influenced the variation in fatty acid profiles.

Results and discussion

Lacticaseibacillus rhamnosus

The determined fatty acid profile of *L. rhamnosus* GG, *L. rhamnosus* MB, and *L. rhamnosus* ATCC 4769 cells demonstrated the presence of 29 fatty acids after the incubation on the growth medium with Tween 80™ (Table 2). The strains of *L. rhamnosus* used in our study were characterized by an intense growth on the MRS agar without Tween 80™. The character of the growth of this species' colonies was different from other lactobacilli species used for this study. The colonies on the line of loop movement were snow-white with characteristic papules and damming, and so obtaining the

biomass required for the analysis was not difficult. Nineteen fatty acids were identified in the fatty acid profile of *L. rhamnosus* GG cells, while the presence of 21 fatty acids was noted in the case of *L. rhamnosus* MB and *L. rhamnosus* ATCC 7469 cells (Table 2).

By comparing the test strains of *L. rhamnosus* species acid, similarities were observed in the sequence fatty acid dominant in the fatty acid profile of the cells. The comparative analysis (conducted using Tukey's test) of the share of all dominant fatty acids in the fatty acid profiles obtained from the biomass of all strains showed significant differences. The fatty acid profile of the *L. rhamnosus* GG strain was dominated (the share >10%) by palmitic (C16:0), dihydrosterculic (*cyc*C19:0,*cis*-9,10), lactobacillic (*cyc*C19:0,*cis*-10,11), and oleic (C18:1,*cis*-9,) fatty acids. Meanwhile, the fatty acid profile of the *L. rhamnosus* MB strain was dominated (the share >10%) by palmitic acid, dihydrosterculic acid (*cyc*C19:0,*cis*-9,10), oleic acid, and *cis*-vaccenic fatty (C18:1,*cis*-11) acids. As for the fatty acid profile of *L. rhamnosus* ATCC 7469 strain, it was dominated by palmitic (C16:0), dihydrosterculic (*cyc*C19:0,*cis*-9,10), lactobacillic (*cyc*C19:0,*cis*-10,11), and *cis*-vaccenic acid (C18:1,*cis*-11) acids (the share >10%). Their contribution to the fatty acid profile changed significantly when Tween 80™ was eliminated from the growth medium. The only fatty acids whose proportion in the fatty acid profile did not change significantly were the following fatty acids: caproic (C10:0), anteiso-12-methyltetradecanoic (C15:0,*anteiso*), palmitoleic (C16:1,*cis*-9), and linoelaidic (C18:2,*trans*-9,*trans*-12) fatty acids. In general, removal of Tween 80™ from the growth medium resulted in a decrease in the proportion of 14 fatty acids in the fatty acid profile, both saturated and unsaturated fatty acids, and an increase in the proportion of 11 fatty acids in the profile of fatty acids, mainly unsaturated fatty acids. Of course, these changes were not observed in every *L. rhamnosus* strains tested. Consequently, this resulted in a significant reduction in the calculated the ratio dihydrosterculic acid (*cyc*C19:0,*cis*-9,10)/lactobacillic acid (*cyc*C19:0,*cis*-10,11) (St/Lb ratio) with the exception for the

L. rhamnosus MB strain, the ratio oleic acid (C18:1,*cis*-9)/*cis*-vaccenic acid (C18:1,*cis*-11) (O/V ratio), and the ratio unsaturated acids/saturated fatty acids (U/S ratio). It is worth noting that removal of Tween 80™ from the growth medium resulted in a significant reduction in the proportion of total unsaturated fatty acids, including conjugated fatty acids (CLA), in the fatty acid profile, but also did not result in a complete change in the proportion of saturated fatty acids in the fatty acid profile.

Kankaanpaa et al. (2004) found that *L. rhamnosus* GG cells grown with Tween 80™ contained oleic (21.5%), *cis*-vaccenic (21.8%), dihydrosterculic (23.5%), and lactobacillic (2.1%) acids as major fatty acids, along with conjugated acids at about 3%. Bacteria produce unsaturated fatty acids with various functionalities *de novo* (Zhu et al., 2019). These modifications, along with other fatty acids, increase the fluidity of the cytoplasmic membrane through their specific structures (Kaneda, 1991). The ability of the strains to synthesize *cis*-vaccenic acid and convert it to lactobacillic acid is noteworthy, with minimal *de novo* synthesis of oleic acid, especially in the absence of Tween 80™. The presence of Tween 80™ appears to inhibit the FAS system, as suggested by (Zhang et al., 2020). Our study indicates that all strains produced vaccenic acid even under anaerobic conditions, which is significant since anaerobic conditions favor the anaerobic vaccenic acid pathway. This contrasts with aerobic conditions in *L. casei* N87, which enhance growth, metabolism, and stress tolerance, influencing vaccenic acid synthesis (Ianniello et al., 2016). Refrigerated storage before biomass extraction can increase the proportion of unsaturated fatty acids (Zhu et al., 2019), which helps maintain membrane fluidity and protein activity (Santivarangkna et al., 2008; Parsons and Rock, 2013). The absence of oleic acid stimulates lactobacillic acid synthesis, while its presence increases dihydrosterculic acid levels (Kankaanpaa et al., 2004). This adaptive modification in fatty acid composition helps control membrane fluidity, aiding bacterial stress defense (Beal et al., 2001; Murga et al., 2001; Montanari et al., 2010; Pawar and Aranha, 2022). Environmental factors significantly influence unsaturated fatty acid proportions in lactobacilli membranes (Zotta et al., 2017a; Fonseca et al., 2019), with oxygen availability playing a crucial role (López de Felipe, 2023). Under aerobic conditions, lactobacilli can convert palmitoleic acid to cis-vaccenic acid (Cronan, 2002; Schujman and Mendoza, 2008; Jimenez et al., 2023). Corcoran et al. (2007) noted a rise in certain acids in *L. rhamnosus* GG cells when exposed to oleic acid (C18:1,*cis*-9). Our research found that adding oleic acid via Tween 80™ increased dihydrosterculic acid (*cyc*C19:0,*cis*-9,10), oleic acid (C18:1,*cis*-9), and conjugated fatty acids, while reducing palmitic (C16:0) and stearic (C18:0) acids. Furthermore, *L. rhamnosus* GG, *L. rhamnosus* MB, and *L. rhamnosus* ATCC 7469 cells cultured without Tween 80™ showed lactobacillic acid (*cyc*C19:0,*cis*-10,11) dominance in

their fatty acid profiles. This difference is likely due to the lack of separation of cyclic acids in the Corcoran et al. (2007) study.

Lacticaseibacillus casei and *Lacticaseibacillus paracasei*

The identified fatty acid profile of *L. casei* 393, *L. casei* 431, and *L. paracasei* subsp. *paracasei* MB grown on MRS agar with Tween 80™ contained 29 and 27 fatty acids for *L. casei* and *L. paracasei*, respectively (Table 3). The predominant fatty acids in the fatty acid profile of the first of these strains were: palmitic acid (C16:0), dihydrosterculic acid (*cyc*C19:0,*cis*-9,10), lactobacillic acid (*cyc*C19:0,*cis*-10,11), and *cis*-vaccenic acid (C18:1,*cis*-11). Meanwhile, fatty acids such as palmitic acid, oleic acid (C18:1,*cis*-9), *cis*-vaccenic acid (C18:1,*cis*-11), and dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) were found to be dominant for the fatty acid profile of *L. casei* 431. On the other hand, dominant fatty acids in the *L. paracasei* subsp. paracasei MB fatty acid profile included oleic acid (C18:1,*cis*-9), dihydrosterculic acid (*cyc*C19:0,*cis*-9,10), and palmitic acid (C16:0). While dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) could potentially be used to differentiate between *L. casei* and *L. paracasei* subsp. *paracasei* MB, the high proportion observed in this study might be due to stress experienced by the bacteria during growth (Rouch et al., 2002; Wu et al., 2020; Klein et al., 2022). Cyclic fatty acids, including dihydrosterculic acid (*cyc*C19:0,*cis*-9,10), are known markers of stress in LAB. Further studies are needed to investigate the influence of growth conditions on the fatty acid profile of *L. paracasei* subsp. *paracasei* MB and confirm its potential as a differentiating factor. *L. casei* and *L. paracasei* grown without Tween 80™ displayed altered fatty acid profiles compared to cultures with Tween 80™. Notably, the absence of oleic acid (C18:1,*cis*-9) triggered *cis*-vaccenic (C18:1,*cis*-11) and lactobacillic acid (*cyc*C19:0,*cis*-10,11) synthesis. Total saturated fatty acids, especially iso-13-methyltetradecanoic (C15:0,iso) and stearic (C18:0) acids, increased in bacteria lacking Tween 80™, although this effect was not universal. Conversely, unsaturated fatty acid content and the U/S ratio decreased without Tween 80™. Interestingly, total CLA and St/Lb and O/V ratios also significantly declined. These changes in *L. casei* and *paracasei* are distinct from those observed previously in *L. rhamnosus*.

We observed significant differences in the proportions of saturated, unsaturated, and cyclic fatty acids compared to previous studies (Rizzo et al., 1987; Kankaanpaa et al., 2004; Machado et al., 2004; Liong and Shah, 2005; Corsetti et al., 2010; Rodrigues et al., 2012). Notably, our findings revealed substantial levels of dihydrosterculic and lactobacillic acids, cyclic derivatives of oleic and vaccenic acids, respectively. These results contrast with some prior studies that may have missed these cyclic acids due to separation and detection challenges (Machado et al., 2004; Liong and Shah, 2005). For *L. casei*, our dominant fatty acids

TABLE 3 The percentage fatty acids composition (mean ± SD, n = 6) in mesophilic *Lacticaseibacillus casei* and *Lacticaseibacillus paracasei* strains profiles obtained from the cell cultured in a growth medium with Tween 80™ (with T80) and without Tween 80™ (no T80).

included dihydrosterculic and lactobacillic acids, alongside palmitic acid. This aligns with the findings of Rizzo et al. (1987) who reported palmitic, octadecenoic, and cyclopropane acids as the major components in *L. casei* ATCC 393. However, some discrepancies exist, such as the presence of palmitoleic acid in Machado et al. (2004) which we did not observe. These differences could be attributed to various factors, including strain variations and growth conditions. While comparisons for *L. paracasei* subsp. paracasei MB were limited due to a scarcity of data specifically for this subspecies, it's important to acknowledge that the *L. casei* group taxonomy has undergone revisions in recent years. Some strains previously classified as *L. casei* may now be identified as *L. paracasei*. Future studies that incorporate a wider range of *Lactobacillus* species, including recently reclassified members of the casei group, along with standardized protocols, would offer valuable insights into the influence of growth media components on bacterial fatty acid composition.

Limosilactobacillus fermentum and *Limosilactobacillus reuteri*

The fatty acid profile of bacterial biomass of *L. fermentum* ATCC 9338 and *L. reuteri* DSM 17938 cultured on growth medium with Tween 80™ was characterized by the presence of 27 and 28 fatty acids, respectively (Table 4). We demonstrated that *L. fermentum* ATCC 9338 was characterized by the share of palmitic (C16:0), oleic (C18:1,*cis*-9), lactobacillic (*cyc*C19:0,*cis*-10,11), *cis*-vaccenic (C18:1,*cis*-11), and dihydrosterculic fatty (*cyc*C19:0,*cis*-9,10) acids, while *L. reuteri* DSM 17938 by palmitic, *cis*-vaccenic (C18:1,*cis*-11), dihydrosterculic (*cyc*C19:0,*cis*-9,10), and lactobacillic (*cyc*C19:0,*cis*-10,11) acids. Each of these strains demonstrated the ability to synthesize vaccenic and lactobacillic (*cyc*C19:0,*cis*-10,11) acids, which were in a pool of dominant fatty acids. We also demonstrated the presence of oleic acid (C18:1,*cis*-9) and its cyclic derivative, dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) (Table 4). *L. fermentum* ATCC 9338 and *L. reuteri* DSM 17938 showed excellent growth on MRS agar without Tween 80™. The fatty acid profile of the first of these strains contained 20 fatty acids, while the second strain was characterized by 22 fatty acids. Removal of Tween 80™ from the growth medium resulted in statistically significant changes in the

fatty acid profile of bacterial strains: an increase in the share of 8 fatty acids (5 unsaturated fatty acids and 3 saturated fatty acids) and a decrease in the share of 11 fatty acids (4 saturated fatty acids and 7 unsaturated fatty acids). This significantly reduced the calculated ratios of O/V and U/S, but increased the calculated St/Lb ratio. It is also worth noting that the changes observed were not the same across all bacterial strains tested, which, as with the lactobacilli strains discussed previously, allows for some differentiation.

Our study confirmed previous findings (Johnsson et al., 1995) that Tween 80™ significantly alters the fatty acid profile of *L. fermentum*. Oleic (C18:1,*cis*-9) and dihydrosterculic (*cyc*C19:0,*cis*-9,10) acids, undetectable without the surfactant, became enriched upon its addition. This effect occurred without affecting growth rate, suggesting independent processes. Furthermore, our results aligned with Rizzo et al. (1987) regarding the overall fatty acid composition of *L. fermentum*, highlighting the consistency of this profile across strains.

Taranto et al. (2006) determined the dominant fatty acid in *L. reuteri* CRL 1098 to be palmitic acid (57.7%). Our study found a similar proportion of palmitic acid (40.07%) in *L. reuteri* cells, suggesting a relatively consistent fatty acid profile for this species. Similar results were observed for stearic acid (3.86% and 3.28%, respectively) and the ratio of oleic acid (C18:1,*cis*-9) to *cis*-vaccenic acid (C18:1,*cis*-11) ratio (0.70% and 0.62%). Comparison of cyclic acids was difficult due to limitations in the cited study (Taranto et al., 2006). The ability of *L. reuteri* strains to synthesize CLA from linoleic acid (C18:2,*cis*-9,*cis*-12) has been demonstrated previously (Jenkins and Courtney, 2003; Hernandez-Mendoza et al., 2009; Macouzet et al., 2010). Our study confirmed CLA synthesis by *L. reuteri* DSM 17938 at a level comparable to other strains. The dominant CLA profile was *cis*-9,*trans*-11-octadecadienoic acid, and the strain exhibited the ability to synthesize CLA even without added oleic acid. Lactic acid bacteria possess the ability to transform unsaturated fatty acids in their conjugated form (i.e., CLA) (Kishino et al., 2002; Lin et al., 2002; Lin et al., 2003; Ogawa et al., 2005; Lin, 2006).

Lactiplantibacillus plantarum

Our study examined three strains of *L. plantarum*, all of which exhibited efficient growth on MRS agar with or without

Tween 80™. Interestingly, the fatty acid profiles of *L. plantarum* 299v and *L. plantarum* B.01149cultured on growth medium with Tween 80™ exhibiting profiles with 24 fatty acids, and B.01834 exhibiting a 24-fatty acid profile. Cultivation on growth medium with the addition of Tween 80™ resulted in the fatty acid profile of all three strains examined being dominated by palmitic acid (C16:0), dihydrosterculic acid, *cis*-vaccinic acid and lactobacillic acid (*cyc*C19:0,*cis*-10,11), with the involvement of the last two of these fatty acids differentiating the strains examined (Table 5). Removal of Tween 80™ from the growth medium resulted in a decrease in the share of 11 fatty acids (4 saturated and 7 unsaturated) in the fatty acid profile and an increase in the share of 9 fatty acids (6 saturated and 3 unsaturated) in the fatty acid profile. It is also worth mentioning that the overall contribution of CLA to the fatty acid profile of the tested strains was also statistically reduced due to the removal of Tween 80™ from the growth medium. As a result, the proportion of total saturated and unsaturated fatty acids in the fatty acid profile increased significantly in some bacterial strains. Instead, a significant increase in the St/Lb ratio and a significant decrease in the O/V ratio were observed.

We identified discrepancies with Johnsson et al. (1995) regarding oleic acid (C18:1,*cis*-9) and lactobacillic acid (*cyc*C19:0,*cis*-10,11) production by *L. plantarum* 2004. Our strains displayed a dominance of lactobacillic acid (11.02%–14.46%) and lower levels of oleic acid (up to 4.18%) compared to their findings. We attribute these differences to potential limitations in their methodology, such as sample size and incubation temperature. Our results for strains cultured without Tween 80™ showed a high proportion of palmitic acid (52.82%–54.78%), aligning with Rozès and Peres (1998). Both studies highlighted the prominence of C18:1 and cyclic C19:0 acids, although the specific compositions were not identical. Similarly, Russell et al. (1995) reported palmitic acid dominance, but stearic acid (C18:0) was not a major component in our analysis. These variations likely stem from differing incubation temperatures and analytical methods. Rizzo et al. (1987) identified palmitic (C16:0), cis-vaccenic (C18:1,cis-11), and cyclic C19:0 acids in *L. plantarum* ATCC 14917. However, their classification of the latter solely as lactobacillic acid (cycC19:0,cis-10,11) might not account for all possible isomers. *L. plantarum*'s ability to produce dihydrosterculic

acid (cycC19:0,cis-9,10), as demonstrated by Johnsson et al. (1995), supports this notion. Our findings support this notion, revealing the presence of both lactobacillic (*cyc*C19:0,*cis*-10,11) and dihydrosterculic (*cyc*C19:0,*cis*-9,10) acids. Our research confirms the ability of *L. plantarum* strains to synthesize CLA (conjugated linoleic acid) from various substrates, as reported in previous studies (Ogawa et al., 2005; Kishino et al., 2009; Corsetti et al., 2010; Rodríguez-Alcalá et al., 2011). Studies by Kishino et al. (2009) CLA levels were significantly higher in cultures supplemented with Tween 80™ (1.67%–2.21%) compared to those without (0.16%–0.19%). The two predominant CLA isomers identified (cis-9,trans-11 and trans-10,cis-12) are consistent with Rodriguez-Alcalá et al. (2011). This study highlights the variability in fatty acid profiles of *L. plantarum* strains and emphasizes the need for standardized methodologies for accurate comparisons. We confirm the prevalence of palmitic (C16:0) and C18:1/cyclic C19:0 fatty acids, with lactobacillic acid (*cyc*C19:0,*cis*-10,11) as the dominant cyclic form. Additionally, our findings support *L. plantarum*'s ability to produce CLA, with levels influenced by the presence of Tween 80™.

Principal components analysis

Fatty acids play a crucial role in the physiology and metabolism of lactobacilli. Their composition can influence various aspects of lactobacilli growth, function, and interaction with the environment. Understanding the fatty acid profiles of lactobacilli can provide valuable insights into their metabolic capabilities and potential applications. Of course, the fatty acid composition of lactobacilli can vary significantly depending on the strain and growth conditions. Principal components analysis revealed that growth medium supplementation with Tween 80™ significantly affected the fatty acid profiles of mesophilic lactobacilli strains, particularly the share of oleic acid (C18:1,*cis*-9), *cis*-vaccenic acid (C18:1,*cis*-11), lactobacillic acid (*cyc*C19:0,*cis*-10,11), and dihydrosterculic acid (*cyc*C19:0,*cis*-9,10). In general, the values of the first two principal components of the PCA statistical analysis of 57.53% are not too high and indicate that they do not fully explain the variability of the original data set. Nevertheless, the first two principal components may be statistically significant for the variables we are interested in. The PCA gives a quick

TABLE 5 The percentage fatty acids composition (mean ± SD, n = 6) in mesophilic *Lactiplantibacillus plantarum* strains profiles obtained from the cell cultured in a growth medium with Tween 80™ (with T80) and without Tween 80™ (no T80).

overview of the connection between the different factors and the samples within. It should be noted that the first main component, which is 57.53% of the model variation, divided the cases into two main groups: the fatty acid profiles obtained from the growth medium with Tween 80™ and without Tween 80™ (Figure 1A). The first principal component separated the cases into two main groups based on the growth medium with or without Tween 80™ (Figure 1A). Notably, some *L. casei* strains did not cluster together, suggesting a potential taxonomic misclassification or high variability within this group. The high share of oleic acid (C18:1,*cis*-9) and CLA was important for the separation of the bacteria cultured on the growth medium with Tween 80™, while linoelaidic (C18:2,*trans*-9,*trans*-12), palmitelaidic (C16:1,*trans*-9), and *cis*-vaccenic (C18:1,*cis*-11) acids were important in case of growth medium without Tween 80™ (Figure 1B). This allowed for the separation of strains cultured on growth medium with Tween 80™ into two main groups: those cultured with Tween 80™ and cultured without Tween 80™. In contrast, no significant

differentiation was observed for strains grown on the same growth medium without Tween 80™.

Recent taxonomic revisions suggest that some *L. casei* strains might be reclassified as *L. paracasei* (Ghosh et al., 2019). Unfortunately, we could not perform phylogenetic analysis on all our strains due to the lack of a genome sequence for C-431. Despite this uncertainty, we observed distinct fatty acid profiles among the three *L. casei* strains (potentially *L. paracasei*). However, further studies with a larger and well-characterized strain collection are necessary to confirm the discriminatory power of fatty acid profiles for differentiation between these closely related species.

The exact effects of the presence of Tween 80™ in the growth medium vary depending on the type of lactobacilli, but in general, Tween 80™ can increase saturated fatty acids and reduce unsaturated fatty acids. The presence of Tween 80™ in the growth medium generally increased the proportion of lactobacillic acid (*cyc*C19:0,*cis*-10,11) in the fatty acid profile of all lactobacilli strains. This was due to the stimulation of the

synthesis of lactobacillic acid (*cyc*C19:0,*cis*-10,11) by lactobacilli cells in response to the absence of oleic acid (C18:1,*cis*-9) from Tween 80™. The presence of Tween 80™ in the growth medium had a mixed effect on the proportion of myristic acid (C14:0) and dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) in the fatty acid profile. In some lactobacilli strains, the proportion of myristic acid and dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) increased, while in other species, the proportion of myristic acid and dihydrosterculic acid (*cyc*C19:0,*cis*-9,10) decreased. The presence of Tween 80™ in the growth medium significantly impacts the fatty acid profile of lactobacilli, generally increased the proportion of palmitic acid in the fatty acid profile of all lactobacilli strains. This was due to the incorporation of oleic acid (C18:1,*cis*-9) from Tween 80™ into the cell membranes of lactobacilli cells, which increased the demand for saturated fatty acids to maintain the fluidity of the cell membranes. While our data suggests a decrease in *cis*-vaccenic acid (C18:1,*cis*-11) in the fatty acid profile of all lactobacilli strains, further investigation is needed to elucidate the underlying mechanisms. Existing literature suggests that Tween 80™ might suppress early fatty acids synthesis, potentially affecting *cis*-vaccenic acid (C18:1,*cis*-11) production later in the growth cycle (Jacques et al., 1980; Zotta et al., 2017b; Reitermayer et al., 2018). Future studies employing time-course experiments could provide valuable insights into the dynamics of fatty acid biosynthesis and incorporation in the presence of Tween 80™, allowing for a more definitive understanding of potential competition or alternative pathways involved.

Conclusion

Our study investigated the influence of Tween 80™, a widely used surfactant in culturing media, on the fatty acid profile of selected mesophilic lactobacilli strains. The fatty acid composition of mesophilic lactobacilli cells plays a crucial role in determining their membrane properties, which are essential for various cellular functions, including cell growth, motility, and stress resistance. Our study investigated the impact of Tween 80™, a common surfactant used in bacterial culturing media, on the fatty acid profile of selected mesophilic lactobacilli strains. Tween 80™ has a significant impact on the fatty acid profile of lactobacilli. The presence of Tween 80™ in the growth medium can alter the proportion of various fatty acids, including saturated and unsaturated. The specific changes in fatty acid composition vary depending on the lactobacilli strains and species. One important aspect to consider is the role of the culturing environment in shaping the fatty acid profile of lactobacilli. Culture media can introduce external fatty acids, such as the oleic acid (C18:1,*cis*-9) present in Tween 80™, a common additive. Notably, oleic acid originating in Tween 80™ can be incorporated into lactobacilli membranes, contributing to the complex interplay between environmental factors and bacterial fatty acid biosynthesis in shaping membrane properties.

Our results reveal that the presence of Tween 80™ in the growth medium decreases the abundance of *cis*-vaccenic acid (C18:1,*cis*-11), a key contributor to membrane fluidity. This suggests that Tween 80™ may not only act as an external fatty acid source but also potentially compete with the bacteria's own synthesis of *cis*-vaccenic acid (C18:1,*cis*-11). While competition with oleic acid (C18:1,*cis*-9) from Tween 80™ for membrane incorporation is a possibility, further investigation is needed. Existing literature suggests that Tween 80™ may initially suppress fatty acid synthesis, potentially impacting the availability of precursors for later *cis*-vaccenic acid (C18:1,*cis*-11) production. This decrease in *cis*-vaccenic acid (C18:1,*cis*-11) may lead to an increase in membrane rigidity, which could negatively impact cell growth, motility, and stress resistance.

Conversely, the addition of Tween 80™ to the growth medium had the opposite effect, increasing the proportion of *cis*-vaccenic acid (C18:1,*cis*-11), likely through precursor availability. This increase may help to maintain membrane fluidity, which is important for these cellular functions. The presence of Tween 80™ can increase the proportion of palmitic acid (C16:0) and lactobacillic acid (*cyc*C19:0,*cis*-10,11). Palmitic acid is a saturated fatty acid that is involved in maintaining cell membrane structure and function. Lactobacillic acid (*cyc*C19:0,*cis*-10,11) is a cyclopropane fatty acid that is unique to lactobacilli and is thought to play a role in their interactions with other organisms.

In conclusion, our study demonstrates that Tween 80™ significantly impact the fatty acid composition of lactobacilli. The presence of Tween 80™ can reduce the proportion of oleic acid and *cis*-vaccenic acid (C18:1,*cis*-11). Oleic acid is a major component of the cell membranes of lactobacilli, and Tween 80™ can compete with oleic acid for incorporation into the membranes. The results of our study are particularly relevant to the industrial application of mesophilic lactobacilli. These changes in fatty acid composition can in turn lead to changes in membrane properties, which could have implications for cell function.

Future studies could explore the specific mechanisms by which Tween 80™ influences fatty acid synthesis and the potential for strain-specific adaptations. Additionally, investigating the functional consequences of altered membrane fluidity on cell function would provide valuable insights for optimizing probiotic performance.

Objective: Diabetes has been identified as a risk factor for intervertebral disc degeneration (IDD). The aim of this study is to investigate the potential mechanism underlying diabetes-related pyroptosis in nucleus pulposus (NP) cells. **Methods**: We used a high-glucose environment to mimic diabetes *in vitro* and examined the endoplasmic reticulum stress (ERS) and pyroptotic response. Furthermore, we utilized activators and inducers of ERS to explore the role of ERS in high-glucose-induced pyroptosis in NP cells. We evaluated the ERS and pyroptosis levels using immunofluorescence (IF) or RT-PCR and measured the expression of collagen II, aggrecan, and MMPs. Additionally, we used ELISA to determine the levels of IL-1β and IL-18 in the culture medium, and CCK8 assay to test cell viability. **Results**: High-glucose conditions promoted the degeneration of NP cells and triggered ERS and pyroptosis. A high level of ERS aggravated pyroptosis, and partially suppressing ERS resisted high-glucose-induced pyroptosis and alleviated the degeneration of NP cells. Inhibiting caspase-1-based pyroptosis under high-glucose conditions helped relieve the degeneration of NP cells but did not affect ERS levels. **Conclusions**: High-glucose induces pyroptosis in NP cells via the mediation of ERS, and suppressing ERS or pyroptosis protects NP cells under high-glucose conditions.

Keywords: Nucleus pulposus cells, endoplasmic reticulum stress, high-glucose, pyroptosis

INTRODUCTION

Low back pain is a common clinical symptom, which may or may not be accompanied by radiating pain, numbness, and muscle strength changes in the lower limbs (Chou, 2014). Intervertebral disc degeneration (IDD) is one of the leading causes of low back pain, pathologically characterized by the dysfunction of nucleus pulposus (NP) cells, the degradation of extracellular matrix (ECM), and the progressive fibrosis of the intervertebral disc (Vadala *et al.*, 2015; Zhao *et al.*, 2007; Che *et al.*, 2020). In addition to age, mechanical damage, and other biomechanical risks, metabolic diseases, especially diabetes, have also been confirmed to have a strong correlation with IDD. The diffusion, distribution, and utilization of glucose play a vital role in the normal function of the intervertebral disc (Cannata *et al.*, 2020). Therefore, the imbalance in the maintenance of normal blood glucose levels in diabetic condition has become a risk factor for IDD (Agius *et al.*, 2016).

In a prospective study by Jhawar and others (Jhawar *et al.*, 2006), the relative risk factor of diabetes for lumbar disc herniation was found to be 1.52, which was higher than smoking, hypertension, and hyperlipidemia. Huang and others (Huang *et al.*, 2016) also found that diabetes duration of more than ten years is a high-risk factor for intervertebral disc herniation. Additionally, Robinson and others (Robinson *et al.*, 1998) discovered that diabetic patients have a lower content of aggrecan in their intervertebral discs compared to non-diabetic patients. Despite the strong correlation between diabetes and IDD that has been reported, the pathogenesis of IDD, especially the mechanism of high-glucose-induced IDD, has not been extensively studied.

Pyroptosis shares several morphological characteristics with apoptosis, such as nuclear condensation and chromosome DNA degradation, as well as a reliance on Caspase activation, making it easy to confuse the two (Shi *et al.*, 2017). However, they can be distinguished from one another based on their biological characteristics and molecular mechanisms. The most significant difference between pyroptosis and apoptosis is the series of inflammatory reactions that occur due to the destruction of cell membrane integrity (Fang *et al.*, 2020). Caspase-1/4/5/11 activation and the release of IL-1β and IL-18 accompany pyroptotic cells, leading to the recruitment of more inflammatory cells and the expansion of local and systemic inflammatory responses (Toldo *et al.*, 2018).

The endoplasmic reticulum (ER) is a critical organelle responsible for protein synthesis and folding in eukaryotic cells, making it very sensitive to various stimuli. Disorders in cellular glucose metabolism can cause protein misfolding and accumulation in the ER cavity, resulting in endoplasmic reticulum stress (ERS) (Wagner & Moore, 2011). Recent studies have shown that ERS is a common feature in subjects with the development of IDD and is closely related to the activation of pyroptosis-related NLRP3 inflammasomes (Han *et al.*, 2018). Since ERS plays a role in the processes of glucose me-

RT-PCR, Reverse Transcription-Polymerase Chain Reaction

tabolism, pyroptosis, and IDD, we can experimentally explore the connection and mechanism of ERS in the high-glucose-induced pyroptosis of NP cells.

MATERIALS AND METHODS

Patient tissue collection and NP cells isolation

We recruited 9 patients (4 males, 5 females; every age: 42 years) who underwent lumbar fracture and needed discectomy. The inclusion criteria for patients is no history of the underlying disease and IDD. This research was approved by the Ethics Committee of the Zhoushan Hospital of Traditional Chinese Medicine. After cutting from patients, the disc tissue was conserved in a culture medium and shipped to the laboratory for NP cell isolation immediately.

The gelatinous NP tissue was removed from the disc, washed 3×PBS, and cut into small pieces. Then, the fragment was digested with type II collagenase (Sigma, St. Louis, MO, USA) for 6 h. After centrifuge, the cell pellets were resuspended in the DMEM low glucose medium supplemented with 10% fetal bovine serum and 1% penicillin-streptomycin (Gibco, Rockville, MD, USA). NP cells were cultured at 37°C, 5% CO_2 concentration, and 95% relative humidity. The medium was changed every three days.

NP Cells isolation and treatments

NP cells were initially cultured in low glucose DMEM (1 mg/mL), and extra glucose (Beyotime, Shanghai, China) was added to the medium to achieve a final concentration of 3, 5, 10, and 15 mg/mL. After assessing cell viability under different conditions, NP cells were cultured with 15 mg/mL glucose for three days to induce cell injury. In addition, NP cells were treated with Belnacasan (Beln, Selleck, China) to inhibit caspase-1 expression, Tunicamycin (TM, Sigma-Aldrich, St. Louis, MO, USA) to induce ERS, and 4-Phenylbutyric Acid (4-PBA, Sigma-Aldrich, St. Louis, MO, USA) to suppress ERS. Further details of the treatments are described in the Results section.

Immunofluorescence (IF)

We assessed the cellular expression of CHOP and caspase-1 using immunofluorescence (IF) staining. NP cells were seeded onto coverslips in 24-well plates at a density of 104 cells per well. After treatment, the coverslips were washed 3 times with PBS, fixed with 4% paraformaldehyde, permeabilized with 0.1% Triton-X, and blocked with 5% bovine serum albumin (Beyotime, Shanghai, China) at room temperature. The coverslips were then incubated with primary antibodies, including Mouse monoclonal CHOP (ab11419, Abcam, Cambridge, MA, USA) and Rabbit monoclonal caspase-1 (Cell Signaling Technology, Danvers, MA, USA), overnight at 4°C. Afterwards, the cells were incubated with a rabbit monoclonal Alexa Fluor 647/mouse IgG and monoclonal Alexa Fluor 488-conjugated secondary antibody (Invitrogen, Carlsbad, CA, USA) in the dark at room temperature. The fluorescence intensity was measured using the Image-Pro Plus software.

Reverse transcription-polymerase chain reaction (RT-PCR)

We isolated total RNA from NP cells using TRIzol reagent (Invitrogen, Carlsbad, CA, USA) following the manufacturer's instructions. The RNA was then reverse-transcribed into cDNA and subjected to PCR using SYBR Green Master (TOYOBO, Osaka, Japan) following the manufacturer's instructions. The PCR primers used are listed in Table 1. The relative gene expression was normalized by the amount of GAPDH and calculated using the method of $2^{-\Delta\Delta Ct}$.

Enzyme-linked immunosorbent assay (ELISA)

The contents of IL-1β and IL-18 in the culture medium were determined by the ELISA kit (ab214025, ab215539, Abcam, Cambridge, MA, USA) according to the manufacturer's instructions. The final OD values were captured using a microplate reader.

Cell counting kit-8 (CCK-8) assay

We used the CCK8 test to determine cell viability. NP cells were seeded in 96-well plates at a density of 5000/well and treated as designed. After treatments, CHs were incubated with a CCK8 kit (Beyotime, Shanghai, China) according to the manufacturer's instructions. The intensity of the CCK8 product was measured at OD of 450 nm using a microplate reader. We set the essential 1 mg/mL glucose treatment as a control group, and the other cell viability was shown relative to the control.

Glucose uptake assay

As the structure of 2-deoxyglucose (2-DG) is similar to glucose, glucose transporters take up 2-DG and

Figure 1. High-glucose injures NP cells' viability.
(**A**) The glucose uptake and cell viability of NP cells after 24-hour culture with ranged concentration of glucose. (**B**) The glucose uptake and cell viability of NP cells after 48hour culture with ranged concentration of glucose. (**C**) The glucose uptake and cell viability of NP cells after 72-hour culture with ranged concentration of glucose. Results are expressed as mean ± S.D. (*$P<0.05$, ***$P<0.001$)

metabolize it to 2-DG-6-phosphate (2-DG6P). The accumulation of 2-DG6P is therefore directly proportional to glucose uptake by cells. We treated NP cells with different concentrations of glucose and 1 mM 13 C-labeled 2-DG. After collecting the metabolites with 70% methanol extraction for LC-MS/MS, we measured glucose uptake using the Glucose Uptake Assay Kit (Colorimetric) (ab136955, Abcam, Cambridge, MA, USA) following the manufacturer's instructions.

Statistical analysis

Data were expressed as mean ± standard deviation (S.D.) of three independent experiments. All statistical analyses were performed by the Statistical Product and Service Solutions (SPSS) 22.0 software (IBM, Armonk, NY, USA) package and GraphPad Prism 8 (La Jolla, CA, USA). Unpaired one-way ANOVA was used to compare the differences among the groups. P-value <0.05 was statistically significant between groups.

RESULTS

High-glucose injures NP cells' viability

To confirm that glucose had an impact on the viability of NP cells, we cultured cells in a range of glucose concentrations and measured glucose uptake and cell viability for each condition. The culture medium was initially supplemented with 1 mg/mL glucose, and additional glucose was added to obtain final concentrations of 3/5/10/15 mg/mL. Compared to the control group, glucose uptake levels began to increase after 72 hours of culture when the glucose concentration was 3 mg/mL, and intracellular glucose uptake increased after 24 hours of culture when the glucose

concentration was higher than 5 mg/mL (Fig. 1A–C, left). Thus, providing more soluble glucose in the medium significantly affected the glucose metabolism of NP cells. However, only the concentrations of 10 and 15 mg/mL had an impact on cell viability compared to the control, with a concentration of 15 mg/mL being more sensitive to NP cells in a short period of time (Fig. 1A–C, right).

High-glucose induces the ERS and pyroptosis of NP cells

To induce cell injury in subsequent experiments, we used a glucose concentration of 15 mg/mL, which quickly and effectively reduces the survival of NP cells. To investigate whether ERS aggravates pyroptosis, we used an ERS inducer in cell culture. NP cells were divided into five groups: 1) control: cells without any treatment, 2) glucose: cells were cultured with 15 mg/mL glucose, 3) glucose + Beln: cells were cultured with 15 mg/mL glucose and 1 nM Beln, 4) TM: cells were cultured with 5 μg/mL TM, 5) TM + Beln: cells were cultured with 5 μg/mL TM and 1 nM Beln. All cells were cultured in the indicated conditions for three days. We tested the ERS markers CHOP, GADD34, GRP78, pyroptosis markers caspase-1, caspase-4, and caspase-11 expression by IF or RT-PCR. Compared to the control, CHOP and caspase-1 were massively increased as a result of both high glucose and TM treatments (Fig. 2A, 2B). The supplement of Beln significantly reduced caspase-1 expression but did not affect the CHOP level. Additionally, the expression of GADD34, GRP78, caspase-4, and caspase-11 was also increased by the treatment of high glucose and TM, which was not affected by the supplement of Beln (Fig. 2C, 2D). Therefore, high glucose triggers the ERS and pyroptotic progress of NP cells, and ERS can trigger the pyroptosis of NP cells. The suppression of caspase-1 would not alleviate the ERS and other pyroptosis markers' expression.

Suppressing caspase-1 alleviates highglucose- induced NP cells degeneration

Continuously, we tested the cell function and pyroptosis-related inflammation under the high-glucose and ERS conditions. In addition to high glucose, TM-induced ERS also injured cell viability. However, the suppression of caspase-1 by Beln was effective in improving the cell viability in high-glucose, but not in terms of ERS (Fig. 3A). In the aspect of the secretory phenotype, high glucose influenced collagen II and aggrecan production, which can be rescued by Beln. Moreover, Beln also alleviated the ERS-caused collagen II and aggrecan downregulation (Fig. 3B). As one of the characteristics, IL-1β and IL-18 are largely synthesized and enter the intercellular substance during cell pyroptosis. Therefore, we tested the IL-1β and IL-18 content in the medium after three days' culture. The results indicated that high-glucose and ERS both raised the IL-1β and IL-18 levels, and the Beln was efficient to suppress the IL-1β and IL-18 production under both high-glucose and ERS conditions (Fig. 3C). Besides, we also analyzed the cellular MMP3 and MMP9 gene expression to value the degenerative degree of NP cells, which were all increased by glucose and TM stimulation, and the suppression of caspase-1 presented an inhibiting effect on MMP3 and MMP9 expression (Fig. 3D). Thus, Beln alleviated the pyroptosis and the resulting NP cell degeneration.

Suppressing ERS alleviates high-glucose-induced pyroptosis

We have ensured that high glucose triggered the ERS and pyroptosis; meanwhile, ERS could naturally result in pyroptosis. However, whether the high glucose aggravated the pyroptosis via the mediation of ERS remains unknown. We further applied the inhibitor of ERS in the high-glucose medium and tested the pyroptotic status. NP cells were divided into four groups, 1) control: cells without any treatments, 2) glucose: cells were cultured with 15 mg/mL glucose. 3) glucose + 4-PBA (+): cells were cultured with 15 mg/mL glucose and 1 mM 4-PBA 4) glucose + 4-PBA (++): cells were cultured with 15 mg/mL glucose and 2 mM 4-PBA. All the cells were cultured in the indicated condition for three days. The result of IF indicated that 4-PBA suppressed CHOP and caspase-1 with a dose-independence (Fig. 4A, 4B). Additionally, the expression of GADD34, GRP78, caspase-4, and caspase-11 was also decreased resulting from the presence of 4-PBA. Similarly, when the inhibitor dose increased, the efficiency became more obvious (Fig. 4C, 4D). Therefore, the 4-PBA successfully suppressed the high-glucose caused ERS and the resulting pyroptosis in NP cells.

Suppressing ERS alleviates high-glucose induced NP cells degeneration

In addition, the cell viability in the high-glucose environment was rescued by suppressing ERS with 4-PBA (2 mM) (Fig. 5A). Compared to the high-glucose group, collagen II and aggrecan synthesis were protected by

adding 4-PBA (2 mM) (Fig. 5B). Furthermore, 4-PBA exhibited excellent anti-inflammatory properties by dose-dependently suppressing IL-1β and IL-18, providing further evidence that suppressing ERS alleviated pyroptosis (Fig. 5C). Finally, we tested the RNA expression of MMP3 and MMP13, which were also inhibited

by 4-PBA treatment (Fig. 5D). Therefore, suppressing ERS could prevent cell degeneration.

DISCUSSION

This study investigated the current evidence that high glucose is a risk factor for pyroptosis of NP cells and explored the role of ERS in this process. Previous studies have identified various factors contributing to intervertebral disc degeneration (IDD), such as inflammation, oxidative stress, and an imbalance in extracellular matrix catabolism. The dysfunction and decreased number of NP cells are considered the main and most direct causes of IDD (Ding et al., 2013). While the specific mechanism is not entirely clear, apoptosis, autophagy, and decreased cell proliferation have been implicated (Feng et al., 2016). However, the role of pyroptosis in IDD remains poorly understood. Pyroptosis is a highly inflammatory programmed cell death process that is triggered by inflammasome-mediated activation of proinflammatory cysteine proteases. In contrast to apoptosis, pyroptosis is typically accompanied by the release of large amounts of IL-1β and IL-18. Currently, caspase-1 mediates pyroptosis in the classical pathway, while the pyroptosis caused by caspase-4, 5, and 11 is defined as a non-classical pathway (Vande & Lamkanfi, 2016; Man et al., 2017).

Although people are typically more familiar with the complications of diabetes affecting the heart, brain, kidneys, peripheral nerves, eyes, and feet, diabetes is also a significant risk factor for intervertebral disc disease (Fletcher et al., 2002; Vijan, 2015). The high-glucose microenvironment can cause IDD due to nutritional metabolism disorder. Long-term hyperglycemia significantly alters the capillaries of the vertebral body's cartilage endplates, leading to the reduced blood supply and nutrient metabolism in the intervertebral discs (van Sloten & Schram, 2018). Additionally, the high-glucose microenvironment increases the production of advanced glycation end products (AGEs), which contribute to NP cell apoptosis (Yamamoto & Sugimoto, 2016). The combination of AGEs and their receptors results in local chronic oxidative stress and induces NP cell death. However, the role of the high-glucose microenvironment in NP cell pyroptosis remains unclear. In our study, high glucose impaired cell viability and upregulated the expression of caspase-1/4/11 and IL-1β/18, suggesting a correlation between them. To further elucidate the potential mechanism linking them, our attention is focused on ERS.

The endoplasmic reticulum (ER) is a crucial cellular organelle responsible for synthesizing, folding, and modifying secreted proteins, regulating lipid synthesis, and maintaining intracellular calcium ion homeostasis (Wang & Kaufman, 2016). However, when the ER's normal function is impaired, ER stress (ERS) occurs. High glucose, which mimics maternal diabetes, is widely reported to be a risk factor that induces ERS in many cell types (Chen et al., 2018; Hadley et al., 2018; Zhang et al., 2014). Consistent with previous studies, we also found that high glucose increased ERS markers in NP cells, including CHOP, GADD34, and GRP78 (Huang et al., 2019). The secreted protein CHOP is a transcription factor specific to the ER, which participates in various cell activities, especially the regulation of energy metabolism, proliferation, differentiation, and apoptosis (Li et al., 2014). Under normal circumstances, CHOP expression is low, but it is significantly increased when ERS occurs, which further activates downstream GADD34 and GRP78. In addition to mediating apoptosis (Oakes

& Papa, 2015; Almanza et al., 2019), ERS can also lead to pyroptosis (Chou et al., 2019; Cheng et al., 2019). By confirming that ERS can induce pyroptosis in NP cells, we found that the pyroptotic response was activated by TM treatments (Yakin et al., 2019). Furthermore, the inhibitor of ERS also played a role in suppressing high-glucose-induced pyroptosis, indicating that high glucose caused ERS in NP cells, which led to subsequent pyroptosis. Suppressing ERS is an effective strategy to alleviate high-glucose-induced pyroptosis. To determine whether suppressing pyroptosis would backwards restrain ERS, we used the caspase-1 inhibitor, which rescued cell viability, protected collagen II and aggrecan expression, and reduced IL-1β/18 but did not affect the ERS response. Therefore, pyroptosis is a consequence of ERS, rather than the cause.

However, there are some limitations to this study. We collected only 9 intervertebral discs from patients, and this sample size may be insufficient. For the concentration and duration of glucose treatment, our in vitro model is a little different, with lower but longer periods of hyperglycemia. Therefore, further studies should be performed on diabetic mice in vivo.

In conclusion, our data indicate that high-glucose induces pyroptosis through ERS in NP cells. Suppressing ERS alleviates the pyroptotic response and reverses the degenerated NP cells under high-glucose conditions. Diabetes is involved in a variety of disease processes, and an in-depth study of the molecular mechanism of a high-glucose environment on NP cell metabolism may help us further understand diabetic IDD.

Pets are inhabiting more and more human homes every year. In 2020, the cat population in Europe was 110 million, including 6.8 million in Poland. Dry food is the most popular dietary model for cats because of its easy storage and efficient satisfaction of pet needs. The high processing temperature of dry food reduces the chance of microbial contamination, but this can occur later, during post-production or storage in the pet's caregiver's home or, in the case of weighed foods, in the store. The purpose of this study was to investigate the microbiological safety of dry feed sold in the original manufacturer's packaging and the same feed from the same manufacturers sold in a retail store by weight. Six discriminants, presence of *Salmonella* spp., number of coliforms, number of coagulase-positive staphylococci, determination of yeast and mould counts, *Enterobacteriaceae* count, *Listeria monocytogenes* and determination of total aerobic microbial count were used for the analysis. Then, cat food was then stored for 45 days according to the manufacturer's recommendations. Based on the samples tested both after opening and after storage, it was concluded that the dry cat food analyzed posed a law microbiological risk to animals and humans.

Keywords: microbiological safety, dry cat food, pet food safety, microbiology of food, cat

INTRODUCTION

According to statistics presented by FEDIAF, within the European Union, 88 million households had pets and the cat population was 110 million in 2020. In Poland, there are 6.8 million cats and more than one-third of households in Poland have at least one cat (FEDIAF, 2020). By 2020, pet food sales were 21.8 billion Euros, representing 8.5 million tons of products annually. Proper feeding of animals, including cats, is essential for a healthy and long life. The development of research and access to information has increased pet owners' awareness of the quality of food provided to their pets (FE-

DIAF, 2020). In the European Union, the Rapid Alert System for Food and Feed (RASFF, 2021) is responsible for controlling the safety of raw materials and food products. According to this organization, pet food can be a significant source of many risks, both biological, chemical, and physical (RASFF. The Rapid Alert System for Food and Feed. Annual Report, 2020). These hazards may be related to diseases and injuries that occur in pets. The foundation for maintaining nutritional safety is compositional and nutrient analyses, as well as microbiological evaluation. Despite the use of the latest dry food production methods to prevent contamination, recalls of a particular batch of products due to microbiological contamination are still evident (Kępińska-Pacelik & Biel, 2021).

Dry food is a regular part of the diet of both cats and dogs. This type of food dominates the market due to its ease of storage and efficient satisfaction of the pet's needs. It is processed at a temperature of 80–160°C (Meineri *et al.*, 2019) which significantly reduces the number of pathogenic microorganisms, however, the product may be contaminated at a later stage of production (Kazimierska *et al.*, 2021). The occurrence of pathogenic microorganisms is associated with cross-contamination and deviation from good manufacturing practices (GMP) (Meghwal *et al.*, 2017). Good microbiological quality of food is a major factor, along with the nutritional value of food, to produce healthy and safe food (Chlebicz & Śliżewska, 2018). In recent years, reports of pathogenic microorganisms (bacteria, fungi, and the toxins they produce) have accounted for about 20% of all RASFF food and feed reports, showing, in particular, the presence of *Salmonella*, *Listeria*, *Escherichia*, and others (Piglowski, 2019).

There have been studies on the microbiological safety of dry dog food (Hołda *et al.*, 2017; Kazimierska *et al.*, 2021) and livestock feeds (Hoszowski *et al.*, 2012; Kukier *et al.*, 2012) in Poland, but no studies have focused on dry cat food in Poland. Previous international studies have also focused on the study of animal foods in general (Błajet-Kosicka *et al.*, 2014; Leiva *et al.*, 2019), without distinguishing between cat and dog foods. However, it was reported that there is a need to distinguish between studies on these two species (Hołda *et al.*, 2017; van Rooijen *et al.*, 2014), which differ not only in their nutritional needs but also in their behavioral patterns towards humans and other animals, which affects the possibility of infection risk.

The study aimed to evaluate dry food for adult cats, with a focus on (1) assessing their microbiological safety, (2) comparing microbiological safety in food sold in a

sealed pack and by weight, and (3) assessing their microbiological safety after 45 days.

MATERIALS AND METHODS

Materials

Microbiological analysis was performed on 6 commercially available dry, whole-food cat foods, including 5 international brands and 1 available on the local market. The criterion for the selection of a particular pet food was its availability for sale both in the form of manufacturer-sealed packages and the availability of the same food sold by weight and packaged at points of sale. All feeds were purchased from a specialized pet store located in the city of Szczecin. To obtain reliable results, five packages (n=5) of each feed were purchased for analysis in five replicates. Prior to purchase, the shelf life was checked and the condition of the packaging was assessed for damage that could affect the microbiological quality of the product tested. The purchased assortment for testing was divided into two groups. The first group consisted of pet food purchased in the manufacturer's original packaging. While the second group consisted of pet foods from the same manufacturers sold by weight. The weight of the finished packages ranged from 340 g to 500 g. After microbiological analysis, the tested cat food was stored for 45 days in accordance with the manufacturer's recommendations, the average shelf life of the food after opening was calculated and after that time the food was again subjected to microbiological tests.

Storage of samples for tests

In the first stage of microbiological tests, both commercial feed from the original manufacturer and feed purchased by weight (collected in sterile bags closed with string) were stored at room temperature (18–22°C). In the second stage of the study (after opening the package), the shelf life of the food was 45 days.

Preparation of samples for testing

All packages were washed with alcohol before opening to exclude product contamination by microorganisms on the surface of the package. The general preparation of samples and dilutions to perform microbiological tests were carried out by the International Standard PN-EN ISO 6887-1:2017-05 "Preparation of test samples, initial suspension and decimal dilutions for microbiological examination – Part 1: General rules for the preparation of the initial suspension and decimal dilutions". Depending on the standard, 25 g or 10 g of feed was used for analysis in five replicates.

Microbiological analysis

Each sample, depending on the discriminant to be tested, was weighed accordingly and mixed with an appropriate diluent according to the standard and homogenized (time 30 seconds, speed 8 strokes/second) in Star-Blender™ Digital Homogenizator (VWR, Pennsylvania, USA).

Detection of *Salmonella* spp.

The test was performed according to the PN-EN ISO 6579-1:2017-04 standard. By mixing 25 g of the sample with 225 mL of buffered peptone water (Scharlab, Bar-celona, Spain), a stock suspension was obtained, which was incubated at 37°C±1°C for 18 h±2 h for pre-enrichment in non-selective liquid medium. Then 0.1 mL of the obtained culture was transferred to 10 mL of Rappaport Vassiliadis Broth (RVS) medium (Scharlab, Barcelona, Spain) and 1 mL to 10 mL of Muller-Kauffmann Tetrathionate-Novobiocin (MKTTn) Broth medium (Graso, Starogard Gdański, Poland). The inoculated RVS medium was incubated at 41.5°C for 24 h±3 h, while the inoculated MKKTn medium was incubated at 37°C for 24 h±3 h. The material obtained from RVS and MKKTn cultures was seeded onto two selectively isolating media, Xylose Lysine Deoxycholate (XLD) agar (Scharlab, Barcelona, Spain) and Salmonella Shigella (SS) agar (Scharlab, Barcelona, Spain), which were incubated at 37°C for 24 h±3 h.

Number of coliforms

The test was performed according to the PN-ISO 4832:2007 standard. Pre-suspension of 1 mL obtained after mixing 10 g of the sample with 90 mL of the dilution fluid was transferred onto two sterile Petri dishes. Then about 15 mL of Violet Red Bile with Lactose (VRBL) agar medium (BioMaxima, Lublin, Poland) was added to the plate. After complete solidification, a top layer of about 5 mL of the same medium was added to obtain relatively anaerobic growth conditions. The plates were incubated at 37°C for 24 h±2 h.

Number of coagulase-positive staphylococci (CoPS), *Staphylococcus aureus*, and other species

The test was performed according to the PN-EN ISO 6888-1:2001 standard. A surface culture of 1 mL of the pre-suspension on Baird-Parker agar medium (Scharlab, Barcelona, Spain) was performed. To obtain 1 mL of the test sample, 0.33 mL of the initial suspension was inoculated onto the surface of three small agar plates (90 mm). The plates were incubated at 37°C for 24 h±2 h and then the incubation was prolonged for another 24 h±2 h. The colonies obtained were checked by coagulase test.

Determination of yeasts and moulds counts

Dry cat food is characterized by low water activity; therefore, the PN-ISO 21527-2:2009 standard for products with water activity lower or equal to 0.95 was applied to determine the number of yeasts and moulds. Pre-suspension of 0.1 mL (10 g of the product was mixed with 90 mL of 0.1% peptone water) was inoculated onto the surface of a DG-18 agar plate (Graso, Starogard Gdański, Poland). The plates were incubated at 25°C±1°C for 5 to 7 days.

Enterobacteriaceae count

The test was performed according to PN-EN ISO 21528-2:2017-08. Pre-suspension of 1 mL obtained after mixing 10 g of the sample with 90 mL of dilution fluid was applied to a sterile Petri dish. Then about 15 mL of Violet Red Bile with Glucose (VRBG) agar medium (BioMaxima, Lublin, Poland) was added to the plate. After complete solidification, a top layer of about 5 mL of the same medium was added to obtain relatively anaerobic growth conditions. The sample was performed in duplicate, according to PN-EN ISO 7218:2008/A1:2013-10. The plates were incubated at 37°C for 24h±2h.

Determination of total aerobic microbial count (TAMC)

The test was performed by depth culture according to the PN-EN ISO 4833-1:2013-12 standard. Pre-suspension of 1 mL was transferred to two sterile Petri dishes each and then about 15 mL of Plate Count Agar medium (BioMaxima, Lublin, Poland) was added. Observations were made after 72 hours of incubation at 30°C, under conditions that ensure the growth and multiplication of aerobic bacteria.

Listeria monocytogenes

Detection of *Listeria monocytogenes*

The test was performed according to PN-EN ISO 11290-1:2017-07. 225 mL of Semi-Fraser Broth (Graso, Starogard Gdański, Poland) was added to 25 g of product. The resulting stock suspension was incubated at 30°C for 25 h±1 h. Subsequently, 0.1 mL of the obtained culture was transferred to 10 mL of Fraser medium (Graso, Starogard Gdański, Poland) and a scratch culture was performed on two selective media ALOA (BioMaxima, Lublin, Poland) and Oxford (BioMaxima, Lublin, Poland). The inoculated Fraser medium was incubated at 37°C for 24 h ±2 h, while the inoculated ALOA and Oxford media were incubated at 37°C for 24 h±2h–48 h±2 h. The material obtained from the culture on Fraser broth was streaked onto two selective media ALOA (BioMaxima, Lublin, Poland) and Oxford (BioMaxima, Lublin, Poland), and then incubated at 37°C for 24 h±2 h–48 h±2 h.

Number of *Listeria monocytogenes*

The test was performed in accordance with PN-EN ISO 11290-2:2017-07. A surface culture of 1 mL of the initial suspension including 10 g of sample and 90 mL of half-Fraser (Graso, Starogard Gdański, Poland) broth on ALOA (BioMaxima, Lublin, Poland) agar medium was performed. The seeded plates were incubated at 37°C for 24 h±2 h–48 h±2 h.

Calculation of results

The results were calculated and presented according to PN-EN ISO 7218:2008/A1:2013-10, using the formula:

$$N = \frac{\sum C}{V \times [n1 + (0,1 \times n2)] \times d}$$

where:

$\sum C$ – total colonies on two selected plates from two successive dilutions, of which at least one contains a minimum of 10 colonies; V – the volume of inoculum applied on each plate, in mL; n1 – number of plates obtained from the first dilution; n2 – number of plates obtained from the second dilution; d – the dilution index corresponding to the first dilution obtained.

If less than 10 colonies were obtained per plate, but the set of two plates contained at least 4 colonies, the result was calculated using the formula:

$$N = \frac{\sum C}{V \, n \, d}$$

where:

$\sum C$ – the sum of colonies counted on two plates; V – the volume of inoculum applied on each plate, in mL; n – number of plates; d – the dilution index corresponding to the first dilution obtained.

Table 1. Microbiological analysis of the tested commercial cat foods was performed after opening.
The table shows the mean obtained from 5 replicates of the analysis of one batch of feed.

TAMC – total aerobic microbial count; a – food in original packaging; b – food purchased by weight; ND – not detected.

Figure 1. Example photos of culture plates showing: (A) Enterobacteriaceae, (B) TAMC, (C) yeasts and molds.

Statistical analysis

The statistical analysis was performed using Tibco Statistica 13.3 (StatSoft, Palo Alto, CA, USA). The values of the parameters were presented as arithmetic means. The normality of variable distributions was verified by the Shapiro–Wilk Test. Data with a normal distribution were analyzed using the Student's *t*-test and the Mann-Whitney U test was used for data with a non-normal distribution.

RESULTS

The results are presented in Table 1. For quantitative methods (coliforms, CoPS, yeasts and moulds, *Enterobacteriaceae*, TAMC, *Listeria monocytogenes*), the notation "not detected" was used for standardization when a result <1.0×10^1 cfu/g was obtained. For the qualitative method in *Salmonella* spp. and *Listeria monocytogenes* the result was "not detection in 25g" with the laboratory's limit of detection (LOD) obtained at 5 cfu/g for *Salmonella*

Figure 2. Comparison of total aerobic microbial count in the tested feeds. *p≤0.05; **p≤0.01; ***p≤0.0001

spp. and 7 cfu/g, for *Listeria monocytogenes*. Therefore, no growth of coliforms, *Salmonella* spp., or CoPS, yeasts and moulds, *Enterobacteriaceae* and *Listeria monocytogenes* were observed. Typical growth of aerobic mesophilic microorganisms was obtained in 10 out of 12 samples (83%).

After 45 days of storage, tests were carried out again. No growth of *Salmonella* spp., coliforms, or CoPS was detected. Growth of yeast and moulds was observed in 3 out of 12 samples (25%, Fig. 1C). Growth of *Enterobacteriaceae* was observed in 1 out of 12 samples (8%, Fig. 1A). No growth of *Listeria monocytogenes* was observed. Detailed results are presented in Table 2. Statistical analysis was carried out to compare results from open and stored feeds. The differentiators at which changes were observed were compared: yeasts and moulds, Enterobacteriaceae, and TAMC. Statistical significance was then verified. For yeasts and moulds and Enterobacteriaceae, the samples reached a statistical difference. In the comparison of TAMC in the two groups, 9 out of 12 trials achieved a statistical difference (Fig. 2).

DISCUSSION

Although the food is processed at high temperatures that destroy microorganisms, still spore forms may be retained, and the contamination itself may occur after the production, for example during storage of the food in a retail shop or at home (FEDIAF, 2018). FEDIAF in its list of hazards during the production of dry pet food in the biological nature of hazards mentions *Aeromonas, Campylobacter, Clostridium botulinum, Clostridium perfringens, Enterobacteriaceae, Escherichia coli, Listeria monocytogenes, Salmonella* spp., *Staphylococcus aureus,* and moulds and yeasts including mycotoxins (FEDIAF, 2018). However, not all of them concern the finished dry food product, but also the raw materials used in its production. For this reason, the organization suggests monitoring the microbiological status by testing environmental samples obtained from surfaces not in and in contact with the product and samples of finished feeds (FEDIAF, 2018). The exact requirements for the production facility are set out in the hazard analysis and critical control points (HACCP) procedures. The procedures based on HACCP principles and other regulations stem from Regulation (EC) No 1069/2009 of 21 October 2009 and Commission Regulation (EU) No 142/2011 of 25 February 2011 (Osinski *et al.*, 2014). These include many areas related to pet food production. In terms of microbiological safety. The regulation sets out the following standards that a product must meet after production: the product must be packaged in packaging which is protected against the intrusion of microorganisms, and 5 samples of the product tested for *Salmonella* spp. in 25 g must not show the presence of these bacteria (n=5, c=0, m=0, M=0). The result for *Enterobacteriaceae* is considered satisfactory if the number of bacteria in all samples does not exceed 10 cfu/g (m) or in two samples the result is between 10 and 300 cfu/g (c) if, in the remaining samples, the value obtained does not exceed 10 cfu/g. The result is considered abnormal if the number of bacteria in one or more samples equals or is greater than 300 cfu/g (M) – (n=5, c=2; m=10; M=300 in 1 g) (European Commission, 2011).

Particularly after 2012, when there were two major outbreaks of human salmonellosis in the US caused by contaminated pet food products, attention was directed toward this pathogen (Chen *et al.*, 2019). Actually, in most previous studies conducted on dry commercial pet

TAMC – total aerobic microbial count; a – food in original packaging; b – food purchased by weight; ND – not detected.

foods, no *Salmonella* sp. was reported, which is consistent with the results of our study (Holda *et al.*, 2017; Kazimierska *et al.*, 2021; Leiva *et al.*, 2019; Nemser *et al.*, 2014; Taymaz *et al.*, 2022; Yang *et al.*, 2016). As the pathogen causes a dangerous disease, salmonellosis, this is good news. In 2020, 5470 cases of *Salmonella* spp. infection was reported in Poland. The chance of infection occurs through human-to-human transmission, animal-to-human transmission, also through contaminated food or drinking water (Milczarek *et al.*, 2022). Cases of the spread of *Salmonella* spp. from cats to other animals and humans have been described. In cats, salmonellosis is mainly manifested by acute enteritis (diarrhea, vomiting, fever, inappetence, abdominal pain, dehydration, lethargy) that may progress to septicemia. Conjunctivitis, neutropenia, excessive salivation, fever without diarrhea, and uterine infections may also be among the usual clinical signs of the disease. Uterine infections are particularly important for pregnant cats because they can cause, stillbirths, weak offspring or abortions, which can be caused, for example, by *S. typhimurium* and *S. enteritidis* causing acute inflammation of the stomach and intestines, which as it progresses affects the development of the fetus in pregnant animals (Kuria, 2023). In addition to the possibility of *Salmonella* spp. infection through consumption of contaminated food, outdoor cats are particularly at risk, as they may become infected by preying on birds weakened by salmonellosis (Söderlund *et al.*, 2019) or drinking water from sources that are not controlled, such as puddles (Kozak *et al.*, 2003).

In our study, no growth of coliforms was noted in any sample. This is consistent with previous studies on dry pet food (Holda *et al.*, 2017; Kazimierska *et al.*, 2021; Leiva *et al.*, 2019; Nemser *et al.*, 2014). This is important

for animal foods because the consumption of food with pathogenic coliforms by a cat can cause food poisoning. In the case of coliforms, the bacteria can also be transmitted from the cat to humans. It is most commonly transmitted by direct contact with the animal or its excreta, especially in the case of a cut or open wound. In humans, symptoms of infection with pathogenic coliforms include food poisoning, flu-like symptoms, fever, abdominal cramps, and diarrhea (Srikullabutr *et al.*, 2021).

In our study, no growth of CoPS was noted in any sample. However, they are known to cause disease in livestock and pets, such as methicillin-resistant strains of *S. aureus* (MRSA). In addition, it has been determined that MRSA can contaminate food in food processing plants and slaughterhouses, with its major presence occurring in meat products, the stuff from which pet food is made. The infection can spread from animal to human. MRSA causes infections in humans such as acne, food poisoning, ear infections and septicemia. In cats, MRSA infection leads to food poisoning and pustular dermatitis (Algammal *et al.*, 2020). Domesticated animals, cats and dogs, are defined as environmental sources of CoPS (Velázquez-Guadarrama *et al.*, 2017).

It was assumed that the number of yeasts and moulds exceeding 10^4 cfu/g indicates the poor microbiological quality of food and levels exceeding the recommended limits to ensure hygienic quality (Kazimierska *et al.*, 2021). No yeast or mould growth was observed in the feeds tested after opening. However, they developed after 45 days of storage in 3 of the 12 samples (25%). The highest value was 1.32×10^3 cfu/g, which is within the suggested microbiological quality value. The presence of yeast and mould in pet food has been reported previously (Kazimierska *et al.*, 2021; Leiva *et al.*, 2019). In

the case of yeast and moulds, the greatest risk is posed by mycotoxins. However, the presence of moulds does not always clearly indicate product contamination with mycotoxins. Specific conditions are needed for the production of toxins (Janik *et al.*, 2020). Mycotoxins may contaminate the product both during production (if the food contains cereals) and outside this stage, e.g. during improper storage of the product. However, there is no legislation in Poland setting a maximum level for these in cat food (Błajet-Kosicka *et al.*, 2014). Mycotoxins can cause adverse effects, in the worst cases even cancer. While analyzing pet food with a cereal content of 6% or more, data were obtained showing a very high presence of mycotoxins in dry food. and cat food was more contaminated than dog food. Among mycotoxins, cats may be more sensitive to the effects of trichothecenes and fumonisins (Macías-Montes *et al.*, 2020). Symptoms of trichothecenes poisoning include immune system disorders loss of appetite, vomiting, diarrhea, ataxia, and gastrointestinal bleeding. Fumonisins, on the other hand, can be responsible for lack of appetite, and blindness. depression, ataxia, and even liver and kidney cancer (Błajet-Kosicka *et al.*, 2014).

The number of microorganisms able to grow and form colonies in the solid medium after incubation under aerobic conditions at 30°C in the samples we tested is shown in Fig. 1B. Compared to other studies conducted on dry animal foods (Hołda *et al.*, 2017; Kazimierska *et al.*, 2021), this is not an outlier. TAMB standards for dry pet food are not specified in the guides for pet food manufacturers in Europe and the US (FEDIAF, 2018; Food and Drug Administration, 2022). Thus in animal feeds this value should not exceed 10^6 cfu/g (Kukier *et al.*, 2012), because an increase in the total number of mesophilic aerobic microorganisms may increase the probability of pathogenic microorganisms and their toxic metabolites in the product (Kazimierska *et al.*, 2021). Our testing for mesophilic aerobic microorganisms resulted in an acceptable level of 10^4 cfu/g.

As in our study, no *Listeria monocytogenes* were found in dry pet food in earlier studies (Bilung *et al.*, 2018; Kazimierska *et al.*, 2021; Nemser *et al.*, 2014). In cats, the disease caused by *L. monocytogenes*, listeriosis, is rare. When infected, it can involve the whole organism, skin wounds, encephalomyelitis, and lymphadenitis (Elbert & Rissi, 2021).

The tested feeds were distinguished by a high level of microbiological safety. Despite the demonstrated increase in the number of microorganisms in tests conducted after 45 days of storage, it is worth emphasizing that this number still remained within acceptable limits in accordance with applicable standards. Carrying out analyzes on feed stored in a manner not recommended by the manufacturer has a significant potential to obtain additional data. Such activities may provide more detailed information on the impact of non-recommended storage on the microbiological quality of feed and possible health and food safety consequences.

Hepatic Mcpip1 regulates adaptation to food restriction in mice

Olga Mucha[1], Bozena Skupien-Rabian[2&], Alicja Slota[1#&], Katarzyna Trzos[1#], Natalia Pydyn[1], Bartosz Podlewski[1], Jolanta Jura[1] and Jerzy Kotlinowski[1✉]

Monocyte-chemoattractant protein-induced protein 1 (MCPIP1, or Regnase-1) is an endoribonuclease that degrades translationally active mRNA molecules. MCPIP1 is mostly known for its anti-inflammatory actions, but it is also an important regulator of adipogenesis and lipid metabolism. Its overexpression impairs adipogenesis by reducing mRNA levels of C/EBPβ and PPARγ, key transcription factors regulating this process. Although adipocytes overexpressing MCPIP1 are characterised by impaired glucose uptake, the function of MCPIP1 in hepatocyte metabolism remains unknown. In this study, conditional deletion of *Zc3h12a* in murine liver epithelial cells was used to characterise the role of Mcpip1 in adaptation to 24-hour food restriction. We found that Mcpip1 deficiency in liver epithelial cells (Mcpip1fl/flAlbCre mice) resulted in higher blood glucose levels in response to fasting in comparison to Mcpip1fl/fl counterparts. Hepatic proteome analysis showed 26 down-regulated and 117 up-regulated proteins in Mcpip1fl/flAlbCre animals that were involved in cellular adhesion, extracellular matrix and metabolic processes. In conclusion, our studies provide new insight into the hepatic function of Mcpip1 and its involvement in metabolic control.

Keywords: MCPIP1, liver, fasting, feeding, food restriction

INTRODUCTION

Both humans and animals adjust their metabolism to an excess or deficiency of food and the liver plays a central role in these processes. During the shift from a feeding to a fasting state, hepatic production of glucose and ketone bodies increases, with concomitant glycogen depletion and triacylglycerol accumulation (Goldstein & Hager, 2015). In contrast, a meal containing carbohydrates stimulates hepatic glucose uptake and glycolysis and repletes glycogen stores. Fatty acid synthesis is induced, while β-oxidation and ketogenesis are inhibited (Moore *et al.*, 2012). As a result, high-energy stores are replenished both in hepatocytes and adipocytes, maintaining metabolic homeostasis during periods of feeding and fasting (Geisler *et al.*, 2016).

Monocyte-chemoattractant protein-induced protein 1 (MCPIP1), encoded by the *ZC3H12A* gene, is mostly known for its anti-inflammatory properties. It is an endoribonuclease that degrades mRNA, pre-miRNA, and viral RNA molecules. The broad spectrum of MCPIP1 targets includes IL-1β (Mizgalska *et al.*, 2009), IL-6 (Matsushita *et al.*, 2009) and IL-2 (Li *et al.*, 2012). MCPIP1 was also shown to regulate glucose and lipid metabolism and its hepatic levels are reduced in humans suffering from Non-alcoholic fatty liver disease (NAFLD) (Pydyn *et al.*, 2023). MCPIP1 inhibits adipogenesis *in vitro* by reducing the levels of key transcription factors, including C/EBPβ (Lipert *et al.*, 2017). Additionally, adipocytes that overexpress the MCPIP1 protein are characterised by a lower level of the insulin receptor Glut4 and impaired glucose uptake (Losko *et al.*, 2020).

In this study, we aimed to analyse the role of hepatic Mcpip1 in murine adaptation to fasting. We performed mass spectrometry analysis of whole-liver lysates from Mcpip1fl/fl and Mcpip1fl/flAlbCre mice that were fasted for 24 h, followed by functional annotation and enrichment analysis of differentially expressed proteins. We demonstrated that Mcpip1 is involved in the regulation of metabolic pathways, including glyoxylate and dicarboxylate metabolism or the pentose phosphate pathway. Our studies provide new insight into the hepatic function of Mcpip1 and its involvement in metabolic control.

MATERIAL AND METHODS

Animals and genotyping

The study used 10-week-old female control Zc3h12a-lox/lox mice (designed as Mcpip1fl/fl) and Mcpip1 liver epithelial cell-specific knockout mice (designed as Mcpip1fl/flAlbCre). Deletion of Mcpip1 protein in Mcpip1fl/flAlbCre mice was present in liver epithelial cells (hepatocytes and cholangiocytes). Its level in whole liver tissue was only partially reduced (Kotlinowski *et al.*, 2021). The animals were genotyped as previously described (Kotlinowski *et al.*, 2021). In brief, DNA was extracted from tail tissue using a KAPA Mouse Genotyping Kit (KAPA Biosystems) according to the manufacturer's instructions. Genotyping for loxP insertion was performed by PCR using the following primers: GCCTTCCTGATCCTATTG-GAG (wild-type), GAGATGGCGCAGCGCAATTAAT (knockout), and GCCTCTTGTCACTCCCTCCTCC (common). Genotyping for AlbCre tg/+ was conducted with the following primers: TGCAAACATCACATG-CACAC (wild-type), GAAGCAGAAGCTTAGGAA-

GATGG (mutant), and TTGGCCCCTTACCATAACTG (common). The animals were housed under SPF conditions in ventilated cages in a temperature-controlled environment with a 14-h light/10-h dark cycle. The mice were randomly divided into 'fed' and 'fasted' groups at 10 weeks of age. Mice from the fed group received food and water *ad libitum*, whereas the animals enrolled in the 'fasted' group were placed into cages containing only water for 24 hours. On the following day, all animals were sacrificed, and blood and liver were collected. All animal procedures were conducted in accordance with the Guide for the Care and Use of Laboratory Animals (Directive 2010/63/EU of the European Parliament) and carried out under a licence from the 2nd Local Institutional Animal Care and Use Committee in Krakow (study no. 272/2017).

Blood analysis

All blood tests were measured by an automated analyser (Arkray) according to the manufacturer's instructions.

Protein isolation and western blot

Liver samples were lysed using RIPA buffer (25 mM Tris-HCl; pH 7.6; 150 mM NaCl, 1% sodium deoxycholate and 0.1% SDS) with Complete Protease Inhibitor Cocktail (Roche) and PhosSTOP Phosphatase Inhibitor Cocktail (Roche). A bicinchoninic acid assay was used to assess protein concentration, and 25 μg of proteins were separated on a 10% SDS/PAGE polyacrylamide gel. After wet transfer to PVDF membranes (Millipore), the membranes were blocked in 5% skim milk and then incubated overnight with primary antibodies at 4°C. On the following day, the membranes were washed and incubated with a secondary antibody for 1 h at room temperature. Chemiluminescence was detected after 5 min of incubation with ECL™ Select Western Blotting Detection Reagent (GE Healthcare) in a ChemiDoc chemiluminescence detector (Bio-Rad). The following antibodies were used: rabbit anti-MCPIP1 (1:2000; GeneTex), rabbit anti-PPARγ (1:1000; Cell Signaling), mouse anti-β-actin (1:4000; Sigma), peroxidase-conjugated anti-rabbit (1:30 000; Cell Signaling) and peroxidase-conjugated anti-mouse (1:20 000; BD).

LC-MS/MS analysis and data processing

Liver fragments were homogenised in lysis buffer (7M urea, 2M thiourea, 4% CHAPS and 30 mM Tris; pH 7.5) using a CTFE/stainless steel pestle. Then, dithiothreitol was added at a concentration of 50 mM and the tissue homogenates were sonicated in a Bioruptor Pico (Diagenode) (15 cycles of 30 s ON/30 s OFF). After this step, the samples were centrifuged and supernatants were collected. Protein concentration was measured by Bradford assay and the samples (100 ug) were prepared for LC-MS/MS analysis using a filter-aided sample preparation (FASP) protocol (Wiśniewski *et al.*, 2009). The LC-MS/MS analysis was performed on a Q Exactive mass spectrometer (Thermo Fisher Scientific) coupled with a nanoHPLC (UltiMate 3000 RSLCnano System, Thermo Fisher Scientific), as previously described (Zacchini *et al.*, 2021). The acquired data were processed using MaxQuant software (version 1.6.7.0) (Tyanova *et al.*, 2016a) and searched with the integrated Andromeda search engine (Cox *et al.*, 2011) against the SwissProt database restricted to Mus musculus taxonomy (17 038 sequences; downloaded on 7 July 2020). The false discovery rate

(FDR) for the peptide and protein identification was set to 1%. The match between runs algorithm was enabled, and label-free quantification (LFQ) was carried out. The MaxQuant output table was further processed with the use of Perseus (version 1.6.5.0) (Tyanova *et al.*, 2016b). The protein groups identified in the decoy database, contaminants and proteins only identified by site were filtered out. The LFQ intensities were log2-transformed. Student's t-test with the permutation-based FDR set to 1% was used to reveal changes between the mutant and wild-type mice. The statistical analysis was performed for the protein groups that had a minimum of 4 valid LFQ intensity values in both animal groups. The final list of differences contained proteins identified based on at least 2 peptides with a significance threshold q value of <0.01 and fold change cutoffs of 1.3 and -1.3.

All proteins selected from mass spectrometry analysis are named according to UniProt nomenclature. A PCA graph, volcano plot and hierarchical clustering were prepared with the Perseus platform (version 1.6.5.0) (Tyanova *et al.*, 2016b). Functional annotation was performed using either the Database for Annotation, Visualization and Integrated Discovery (DAVID) (Huang *et al.*, 2009a; Huang *et al.*, 2009b) tools or STRING tools (Szklarczyk *et al.*, 2023). The results were further visualised using a free online platform for data analysis and visualisation: https://www.bioinformatics.com.cn/en.

The mass spectrometry data were deposited to the ProteomeXchange Consortium (Vizcaíno *et al.*, 2014) via the MassIVE repository with the dataset identifier PXD041676.

RNA isolation and real-time PCR

Total RNA from livers was isolated using Fenozol (A&A Biotechnology), followed by spectrophotometric measurement of RNA concentration using a NanoDrop 1000 (Thermo Fisher Scientific). For reverse transcription, 1 μg of total RNA, oligo(dT) 15 primer (Promega) and M-MLV reverse transcriptase (Promega) were used. Real-time PCR was carried out using SYBR Green Master Mix (A&A Biotechnology) and a QuantStudio Real-Time PCR System (Applied Biosystems). Gene expression was normalized to *Ef2*, and then the relative transcript level was quantified by the 2^deltaCt method. The primer sequences (Sigma) are listed in Table S1 in the Supplementary Material at https://ojs.ptbioch.edu.pl/index.php/abp/.

Statistical analysis

The results are expressed as means ± SEM. One-way ANOVA with Tukey's post hoc test was applied for the comparison of multiple groups, and Student's t-test for two-group comparisons. The p-values are marked with asterisks in the charts (*$p<0.05$, **$p<0.01$ and ***$p<0.001$).

RESULTS

Biochemical characterisation of 'fed' and 'fasted' Mcpip1^fl/fl^Alb^Cre^ mice

Deletion of Mcpip1 in liver epithelial cells leads to hepatomegaly, previously described in male mice (Kotlinowski *et al.*, 2021). As shown in Table 1, the female Mcpip1^fl/fl^Alb^Cre^ animals were also characterised by larger livers and higher liver/body ratios in comparison to the Mcpip1^fl/fl^ controls (Table 1). There were no differenc-

Data are presented as means ± S.E.M. Data were compared using one-way ANOVA with Tukey's post hoc test, *$p<0.05$, **$p<0.01$ *vs* Mcpip1[fl/fl] and #$p<0.05$, ##$p<0.01$, ###$p<0.001$ *vs* counterparts from the fed group.

es in serum biochemical markers – cholesterol, HDL, LDL, triglycerides, AST, ALT and glucose – between the two groups. After 24 h of food restriction, all mice lost weight and had lower serum glucose concentrations in comparison to their fed counterparts. In the fasted group, the Mcpip1[fl/fl]Alb[Cre] animals had higher glucose concentrations than the age-matched Mcpip1[fl/fl] controls,

which may suggest better adaptation to food restriction (Table 1).

Proteomic analysis revealed metabolic pathways to be affected by the lack of Mcpip1 in fasted mice

In order to investigate how Mcpip1 deletion in liver epithelial cells affects murine adaptation to fasting, we

Figure 2. Levels of transcription factors regulating metabolism in livers
(**A**) Western blot analysis and (**C**) Densitometric quantification of Mcpip1, Pparα, Pparγ and C/ebpβ levels in the livers collected from Mcpip1fl/fl control and Mcpip1fl/flAlbCre knockout animals fed *ad libitum*; (**B**) Western blot analysis and (**D**) densitometric quantification of Mcpip1, Pparα, Pparγ and C/ebpβ levels in the livers collected from Mcpip1fl/fl control and Mcpip1fl/flAlbCre knockout animals after 24 h of fasting; graphs show the means + S.E.Ms; n=6–7; *p<0.05.

performed a mass spectrometry experiment utilising the label-free (LF) method. The analysis showed satisfactory separation of the groups and 143 differentially expressed proteins (Fig. 1A, Table S2 at https://ojs.ptbioch.edu.pl/index.php/abp/), 26 and 117 of which were potently down-regulated and up-regulated, respectively, in the Mcpip1fl/flAlbCre animals (Fig. 1B, Table S2 at https://ojs.ptbioch.edu.pl/index.php/abp/). Among the most down-regulated proteins in Mcpip1fl/flAlbCre mice, we identified perilipin 2 (PLIN2), pyrethroid hydrolase Ces2e (EST2E), 40S ribosomal protein S6 (RS6), acyl-CoA synthetase short-chain family member 3, mitochondrial (ACSS3) and glutathione S-transferase theta-3 (GSTT3) (Fig. 2B, green dots). Cytoglobin (CYGB), transforming growth factor-beta-induced protein ig-h3 (BGH3), laminin subunit beta-2 (LAMB2), laminin subunit gamma-1 (LAMC1) and nidogen-1 (NID1) were the most up-regulated upon Mcpip1 deletion (Fig. 2B, red dots).

In the next step, we used DAVID bioinformatics resources for functional annotation and enrichment analysis of differential proteins. We were able to distinguish several enriched biological themes among gene ontology terms and KEGG pathways (Supplementary Fig. 1A at https://ojs.ptbioch.edu.pl/index.php/abp/). A substantial number of the identified processes were related to cellular adhesion, the cytoskeleton and the extracellular matrix. Among the less affected, but still significant, we observed themes such as angiogenesis, glutathione metabolism, cell migration and proliferation. Interestingly, we also showed several processes related to the metabolic pathways that were enriched, including glyoxylate and dicarboxylate metabolism, the pentose phosphate pathway and carbon metabolism (Fig. 1C). The hierarchical clustering of proteins associated with metabolism confirmed the observed differences (Supplementary Fig. 1B at https://ojs.ptbioch.edu.pl/index.php/abp/), which were then demonstrated on the bar graph using the corresponding fold change (FC) (Fig. 1D). Fourteen and 11 proteins were significantly down-regulated and up-

regulated, respectively, with an FC higher than 2 for 5 proteins: UDP-N-acetylhexosamine pyrophosphorylase-like protein 1 (UAP1L), creatine kinase B-type (KCRB), glycogen phosphorylase, brain form (PYGB), glucose-6-phosphate 1-dehydrogenase (G6PD1) and glutathione peroxidase 3 (GPX3). A more thorough analysis of those 25 proteins using the STRING software tool for known and predicted protein–protein interactions was performed and visualised on a chord diagram (Fig. 1E). As a result, we graphically demonstrated the distribution of the proteins significantly changed in our analysis within several metabolism-related themes, including the primary metabolic process, carbon and pyruvate metabolism, the glucose metabolic process, the pentose phosphate pathway, the tricarboxylic acid metabolic process and mitochondrion localisation.

Evaluation of metabolic pathways that regulate glucose and lipid turnover in the livers of Mcpip1fl/fl and Mcpip1fl/flAlbCre mice

It was already shown, that the MCPIP1 protein influences lipid metabolism by regulating C/ebpβ and Pparγ transcription factors (Lipert *et al.*, 2014). Since the turnover of lipids is a key adaptation to fasting, we also tested these proteins in the livers of control and food-restricted animals. The Mcpip1fl/flAlbCre mice in the fed group were characterised by lower hepatic Mcpip1 in comparison to their Mcpip1fl/fl counterparts, but there were no differences in the levels of Pparα, Pparγ or C/ebpβ (Fig. 2A, C). Upon fasting, hepatic Mcpip1 deletion led to a reduction of Pparα, but the other protein levels did not change (Fig. 2B, D). In the next step, we tested whether changes in protein levels resulted from different amounts of their transcripts, which might be directly regulated by Mcpip1 *via* its RNase activity. Under fed conditions, Mcpip1 deletion did not affect glycolysis (*Pkm*) – neither glycogenolysis (*Pygb, Pgm2*), fatty acid metabolism (*Cpt1a, Fabp4, Acox1* and *Lcad*) nor keton bodies production (*Hmgcs2*) (Fig. 3A–F). There

Figure 3. Hepatic Mcpip1 deletion in Mcpip1fl/flAlbCre mice impairs gluconeogenesis after 24 h of fasting

Expression of key enzymes regulating (**A**) glycolysis (*Pkm* – pyruvate kinase), (**B**) glycogenolysis (*Pygb* – glycogen phosphorylase; *Pgm2* – Phosphoglucomutase-2), (**C**) gluconeogenesis (*Pck1* – phosphoenolpyruvate carboxykinase 1; *G6pc* – glucose-6-phosphatase), (**D**) fatty acid transport (*Cpt1a* – carnitine palmitoyltransferase 1A; *Fabp4* – fatty acid binding protein 4), (**E**) β-oxidation (*Acox1* – peroxisomal acyl-coenzyme A oxidase 1; *Lcad* – acyl-CoA dehydrogenase, long chain) and (**F**) ketone body production (*Hmgcs2* – 3-hydroxy-3-methylglutaryl-CoA synthase 2); graphs show the means + S.E.Ms; n=6–7; *$p<0.05$; **$p<0.01$; ***$p<0.001$

was only a reduction in *Pck1* expression in the livers of Mcpip1fl/flAlbCre mice that were fed *ad libitum* (Fig. 3C). After 24 h of fasting, Mcpip1 deletion led to increased expression of *Pygb*-encoding glycogen phosphorylase, which catalyses the phosphorolysis of glycogen to yield glucose 1-phosphate (Fig. 3B). In the livers of Mcpip1fl/flAlbCre mice, the expression of *Pck1* and *G6pc*-encoding phosphoenolpyruvate carboxykinase 1 and glucose-6-phosphatase, respectively, was reduced in comparison to the Mcpip1fl/fl animals in the fasted group (Fig. 3C). Similarly to fed conditions, there were no changes in the expression of the other genes tested (Fig. 3).

DISCUSSION

The demonstration that Mcpip1fl/flAlbCre mice have higher serum glucose levels after food deprivation, is a major finding of this study. During fasting, hepatic glucose production relies on either glycogen breakdown or gluconeogenesis from glycerol, amino acids or TCA cycle intermediates. According to a study by Geisler *et al.*, for the first 8 hours of fasting, the serum glucose level is balanced by depletion of the hepatic glycogen content. When the duration of fasting exceeded 8 h, the researchers observed increases in hepatic gluconeogenic potential (phosphoenolpyruvate carboxykinase activity and mRNA expression) from TCA cycle intermediates (Geisler *et al.*, 2016). In line with these data, after fasting we observed increased expression of phosphoenolpyruvate carboxykinase 1 (*Pck1*) and glucose-6-phosphatase catalytic subunit (*G6pc*) – key gluconeogenic enzymes – in the livers of Mcpip1fl/fl mice. Although fasting did not induce *Pck1* or *G6pc* in Mcpip1fl/flAlbCre livers, these mice had a higher serum glucose level than their Mcpip1fl/fl counterparts.

According to the literature, glycogenolysis is the first adaptation to fasting and is followed by a metabolic shift toward gluconeogenesis, β-oxidation and ketogenesis – which were all observed in our experimental model. For

example, the activation of β-oxidation and ketogenesis, mediated *via* induction of Cpt1 and Hmgcs2, respectively, was detected after only 12 h of food deprivation (Vilà-Brau *et al.*, 2011; Monsénégo *et al.*, 2012). In line with these results, *Hmgcs2* knockdown completely eliminates the increase in serum β-OH butyrate upon fasting (Hepler *et al.*, 2016). Although proteomic analysis did not give us a clear answer as to why Mcpip1fl/flAlbCre mice adapt better to fasting than Mcpip1fl/fl mice, we detected a few differentially expressed proteins involved in metabolic control. As shown in Fig. 1, the liver proteome of Mcpip1fl/flAlbCre mice significantly differed from their Mcpip1fl/fl counterparts when it comes to proteins involved in carbon, pyruvate and glucose metabolism, together with the pentose phosphate pathway and the tricarboxylic acid process. Perilipin 2 (PLIN2) was the most strongly down-regulated liver protein among them in the knockout animals.

Perilipin 2 belongs to a family of lipid droplet coat proteins that have emerged as physiological regulators of lipid accumulation in many tissues, including adipose and liver tissue (Ducharme & Bickel, 2008). It is constitutively located on the lipid droplet surface and has no lipolytic function, but it can block lipases, limiting triglyceride hydrolysis. Thus, the low level of perilipin 2 in Mcpip1fl/flAlbCre livers might facilitate triglyceride catabolism (LL *et al.*, 2007; Bell *et al.*, 2008). It was also shown that PLIN2 is the predominant lipid droplet coat protein in hepatocytes in humans and rodents subjected to NAFLD induced by a high-fat diet (Imai *et al.*, 2007). Mice with whole-body PLIN2 knockout are resistant to obesity, adipose tissue inflammation and liver steatosis when fed a high-fat diet for 12 weeks (McManaman *et al.*, 2013). Similarly, PLIN2 liver-specific ablation in mice alleviates diet-induced hepatic steatosis, inflammation, non-alcoholic steatohepatitis and liver fibrosis (Najt *et al.*, 2016; DJ *et al.*, 2019). Thus, perilipin 2 is a potentially valuable molecular target for future studies.

A growing body of evidence shows that MCPIP1 is involved in the regulation of metabolism. Its overexpression impairs adipogenesis by reducing mRNA levels of C/EBPβ and PPARγ, key transcription factors regulating this process (Lipert *et al.*, 2014). Later studies showed that MCPIP1-overexpressing adipocytes exhibit lower levels of the proteins involved in lipid and carbohydrate metabolism, and up-regulation of the proteins involved in cellular organisation and movement (Losko *et al.*, 2018). Adipocytes overexpressing MCPIP1 are additionally characterised by impaired glucose uptake due to a lower level of insulin receptor, reduced insulin-induced Akt phosphorylation and depleted Glut4 (Losko *et al.*, 2020). The level of MCPIP1 is also lower in the adipose tissue of obese subjects and in patients suffering from NAFLD (Losko *et al.*, 2018; Pydyn *et al.*, 2023). In line with these data, fatty liver disease induced by a high-fat diet in C57BL/6J mice was followed by a reduced hepatic level of Mcpip1 (Pydyn *et al.*, 2019). However, quite surprisingly, Mcpip1$^{fl/fl}$Alb^{Cre} mice on a high-fat diet for 12 weeks were not susceptible to the development of fatty liver disease. Liver fat content did not change significantly in comparison to age-matched Mcpip1$^{fl/fl}$ controls (Pydyn *et al.*, 2021).

Mcpip1 was recently described as an important regulator of hepatic homeostasis, in both physiological and pathophysiological conditions. Sun and others (Sun *et al.*, 2018) described the protective role of Mcpip1 in mice subjected to liver ischemia/reperfusion injury. Hepatocyte-specific Mcpip1 gene knockout and transgenic mice demonstrated that Mcpip1 functions to ameliorate liver damage, reduce inflammation, prevent cell death and promote regeneration. As we previously reported, the deletion of Mcpip1 in Mcpip1$^{fl/fl}$Alb^{Cre} mice led to the development of primary biliary cholangitis symptoms. In the livers of these animals, intrahepatic bile ducts displayed proliferative changes with inflammatory infiltration, bile duct destruction and fibrosis leading to cholestasis (Kotlinowski *et al.*, 2021). Massive fibrosis was already detected in young, 6-week-old Mcpip1$^{fl/fl}$Alb^{Cre} mice. Thus, the high amount of fibrosis-related or extracellular matrix proteins in the liver upon fasting was not surprising to us. Since Mcpip1 is an endoribonuclease, it is possible that some of the mRNAs encoding these proteins are direct targets of Mcpip1. In the future, it would be interesting to test whether Mcpip1 binds and digests transcripts encoding the proteins involved in the remodeling of the ECM other than MMP9 (Szukala *et al.*, 2021).

Out of 10 the most strongly up-regulated proteins, 9 were related to fibrosis. Cytoglobin (Cygb) was induced 13.1 times. In 2001 cytoglobin was discovered in hepatic stellate cells (HSCs), and it was later demonstrated to be an important regulator of HSC O_2 homeostasis under hypoxic conditions (Kawada *et al.*, 2001; Yoshizato *et al.*, 2016). Upon deletion of the *Cygb* gene in mice, hepatic O_2 homeostasis was disrupted, leading to the activation of HSCs and liver fibrosis (Yoshizato *et al.*, 2016). Cytoglobin inhibits HSC activation by maintaining its quiescent state. However, its induction in Mcpip1$^{fl/fl}$Alb^{Cre} livers does not reduce liver fibrosis in these mice, which is demonstrated by the significant overexpression of ECM-related proteins. On the contrary, in our model cytoglobin induction may result from disturbed liver homeostasis, i.e. fibrosis or inflammatory infiltration, which are both characteristic of Mcpip1$^{fl/fl}$Alb^{Cre} mice (Kotlinowski *et al.*, 2021). In fact, cytoglobin induction was already reported after long-term thioacetamide-induced liver fibrosis (Thi Thanh Hai *et al.*, 2018).

In summary, we demonstrated that hepatic deletion of Mcpip1 led to higher serum glucose concentration in mice subjected to fasting. For future studies, it would be interesting to concentrate on the liver and serum metabolome to better understand the role of Mcpip1 in metabolic homeostasis.

The phenomenon of growth is a leading factor for aquaculture success. The uneven growth of major Indian carps (*Labeo rohita, Catla catla,* and *Cirrhinus mrigala*) is a serious issue in fish culture from an economic point of view. The growth hormone (GH) gene is crucial for selection in commercially cultivated fish species for better growth and production. Indian major carp (*L. rohita, C. catla,* and *C. mrigala*) are commonly cultured in Pakistan. The *GH* expression was examined using qPCR to understand growth in fish species better. Muscle tissue samples (*n*=480) from 160 individuals of the same age were collected from three species (*L. rohita, C. catla,* and *C. mrigala*). Individuals were divided into two groups (high-weight and low-weight groups), cultured under normal conditions. The housekeeping gene β-actin validated *GH* expression in fast and slow-growing fishes from the same species. Results showed that *GH* expression varies across species and fish specimens that overweight their counterpart feature have higher *GH* expression. A selection for overweight fish in the aquaculture breeding systems is preferable as those fish could inherit their genomics to the future cohort, enhancing production, and commercial profit for farmers. Comprehensive research about different growth genes and the environmental aspects that influence fish growth is mandatory. No work has been reported regarding the growth gene analysis of fish from Pakistan. This report was Pakistan's first and baseline study regarding growth analysis of main culturable fish species at the molecular level.

Keywords: *Labeo rohita, Cirrhinus mrigala, Catla catla*, Growth hormone, Beta-actin gene, Q-PCR

Received: 02 June, 2023; revised: 20 September, 2023; accepted: 02 November, 2023; available on-line: 14 November, 2023

INTRODUCTION

Pakistan is blessed with fish fauna and water resources, but only nine species (7 warm and 2 cold water) are commercially cultured. Moreover, only carp culture is carried out through extensive farming depending on natural water resources. Among polyculture, carp poly-culture systems primarily consisting of major carps (*Labeo rohita, Catla catla, and Cirrhinus mrigala*) are more prevalent due to their high growth rate and ability to adapt in captive conditions (FAO, 2016; Wasim, 2007). Aquaculture success is mainly dependent on the maximum growth and production of fish. Vertebrate growth is regulated by several genes and various morphological characters (Dunham, 2011). The growth expression is correlated with a screening of candidate genes involved in the growth and selection of fish species. Higher fish growth is essential for boosting the aquaculture industry (Khan *et al.*, 2023; Canestro *et al.*, 2013). The role of the *GH* is extensively studied in many fishes like Mandarin fish (*Siniperca chuatsi*; Yi *et al.*, 2015), Nile tilapia (*Tilapia nilotica*; Tanamati *et al.*, 2015), Tench (*Tinca tinca*; Kocour *et al.*, 2011), Ganges Jewfish *(Nibea coibor*; Zhang *et al.*, 2009), and Mandarin fish (*Siniperca chuatsi*; Tian *et al.*, 2014). In recent years, marker-assisted growth selection has been employed in the aquaculture and livestock sector for better performance (Ling *et al.*, 2023; Biswas *et al.*, 2003; Pal *et al.*, 2004; De Faria *et al.*, 2006).

Fish growth is a key feature for many fish biologists regarding fish production and the selective breeding program of many economically significant fish species (Gjedrem *et al.*, 2012; Hulata, 2001). Growth is a quantitative trait controlled by many genes (Mullis, 2005) and environmental factors (Mackay, 2001; Moriyama *et al.*, 2000). The *GH*, growth hormone receptor (*GHR*), insulin-like growth factors *(IGF)*, and myostatin (*MSTN)* genes are observed in tamed animals and aquaculture species. Among them, *GH* is the main regulator of postnatal development. Moreover, it is also associated with strengthening anabolic functions such as protein interaction, cell growth, and muscle development (Reinecke *et al.*, 2005). In addition to hormone-flagging procedures, it participates in other pathways that make its physiology challenging to understand (Vairamani *et al.*, 2017). The primary genes that control fish growth have been studied using various experimental methods. Research on such fish ranges from those whose growth has been retarded through starvation during gametogenesis to those whose growth has been accelerated through refeeding after starvation, GH-transgenesis, or domestication. These studies also discovered a complicated association among factors that control growth and other biological processes. Moreover, it is also

Table 1. Feeding and water quality monitoring data during tissue sampling.

Seed Rearing Stage					Production Stage
Total Age: 19 Months	Jun–Aug	Aug–Nov	Dec–Jan	February	March–October

*DO, dissolved oxygen; *TDS, total dissolved solid

revealed that many somatotropic genes such as *GH*, *GHR*, and insulin-like growth factors *IGFs* are more expressed in fast-growing fishes, i.e., rainbow trout (*Oncorynchus mykiss*) (Devlin *et al.,* 2013) and regulate muscle growth (Sheridan & Hagemeister, 2010).

GH is secreted by somatotropic cells and comprises a single-chain polypeptide of about 22kDa. It plays a vital role in metabolic processes, i.e., reproductive and immune systems and seawater adaptability. Moreover, it is also involved in problems related to appetite and food conversion (Rajesh & Majumdar, 2007; Canosa *et al.,* 2007). Previously DNA and cDNA sequences of the *GH* have been well studied in various economically important fish species like *Cyprinus carpio* (Chiou *et al.,* 1990), *Protopterus annectens* (May *et al.,* 1999), *Cynoglossus semilaevis* (Ma *et al.,* 2012), and *Pelteobagrus fulvidraco* (Li *et al.,* 2017). The total length of the *GH* was almost 3-4kb and its structures differed in different fishes. The *GH* genome in some fishes consists of 5 exons and 4 introns; in other fish species, it was 6 exons and 5 introns (Chiou *et al.,* 1990; Li *et al.,* 2017). The current study was undertaken to determine the differential expression levels of the *GH* in fast and slow-growing fish species of Indian major carps (*Labeo rohita, Catla catla,* and *Cirrhinus mrigala*), which are commonly cultured in Pakistan.

MATERIALS AND METHODS

Sample Collection for Growth Expression Analysis

A total of 480 fish individuals (*Labeo rohita*/*n*=160, *Cirrhinus mrigala*/*n*=160*,* and *Catla catla*/*n*=160) of similar age were collected from the Umer Fish Farm, located at District Rajanpur, Pakistan. The capturing and experiments on fish species were conducted following relevant institutional, national, and international guidelines and legislation. Out of 160 muscle tissue samples (Skeletal Muscle, 5 g) from each fish species, 80 samples were captured from extremely high-weight fishes (≥1.3; ≥2 and ≥0.9 Kg) and 80 from extremely low-weight fishes (≤0.5; ≤1 and ≤0.5 kg) from *L. rohita, C. catla,* and *C. mrigala,* respectively. Fish samples were collected in a centrifuge tube (1.5 ml), containing RNA later solution. Samples were stored immediately in liquid nitrogen and then at –80°C for later analysis. During sampling, feeding and water quality data were continuously collected (Table 1).

Total RNA isolation and cDNA synthesis

Total RNA isolation from the muscle tissue sample was carried out using TRIzol reagent (Life Technologies cat no. 15596026). Samples were ground in liquid nitrogen using a pre-chilled mortar and pestle. The homogenate of muscle tissue samples was made in a 2.0 ml microcentrifuge tube with 1.5 mL of TRIzol® reagent and incubated for 5 minutes at room temperature. After shaking strongly for 30–40 seconds, 200 μl of chloroform was added per 1 ml of TRIzol® reagent and the content was mixed vigorously for 15 seconds and incubated at room temperature for 10 minutes followed by centrifugation for 5 minutes at 13000 rpm (at 4°C). As a result of centrifugation, three distinctive layers were formed consisting of the upper colorless, middle whitish layer and bottom dark layer. The upper clear phase containing nucleic acid was transferred to another nuclease-free 2.0 ml Eppendorf tube and 750 μl of pre-chilled isopropanol was added to precipitate the RNA and incubated for 10 minutes at room temperature followed by centrifugation. To clean the RNA pellet, 750 μl of 75% ethanol was used and centrifuged again at 13000 rpm (at 4°C) for 15 minutes (2×) by discarding the upper content. The RNA pellet was air-dried by incubating at room temperature for 10 minutes. The air-dried RNA samples were resuspended in 30 μl DEPC water and immediately stored at -70°C. The quality and quantity of the isolated RNA were determined by using Spectrophotometer ND 1000 NanoDrop®. and the Size of RNA was determined by 1.5 % gel electrophoresis (Fig. 1).

Synthesis of complementary DNA (cDNA)

The cDNA was synthesized using the Revert Aid First-Strand cDNA synthesis kit (Thermo Fisher Sci-

Figure 1. Confirmation of RNA by gel electrophoresis (1.5%)

Figure 2. Thermal conditions for cDNA synthesis

entific, cat no. 1622). 1 μg of total RNA template isolated from each fish sample was used to synthesize cDNA. The reaction mixture for cDNA synthesis contained 10 pm of random hexamer primers, 1.2 μl of RNA (1 μg) and nuclease-free DEPC treated water was used to make a final volume of 11 μl. PCR tube containing the cDNA mixture was centrifuged for 5–10 seconds. The reaction mixture was incubated at 70°C for 5 minutes and tubes were immediately placed on ice. After that 4.0 μl of 5x reaction buffer, 1.0 μl (20 units) of ribonuclease inhibitor, and 2.0 μl of dNTPs mixture (40 mM) were supplemented. The reaction mixture was incubated for 5 minutes at 37°C and 2.0 μl (40 units) of reverse transcriptase (MMuLV) was supplemented. The final reaction mixture of 20 μl was finally incubated at 37°C for 60 minutes. The cDNA reaction mixture was additionally incubated at 70°C for 10 minutes to break the reaction. The obtained cDNA product was immediately placed on ice. The thermal profile of the reaction is shown below.

Table 2. RT-PCR primers selection

Gene	Primers	Sequence of primers	Product size
GH	*GH*–F	ATAACGACTCCCTGCCACTG	125 bp
	GH–R	CCTTGTGCATGTCCTTCTTG	
β-actin	β-actin-F	ACCCACACTGTGCCCATCTACG	146 bp

Figure 4. RT-PCR Amplification thermal conditions to amplify targeted genes

Primer Designing and Optimization

Primer Express 3.0 software was used to design primers for the *GH* and housekeeping genes (*β-actin)*. The *β-actin* was selected as an internal control for precise validation of qPCR (Table 2). Both primers (*GH* and *β-actin)* were optimized using certain qPCR conditions. The results of the optimized protocol were assessed by the gel documentation system (Fig. 3).

Amplification of targeted genes by reverse transcriptase Polymerase Chain Reaction (RT-PCR)

Real-time PCR was used to quantify differential *GH* expression of fishes with the highest and lowest weight under uniform pond conditions. The RT-PCR process was accomplished using PikoReal™ Q-PCR to quantify selected samples. Amplification of the targeted genes was carried out using gene-specific primers (Table 2) and DreamTaq Green PCR Master mix 2x (Thermo Fisher Scientific, cat no. K1081). The PCR reaction contained 10 μ-L of DreamTaq Green PCR master mix, 0.8 μ-L template cDNA and 0.4 μ-L of both forward and reverse primers (10 μ-mol) added to PCR tube (0.2 mL) and nuclease-free water to a final volume of 20 μ L. The PCR thermal conditions were; preliminary incubation for 4 minutes at 94°C, 30 cycles of amplifications with denaturation at 94°C for 45 seconds, primer binding at 56–58°C for 30 seconds and amplification at 72°C for 40 seconds and then ending extension for 5 minutes at 72°C (Fig. 4). The $2^{-\Delta\Delta CT}$ mode was selected to assess *GH* expression (Livak & Schmittgen, 2001).

Data analysis

Data were coded and entered using the statistical package SPSS (IBM SPSS Statistics V.22). The data were checked for satisfying parametric test assumptions, and continuous variables were tested for normality using Shapiro-Wilk and Kolmogorov-Smirnov tests. Data were presented as mean and standard deviation. A student *t*-test was conducted for experimental groups, while a Tukey pairwise comparison was conducted in MiniTab V14 for post-hoc analysis. The *P*-value was considered significant at<0.05. Data was visualized when possible, using R studio V 2022.02.4.

RESULTS

In this study, we observed significant differences in body weights between high-weight and low-weight groups of similar ages in all three fish species (Fig. 5).

Figure 6. Comparative analysis of differential growth hormone gene expression (GH) among three fish species having a High-Weight and Low-Weight group.
Data undergoes the Mann-Whitney U test, after being evaluated for normality. NS=non-significant; *<0.05; **<0.01: ***<0.001

Differential GH Analysis

Labeo rohita

Average values of *GH* expression and body weight of selected fish samples were utilized to determine the relationship between *GH* expression and body weight. Larger body weight fishes (1.88±0.50 kg) have significantly higher *GH* expression relative to lower body weight fishes (0.83±0.38 kg) (Fig. 6).

Catla catla

Similar to *Labeo rohita*, individuals having high body weight (80±0.30 Kg) had significantly higher *GH* expression than lower body weight individuals (Fig. 6).

Cirrhinus mrigala

Like the other two fish species, *Cirrhinus mrigala* expressed *GH* significantly higher in higher body weight fishes (1.65±0.36 Kg) as compared to lower body weight fishes (0.65±0.25; Fig. 6).

We found a very surprising correlation between *GH* expression and the body weight of selected fish species (Fig. 7). The analysis revealed a statistically significant positive correlation between body weight and gene expression for both groups of low and high body weight fish. The strength of association was greater in the high-weight groups compared to the low-weight groups for all three species. For *L. rohita*, the correlation coefficient was 0.965 and 0.729 for the high and low-weight groups,

Figure 7. Correlation coefficient between observed fish weight in low and high weight groups and the gene expression values of GH hormone
NS=non-significant; *<0.05; **<0.01: ***<0.001

respectively. Similarly, for *C. catla* the correlation coefficients were 0.744 and 0.696, and for *C. mrigala* they were 0.871 and 0.677 for the high and low-weight groups, respectively. In summary, the degree of correlation between body size and gene expression intensified as body weight increased for all species.

The analysis revealed a statistically significant positive correlation between body weight and gene expression for both groups of fish with low and high body weight. The strength of association was greater in the high-weight groups compared to the low-weight groups for all three species. For *L. rohita*, the correlation coefficient was 0.965 and 0.729 for the high and low weight groups, respectively. Similarly, for *C. catla* the correlation coefficients were 0.744 and 0.696, and for *C. mrigala* they were 0.871 and 0.677 for the high and low weight groups, respectively. In summary, the degree of correlation between body size and gene expression intensified as body weight increased for all species.

DISCUSSION

Growth in vertebrates is mainly controlled by GH, a vital gene influencing growth physiology (Quik *et al.*, 2010; Clayton *et al.*, 2010). Indian major carp species (*Labeo rohita, Catla catla, Cirrhinus mrigala*) are widely cultured in Asia. *GH* might directly or indirectly affect the growth mechanism of these economically important fish species. We therefore investigated the connection of *GH* expression with the growth characteristics of carp species. In recent years, *GH* association with growth traits

has been studied well in domestic animals (An *et al.,* 2011; Sugita *et al.,* 2014) and poultry (Xu *et al.,* 2007; Wu *et al.,* 2012). The GH is the chief controller of IGF-I production in fry, fingerling, and adult fishes. Studies reported that injecting GH boosts the expression of IGF-I in salmon, (Duguay *et al.,* 1994), rainbow trout (Shamblott *et al.,* 1995), and gilthead sea bream (Duguay *et al.,* 1996), zebrafish (Maures *et al.,* 2002). The *IGF-I* mRNA levels in plasma or serum and its expression in tissues also confirmed its dependency on GH as observed in goldfish (Marchant & Moroz, 1993), salmonids (Moriyama *et al.,* 1995) and tilapia (Kajimura *et al.,* 2001).

We reported that *GH* expression varies in high and low-body-weight fish species of Indian major carp. The variable expression of growth-related genes has also been observed in fish and other animals in previous scientific studies (Carnevali *et al.,* 2006; Filby & Tyler, 2007; Opazo *et al.,* 2017). In fish, somatic growth is accelerated at the juvenile stage while it slows down during the adult stage as fish utilizes its energy for gonadal development and sexual maturation (Le Gac *et al.,* 1993; Chen *et al.,* 2018). In the present study, fish with the same age class and different body weights exhibit high *GH* expression as fish weight increases. Differences in recorded body weight of fish within the same age group could rely on stress factors, that can minimise fish growth and production. This stress may be caused due to internal factors (stocking density, fish species' competition for space and food) or external factors (low water quality) (Karakatsouli *et al.,* 2008). If the stress factor is negated, then the role of the gene can be observed and explained well in experimental fishes, which enlightens the present study findings. Considering this scenario, present cultured fishes undergo uniform culturing conditions by following good feeding practices and healthy water quality management so that possible genetic effects on fish growth can be assessed effectively. The differential expression level of *GH* in three fish species defined that fish growth rates are different concerning *GH* content in muscle tissue. Similar observations were recorded in red spotted grouper (*Epinephelus akaara*) regarding expression analysis of growth genes like *GH, GHR,* and *IGF1* from fish tissue (Mun *et al.,* 2019).

A direct relationship was noticed between body weight and *GH* expression in *L. rohita,* which depicts that expression of the *GH* increases or decreases with the gradual increase or decrease in body weight of fish samples. *GH*-mRNA expression was found higher in a high-weight group while lower in low-weight populations, similar to those mentioned for crucian carp *C. auratus* (Zhong *et al.,* 2012); European sea bass (*Dicentrarchus labrax*), which had a significantly higher *GH*-mRNA expression in fast-growing as compared to slow-growing fish samples (Carnevali *et al.,* 2006). However, such differential *GH*-mRNA expression level was not obvious in zebrafish, *Daniorerio* (Opazo *et al.,* 2017). Similar to *L. rohita,* we found the same findings for *C. catla.* Results of *GH* expression concerning the body weight of *C. catla* fish samples were very interesting as we found the same high per unit expression of *GH* with respect to a gradual increase in weight in higher body weight fishes. Such kind of growth pattern may reflect some ongoing interconnected morphological as well as physiological changes inside the body of *C. catla.* In contrast, a low level of *GH* expression was reported in high-body weight fish of Nile Tilapia (*Oreochromis niloticus*), which may be compensated by expression in some other tissues of the fish body (Aboukila *et al.,* 2021). The low level of *GH* expression may depict its low synthesis from the pituitary due to the influence of endocrine and environmental aspects correlated with the body physiology, suggesting that *GH* expression in fish is a very complicated phenomenon (Tymchuk *et al.,* 2009).

A direct correlation was also identified between body weight and *GH* expression in collected *C. mrigala.* Such results indicated a higher chance of reciprocal effect of *GH* expression in low-body-weight fish than in the high-body-weight group. A previous study on *GH* expression analysis of red-spotted grouper revealed that *GH*-mRNA expression was slightly higher in higher body weight samples than in moderate and slow-growing samples (Mun *et al.,* 2019). Likewise, in *C. mrigala GH* expression results, a marine water fish named gilthead sea bream (*Sparus aurata*) possessed similar influential growth patterns of *GH* on high and low-weight fish tissues (Perez-Sanchez *et al.,* 1994). Comparing *GH* expression among high and low body weight Indian major carp species revealed that *GH* expression varies from species to species in these fishes, however, it follows a similar trend with increasing or decreasing body weight. Certain other vital growth genes and various ambient environmental factors important for fish's body development and growth may cause current variation in expression results. The intricate phenomenon of the endocrine system in fishes reveals that the growth pattern with respect to hormonal state is very complex. This pattern gradually fluctuates among fresh and marine water fish species. More research in this area is necessary to properly understand growth governing endocrinology in fish.

CONCLUSION

Our research focused on *Labeo rohita, Catla catla,* and *Cirrhinus mrigala,* which are major Indian carp species commonly cultured in Pakistan. The uneven growth of these species is a significant challenge in aquaculture, impacting economic outcomes. The growth hormone (GH) gene is pivotal in selecting fish with superior growth and production potential in aquaculture. By validating GH expression using the housekeeping gene β-actin, we discovered that GH expression varies not only among species but also within the same species based on weight, with better-weight fish exhibiting higher GH expression levels. The significance of our findings lies in their potential application within the aquaculture sector in Pakistan. Selecting and breeding better-weight fish, which demonstrate higher GH expression can lead to improved production outcomes and increased profitability for farmers. Furthermore, this study represents the first molecular-level analysis of growth genes in fish species from Pakistan, making it a baseline study for future research in this region.

Availability of data and materials. All data generated or analyzed during the study are included in the manuscript.

Aloe barbadensis is a stemless plant with a length of 60–100 cm with juicy leaves which is used for its remedial and healing properties in different suburbs of various countries. The present study was conducted to investigate the effect of *A. barbadensis* leaf extract (aqueous and ethanolic) in yeast induced pyrexia and acetic acid induced writhing in rat model to evaluate the antipyretic biomarkers and its phytochemical screening with computational analysis. For analgesic activity model 60 Albino rats (160–200 kg) were divided into four groups. Of the 4 groups, control consisted of 6 rats (Group I) treated with normal saline, standard comprised of 6 rats treated with drug diclofenac (Group I). Experimental groups consisted of 48 rats, treated with *A. barbadensis* ethanolic and aqueous leaf extracts at doses of 50 mg/kg, 100 mg/kg, 200 mg/kg, and 400 mg/kg (Group III. IV). For antipyretic activity group division was same as in analgesic activity. All groups were treated the same as in the analgesic activity except for the second group which was treated with paracetamol. In both antipyretic and analgesic activity at the dose of 400 mg/kg, group III showed significant inhibition. TNF–α and IL-6 showed significant antipyretic activity at a dose of 400 mg/kg. For molecular docking aloe emodin and cholestanol were used as ligand molecules to target proteins Tnf-α and IL-6. Acute oral toxicity study was performed. There was no mortality even at the dose of 2000 mg/kg. Quantitative and qualitative phytochemical screening was performed for the detection of various phytochemicals. Hence, *A. barbadensis* leaf extracts can be used in the form of medicine for the treatment of pain and fever.

Keywords: induced pyrexia, pain, antipyretic biomarkers, *in-silico, in vivo, Aloe barbadensi*

INTRODUCTION

An unpleasant signal that something hurts, which is basically a complex experience that differs greatly from person to person, is called pain. We can also define pain as a somatic sense of severe discomfort, a sign of a disorder and physical injury or even emotional sorrow. The body's defense mechanisms depend largely on pain which also serves as a rapid warning system that instructs the motor neurons in the central nervous system to prevent physical harm. There are two categories of pain: acute and chronic pain (Kumar *et al.*, 2015). NSAIDs reduce pain by blocking the formation of prostaglandins, which is accomplished by decreasing the activity of the enzyme Cyclooxygenase 1 and 2 (COX-1 and COX-2) (PG) (Hayat *et al.*, 2023; Naveed *et al.*, 2023; Waseem *et al.*, 2023; Aqib *et al.*, 2023; Naveed *et al.*, 2022a; Naveed *et al.*, 2022b; Ayesha *et al.*, 2022; Li*et al.*, 2009). Fever is a common component of inflammation in animals, and it amplifies the host's reaction. The hypothalamus generally regulates fever, but certain bacterial or viral illnesses can promote the formation of pyrogens, substances that effectively alter the hypothalamic "thermostat setting" to raise body temperature and cause fever. Endogenous or exogenous pyrogens are both possible (Walter *et al.*, 2016). Infection, tissue injury, inflammation or other disease conditions can cause pyrexia or fever. Among the most common symptoms of these conditions is an increase in the production of cytokines, such as Interleukin-1, Interleukin-6, interferon, and tumor necrosis factor among others. PGE2 synthesis is boosted by the cytokines because they stimulate the arachidonic acid pathway. To elevate body temperature PGE2 activates the hypothalamus, which causes it to increase heat production while minimizing heat loss (Ahmad B *et al.*, 2023; Mathew *et al.*, 2021).

Thousands of people around the world, mostly in developing nations, depend on herbal medication for their health. Traditional and complementary medicine practitioners have extensive experience in the inhibition, diagnosis, and management of a wide range of disorders including infectious diseases, allergies, and hypertension (Hamid *et al.*, 2023; Ammara *et al.*, 2023; Ejaz Ahmad

et al., 2023; Ahmad *et al.,* 2023; Rauf *et al.,* 2023; Nayakudya *et al.,* 2020; Sajjad *et al.,* 2014). *Aloe barbadensis* is one of the most popular plant these days and it is attracting a lot of scientific attention. The use of this plant may be traced all the way back to the Babylonian era. It grows in warm areas and is unable to survive in freezing temperatures. According to WHO estimates, traditional medicines are being used by up to 80% of the population. *A. barbadensis* is a stemless plant with a length of 60–100 cm with juicy leaves (Sana *et al.,* 2023; Aziz *et al.,* 2023a; Hena *et al.,* 2023; Wajid *et al.,* 2023; Nureen *et al.,* 2023; Gul *et al.,* 2023). On several plants, *A. barbadensis* bears thick green leaves with white dots on the lower and upper surface of the stem. In Ayurveda, ghritkumari is defined as an *A. barbadensis* being a blood cleanser, anti-inflammatory, uterine tonic, laxative, diuretic, spermatogenic and fever reliever (Saleem *et al.,* 2023; Aziz *et al.,* 2023b; Narjis *et al.,* 2023; Zawar *et al.,* 2023a; Farooq *et al.,* 2022).

Many phytochemicals, vitamins, minerals, and antioxidants are found in the plant. A class of substances known as phytochemicals (derived from the Greek word "phyto," which literally means "plant") are physiologically active molecules found in minute amounts in plants that are not recognized as nutrients, but which appear to protect against degenerative diseases (Zawar *et al.,* 2023b; Tayyaba *et al.,* 2023; Zawar *et al.,* 2023c; Dalia *et al.,* 2017). Molecular docking is a computer simulation technique for predicting the form of a receptor-ligand complex, in which the receptor is a protein, or a nucleic acid molecule (DNA or RNA) and the ligand is a small molecule or another protein; the receptor and ligand are both proteins. Also known as simulation-based prediction, it is a technique for forecasting the location of a ligand in an expected or pre-defined binding site (Ahmad *et al.,* 2023; Bermen *et al.,* 2000).

MATERIALS AND METHODS

Collection of samples and their extracts

A. barbadensis leaves were collected, aqueous and ethanolic extract was prepared by cold maceration method (Singh *et al.,* 2010).

Albino rats

Albino rats (160–200 g) of both sexes were purchased from the animal home for the experiment. Rats were kept in polypropylene cages at the University of Lahore animal house. Rats were fasted before being used in the experiments. After that they were given distilled water and balanced feed.

Groups and treatment schedule

In group I, rats were treated with distilled water 10ml/kg. In analgesic and antipyretic activity in group II rats were treated with diclofenac and paracetamol 100 mg/kg. In group III and IV rats were treated with different quantities of *A. barbadensis* ethanolic and aqueous leaf extracts.

Steps

Fever induced by yeast.

All the groups were injected with yeast below the nape of neck to induce fever after 21 hours, and the

highest temperature was 101.58 Fahrenheit. Control rats were injected with normal saline, group II, the rats were treated with a dose of paracetamol, while group III and IV rats were treated with the different concentrations of ethanolic and aqueous leaf extracts of *A. barbadensis*. The body temperature (rectum) of rats was measured with digital thermometer after the equal time intervals until fourth hour.

Analgesic activity model

All groups were treated the same as in the analgesic activity except the second group which was treated with diclofenac.

Procedure

Writhing induced by acetic acid

By the injection of acetic acid, the writhing process began in rats. It was injected to determine the potential of leaf extract of *A. barbadensis* in pain process. But 1 hour before the experiment, rats in group I were injected with normal saline (10 ml/kg) intraperitoneally. In group II, the rats were treated with a dose of diclofenac 100 mg/kg. While in groups III and IV the rats were treated with different concentrations of ethanolic and aqueous leaf extracts of *A. barbadensis* at a dose of 50, 100, 200, and 400 mg/kg. For counting the writhes, a stopwatch was used. The rats were placed into different cages during activity.

Acute oral toxicity study

Acute oral toxicity study was carried out using a protocol as described by Srinivasan *et al* (2018).

Qualitative phytochemical analysis of *Aloe barbadensis*

Qualitative and quantitative phytochemical analysis of *A. barbadensis* was done by standard protocol (Usman *et al.,* 2020).

In silico antipyretic and analgesic activity of *A. barbadensis*

For *in-silico* investigation, various software of bioinformatics was used to support *A. barbadensis* antipyretic and analgesic activity. Chemskech, chimaera, pymol, pyrx, depth residue, and discovery studio were the computational tools used.

Data analysis

Data were analyzed using PROC GLM in SAS software (version 9.1).

RESULTS

Ethanolic and aqueous extracts of *A. barbadensis*

In this study, the potential of *A. barbadensis* leaf extracts at different doses were observed against rat models. The difference between the groups of rats treated with extracts and the control group was at a significant level. All groups showed a remarkable increase in temperature after being injected with yeast. Group I showed a marked increase in temperature after 1–4 hrs of injection. Meanwhile, experimental groups treated with *A. barbadensis* leaf extracts reduced the temperature from 1 to 4 hours as compared to group I. The improvement was more pronounced at fourth hour in a dose depend-

Table 1. Inhibition (%) of pain by ethanolic and aqueous extracts of *A. barbadensis* and diclofenac on acetic acid induced pain in rats

Treatment	Ethanolic	Aqueous
Control	18.83±0.40	18.83±0.40
Standard	7.36±0.91 (61%)	7.36±0.91 (61%)
Treated at dose 50mg/kg	17.00±0.41 (9%)	17.75±0.95 (-5%)
Treated at dose 100mg/kg	15.25±0.48 (19%)	16.5±0.29 (12%)
Treated at dose 200mg/kg	12.25±0.75 (34%)	13±0.91 (30%)
Treated at dose 400mg/kg	6.50±1.04 (65%)	9.75±0.63 (48%)
p-value	<0.0001	<0.0001

ent manner. Within the experimental groups, *A. barbadensis* leaf ethanolic extract (group III) showed the most pronounced effect as compared to *A. barbadensis* leaf aqueous extracts (group IV). Interleukin-6 and TNF-alpha concentrations in the plasma were increased as a result of yeast injection. In both ethanolic and aqueous extracts TNF-alpha and IL-6 marker values differ considerably between treatment groups. Effect of *A. barbadensis* leaf extracts on IL-6 and TNF-alpha in group III and IV indicated a significant decrease in pyrexia in comparison to control (Fig. 1 and Table 1).

Analgesic activities

In analgesic activity, all groups showed a significant increase in pain which was induced with acetic acid.

Group I showed the most evident increase in pain after injection. While group III and IV treated with *A. barbadensis* leaf extracts reduced the temperature as compared to group I.

The acute toxicity results showed that the ethanolic extracts had a high safety profile as neither death nor signs related with toxicity were observed at the highest dose level (2000 mg/kg orally) in the rats. Rats did not show any change in their gross behavior or associated stereotypical symptoms as shown in Table 2.

1	Tannins	+	+
2	Saponins	+	+
3	Anthraquinones	+	−
4	Glycosides	+	+
5	Alkaloids	−	+
6	Flavonoids	+	+
7	Phenolics	+	+
8	Steroids	−	−
9	Terpenoids	−	−

Figure 3. IL-6 and ligand molecules aloe emodin, cholestanol and paracetamol.

Figure 4. IL-6 and ligand molecules aloe emodin, cholestanol and diclofenac

showed the presence of tannins, saponins, phenolics and flavonoids. Proteins were present in ethanolic extract but absent in aqueous extract while glycosides and alkaloids were present in aqueous extract but absent in ethanolic extract. Terpenoids and steroids were absent in both extracts (Table 3).

Quantitative phytochemical screening showed that ethanolic extract showed a high quantity of phytochemicals as compared to aqueous extract. These bioactive chemicals are important in medicine because they have anti-inflammatory, anti-diabetic, analgesic, anti-oxidant, and antipyretic properties (Fig. 2).

In-silico studies

The objective of the in-silico analysis is to study the potential of phytochemicals to target the cytokine TNF-Alpha and Il-6 protein, hence, showing its antipyretic and analgesic activity. The molecular binding score of the phytochemicals of *A. barbadensis* and the stand-ard drug paracetamol against target TNF-Alpha protein and IL-6 was -4.2 and -5.9 kcal/mol and -6 while the cholestanol showed the highest score amongst the three (Fig. 3 and Fig. 4).

DISCUSSION

This study was conducted to evaluate the medicinal prospective of *Aloe barbadensis* ethanolic and aqueous leaf extracts against pain and fever. The presence of distinct chemical ingredients was recognized during phytochemical screening of aqueous and ethanolic ex-

tracts of *A. barbadensis*. Previous studies reported that several endogenous pyrogens, including prostaglandin, interleukin-1, interleukin-6, interleukin-8, tumour necrosis factor-alpha, and macrophage protein-1 to induce fever. Tumor necrosis factor and phospholipase A2 may activate prostaglandin production. Brewer's yeast causes pathogenicity by inducing TNF-α and prostaglandin production (Ridtitid *et al.*, 2008).

In the present study, fever was significantly ($p<0.05$) reduced in group III and IV in a dose dependent manner. The higher the dose (400 mg/kg) the greater was inhibition of fever. Brewer's yeast intravenously causes pyrexia by increasing the synthesis of prostaglandins. It is a beneficial test for determining the antipyretic activity of plant materials as well as synthetic medications (Khan *et al.*, 2009). Antipyretic efficacy could be mediated by inhibiting prostaglandin synthesis, similar to how paracetamol works by inhibiting cyclo-oxygenase enzyme activity. Pyrexia is caused by a variety of mediators and inhibiting these mediators has an antipyretic effect. Results of another study were concurrent with our findings (Safari *et al.*, 2016; Okokon *et al.*, 2010; Demoze A *et al.*, 2020; S Alyas *et al.*, 2023; Ghosh *et al.*, 2015; Velázquez-González *et al.*, 2014). Previous studies revealed that antipyretic activity of these extracts could potentially be due to the presence of alkaloids. Prostaglandins, which are involved in pyrexia, are known to be targeted by flavonoids. As a result, the presence of flavonoids in *A. barbadensis* aqueous leaf extract may contribute to its antipyretic activity (Hussain *et al.*, 2022; Safari *et al.*, 2016).

The medicinal ability of ethanolic and aqueous leaf extract of *A.barbadensis* was evaluated against pain. A system of sensory neurons and neural afferent pathways that selectively respond to potentially unpleasant, tissue-damaging stimuli support the sense of pain. The myelinated A delta and unmyelinated C fibres, which are found in skin nerves and in deep somatic and visceral regions, are most responsive to painful stimuli. The primary afferent nociceptors are these pain receptors (Okokon *et al.*, 2010). In this study, fever was remarkably decreased in group III and IV in a dose dependent manner. Endogenous substances, such as bradykinins, serotonin, progesterone, histamine, and substance P are released when acetic acid is exposed to a painful stimulus. The abdominal constriction reaction is thought to be mediated by local peritoneal receptors. Therapy has been linked to levels of PGE2 and PGF2 in peritoneal fluids as well as lipoxygenase products. Previous studies confirmed that the chemo sensitive nociceptors of rats were activated by intraperitoneal dose of acetic acid, resulting in abdominal writhing (Apu *et al.*, 2012; Ara *et al.*, 2010; Zulfikar *et al.*, 2010). The findings of this study are congruent with another study (Ghosh *et al.*, 2015).

The phytocompounds found in the ethanolic and aqueous extracts of *A. barbadensis* may be responsible for the analgesic effects shown in this investigation. The ethanolic extracts may have functioned in a similar way to NSAIDs by inhibiting the COX pathway metabolically. The cyclooxygenase and lipoxygenase pathways, which are important for peripheral nociception, have been revealed to be inhibited by flavonoids (Velázquez-González *et al.*, 2014). Previous studies reported that flavonoids reduce prostaglandin production by reducing prostaglandin synthase's action. Prostaglandin production, which is implicated in pain perception via an opioidergic mechanism, has been shown to be targeted by flavonoids (Lenard *et al.*, 2023; Panda *et al.*, 2009). Flavonoids lower intracellular calcium levels through inhibiting *N*-methyl-D-aspartate (NMDA) receptor activation.

The nitric oxide synthase enzyme and phospholipase A2 activity are lowered, leading to a reduction in NO and prostaglandin formation (Ara *et al.*, 2010; Valdes *et al.*, 2023). Previous studies reported that analgesic properties have been attributed to tannins, alkaloids, and steroidal substances. Terpenoids have also been linked to antinociceptive properties via inhibiting thrombocyte aggregation and interfering with pain signaling processes (Ali *et al.*, 2012). Acute toxicity was also performed to evaluate possible adversative effect of repetitive extract's administration to rats at different doses. Our study was correlated with a previous study (Paul *et al.*, 2018; Devaraj *et al.*, 2011).

CONCLUSIONS

Qualitative phytochemical study showed that the crude extract of *A. barbadensis* showed the presence of alkaloid, saponins, flavonoid, terpenoids, tannins, anthraquinones, phenols and steroids. The presence of phytochemicals, such as polyphenols and flavonoids in plants, reduces the risk of chronic diseases and increases the ability of biological systems to trap highly reactive free radical species. Its antipyretic and analgesic action is attributed to the presence of these polyphenols. The results of phytochemical screens were identical to those discovered by other researchers, including alkaloids, saponins, tannins, flavonoids, and steroids.

Declarations

Ethical Approval. The ethical approval for this study was provided Molecular Biology and Biotechnology Bioethical, Biosafety and Biosecurity Committee, The University of Lahore under Ref no: CRiMM/22/ Research /146 dated 02/12/2022.

Competing interests. The authors declare no conflict of interest.

Availability of data and materials. All the data has been included in the manuscript.

Regular paper

Overexpressed *RAD51* promoted osteogenic differentiation by activating IGF1R/PI3K/AKT pathway in osteoblasts

Minli Qiu, Ya Xie, Liudan Tu, Minjing Zhao, Mingcan Yang, Linkai Fang and Jieruo Gu✉

Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, 600 Tianhe Road, Tianhe District, Guangzhou, 510630, China

Background: Osteoporosis (OP) is a skeleton disease induced by imbalance between osteoblast and osteoclast. Osteogenic differentiation of osteoblasts is of great importance, and the regulatory mechanisms are urgent to be studied. Methods: Differentially expressed genes were screened from microarray profile related to OP patients. The dexamethasone (Dex) was used to induce osteogenic differentiation of MC3T3-E1 cells. MC3T3-E1 cells were exposed to microgravity environment to mimic OP model cells. Alizarin Red staining and alkaline phosphatase (ALP) staining were used to evaluate the role of *RAD51* in osteogenic differentiation of OP model cells. Furthermore, qRT-PCR and western blot were applied to determine expression levels of genes and proteins. Results: *RAD51* expression was suppressed in OP patients and model cells. Alizarin Red staining and ALP staining intensity, the expression of osteogenesis-related proteins including runt-related transcription factor 2 (Runx2), osteocalcin (OCN), and collagen type I alpha1 (COL1A1) were increased by over-expressed *RAD51*. Furthermore, *RAD51* related genes were enriched in IGF1 pathway, and up-regulated *RAD51* activated IGF1 pathway. The effects of oe-RAD51 on osteogenic differentiation and IGF1 pathway were attenuated by IGF1R inhibitor BMS754807. Conclusions: Overexpressed *RAD51* promoted osteogenic differentiation by activating IGF1R/PI3K/AKT signaling pathway in OP. *RAD51* could be a potential therapeutic marker for OP.

INTRODUCTION

Osteoporosis (OP) has become one of the epidemic diseases affecting people's quality of life due to its diverse etiology and complex molecular mechanism. OP is characterized by decreased bone mass, destroyed microstructure of bone tissue, increased bone brittleness, as well as high rate of fracture(Lupsa & Insogna, 2015).

Currently, bone mineral density (BMD) is the accepted gold standard for the diagnosis of OP, but due to its low sensitivity, many patients with potential fracture risk will be missed (Lupsa & Insogna, 2015; Black & Rosen, 2016). At present, systemic drug therapy is the main treatment for OP. However, the emerging side effects neutralized the clinical outcome. For instance, bisphosphonates may lead to mandibular osteonecrosis; hormones are associated with an increased risk of cardiovascular disease; the composition of traditional Chinese medicine is complex and its efficacy is not exact. Therefore, it is of great significance to find safer and more effective treatments (Miller, 2016; Liu *et al.*, 2018).

The basic process of bone formation is divided into bone formation and bone resorption, which are reflected as the dynamic balance between osteoblasts and osteoclasts at the cellular level (Chen *et al.*, 2018; Li *et al.*, 2019). The processes of osteogenic and osteoclastic differentiation are influenced by a variety of cytokines, cellular signaling pathways, and intercellular communication (Muruganandan *et al.*, 2020; Yang *et al.*, 2020). In recent years, the researches have attached great attention to on its complex molecular biological mechanism

Gene therapy, as a rising therapeutic method in recent years, can be targeted for gene defects and diseased tissues of diseases, direct to the lesions, with little side effects (Shan *et al.*, 2019; Fei *et al.*, 2020; Gu *et al.*, 2020; Bonnet *et al.*, 2019). The human *RAD51* gene located at 15q15.1 has been found to be aberrant expressed in OP through microarray analyses. The RAD51 protein interacts with the ssDNA-binding protein replication protein A (RPA) and RAD52, and is involved in DNA homologous pairing and chain transfer (Bonilla *et al.*, 2020; Wassing & Esashi, 2021). Studies have shown that *RAD51* is abnormally expressed in breast cancer (Cruz *et al.*, 2018), cervical cancer (Sun *et al.*, 2020), pancreatic cancer (Zhang *et al.*, 2019), prostate cancer (Maranto *et al.*, 2018), esophageal cancer (Wang *et al.*, 2019), and is associated with poor prognosis (Zhang *et al.*, 2019; Zhang *et al.*, 2019; Xue, *et al.*, 2019). What's more, bone marrow mesenchymal stem cell (BMMSC)-derived exosomes restore radiation-induced bone loss by alleviating DNA and oxidative stress damage (Zuo *et al.*, 2019). Hence, we suspected that *RAD51* may be a novel target for OP.

Thereby, this study aimed to elucidate the regulatory mechanisms of *RAD51* in osteogenic differentiation. These findings may help to uncover newfound diagnostic biomarkers for OP.

MATERIALS AND METHODS

Bioinformatics

A microarray profile GSE100609 associated with genes of Indian post menopausal female and non-OP post menopausal female was downloaded from the Gene Expression Omnibus (GEO) database (http://www.

ncbi.nlm.nih.gov/geo). R language was used to analyse the dataset, then limma package was applied to identify all differentially expressed genes (DGEs) of OP group (n=4) and non-osteoporotic group (n=4). Finally DGEs in this study were screened under the standard of $P<0.05$ and $|\log_2 FC| \geq 1.5$, and the heatmap was drawn by heatmap package. Pearson correlation and KEGG analysis were also carried out to analyse DGEs.

Subjects

Total number of 80 volunteers (healthy controls, n=40; OP patients, n=40) in this study were from The Third Affiliated Hospital of Sun Yat-Sen University. All the volunteers have signed the informed consent. This study was approved by Ethics Committee of The Third Affiliated Hospital of Sun Yat-Sen University. Fasting blood was collected for the follow-up experimental studies.

Isolation of human monocytes

Peripheral blood samples were collected from patients with osteoporotic fractures in the case group and healthy controls, and monocytes were obtained by density gradient centrifugation using sodium citrate anticoagulation tube (Histopaque-1077; Sigma, New Jersey, USA). Then monocytes were incubated at 37°C under 5% CO_2 in a humidified atmosphere with DMEM (pH 7.2).

Cell culture

Osteoblastic MC3T3-E1 cells were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). MC3T3-E1 cells were incubated in α-MEM medium (Gibco, Grand Island, USA) containing 10% fetal bovine serum (FBS, Gibco, Grand Island, USA) in 5% CO_2 at 37°C.

OP model cell establishment

2D Rotating Wall Vessel Bioreactor (RWVB) clinostat was used to simulate microgravity. 1×10^5 of MC3T3-E1 cells were seededon cell climbing pieces. 1×10^5 MC3T3-E1 cells were seeded on coverslips. After culture for 24 h, the climbing pieces were placed in a box 12.5 mm away from therotational axis. After the air bubbles were removed, the chambers were fixed in the clinostat and rotated around a horizontal axis at 28 rpm for 15 min. The vertical rotation groups were used as controls. The rotation process was taken at 37°C under 5% CO_2.

Induction of osteogenic differentiation

Osteoblastic MC3T3-E1 cells were seeded into 6-well plates at a density of 5×10^4 cells per well, and cultured with 100 nM dexamethasone (Dex; Sigma, Merck, USA), 10 nM beta-glycerophosphate (Sigma, Merck, USA) along with 50 mg/mL ascorbic acid (Sigma, Merck, USA). The mixed medium were replenished every 3 days. Cells treated with Dex was deemed as negative control (NC), and microgravity stimulated cells treated with Dex were named as OP group.

Cell transfection

To detect the role of *RAD51* in osteogenic differentiation, over-expressed RAD51 (oe-RAD51) vector (GenePharma, Shanghai, China) was transfected into OP model cells using Lipofectamine3000 (Invitrogen, Carlsbad, USA) according to instruction manuals. The transfection efficiency was verified by qRT-PCR.

qRT-PCR

Total RNA was isolated from blood sample, monocytes, and MC3T3-E1 cells by Trizol method (Takara, Kyoto, Japan) and measured at the absorbance of 260 nm (NanoDrop 2000; Thermo Fisher, MA, USA). Then, quantified RNA were conversed into complementary DNA by the reverse transcription kit (TaKaRa, Kyoto, Japan) according to manufacturer's protocols. RT-PCR was then performed using Power SYBR® Green PCR Master Mix (Takara) on the ABI StepOnePlus System (Applied Biosystems, Warrington, UK). GAPDH was used as a housekeeping gene. The relative mRNA expressions were calculated using the $2^{-\Delta\Delta Ct}$ method. Primer sequences were listed in Table 1.

Table 1. Primer sequences

Primer	Sequence	
RAD51	forward	5'-TGGGTTTCACCACTGCAACT-3'
	reverse	5'-AAACATCGCTGCTCCATCCA-3'
Runx2	forward	5'-TAAGATGGGGAGGGCGTGAGA-3'
	reverse	5'-GTCGAGAGGATGAAGGAGCG-3'
OCN	forward	5'-CACTCCTCGCCCTATTGGC-3'
	reverse	5'-CCCTCCTGCTTGGACACAAAG-3'
COL1A1	forward	5'-TGGATACTGGGAGGGTGAGG-3'
	reverse	5'-CCCTTACCTGAGATGGGGGA-3'
GAPDH	forward	5'-CGAGCCACATCGCTCAGACA-3'
	reverse	5'-GTGGTGAAGACGCCAGTGGA-3'

Alizarin red staining and alkaline phosphatase (ALP) staining

OP model cells were seeded into 12-well plates, and fixed with 4% paraformaldehyde (Sigma, New Jersey, USA) for 15 min, then washed with PBS for three times. For alizarin red staining, cells were washed with distilled water, and incubated with 0.5% solution of alizarin red solutions for 30 min at room temperature. Afterwards, the relative values of alizarin red staining were measured at 560 nm using a microplate reader (ELX808; BioTek). The readings of all samples were normalized to the alizarin red staining intensity. For ALP staining, an ALP Staining Kit (Beyotime, Nantong, China) was used after the cells were washed with distilled water for three times. The stained cells were photographed by a microscope (Zeiss, Oberkochen, Germany), and calculated at the absorbance of 562 nm using microplate reader (BioTek, Winooski, USA).

Western blot assay

OP model cells were lysed in a RIPA lysis buffer (Beyotime, Nantong, China) for 30 min at 4°C. The supernate was harvested by centrifuging at $12\,000 \times g$ for 5 min at 4°C. The proteins were separated by 10% SDS-PAGE and transferred to polyvinylidene fluoride membranes (Millipore, MA, USA). Then the membranes were blocked with 5% skimmed milk for 1 h, and then incubated with primary antibodies, such as anti-Runx2 (1/1000, ab236639), anti-OCN (1/1000, ab133612), anti-COL1A1 (1/1000, ab34710), anti-IGF1R (1/1000, ab182408), and anti-p-IGF1R (1/1000, ab39398), anti-PI3K (1/1000, ab32089), anti-p-PI3K (1/1000, ab182651), anti-AKT (1/10000, ab179463),

anti-p-AKT (1/1000, ab38449), and GADPH (1/1000, ab8245) at 4°C overnight, and then with secondary antibody (1/5000, ab6721) for 1 h at room temperature. The Infrared Imaging System (LI-COR, Lincoln, USA) was used to scan and analyze the images. All antibodies were purchased from Abcam company (Cambridge, England).

Statistical analysis

Statistical analysis was performed with GraphPad Prism 8.3 (GraphPad, San Diego, USA). All data were expressed as mean ± S.D. Statistical comparisons were performed by using the student's t-test between two groups and one-way ANOVA followed by Tukey's test for multiple groups. P values less than 0.05 were considered as statistically significant.

RESULTS

RAD51 expression was decreased in OP

Firstly, we identified prominently expressed DEGs through the bioinformatic analysis, and the results showed that total number of 107 genes were abnormally down-regulated genes and 42 up-regulated, compared with healthy controls, among which *RAD51* expression was most significantly suppressed (Fig. 1A). To further verify the roles of *RAD51* in OP, we determined the expression of RAD51 in blood samples of OP patients. As shown in Fig. 1B, the mRNA expression of *RAD51* was significantly decreased in blood samples of OP patients compared with healthy controls (Fig. 1B). Furthermore, *RAD51* expression levels were also downregulated in isolated monocytes of patients with OP (Fig. 1C).

Osteogenic differentiation of OP model cells was weakened

Then, Dex was used to induce osteogenic differentiation of MC3T3-E1 cells, and osteogenic differentiation ability of OP model cells were measured. After microgravity stimulation, both alizarin red and ALP intensity of MC3T3-E1 cells were dramatically decreased, indicating that mineralization levels of OP model cells were declined (Fig. 2A–B). Meanwhile, both protein and mRNA expression levels of osteogenesis-related proteins including Runx2, OCN, and COL1A1 were markedly suppressed in OP model cells (Fig. 2C–E). Furthermore, *RAD51* was also suppressed in OP model cells (Fig. 2F). Hence, osteogenic differentiation of OP model cells was significantly weakened.

Up-regulated RAD51 promoted osteogenic differentiation of OP model cells

Next, whether RAD51 could modulate osteogenic differentiation of MC3T3-E1 cells was investigated. After *RAD51* was prominently up-regulated in MC3T3-E1 cells transfected with overexpressed RAD51 vectors (Fig. 3A), alizarin red staining and ALP staining intensity of OP model cells were dramatically increased (Fig. 3B), so did the mRNA and protein expression levels of Runx2, OCN, and COL1A1 (Fig. 3C–D).

Figure 1. RAD51 was suppressed in OP.

(**C–D**) Expression levels of Runx2, OCN, and COL1A1 measured by qRT-PCR and western blot of OP model cells. **$P<0.01$, compared with oe-nc and NC group. ##$P<0.01$, compared with OP+ oe-nc group. oe: overexpressed.

Over-expressed *RAD51* promoted osteogenic differentiation of OP model cells by activating IGF1R/PI3K/AKT signaling pathway

Subsequently, molecular mechanism of RAD51 regulating osteoporosis was then studied. Pearson correlation analysis between *RAD51* expression levels and other genes expression levels suggested that most aberrant expressed genes identified were positively related to *RAD51* (Fig. 4A). Subsequently, KEGG analysis demonstrated that genes related to *RAD51* were enriched in ten pathways, including IGF1 pathway, EGF receptor signaling pathway, C-MYB transcription factor network and so on. (Fig. 4B). Interestingly, downstream proteins in IGF1 pathway including phosphorylated IGF1R, PI3K, and AKT were up-regulated induced by oe-RAD51, suggesting the activation of IGF1R/PI3K/AKT signaling pathway (Fig. 5A). Meanwhile, alizarin red and ALP stained cells as well as expression of Runx2, OCN, and COL1A1 were markedly increased after *RAD51* was overexpressed in OP model cells (Fig. 5B–D). Furthermore, BMS754807, an IGF1R inhibitor, attenuated the effects of oe-RAD51 on mineral intensity and ALP activity number and the expression of Runx2, OCN, and COL1A1 (Fig. 5B–D).

DISCUSSION

OP has become one of the epidemic diseases affecting people's quality of life due to its diverse etiology and complex molecular mechanisms (Black & Rosen, 2016). In our study, *RAD51* was down-regulated in OP patients as well as OP model cells. Over-expressed *RAD51* promoted osteoblast differentiation by activating IGF1R/PI3K/AKT signaling pathway.

Recently evidence suggested that various aberrant expressed genes are involved in osteogenesis. For instance, osteogenic differentiation can be inhibited by blocking the correlation between RANKL and its only known receptor RANK (Bonnet *et al.*, 2019). Likewise, SOST secreted sclerostin to promote bone formation, thus alleviating the progression of OP (Shan *et al.*, 2019; Weivoda *et al.*, 2017). Our data suggested that *RAD51* was down-regulated in both OP patients and OP model cells.

Over the past decade, specific biochemical markers associated with metabolic bone disease have been identified and described to determine whether there is an imbalance in bone metabolism by measuring biochemical markers of bone turnover (Greenblatt *et al.*, 2017; Szulc, 2018). Our

study showed that osteogenic differentiation was promoted as represented by higher Runx2, OCN and COL1A1 secretion. Runx2, OCN and COL1A1 were biochemical markers of OP widely studied in various studies. Runx2 is an osteoblast differentiation specific transcription factor which can regulate the transcription of many genes, and is significant for the differentiation of stromal cells into osteoblast lineage (Komori, 2018). Besides, Runx2 is reported to promote secretion of proteins including OPN, OCN, and collagen type I alpha1 (Yin *et al.*, 2019; Lu *et al.*, 2019; Komori, 2020). Furthermore, bone matrix mineralization is recognized as an indicator of osteogenic differentiation (Li *et al.*, 2018). In present study, the osteogenic differentiation, and the expression of *RAD51* of MC3T3-E1 cells was significantly suppressed by microgravity treatment. What's more, up-regulated *RAD51* promoted osteogenic differentiation of OP model cells, which was in line with previous studies (Shan *et al.*, 2019; Bonnet *et al.*, 2019; Weivoda *et al.*, 2017).

IGF-1 is known to play an anabolic role in bone (Frater *et al.*, 2018). Decreased IGF-1 levels are associated with an increased risk of bone fragility and fracture (Yan *et al.*, 2016). IGF1R is a homodimer of two protein subunits consisting of α and β chains, and is associated with bone and glucose metabolism and is a key mediator of glucose and bone metabolism disorders (Xian *et al.*, 2012). The conformation of IGF1R is altered by binding to the ligand IGF-1, which is then fully activated by ligand-independent autophosphorylation. This induces phosphorylation of various substrates, such as insulin receptor substrates and Shc proteins, and triggers specific signaling cascades, such

as the PI3K/AKT and Ras/MAPK pathways (Yoshida & Delafontaine, 2020; Vitiello *et al.*, 2019).

In recent years, many studies have explored the influence of some factors on BMMSC through PI3K/AKT signaling pathway (Shen *et al.*, 2019). For instance, macrophage MSR1 contributed to osteogenic differentiation of BMMSC through PI3K/AKT pathway (Zhao *et al.*, 2020). Fang *et al* found that calycosin stimulates the osteogenic differentiation of rat calvarial osteoblasts by activating the IGF1R/PI3K/Akt signaling pathway (Fang *et al.*, 2019). Furthermore, our data demonstrated that the activation of IGF1R/PI3K/AKT signaling pathway induced by over-expressed *RAD51* was suppressed by IGF1R inhibitor, so did the osteogenic differentiation. These results indicated that up-regulated *RAD51* promoted osteogenic differentiation via activating IGF1R/PI3K/AKT signaling pathway.

CONCLUSION

In a word, overexpressed *RAD51* promoted osteogenic differentiation of osteoblasts via activating IGF1R/PI3K/AKT signaling pathway.

Variability of plant transcriptomic responses under stress acclimation: a review from high throughput studies

Michał Rurek* and Mikołaj Smolibowski

Department of Molecular and Cellular Biology, Institute of Molecular Biology and Biotechnology, Faculty of Biology, Adam Mickiewicz University, Poznań, Poland

Plant transcriptomes are complex entities shaped spatially and temporally by a multitude of stressors. The aim of this review was to summarize the most relevant transcriptomic responses to selected abiotic (UV radiation, chemical compounds, drought, suboptimal temperature) and biotic (bacteria, fungi, viruses, viroids) stress conditions in a variety of plant species, including model species, crops, and medicinal plants. Selected basic and applicative studies employing RNA-seq from various sequencing platforms and single-cell RNA-seq were involved. The transcriptomic responsiveness of various plant species and the diversity of affected gene families were discussed. Under stress acclimation, plant transcriptomes respond particularly dynamically. Stress response involved both distinct, but also similar gene families, depending on the species, tissue, and the quality and dosage of the stressor. We also noted the over-representation of transcriptomic data for some plant organs. Studies on plant transcriptomes allow for a better understanding of response strategies to environmental conditions. Functional analyses reveal the multitude of stress-affected genes as well as acclimatory mechanisms and suggest metabolome diversity, particularly among medicinal species. Extensive characterization of transcriptomic responses to stress would result in the development of new cultivars that would cope with stress more efficiently. These actions would include modern methodological tools, including advanced genetic engineering, as well as gene editing, especially for the expression of selected stress proteins *in planta* and for metabolic modifications that allow more efficient synthesis of secondary metabolites.

KEYWORDS

acclimation, differentially expressed genes, plant transcriptome, RNA-seq, stress response

Introduction

Higher plants, known as vascular or telome plants (Thelomophyta), appeared during plant evolution back in the Palaeophytic era. They are characterized by the development of tissues that distribute water, mineral compounds, and photosynthesis products, and the dominance of the sporophyte (Kenrick and Crane, 1997; Forster et al., 2007). Due to the sessile life cycle,

higher plants respond adequately to unfavorable conditions at multiple levels, including transcriptomic one (Morris et al., 2018).

The plant transcriptome is a complete pool of various RNA molecules (mRNA, rRNA, tRNA, as well as numerous ncRNAs) belonging to the translated fraction of the genome that responds to its environment (Imadi et al., 2015). Transcriptomics belongs to key "omics" studies that link genomic and proteomic "worlds" by analyses of RNA, a biopolymer with a central role in the transfer of genetic information and regulation of gene expression. Transcriptomics shows a more universal status than other "omics" disciplines. It offers complex and deep insights into studying gene expression in whole plants or plant organs/tissues; factors that regulate the transcriptome spatially and temporally can also be characterized (Alkan et al., 2011; Lowe et al., 2017; Zhang, 2019; Athanasopoulou et al., 2021). Moreover, plant genome assembly is more complex and expensive compared to RNA sequencing (RNA-seq), and when a reference genome is absent, the transcriptome can be used to assess plant overall transcriptional activity. Transcriptomics also allows for the quantification of low-abundance transcripts or their structural variants and estimation of the correlation of gene expression with biological traits. Additionally, the transcriptome outperforms the genome, allowing the characterization of genes related to therapeutic compound biogenesis (Wang et al., 2009). However, transcriptomics seems to be inappropriate for identifying genes with large impacts on adaptive responses to the environment due to a small number of genes with large impacts on fitness. When only transcriptomics is used to identify genes underlying environmental adaptations, constitutively expressed regulatory genes that play a major role in setting tolerance limits are often over-represented (Evans, 2015). Other disadvantages are serious challenges in analysing large datasets, as they demand a lot of bioinformatic tools, and most importantly, costs of sequencing (discussed below). The transcriptomic data may also contain noise enhanced by technical variations and batch effects resulting from inter-sample differences that were not rooted in the experimental design (Sprang et al., 2022).

Tissue-specific transcriptomics offer particularly valuable information on the underlying molecular processes that govern tissue-specific functions; furthermore, specific genes and regulatory mechanisms that display unique roles in diverse tissues can be better characterized (Booth et al., 2022). Droplet single cell RNA-seq (with most prominent platforms, including 10x Genomics) and spatial RNA-seq (with microdissection, spatial imaging and spatial coding approaches) allow the possibility of getting insight into the heterogeneity of tissue transcriptomes, to identify cell types and markers, and to analyse gene and regulatory networks under developmental and environmental factors. Their strengths include, for instance, the availability of spatial information and high resolution performance (Cervantes-Pérez et al., 2022; Chen et al., 2023; Wang et al., 2024).

The recent and prompt development of high-throughput RNA-seq platforms with a subsequent decrease in sequencing costs, as well as data meta-analyses, advanced on plant transcriptome studies (Tyagi et al., 2022). Currently, third-generation sequencing, including SMRT (single-molecule real-time) and Nanopore sequencing allows to obtain longer sequence reads, which challenged transcriptomic analyses. Long read sequencing is accurate and allows detection of alternative splicing events. SMRT sequencing employs sequencing by synthesis, linking of chemical groups to reduce background noise and is based on properties of zero-mode waveguides. In SMRT protocol, there is no need for amplification. SMRT sequencing was used by Pacific Biosciences of California (PacBio) platform. Nanopore platform is based on electrical signal sequencing and offers particularly long reads (Li et al., 2018; Ma L. N. et al., 2019; Huang et al., 2021). However, Illumina RNA-seq is still the most preferred sequencing platform in quantitative analyses (Supplementary Table S1).

The study of tissue-specific changes in gene expression under stress is instrumental in the development of strategies to improve plant response under environmental conditions (Berkowitz et al., 2021; Tyagi et al., 2022). In previous years, some reviews focused on methodological advances in plant transcriptomics (Schliesky et al., 2012; Tyagi et al., 2022; Chen et al., 2023; Wang et al., 2024). Species-specific omics analyses characterized the relevance of transcription factors (TFs), hormones, translational reprogramming and epigenetic level, as well as phenotypic and physiological levels in stress response (Singh et al., 2016; Ahmad, 2022; Bhat et al., 2022; Hu et al., 2022; Kourani et al., 2022; Son and Park, 2023; Tu et al., 2023). Some studies also focused on the roles of non-coding RNA in stress response (Yu et al., 2019; Jin et al., 2024). However, an updated review discussing transcriptomic responses to various stress conditions assayed by high-throughput approaches from various plant species is currently needed.

In this paper, the diversity of transcriptomic responses to various stressors, both abiotic (including chemical treatments, UV radiation, drought, cold and heat) and biotic (fungal, bacterial, and viral/viroid infections) ones, will be presented, and the results will be discussed in tissue/developmental and temporal contexts, reflecting the transcriptomic dynamicity. We will focus on current studies employing high-throughput analyses, for instance, RNA-seq from various experimental platforms, as well as microarrays. We will also summarise the transcriptomic responses of not only the model but also useful crop and medicinal species, which can be used for the development of future stress-resistant cultivars by genetic and metabolic engineering (Figure 1).

Alterations in plant transcriptomes during abiotic stress

Stress conditions can be defined as internal and external cues that affect the efficiency of physiological, metabolic, and

FIGURE 1
Plant transcriptome as a central stress-responsive entity in the cell. The plant transcriptome is a highly dynamic structure in plant cells (*bluish ovals at the top*). It links genomic, proteomic, and metabolomic levels, responding on a multidimensional scale, across various tissues, and along time (*the center*). The response of plant nuclear and organellar transcriptomes is also shaped by a number of factors, including abiotic and biotic stressors (*green and black arrows encompassing the light brown central rectangle*), which affect the differential expression pattern of various gene sets (*bottom*). For proper organellar biogenesis under stress acclimation, inter-organellar signaling between actively transcribed nuclear, plastid, and mitochondrial genomes is indispensable (*small arrows within marked organelles on the panel in the center and to the left*). The diversity of transcriptomes from model, crop, and medicinal species (*bottom*) under selected stress conditions was discussed in this paper. More details in the text.

molecular plant processes, leading to a reduction in the efficiency of energy-to-biomass conversion. They can be divided into abiotic and biotic ones (Umar et al., 2021).

Abiotic stress results from the action of multiple physical or chemical stimuli (Gull et al., 2019; Wang et al., 2020). A comparison of the plethora of enriched functional terms representing numerous genes and transcription factors (TFs) responsive to various abiotic stressors from RNA-seq studies is shown in Figure 2 and additional quantitative details on genes affected by abiotic stress from high-throughput transcriptomic studies are also given in Supplementary Table S1, where details on stress treatments and the respective references to the literature are also shown. The experimental studies discussed in this review showed the huge variability of the gene response under those conditions, even between similar treatments. However, the stress response involves not only functional terms/ TFs common for all abiotic stressors discussed here (representing differentially expressed genes [DEGs] for photosynthetic genes or genes controlling secondary metabolite biosynthesis as well as MYB TFs), but also specific ones for each treatment; they were also presented in Venn diagrams, although depending on the stressor (Figure 2). Leaves, which are involved in the metabolism of carbon skeletons and the capture of photosynthetic energy, belong to plant organs particularly affected by unfavorable environmental conditions. However, studies on the impact of stress on leaf tissues, contrary to roots, are still underrepresented (Berkowitz et al., 2021).

UV radiation and chemical treatments

Variability of Arabidopsis leaf tissue transcriptomic responses under UV radiation, as well as under chemical treatments [e.g., antimycin A, 3-amino-1,2,4-triazole, methyl

FIGURE 2

Comparison of the most relevant gene ontology (GO:) terms of plant genes and transcription factors active under abiotic stress conditions from various RNA-seq studies. The data were presented in Venn diagrams (drawn by Venny v. 2.1 from https://bioinfogp.cnb.csic.es/tools/venny/). The top enriched GO: terms (mostly relevant molecular functions and biological procesess) as well as transcription factors for regulated genes from the discussed studies were indicated. The data specific for the given stressor were denoted in *italics* and by different font colors (for the chemical

(Continued)

viologen, and salicylic acid (SA)] was characterized by Berkowitz et al. (2021). Responses of leaf tissues to these stressors were complex; for example, UV-affected genes were expressed mainly in the vasculature and epidermis. Treatment with 3-amino-1,2,4-triazole and SA downregulated genes for photosynthetic proteins in all tissues of Arabidopsis, while methylviologen upregulated the genes for the PS subunits, and UV radiation downregulated the photosynthetic genes in epidermis and upregulated them in mesophyll. Arabidopsis genes for oxidoreductase activity, porphyrin metabolism, plastid organization, and carbohydrate metabolism regulation were also affected by UV-B. Interestingly, Arabidopsis genes for proteins for chlorophyll biogenesis, protein folding, oxidoreductase and ligase genes, and glyceraldehyde-3-phosphate dehydrogenase were differentially regulated between UV-A and UV-B treatments. Tissues studied also showed distinct mitochondrial responses to antimycin A, which affected the expression pattern of respiratory genes, general oxidoreductase activity genes, glutathione transferase, as well as genes related to Ser/Thr kinase activity and membrane transport (Berkowitz et al., 2021).

Among DEGs upregulated in *Vaccinium corymbosum,* genes involved in plant hormone signal transduction were significantly enriched after 1 h, followed by genes involved in phenylpropanoid biosynthesis after 3 h, and genes involved in the flavonoid anthocyanin pathway after 6 h of exposure to UV-B. These results suggest that phytohormone-related genes contribute to the primary response to UV-B radiation. However, the highest number of DEGs appeared among *V. corymbosum* plants exposed to UV-B treatment for 24 h. Genes involved in proanthocyanidin and flavanol biosynthesis (*PAL1, 4CL2, CHS, CHI3, VcFLS* and *VcUFGT*) were upregulated by UV, and their expression level lasted a long time after 24 h of treatment (Song et al., 2022). These DEGs resembled Arabidopsis genes affected by radiation (Berkowitz et al., 2021). Common genes for UV-B response in Arabidopsis and *Pachycladon cheesemanii* included genes for amino acid, vitamin, pigment, and secondary compound metabolism (Dong, 2024).

The impact of UV-B radiation on the transcriptome of *Glycyrrhiza uralensis*, a potent medicinal species, was investigated by Zhang et al. (2018). Participation of amino acid metabolism and enzymes in secondary metabolite pathways in the response to radiation at five different time points was suggested. Genes for various amino acid metabolic pathways were differentially enriched depending on UV-B duration, however, DEGs for enzymes of cysteine and methionine metabolism were mainly enriched in all treatments.

Polygonum cuspidatum, a medicinal plant species used in traditional Chinese medicine, exhibits numerous medicinal applications (Ke et al., 2023). The impact of UV-C radiation on the transcriptome of *Polygonum cuspidatum* leaves was studied by Liu et al. (2019); more DEGs (including more downregulated genes) were involved in shorter radiation response. Furthermore, this was accompanied by an increased concentration of resveratrol (the most important stilbene phytoalexin polyphenolic compounds) in the leaves of *P. cuspidatum.* Resveratrol used in the nutraceutical industry exhibits anticancer and anti-ageing properties. Under UV-C radiation, upregulated DEGs coded enzymes involved in proanthocyanidin and flavanol biosynthesis, however, chalcone synthase (*CHS*) gene was downregulated. Furthermore, MYB, bHLH, and ERF TFs appeared to be potential regulators of resveratrol biosynthesis genes. These results will help to find more practical applications of resveratrol synthesis (Liu et al., 2019). Upregulation of PAL, C4H, 4CL, and STS enzymes by means of genome editing may be positively associated with the resveratrol levels (Hasan and Bae, 2017).

Under high light treatment (with the enhanced UV radiation) of ginseng (*Panax ginseng*), another medicinal species, affected DEGs in the leaf transcriptome were mostly involved in various metabolic pathways and in the stress response. Stress-responsive functions were enriched among 33% of the upregulated DEGs, and the high light intensity and/or ROS response was associated with another 6% of the affected DEGs (Jung et al., 2020).

Lettuce (*Lactuca sativa*) grown under greenhouse conditions usually contains a lover level of ascorbic acid (ASC), an essential antioxidant nutrient for human health, compared to field-grown plants. To investigate the effect of radiation on ASC level in plants, lettuce plants were treated with various UV-B doses. Numerous DEGs were identified within lowly and highly radiated plants (Zhou et al., 2023). It was suggested that the expression of *MIOX* (for *myo*-inositol oxygenase, a key enzyme in the *myo*-inositol pathway), *APX,* and *MDHAR* may contribute to the indirect increase in the level of ASC induced by UV-B radiation (Lorence et al., 2004).

In general, plant transcriptomic responses to UV and chemical compound treatments were specifically enriched in genes for aminoacid biosynthesis, ascorbate and glutathione metabolism, kinase activity, membrane transport, mitochondrial electron transport proteins, organellar ribosome biogenesis and seed development (Zhang et al., 2018; Liu et al.,

2019; Berkowitz et al., 2021; Song et al., 2022; Zhou et al., 2023; Dong, 2024). Interestingly, as shown on the Venn diagram, ERF proteins belong to TFs active under chemical treatment and UV radiation (Figure 2).

Water deficiency (drought)

As drought belongs to factors that affect the largest part of crop productivity, the analysis of multiple molecular responses by omics studies would allow characterising the mechanisms of drought in crops that result in the search for stress-resistant cultivars (Verma et al., 2013; Shanker et al., 2014).

Analysis of sweet potato (*Ipomoea batatas*) transcriptome in drought allowed identification of various upregulated genes for ABA, ethylene, and JA biosynthesis, indicating the relevance of hormonal signaling in a water deficit. Genes for ABI phosphatase and Ca^{2+}-ATPase were severely altered, while genes for SA synthesis appeared not affected (Zhu et al., 2019). Also in chickpea (*Cicer arietinum*) numerous genes for AP2-EREBP, bHLH, bZIP, C3H, MYB, WRKY or MADS TFs that regulate signaling regulation, secondary metabolism, or transition to the generative phase were involved in drought acclimation (Kumar et al., 2019). The transcriptomic response of *Phoebe bournei*, a Chinese wood species, to drought also used DEGs for plant hormone signal transduction in addition to genes for redox homeostasis (*POD, SOD,* and *CAT*), phenylpropanoid, flavonoid and porphyrin biosynthesis, starch and sucrose metabolism, chlorophyll *a/b* binding proteins, and genes for numerous TFs from 25 families (Li et al., 2022).

Recent investigation of transcriptomes of two rice (*Oryza sativa*) cultivars that varied with stress resistance revealed that genes for hormone signaling (in line with Kumar et al., 2019; Zhu et al., 2019; Li et al., 2022 studies), LEA proteins, proteins related to redox homeostasis and NAC and ZIP TFs played crucial roles in developing drought tolerance (Tyagi et al., 2023). Additionally, in the transcriptome of *Medicago falcata* seedlings, DEGs for hormone signaling (ABA biosynthesis, JA biosynthesis), nucleic acid helicases, and diverse genes for RNA polymerases and DNA repair proteins were enriched. In contrast, gibberellin biogenesis genes were antagonistically expressed compared to ABA-related genes (except for the *GID1* gene). Numerous TFs were also affected (Miao et al., 2015).

In *Ceratostigma plantagineum*, a resurrection species, studied by Xu et al. (2021), affected DEGs encoded proteins also active in hormone signaling, and in photosynthesis, stress response, amino acid catabolism, sucrose and fatty acid biogenesis, RNA processing and regulation, energy metabolism (distinctive in mild drought), protein modification and transport, and membrane organisation. Those data indicate the flexibility of primary and secondary metabolism in water shortage and re-watering, using, among others, an alternative respiratory pathway, the C3-CAM switch, and the GABA shunt. During

global reanalysis of the *Glycine max* transcriptome, DEGs for proteins for hormone signaling, cell division, cell cycle, cell wall organization, stress responses, signal transduction, and regulation of gene expression, were regulated by progressing drought (De Oliveira-Busatto et al., 2022).

Mild drought-affected Arabidopsis genes code proteins that participate in ABA signaling, ROS biogenesis, response to osmotic stress, and also in cell wall remodelling and cell growth, among which multiple genes were previously not associated with drought-responsive mechanisms. Hormone signaling genes for PYRABACTIN RESISTANCE/ ABA receptors, two ACC oxidases and four ethylene response factors were downregulated and protein phosphatases 2C, HAB proteins, some ABA-responsive element-binding factors as well as some their target genes were all upregulated. Cell wall-loosening expansins, pectin lyases were also upregulated (Clauw et al., 2015). These data, which allowed insight into the transcriptomic landscape of six Arabidopsis accessions in drought, were further re-analysed by Benny et al. (2019), who underlined the importance of hydrogen peroxide, water deprivation, salinity, osmotic stress, and ABA-responsive proteins among upregulated genes. Transcriptomic analysis of rapeseed (*Brassica napus*), another representative of Brassicaceae, revealed that upregulated DEGs were related to the response to water deprivation, ABA signaling, osmotic stress, and other abiotic stimuli and lipid metabolism, as well as cutin, suberin, and wax biogenesis, fatty acid degradation, and secondary compound metabolism (Fang et al., 2022).

The multitude of various TFs was associated with the response to drought of *Dendrobium sinense*, an endemic species (Zhang et al., 2021). DEGs coded proteins for carbohydrate derivative and nucleotide binding, ATPase and oxidoreductase activity, pectin metabolism, and multiple TFs. Interestingly, more DEGs participated in a mild drought response, where detrimental downregulation prevailed (Zhang et al. (2021). Furthermore; Xia et al. (2024) broadened the analysis of *Dendrobium* drought responses by three additional species; the highest count of DEGs appeared in *D. fimbriatum*. Multiple DEGs among various *Dendrobium* species were involved in carbon metabolism and anthocyanin biosynthesis. Noticeable differences in the expression level of the *PEPC* gene (for phosphoenolpyruvate carboxylase) were associated with CAM and improved drought tolerance.

Artemisia annua, a medicinal species, is a potent worldwide source of artemisinin, an antimalarial compound. Attempts have been made to significantly increase artemisinin yield, and stress tolerance engineering would be one of such strategies. Drought response of *A. annua* leaf transcriptome employed many DEGs, including those coding for Δ-1-pyrroline-5-carboxylate synthetase, aquaporins, glyceraldehyde-3-phosphate dehydrogenase, LEA proteins, HSPs, glyoxalase I, glutathione-S-transferase, PR proteins, Ca^{2+}-dependent protein kinases, as well as

proteins involved in ethylene and oxylipin biosynthesis as well as NAC and MYB-related TFs (Vashisth et al., 2018).

Transcriptomes of two wheat (*Triticum aestivum*) varieties with contrasting drought resistance were compared; in stress resistant cultivars, the drought response involved genes for the synthesis of secondary metabolites and important transcription coregulators and TFs (Kumar et al., 2018).

Growth regulator 5-aminolevulinic acid (ALA) has been used to alleviate drought in grapevine (*Vitis vinifera*), by increasing antioxidative responses (Yang et al., 2023). Chlorophyll metabolism and photosynthetic apparatus were primarily affected by ALA, which uses synergistic mechanisms to alleviate drought. In the presence of ALA, alterations in the expression pattern of DEGs for chlorophyll biogenesis and Rubisco-related genes played an important role that allowed ALA to maintain cell homeostasis under water scarcity.

Little was known about the combined action of drought and cold on the plant transcriptome. Sharma et al. (2018) provided a comparative study of the impact of both stressors on the Arabidopsis transcriptome by meta-analysis of publicly available transcriptomic data. Responsive DEGs encoded proteins related to photosynthesis, respiratory burst, hormone response, signal transduction, and water deprivation, as well as some stress-specific genes. Furthermore, at least 43 diverse TFs were expressed in both treatments. Coolen et al. (2016) analysed Arabidopsis plants under drought combined with biotic treatments. The water deficit alone increased expression level of DEGs coding for proteins responding to oxygen-containing compounds and cell wall biogenesis. As the drought progressed, the more pronounced were the alterations in gene profiles. Each of the stressors induced specific expression profiles over time. In sequential stress application, Arabidopsis displayed transcriptome profiles similar to those of the second treatment, regardless of the nature of the first stressor. Overall, this study highlights the importance of stress signatures in identifying key molecular responses that act between various response pathways.

In general, hormone signaling pathways belong to the common terms for UV treatment (as discussed above; Figure 2; Song et al., 2022) and drought (Figure 2; Miao et al., 2015; Sharma et al., 2018; Kumar et al., 2019; Zhu et al., 2019; Fang et al., 2022; Li et al., 2022). The transcriptomic response in drought specifically affects a multitude of genes involved in alternative respiratory pathways, aminoacid catabolism and carbohydrate metabolism, developmental processes, DNA metabolism, kinase binding, membrane organisation, postranslational modifications, protein turnover, regulation of protein synthesis, RNA processing, and stress response. It is also specifically regulated by a particularly broad variety of TFs and transcriptional coactivators of various families (Figure 2; Kumar et al., 2018; Kumar et al., 2019; Benny et al., 2019; Zhu et al., 2019; Xu et al., 2021; De Oliveira-Busatto et al., 2022; Yang et al., 2023; Xia et al., 2024).

Elevated temperature (heat stress)

Elevated temperature affects cereal productivity, particularly male generative organ development and pollen maturation and viability (Young et al., 2004; Asseng et al., 2011; Wu et al., 2015). Heat stress leads to an increase in the level of reactive oxygen species (ROS) and a simultaneous decrease in ROS scavenger activity, leading to biomolecul damage and apoptosis (Bita and Gerats, 2013; Guan et al., 2013). *Chrysanthemum* leaf transcriptomes were analyzed in heat with or without melatonin (to alleviate the consequences of heat treatment; Xing et al., 2021). Heat alone resulted in massive downregulation of DEGs. In contrast, heat combined with melatonin increased expression level of several DEGs. Melatonin affected *HSF* and *HSP*, starch and sucrose metabolism, cell signaling, chlorophyll, flavonoid, carotenoid biosynthesis genes, and genes for various TFs.

Comparison of microspore transcriptomes under heat in two tomato (*Solanum lycopersicum*) cultivars with contrasting stress tolerance revealed among upregulated DEGs at least 11 *HSP* genes. Increased expression of the *HSP* and *APX* genes pinpoints the key role of antioxidant enzymes in the heat response (Frank et al., 2009). Valdés-López et al. (2016) studied dynamics of root hair transcriptome in soybean (*G. max*) subjected to heat at various time points. Responsive genes were classified into 10 functional modules regulated by a few TFs. In general, heat affected the expression pattern of DEGs for protein folding genes, but also for genes coding proteins for chromatin remodeling, and lipid and ATP synthesis, indicating for the importance of controlling water/nutrient intake by roots and the relevance of maintaining high ATP level under heat response.

Rice leaf transcriptome under thermal shift was studied by Rashid et al. (2020). Multiple genes were affected for the abiotic stress response and metabolite biosynthesis. Among the DEGs affected, only a few photosynthetic/ OXPHOS genes as well as some genes for glycolytic enzymes were present. Chen and Li (2017) investigated *Brachypodium distachyon* leaf transcriptome in heat. Affected DEGs coded proteins that participate in alternative RNA splicing, spliceosome, and PS biogenesis, indicating an increased extent of such events in response to high temperature in order to synthesize protein isoforms alleviating heat detrimental effects.

To describe thermotolerance and protective mechanisms against thermal stress in desert species, the *Rhizya stricta* transcriptome, the evergreen shrub, was analysed at elevated temperature. Upregulated genes coded HSPs, chaperones, UDP-glycosyltransferase, aquaporins and transparent protein *testa 12*, suggesting the distinctness of thermotolerance in leaves of *Rhizya stricta*, which is controlled primarily by improving protein folding and preventing protein degradation (Obaid et al., 2016). *HSP* genes and genes for flavonoid biosynthesis were upregulated in leaves of three tea cultivars (*Camellia sinensis*), important medicinal species, under heat (Huang et al., 2024).

Studied cultivars differed in stress tolerance and exhibited mainly upregulated DEGs under heat acclimation, however, among the affected DEGs in all cultivars, the genes for photosynthetic activity were the most notable. In heat-tolerant cultivars at elevated temperatures, genes for proteins containing the chaperone domain, including universal stress proteins (USPs), small heat shock protein sHSP18.1, chaperonin-like protein 2 (CLP2), and the LEA5 protein were preferentially expressed. Additionally, the level of flavonols increased in heat-tolerant varieties, accompanied by increased expression of *FLS* genes. Therefore, in accordance with Obaid et al. (2016), Xing et al. (2021) and Frank et al. (2009) reports, the study by Huang et al. (2024) highlights the importance of chaperones and secondary metabolism in the heat response.

Heat stress often acts simultaneously with water deficit. Mikołajczak et al. (2023) focused on investigating the impact of heat stress, drought, and their joining effects on transcriptome of barley (*Hordeum vulgare*) flag leaves. In medium-sized leaves, short heat stress (similarly to drought) affected multiple genes, regardless of the duration of the stress. However, under longer heat and drought, more DEGs were affected in large leaves. Investigated stressors affected mainly the *LEA* and *HSP* genes. Overall, Mikołajczak et al. (2023) provided novel data on the molecular mechanisms of barley flag leaf that determine the response to drought and heat. Furthermore, according to Mahalingam et al. (2022), the number of DEGs increased in barley heads in the stress-tolerant genotype as heat progressed. Heat response involved genes for transporter proteins, and ABA response, and resulted in differential expression of *LEA* genes in stress-sensitive genotype. In contrast, genes for nonspecific lipid transfer proteins and carbonate dehydratase were enriched in a stress-tolerant cultivar. Heat with drought resulted in a notable increase in DEG number only in the stress-sensitive cultivar. In particular, at least 900 TFs controlled transcriptional reprogramming in two barley cultivars in all treatments.

Cellular signalling, including hormone signaling, is particularly important in multiple treatments, when heat is combined with other stressors. Martin et al. (2021) pointed out the broadening range of DEGs affected by double treatment (heat and drought) of *Lolium temulentum*, which encoded proteins for cell signaling, cell cycle, organellar biogenesis, binding, transport, oxidoreductase and antioxidative activit, as well as chaperones and multiple TFs. When heat stress acted together with an elevated level of CO_2, detrimental effects were only partially alleviated by deregulation of primary and secondary metabolism genes in flag leaves of durum wheat (*Triticum durum*) flag leaves. Most affected DEGs coded proteins involved also in cellular signaling but also in stress response and nucleic acid metabolism. In particular, genes upregulated by CO_2 were often downregulated by heat (they coded, among others, photosynthetic and OXPHOS proteins, proteins for hormone signaling, enzymes of lipid and amino acid metabolism and the glutathione-ascorbate cycle, nucleic acid

metabolism, and transport proteins (Vicente et al., 2019). Suzuki et al. (2016) investigated the impact of heat and salinity on Arabidopsis transcriptome. DEGs regulated by heat and salt stress were enriched in genes coded proteins for ABA signaling, stress response, developmental processes, protein metabolism, and DNA-dependent transcription. However, in heat, DEGs for ABA-responsive proteins, glyoxylase 17 and catalase, among others, appeared to be responsive, indicating the importance of the antioxidative response.

Arabidopsis leaf transcriptome under various stress conditions (salinity, osmotic stress, and heat) was also investigated by Sewelam et al. (2020). Of all these treatments, elevated temperature appeared to have the most notable effect on transcriptomic profiles. DEGs affected by heat covered induction of eleven *HSP* genes, late embryogenesis abundant (LEA) proteins, receptor-like kinases (RLKs), glutathione S-transferases, genes for carbohydrate binding, UDP-galactosyltransferases, membrane transporters, and programmed cell death (PCD), and genes for WRKY TFs. However, heat treatment repressed several cell cycle genes, ribosomal protein genes, and genes involved in DNA synthesis and repair. In particular, osmotic stress and heat acted antagonistically, while double treatment largely reprogrammed the gene expression pattern. Heat in combination with salinity and osmotic stress also induced numerous mitochondrial genes, presumably as a compensatory response to excessive protein degradation (Rurek et al., 2018).

In general, multiple stress treatment (including heat) in plant transcriptomes results in different and distinct transcriptomic responses under single treatments. In particular, although drought often accompanies heat, those stressors result in the upregulation of different gene sets in various plant species (Mahalingam et al., 2022; Mikołajczak et al., 2023). The transcriptomic response to heat stress specifically engages DEGs for cellular signaling (particularly in multiple stress treatments and under melatonin supplementation; Suzuki et al., 2016; Vicente et al., 2019; Martin et al., 2021; Xing et al., 2021), and also genes for chromatin remodelling, DNA synthesis, endopeptidase activity, heat response, regulation of protein phosphorylation and dephosphorylation, RNA metabolism, spliceosome biogenesis, transcription regulation, volatile compound biosynthesis as well as AP2/EREBP, C2H2, G2-like, GRAS, HSF, MADS-box and RWP-RK TFs (Figure 2; Frank et al., 2009; Obaid et al., 2016; Suzuki et al., 2016; Valdés-López et al., 2016; Chen and Li, 2017; Rurek et al., 2018; Vicente et al., 2019; Rashid et al., 2020; Sewelam et al., 2020; Martin et al., 2021; Xing et al., 2021; Mahalingam et al., 2022; Mikołajczak et al., 2023; Huang et al., 2024).

Low temperature (cold, freeze)

Similarly to heat, also cold treatment and freeze result in plant growth and development aberrations, as well as direct

inhibition of metabolic reactions. Due to the limited osmosis, cell dehydration and oxidative stress occur simultaneously with other detrimental responses. Most plants can gain tolerance to ice formation by gradually being exposed to reduced (non-freezing) temperatures under cold acclimation (Chinnusamy et al., 2007). In general, genes for the early cold response encoded a wide variety of TFs that regulate other gene expression (Gull et al., 2019).

Signal transduction and hormone signaling appeared also to be important for the low-temperature response. Amur vine (*Vitis amurensis*) transcriptomic response under cold used DEGs that encode proteins for signal transduction, transcription regulation, and alternative splicing. At least 38 major families of TFs (with 326 genes for TFs) involved in the regulation of cold response were detected, including several previously uncharacterized TF families homologous to Arabidopsis proteins (e.g., HAP2, ABI3VP1, ARF, PLATZ, LIM, atypical HD and MYB factors, BBR-BPC, zinc Dof, C3H-type I, EIL, GARP G2-like and Trihelix). Genes for CBL-interacting protein kinases participating in signal transduction were upregulated (Xu et al., 2014). Du et al. (2017) analysed the cold response of *Agropyron mongolicum* ABA receptors and upregulated genes for bZIP and NAC TFs. Most DEGs participated in carbohydrate metabolism, hormonal and phosphatidylinositol signaling, as well as biogenesis of numerous secondary metabolites. Also, the cold response of *M. falcata* focused on phytohormone and nodulation signaling, revealing some similarities with the drought replies; however, *ABF1*, *GID1,* and *AUX* genes were downregulated. Interestingly, *GH3* auxin-responsive gene was extensively upregulated in cold (similarly to *DIMI1*, but contrary to *DIMI2* and *DIMI3*, all of which encode important nodulation factors). Furthermore, at least 16 genes for MYB and 12 genes for NAC TFs were induced by cold, indicating their participation in cold tolerance (Miao et al., 2015). The transcriptomic response to cold in two rape cultivars (*Brassica rapa*) cultivars, varying with stress tolerance, also involved DEGs coding proteins for plant hormone signal transduction (MAPK signaling pathway) and also for photosynthesis, phenylpropanoid biosynthesis, lipid binding, plant-type cell wall, positive regulation of circadian rhythm, abaxial cell fate specification and basal TFs (Ma L. et al., 2019).

Arabidopsis chilling response covered almost half of expressed genes (Calixto et al., 2018; Liu et al., 2022). Cold response also involved genes for plant hormone signaling, but also for glucosinolate biosynthesis, transporter proteins, long ncRNA, RNA splicing, and spliceosome biogenesis, as well as multiple TFs from 52 families. Cold downregulated photosynthetic genes and short cold-induced quickly responding DEGs coding proteins for chloroplast organisation, ribosome biogenesis, and rRNA processing, which may activate cold tolerance. On the contrary, long cold affected DEGs for the cell response to hypoxia, fatty acid and flavonoid biosynthesis, as well as redox homeostasis and diverse *HSP* genes (Liu et al.,

2022). Massive alternative splicing events occurred in the first few hours of cold treatment, including mobilisation of cold-responsive TFs, splicing factors, and selected RNA-binding proteins (Calixto et al., 2018). Interestingly, in *P. cheesemanii*, contrary to Arabidopsis, the cold response employed genes for glucosinolate metabolism. For Arabidopsis and *P. cheesemanii*, genes for wound-like circadian clock, as well as for secondary metabolite biogenesis, responded under the early cold response (Dong et al., 2023).

Cheng et al. (2019) described the effects of *Me*TCP4 (a specific cassava [*Manihot esculenta*] TF) overexpression in Arabidopsis plants during cold stress. Affected genes were classified as stress-responsive under all tested conditions, to DNA binding and TF activity in control, and to oxidoreductase, peroxidase, and antioxidative activity under cold treatment. Analysis of transcriptomic response of leaves of *Lavandula angustifolia* to cold revealed DEGs coding for photosynthetic proteins among affected genes. The most important functions of DEGs were also associated with the decreased stomatal conductance, ROS scavenging, and the development of cold tolerance. In general, these findings may allow for further engineering of cold tolerance in *L. angustifolia* to improve its medicinal potential, as this species is a source of aromatic compounds in traditional Chinese medicine (Li L. et al., 2023). In the leaf transcriptome of another medicinal species, *A. annua*, cold induced a multitude of genes for kinases, peroxidases, ABA biosynthesis, LEA and LEA-like proteins, various desaturases, glyoxalase I family protein, proteins for oxylipin and polyamine biosynthesis, Δ-1-pyrroline-5-carboxylate synthetase, NAC and MYB TFs (Vashisth et al., 2018).

Important metabolic regulations occur in plant organelles under cold acclimation. Naydenov et al. (2010) investigated the mitochondrial and nuclear transcriptomes of germinated wheat (*T. aestivum*). The upregulated genes encoded mitochondrial proteins, including Mn superoxide dismutase (SOD) and alternative oxidase (AOX); however, the level of expression of nuclear genes essential for mitochondrial biogenesis was visibly reduced. This indicates a fine-tuning of gene expression between mitochondrial and nuclear transcriptomes, executed by anterograde and retrograde signaling, affected by stress conditions.

On the whole, the cold response of plant transcriptomes specifically employs DEGs involved in abaxial cell fate specification, lipid binding, nucleic acid metabolism, post-translational modifications, protein degradation, regulation of transcription, and biomolecule transport. Cold response also specifically mobilizes a variety of TFs, including BBR-BPC, C3H-type I, EIL, GARP G2-like, HAP, LIM, NIN-like, PcG, PLATZ, TUB, and WHIRLY proteins (Figure 2; Naydenov et al., 2010; Xu et al., 2014; Miao et al., 2015; Du et al., 2017; Calixto et al., 2018; Vashisth et al., 2018; Cheng et al., 2019; Gull et al., 2019; Ma L. et al., 2019; Liu et al., 2022; Dong et al., 2023; Li L.

FIGURE 3
Comparison of the most relevant gene ontology (GO:) terms of plant genes and transcription factors active under biotic stress conditions from various RNA-seq studies. The data were presented in Venn diagrams (drawn by Venny v. 2.1 from https://bioinfogp.cnb.csic.es/tools/venny/). The top enriched GO: terms (mostly relevant molecular functions and biological procesess) as well as transcription factors for regulated genes from the discussed studies were indicated. The data specific for the given stressor were denoted in *italics* and by different font colors (for bacterial

(Continued)

et al., 2023). Hormone signalling is also affected by the cold response in numerous studies, including members of *Fabaceae* and *Brassicaceae* (Miao et al., 2015; Du et al., 2017; Vashisth et al., 2018; Gull et al., 2019; Ma L. et al., 2019; Liu et al., 2022).

Plant transcriptomic responses under biotic stress

Under global climate alterations, crop species are gradually exposed to increasing biotic stress. The findings discussed below may help develop plant cultivars that are highly resistant to fungal, bacterial and virus infections. To cope with biotic stress, plants have developed defensive responses precisely induced by pathogen attack (Verma et al., 2013). Plant cells contain plasma membrane receptors, which recognize pathogen-associated molecular patterns (PAMP). Subsequently, PAMP-triggered immunity (PTI) usually stops the infection before it spreads throughout the plant. Due to the constant combat between pathogens and their victims, pathogens can neutralize PTI by secreting special effector proteins into the cytosol. In response, plants developed the ability to detect microorganisms by effector-triggered immunity (ETI). Interactions between intracellular receptors designed to recognize effector molecules produced by pathogens and effectors trigger a complex network of cell responses to achieve infection resistance (McDowell and Dangl, 2000). To protect against pathogens, plants use an "oxidative outbreak" that initiates a hypersensitive response (HR) limiting the pathogen spread (Sato et al., 2010).

A comparison of the multitude of enriched functional terms representing numerous genes and transcription factors (TFs) that respond to various biotic stressors (fungal, bacterial, and virus/viroid infections) from RNA-seq studies is shown in Figure 3 and further quantitative details on genes affected by abiotic stress from high-throughput transcriptomic studies are also given in Supplementary Table S1, where details on various biotic treatments and references from the respective literature were given. Fungal, bacterial, and virus/ viroid infections involve common DEGs for carbohydrate metabolism, defence response, photosynthesis, protein phosphorylation, ribosome biogenesis, secondary metabolite biosynthesis, and transcription regulation. Biotic stress influence also expression patter of genes for hormone signaling/ signal transduction (more details below). All conditions of biotic stress mobilize WRKY factors responding to pathogen infection (Figure 3). Interestingly, terms for photosynthesis and secondary metabolite biosynthesis overlap with those for abiotic stress response; however, most functional terms and TFs in biotic infections differ from those of abiotic stressors (Figures 2, 3).

Fungal infections

Pathogenic fungi can be divided into biotrophic, necrotrophic, and hemibiotrophic species (biotrophic in their early stages and necrotrophic in their later stages of the life cycle). Analysis of transcriptome of pumpkin leaves (*Cucurbita moschata*) infected with powdery mildew (*Blumeria graminis*) 24 and 48 h after the infection onset showed a downregulation of multiple DEGs, including genes coding for resistance to powdery mildew and various TFs for ethylene signaling. Numerous host photosynthetic genes were also regulated. Upregulation of photosynthetic genes after 48 h of infection was associated with the appearance of initial fungal hyphae, which was also shown in infected wheat (*T. aestivum*) (Guo et al., 2018).

The transcriptomes of wheat leaves infected with powdery mildew (*Erysiphales* species) and striped rust (*Puccinia striiformis*) were analysed by Zhang et al. (2014). In powdery mildew infection, DEGs coded proteins for α-linolenic acid metabolism, as well as phenylpropanoid, flavonoid, phenylalanine, tyrosine and tryptophan biosynthesis. However, striped rust upregulated DEGs for photosynthetic proteins and proteins for ubiquinone biosynthesis. These results indicate the participation of different genes in response to various fungi (Zhang et al., 2014). Coolen et al. (2016) investigated Arabidopsis transcriptome under infection of the necrotrophic fungus, *Botrytis cinerea*, alone or in combination with drought. DEGs responding to chitin, defence response, incompatible interactions, and RNA methylation were upregulated, and photosynthetic ones were deregulated up to 1 day after infection. Massive upregulation of core DEGs coding proteins that respond to oxygen-containing compounds according to the impact of drought. Kumar et al. (2022) compared two transcriptomic data sets of maize (*Zea mays*) silk infected with different fungal species. Set A contained data for silk samples affected by *F. graminearum* and *U. maydis*, while set B contained data from samples infected with *F. verticillioides* and *Trichoderma atroviride.* Interestingly, only 21 DEGs were found in all variants tested. Among these DEGs, peroxidase genes that control the lengthening of the germ tube to protect maize kernels from fungal disease were upregulated. The differential expression pattern was also found for the osmotine-like protein gene, which

improves host defense and immune defense against stress, and for genes coding the receptor-like protein kinase subfamily. These genes appeared to be upregulated under infection with *Fusarium verticillioides*, *Fusarium graminearum*, and *Ustilago maydis* and downregulated when samples infected with *T. atroviride.*

Generally, host DEGs specifically regulated during fungal infections code proteins related to α-linolenic acid metabolism, aminoacid biosynthesis, cell wall organisation, chitin response, osmotin-like protein activity, pollen-pistil interactions, receptor-like protein kinases, resistance genes, RNA methylation, sterol biosynthesis process, as well as valine, leucine, and isoleucine degradation. SA signaling is believed to be mainly involved in resistance to biotrophic and hemibiotrophic pathogens. On the contrary, JA and ethylene signaling appeared to be indispensable for necrotrophic resistance (Pieterse et al., 2009; Guo et al., 2018). In addition, ERF belong to main TFs specifically regulating gene expression of plant host under fungal infections (Figure 3; Zhang et al., 2014; Coolen et al., 2016; Guo et al., 2018; Kumar et al., 2022).

Bacterial infections

Analysis of rice (*Oryza indica*) infected with *Xanthomonas oryzae* revealed multiple upregulated genes that encode proteins involved in signal transduction, carbohydrate metabolism, and transcription regulation. On the contrary, the downregulated genes encoded TFs and proteins necessary for lipid catabolism, oxidative burst, and cell cycle (Kottapalli et al., 2007). Furthermore, analysis of the transcriptome of tomato (*Solanum lycopersicon*) infected with *Clavibacter michiganensis* allowed the identification of upregulated genes that encode proteins that also participated in hormonal signaling, but also in protein phosphorylation, and the plant defence response (including numerous TFs, such as WRKY, NAC, HSF, and CBP60). Resistance gene analogues (RGA) that included *RLK* genes were also upregulated. Exogenous treatment with SA resulted in induction of genes for WRKY TFs, therefore, SA-driven gene expression resulted in improved quality of the plant immune response (Yokotani et al., 2021).

Analysis of transcriptomes of rice (*O. sativa*) cultivars resistant and susceptible to infection with *Xanthomonas oryzaena*, which causes a cereal disease called bacterial leaf streak (BLS), revealed more DEGs among the infection-susceptible cultivar. Upregulations of genes encoding proteins involved in secondary metabolism, as well as participation of selected WRKY, NAC, MYB, and bHLH TFs in plant response to bacterial infection were notable (Lu et al., 2020). Deng et al. (2023) study on resistant ("*IBL2353*") and susceptible ("*Ohio88119*") tomato (*S. lycopersicum*) cultivars infected by *C. michiganensis* identified new gene families that participate in antibacterial defence. The key role of WRKY TFs in this

process was revealed. At least 25 genes for proteins associated with the plant defense response and *WAKL20* gene (for the wall-associated receptor kinase similar to wall 20 and the only member of the WAKS subfamily that participates in innate resistance to pathogens) were upregulated in "*IBL2353*" cultivar. Viral-induced silencing of *WAKS20* gene in the "*IBL2353*" cultivar resulted in the appearance of susceptibility to *C. michiganensis* infection, suggesting an important role for the *WAKS20* gene in antibacterial defence (Deng et al., 2023).

In general, plant host genes specifically affected by bacterial infections code proteins related to the cell cycle, lipid catabolism, oxidoreductase activity, and positive regulation of ubiquitin protein ligase activity as well as transferase activity. Hormone signaling is also important for the antibacterial response of host plants (Kottapalli et al., 2007; Yokotani et al., 2021). Additionally, the host response to bacterial infections specifically mobilizes MYB and NAC TFs (Figure 3; Kottapalli et al., 2007; Lu et al., 2020; Yokotani et al., 2021; Deng et al., 2023).

Viral and viroid infections

Plant transcriptomes also respond to the plethora of viral and viroids, which may leave their genome fragments within the host genome/transcriptome (Jo et al., 2018; Mifsud et al., 2022; Raza and Wu, 2022). The enriched functional terms for genes affected by viral and viroid infections are presented in Figure 3 and the summary of quantitative data from discussed experimental reports is available in Supplementary Table S1. Most viral proteins interact with host proteins, which promote the appearance of symptoms. Plants counteract this initial symptom development by using adaptive immunity; defence hormones are also active, resulting in hampering of virus biogenesis (Malavika et al., 2023).

Viroids are among the smallest and most infectious pathogens of crops, having short ssRNA genomes. They can affect host genes whose products participate in defense response, phytohormone signaling, cell wall modification, photosynthesis, secondary metabolism, transport, gene expression, and protein modification (Joubert et al., 2022).

Tobacco transcriptomes (*Nicotiana tabacum*) infected with seven genotypes of tobacco etch potyvirus (TEV) varying in fitness were compared. Host genes (including those for hormone signaling and RNA silencing-mediated pathways of plant defense) whose expression was correlated with the fitness level of TEV were examined (Cervera et al., 2018). The relevance of hormone signalling and signal transduction in the host response under virus attack was also pinpointed by other reports. Recently, Li Z. et al. (2023) focused on the analysis of antiviral response of bottle gourd (*Lagenaria siceraria*) under cucumber green mottle mosaic virus (CGMMV) infection. Affected DEGs were involved in the biosynthesis of secondary metabolites, hormone signal transduction (JA biogenesis), plant–pathogen interactions, and

carbohydrate metabolism. Méndez-López et al. (2023) investigated the impact of the pandemic infection of the Pepino mosaic virus (PepMV) on two tomato cultivars. The *Sl*GSTU38 protein belongs to PepMV-specific susceptibility factors. The transcriptomes of healthy and virus-infected knocked out plants (*gstu38*) were examined. When *gstu38* plants were compared with healthy wild-type plants, some key stress-related genes (including those for WRKY TFs) were upregulated and genes for intracellular signal transduction proteins, various TFs, HSP70, and proteins involved in sugar metabolism and transport were downregulated. Among DEGs affected in both tomato cultivars, genes for peroxidases, various kinases, RNA binding proteins, resistance proteins, PDH, DNA repair, recombination proteins, and chaperonins and GATA TFs were also notable. Furthermore, the rice transcriptome was assayed during *planta* overexpression of the *Os*NF-YA protein displaying antiviral defense against rice stripe virus (RSV) and Southern rice blackstreaked dwarf virus (SRBSDV). Interestingly, the expression pattern of genes for JA biogenesis was decreased in plants overexpressing NF-YA under viral infection, due to interference between the NF-YA protein and TFs that regulate JA signaling (Tan et al., 2022). On the other hand, Arabidopsis cabbage leaf curl virus (CaLCuV) infection triggered the SA-dependent pathogen response and induced the expression of genes involved in PCD, genotoxic stress, DNA repair, and cell cycle (Ascencio-Ibáñez et al., 2008).Signal transduction is also crucial when plant viruses could alter host plant traits so that they modify their insect behavior. When *Myzus persicae* aphids were foraging in Arabidopsis and *Camelina sativa* plants, cauliflower mosaic virus (CaMV) infection appeared more severe than turnip yellows virus (TuYV) and affected DEGs that encode proteins for photosynthesis, oxidation reduction proteins, microtubule-based movement, as well as enzymes for JA, ethylene, and glucosinolate biogenesis. TuYV infection in Arabidopsis plants resulted in alterations in DEGs for carbohydrate transport, defence and stress response proteins (Chesnais et al., 2022).

Zhu et al. (2018) investigated the impact of cucumber mosaic virus (CMV) infection on hot pepper (*Capsicum annuum*) transcriptome. Affected genes were involved in stress and defence response, and plant-pathogen interactions. DEGs for chitinase, pathogenesis-related protein (PR), tobacco mosaic virus resistance protein (TMV), WRKY TFs, and jasmonate ZIM-domain protein, were upregulated after inoculation. Intron retention for *WRKY23* transcripts indicated a deep reprogramming in alternative splicing pattern under viral infection.

Zhou et al. (2019) studied transcriptomes of tomato (*S. lycopersicum*) plants grown from neutron-irradiated seeds and infected with tomato yellow leaf curl virus (TYLCV). Transcriptomes of plants grown from presoaked seeds were highly altered compared to those developed from dry seeds. Various doses of neutron irradiation affected the expression pattern of various DEGs. At least regulated DEGs that were

common for all irradiated mutants encoded proteins for metabolism, transport, binding and responses to various stimuli, photosynthesis, and transcription. Spanò et al. (2020) applied the RNA sequence to study the transcriptomic profiles of tomato cultivars varying with resistance level, as well as their graft combinations, exposed to potato virus Y recombinant strain. Graft wounding and virus Y infection had various impacts on the tomato transcriptome, depending on genotype.

Roy et al. (2023) have used 3′RNA-seq to identify transcriptomic alterations in *N. benthamiana* plants infected by two strains of grapevine fanleaf virus (GFLV). During appearance of peak vein clearing symptom at 7 days post-inoculation (dpi), the genes involved in the immune response, gene regulation, and secondary metabolite production were over-represented. In other stages, DEGs related to chitinase activity, hypersensitive response, and transcriptional regulation were notable. Previously, Medzihradszky et al. (2019) investigated the transcriptomic reprogramming in the shoot apical meristem of *Nicotiana benthamiana* plants infected with Cymbidium ringspot virus (CymRSV). Upregulated genes coded proteins indispensable for cell defense, and downregulated DEGs were related to DNA replication and organization, shoot meristem development and plasmodesmata functions.

On the whole, plant host genes specifically affected under virus and viroid infections are related with carbohydrate transport, cell cycle regulation, DNA binding, DNA repair and recombination, DNA replication, glutathione binding, lipid metabolism, microtubule-based movement, oxidation-reduction proteins, OXPHOS activity, programmed cell death regulation, protein domain specific binding, protein folding and processing, regulation of hydrogen peroxide metabolism, senescence as well as signal transduction (with hormone signaling, highlighting relevance of JA signaling in host antiviral defence, e.g., Chesnais et al., 2022; Tan et al., 2022; Li Z. et al., 2023). Among TFs specifically mobilized under virus/viroid infection, GATA proteins were discernible (Figure 3; Ascencio-Ibáñez et al., 2008; Cervera et al., 2018; Zhu et al., 2018; Medzihradszky et al., 2019; Zhou et al., 2019; Spanò et al., 2020; Chesnais et al., 2022; Tan et al., 2022; Li Z. et al., 2023; Méndez-López et al., 2023; Roy et al., 2023).

Discussion

Transcriptomic datasets, together with proteomic and metabolomic analyses, belong to the valuable and prospective components of modern systems biology in the functional network study (Figure 1; Cramer et al., 2011). In plant cells, in addition to the transcriptome being a product of nuclear genome expression, plastid and mitochondrial transcriptomes are also present (Barkan and Goldschmidt-Clermont, 2000; Daniell et al., 2016; Rurek, 2016; Rurek et al., 2018; Best et al., 2020a). They are dynamically shaped by multiple factors at

FIGURE 4

The detailed number of publications per year related to RNA-seq and specified stressors (*values indicated above each bar; subterms indicated by the various color and checking pattern in the histogram*). The key words used in the NCBI PubMed search (https://pubmed.ncbi.nlm.nih.gov/) included: plant, RNA-seq, and the given subterm (*indicated in the legend below the histogram*). The data for "UV" (*in dark magenta*), "drought" (*in gray*), "heat" (*in orange*), "cold" (*in blue*) and "pathogen" (*in green*; the joint data for bacterial, fungal and viral/viroid infections) were presented from 2010 onwards. The analysis was performed in September 2024.

multiple levels of biological diversity (Zhu, 2002; Wang et al., 2020). Studies on plant transcriptomes, which participate in stress response, may thus allow for better understanding how plants properly react to changing environmental conditions (Zhu, 2002).

Plant stress studies employing RNA-seq

Extensive research on the plant transcriptome is being developed at various levels. Transcriptomic data can be acquired both from differential expression studies in tissue/organs or even from single cells, and modern RNA-seq approaches. From 2010 the number of experimental reports on RNA-seq and stress response among diverse plant species increased almost exponentially. In total, between 2010 and 2024 at least 4,710 plant studies related to RNA-seq and UV, drought, cold, heat and pathogen response were published (Figure 4; the data valid to 25 September 2024). This indicates the growing interest of these topics in plant molecular biology. Interestingly, reports on pathogen attack and drought using RNA-seq dominate in number from at least 2014 and those for temperature treatments (cold, heat) are generally in the third place in each year indicated (Figure 4).

Similarities and differences in transcriptomic response under various stressor conditions

The plant transcriptomic response depends greatly on the quality of the stressor and its duration, leading to metabolic flexibility (Supplementary Table S1; Wang et al., 2020; Xu et al., 2021; De Oliveira-Busatto et al., 2022). Commonly regulated genes under the action of almost all abiotic stressors often encode proteins for the photosynthetic apparatus and enzymes for secondary metabolism; interestingly, limited TFs (MYB mostly) overlap for all abiotic stressors (Figure 2).

In contrast, all conditions of biotic stress employ a large number of DEGs that represent a particularly broad landscape of enriched functional terms. DEGs for carbohydrate metabolism, defence response, protein modifications, ribosome biogenesis, transcription regulation, and secondary metabolism overlap both for bacterial, virus/viroid infections and for fungal infections across a plethora of host species (Figure 3). Furthermore, the WRKY proteins belong to universal TFs that regulate gene expression in biotic stress.

In general, photosynthesis and secondary metabolite biosynthesis belong to commonly enriched functional categories for all stress treatments discussed here.

From abiotic stressors, drought and heat stress employ the highest number of specific terms for these stressors (twelve and eleven terms, respectively, Figure 2). Drought stress appeared to be particularly detrimental at the transcriptomic level (Kumar et al., 2019; Zhu et al., 2019; Tyagi et al., 2023). Chemical treatments and UV as well as cold/freeze stress resulted in a lower quantity of terms specific to DEGs affected under action of those stressors. Furthermore, double stress treatments led to highly specific responses, sometimes increasing the number of DEGs (Zhou et al., 2019; Sewelam et al., 2020; Martin et al., 2021). It should be underlined that highly specific TFs from different families regulate gene expression under each abiotic stress conditions (with the highest number of TFs participating in drought and cold and freeze). Therefore, the most harmful

stressors employ particularly numerous TFs within adaptive responses (Figure 2; Mahalingam et al., 2022).

Regarding biotic stress, virus and viral infections employ DEGs for host proteins with broadening functional categories that are specific only to those stressors. Less quantities of functional GO terms were also observed from the data representing fungal and bacterial infections (comparing with virus infections) were also notable. Genes for hormone signaling appeared to be important for both bacterial and fungal infections, and DEGs for signal transduction proteins were notably over-represented in virus/viroid infections (Figure 3). Overall, such a pattern differs from the one for abiotic stress treatments, where only a limited number of common GO terms for all treatments was evident (Figure 2). Furthermore, distinct TFs specifically regulate host gene expression under various biotic stressors, with MYB/NAC proteins mainly for bacterial infections and GATA and ERF factors for virus/virus and fungal infections, respectively (Figure 3).

As shown in Supplementary Table S1, stress-sensitive cultivars engage more DEGs in their stress responses; however, these patterns are highly tissue dependent (Mahalingam et al., 2022). Plant responses to biotic stress indicated the challenging importance of plant-microorganism interactions, which can generally influence stress tolerance (Rivero et al., 2022).

Future outlines

From the data discussed within the present review, few conclusions for future actions can be presented. Hopefully, they will increase both the quantity and quality of the data. First, more organellar transcriptomes for important crop species should be analysed to better understand the responses of the plastome and mitogenome to stress and their relevance in plant developmental steps. Furthermore, due to the peculiar under-representation of transcriptomic data on stress in some plant organs, future studies should improve such biases (Best et al., 2020a; Best et al., 2020b; Berkowitz et al., 2021).

Most of the transcriptomic data discussed here came from plant material grown under controlled conditions. Therefore, field experiments that test the variations of multiple stress responses are still awaited. Additionally, both the complexity of plant viromes and impact of the plant microbiome on stress response at the transcriptional level should be widely investigated (Jo et al., 2018; Mifsud et al., 2022; Raza and Wu, 2022).

Due to the importance of DEGs for secondary metabolite synthesis in the analysed data, it would also be important (1) to

investigate further the biogenesis of active compounds, (2) to better understand how metabolic pathways contribute to various stress acclimation strategies, and (3) to develop new more stress-resistant cultivars after genetic and metabolic engineering of medicinal and crop plant species. These actions should include modern methodological tools, for example, genetic engineering and gene editing, as well as metabolome engineering (Singh et al., 2016; Yan et al., 2020; Guo et al., 2021; Kumar et al., 2023; Dong, 2024).

Author contributions

MR and MS contributed to the conception and design of the paper. MR conceived the idea for the review, supervised submission, reviewed and edited first manuscript draft. MR and MS compiled the literature and wrote first manuscript draft. MR prepared all figures and the Supplementary Material. All authors contributed to the article and approved the submitted version.

Glossary

ABA	abscisic acid		**CXIP**	CAX-interacting protein
ABI3VP1	ABSCISIC ACID INSENSITIVE 3 VIVIPAROUS 1		**CymRSV**	Cymbidium ringspot virus
ABF	ABSCISIC ACID RESPONSIVE ELEMENT-BINDING FACTOR		**DEGs**	differentially-expressed genes
ACC	1-aminocyclopropane-1-carboxylic oxidase		**DIMI**	DIMINUTO
ALA	5-aminolevulinic acid		**Dof**	DNA-binding with one finger
AOS	allene oxide synthase		**EIL**	ethylene insensitive-like
AOX	alternative oxidase		**ER**	endoplasmic reticulum
AP	APETALA		**EREBP**	ethylene-responsive element binding protein
APX	ascorbate peroxidase		**ERF**	ethylene response factor
ARF	auxin response factor		**ETI**	effector-triggered immunity
ARID	AT-rich interactive domain		**FLS**	flavonol synthase
ASC	L-ascorbic acid		**FRS**	FAR1-RELATED SEQUENCE
AUX	auxin receptor		**FT**	FLOWERING LOCUS T
BBR-BPC	Barley B Recombinant/Basic PentaCysteine		**G2-like**	GOLDEN2-LIKE
BIM	BES1-INTERACTING MYC-LIKE		**GABA**	γ-aminobutyric acid
bHLH	basic helix–loop–helix		**GARP**	GOLDEN2, ARR-B and Psr1 superfamily
BLS	bacterial leaf streak		**GFLV**	grapevine fanleaf virus
BPM	BTB/POZ and MATH domain-containing protein		**GH3**	Gretchen Hagen3
BT	BTB and TAZ domain protein		**GID**	GA-INSENSITIVE DWARF
bHLH	basic helix-loop-helix		**GRAS**	GIBBERELLIC-ACID INSENSITIVE, REPRESSOR of GAI and SCARECROW
bZIP	basic (region) leucine zipper		**GRF**	growth regulating factor
CaLCuV	cabbage leaf curl virus		**GSTU**	glutathione S-transferase belonging to the *tau* class
CAM	crassulacean acid metabolism		**HAB**	HYPERSENSITIVE TO ABSCISIC ACID
CaMV	cauliflower mosaic virus		**HAP**	CCAAT-box binding protein
CAT	catalase		**HD**	homeodomain
CBP	calmodulin-binding protein		**HLH**	helix-loop-helix
CDP	CAAT displacement protein (transcriptional repressor)		**HR**	hypersensitive response
CGMMV	cucumber green mottle mosaic virus		**HSF**	heat shock factor
C2H	zinc finger protein		**HSP**	heat shock protein
C3H	zinc finger CCCH domain-containing protein		**JA**	jasmonic acid
C4H	4-cinnamate hydroxylase		**LEA**	late-embryogenesis abundant
CHI	chalcone isomerase		**LHC**	light-harvesting complex
CHS	chalcone synthase		**LIM**	homeobox transcription factor
4CL	4-coumarate: CoA ligase		**LOX**	lipoxygenase
Clp	caseinolytic protease		**MADS**	MINICHROMOSOME MAINTENANCE 1/AGAMOUS/DEFICIENS/SERUM RESPONSE FACTOR
CLP	chaperonin-like protein		**MAPK**	mitogen-associated protein kinase
CMV	cucumber mosaic virus		**MDHAR**	monodehydroascorbate reductase
CRISPR/Cas	clustered regularly interspaced short palindromic repeats/CRISPR-associated		**MIOX**	*myo*-inositol oxygenase
CRK	cysteine-rich receptor-like kinase		**MYB**	myeloblastosis

NAC	no apical meristem/ATAF1/cup-shaped cotyledon
NF-Y	nuclear factor Y
NIN	nodule inception
OXPHOS	oxidative phosphorylation
PAL	phenylalanine ammonia-lyase
PAMP	pathogen-associated molecular pattern
PCD	programmed cell death
PcG	Polycomb group
PDH	proline dehydrogenase
PEPC	phosphoenolpyruvate carboxylase
PepMV	pepino mosaic virus
PLATZ	plant AT-rich sequence and zinc-binding protein
POD	peroxidase
PR	pathogen-related
PS	photosystem
PTI	PAMP-triggered immunity
RGA	resistance gene analogue
RLK	receptor-like kinase
ROS	reactive oxidative species
RR	response regulator
RSV	rice stripe virus
RWP-RK	transcription factor with RWPxRK motif
SA	salicylic acid
SBP	SQUAMOSA-PROMOTER BINDING PROTEIN
SOD	superoxide dismutase
SMRT	single-molecule real-time
SRBSDV	Southern rice blackstreaked dwarf virus
STS	stilbene synthase
TCP	bHLH DNA-binding domain
TEV	tobacco etch potyvirus
TF	transcription factor
TMV	tobacco mosaic virus
TUB	Tubby family of bipartite transcription factors
TuYV	turnip yellows virus
TYLCV	tomato yellow leaf curl virus
UFGT	UDP-glucose:flavonoid 3-O-glucosyltransferase
USP	universal stress protein
WAKL	wall-associated receptor kinase-like
WAKS	wall-associated kinases
WRKY	transcription factor family
WT	wild type

WUS	WUSCHEL
ZIM	zinc-finger inflorescence meristem
ZIP	leucine zipper

circROCK1 Promotes septic myocardial injury through regulating miR-96-5p/OXSR1 axis

ZhiYu He[1], Lingling Xu[1], Xiaojun Zeng[1], Biqing Yang[2], Peiying Liu[1], Dunzheng Han[1], Hao Xue[3] and Bihui Luo[1]✉

[1]Department of cardiovascular, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou City, Guangdong Province, 510120, China; [2]Stroke Center of Guangzhou Panyu Central Hospital, Guangzhou City, Guangdong Province, 511486, China; [3]Department of Cardiovascular, Meizhou People's Hospital, Meizhou City, Guangdong Province, 514011, China

Objective: A recent high-throughput sequencing showed that circular RNA Rho-associated kinase 1 (circROCK1) is abnormally highly expressed in sepsis, but whether it is involved in sepsis development remains unclear. The objective of this study was to investigate the biological function of circROCK1 in sepsis-induced myocardial injury and reveal its potential downstream molecular mechanism. **Methods:** Real-time reverse transcriptase-polymerase chain reaction was applied to detect circROCK1 and miR-96-5p expressions in the serum of septic patients. Spearman correlation analysis examined the correlation between circROCK1 and the clinicopathological characteristics of septic patients. The Cecal puncture and ligation (CLP) method was used to establish an *in vivo* sepsis model. circROCK1 and miR-96-5p expressions in mice were modified by injection of lentivirus or oligonucleotide. The left ventricular systolic pressure, left ventricular end-diastolic pressure, and the maximum increase/decrease rate of left ventricular pressure were checked. ELISA was applied to detect inflammatory factors levels as well as myocardial injury markers levels. Hematoxylin and eosin staining was performed to observe pathological changes in myocardial tissues, and Western blot examined phosphorylated nuclear factor (NF)-κB and oxidative stress-responsive 1 (OXSR1) expression. Dual luciferase reporter experiment was conducted to confirm the targeting relationship between circROCK1, OXSR1, and miR-96-5p. **Results:** circROCK1 and OXSR1 were highly expressed in sepsis and miR-96-5p was under-expressed. circROCK1 was positively correlated with serum creatinine, C-reactive protein, procalcitonin, and sequential organ failure assessment scores in septic patients. Silencing circROCK1 could improve the diastolic and systolic function of CLP mice, as well as myocardial damage, reduce myocardial tissue edema and necrosis, and inhibit inflammatory factor level and phosphorylated NF-κB expression. Down-regulating miR-96-5p promoted myocardial injury in CLP mice. Silencing circROCK1 and miR-96-5p inhibited and promoted OXSR1 expression, respectively. Both circROCK1 and OXSR1 had a targeting relationship with miR-96-5p. **Conclusion:** CircROCK1 promotes myocardial injury in septic mice by regulating the miR-96-5p/OXSR1 axis, and it can be used as a potential target for treating septic myocardial dysfunction.

INTRODUCTION

Sepsis is an acute systemic infection caused by a variety of bacteria invading the blood circulation. The main clinical manifestations are rapid onset, fever, tachypnea, shivers, hepatosplenomegaly, etc. (Stanski & Wong, 2020; Rubio *et al.*, 2019). In severe cases, septic shock and multiple-organ failure (MOF) may occur (Lelubre and Vincent 2018). Sepsis has a high morbidity and mortality rate, especially for those with weakened immune systems, and about 50% of patients with sepsis require admission to an intensive care unit (Salomão *et al.*, 2019). Among common complications of sepsis, cardiac dysfunctions, such as myocardial injury and depression (Yang *et al.*, 2023), are characterized by impaired myocardial contractility and ejection fraction, with mortality up to 70% (Li *et al.*, 2013; Settergren & Henareh, 2014; Bansal *et al.*, 2023). Sepsis triggers a systemic inflammatory response that activates the body's immune system and releases a variety of inflammatory mediators. These inflammatory mediators cause damage to cardiomyocytes and induce apoptosis (Zhou *et al.*, 2022; Zhen *et al.*, 2022). Therefore, exploring the potential molecular mechanism of sepsis-induced myocardial injury is essential for promoting the survival rate of patients with sepsis-induced myocardial injury.

Circular RNA (circRNA) is formed under special and selective shearing. Unlike linear RNA, circRNA is basically derived from the exons or introns of its parent gene (Kristensen *et al.*, 2018; Memczak *et al.*, 2013). Based on a recent genome-wide analysis of non-coding RNA, in comparison with healthy individuals, more than 80% of septic patients showed differential expression. These molecules act in innate cell immunity, mitochondrial function, and apoptosis (Nie *et al.*, 2020). As a non-coding RNA, circRNA recently has been considered to have a vital relationship with sepsis occurrence and development. CircRNA is involved in regulating multi-

ple-organ injury in septic patients, like lung (Zou *et al.,* 2020), kidney (Shi *et al.,* 2020), and liver injury (Xiong *et al.,* 2021). Circular RNA Rho-associated kinase 1 (circROCK1) is an essential member of the circRNA family and has been shown to be differentially expressed in sepsis (Bao *et al.,* 2019). However, it is not clear whether it has an impact on septic myocardial injury.

This work investigated serum circROCK1 expression level and its clinical effect on septic patients. The effect of circROCK1 on myocardial function and myocardial inflammation in sepsis was investigated *in vivo* by establishing a mouse model by cecal puncture and ligation (CLP). The results revealed that circRNA promoted myocardial injury in sepsis by sponging miR-96-5p to mediate oxidative stress-responsive 1(OXSR1) expression.

METHODS

Clinical samples

Healthy people (n=37) were randomly selected from the health examination center of The First Affiliated Hospital of Guangzhou Medical University. From September 2018 to January 2020, blood samples were obtained from patients with sepsis (n=44) and septic shock (n=19) at The First Affiliated Hospital of Guangzhou Medical University. The diagnosis of sepsis or septic shock is based on the International Guidelines for the Management of Sepsis and Septic Shock: 2016. This research was approved by The First Affiliated Hospital of Guangzhou Medical University Institutional Ethics Committee. All subjects and their families had signed the informed consent form.

Diagnostic criteria

Sepsis is diagnosed in reference to *International Guidelines for the Management of Sepsis and Septic Shock: 2016*, with a Sequential Organ Failure Assessment (SOFA) score of more than 2. Patients diagnosed with sepsis who required adequate volumetric resuscitation and sustained hypotension with pressors to maintain arterial pressure of 65 mmHg or higher and serum lactate levels greater than 2 mmol/L (18 mg/dL) were identified as having septic shock.

Exclusion criteria

Exclusion criteria: (1) Under 18 years old; (2) MOF caused by other non-infectious factors; (3) Autoimmune diseases treated with steroids or immunosuppressive therapy; (4) Complications with other diseases that affect blood coagulation; (5) Malignant tumors; (6) Complications with other diseases that may affect this study results; (7) Immunosuppressive drug treatment within the last three months.

Clinical data collection

Clinical information was recorded, including age, gender, body mass index (BMI), and SOFA score. Additionally, Quzhou People's Hospital clinical laboratory provided routine blood test results (serum creatinine [Scr], white blood cells, albumin, C-reactive protein [CRP], and procalcitonin [PCT]).

Septic animal model establishment

C57BL/6 mice (25±5 g) were kept in cages in a temperature-controlled room with a 12-hour light/dark cycle and a free diet and water. Twenty-four mice were allocated into the sham group (n=12) and the CLP group (n=12) to evaluate the survival rate within 48 hours after surgery. The survival rate of mice after CLP was measured every 2 h for 48 h.

In the following experiment, another 72 mice were used, 12 of which underwent sham surgery and the rest received CLP. These mice were allocated into 5 groups (n=12 for each): Sham group (CLP without ligation and puncture on the cecum), CLP group (CLP surgery), sh-circROCK1 group (injection with 5×10^7 sh-circROCK1 lentiviral vector particles via tail vein one week before CLP), sh-NC group (injection with 5×10^7 sh-NC lentiviral vector particles via tail vein one week before CLP), miR-96-5p antagomir group (injection with 10 μg miR-96-5p antagomir via tail vein one week before CLP), and NC antagomir group (injection with 10 μg NC antagomir via tail vein one week before CLP). sh-circROCK1/NC lentiviral vectors and miR-96-5p/NC antagomir were provided by GenePharma (China). The cardiac function of mice was monitored 12 h after CLP, myocardial tissue and serum samples were collected from 6 mice in each group, and myocardial tissues from the remaining 6 mice were stained with hematoxylin and eosin (HE). miR-96-5p antagomir sequence: 5'-TAACACT-GTCTGGTAACGATGT-3'.

CLP procedures: Midline laparotomy was performed, and a 3 cm dissection was performed to expose the cecum. At the site designated for high severity, the cecum was ligated with a 4–0 silk thread and pierced at two sites 1 cm apart with a 20-gauge needle. The cecum was then gently pressed to squeeze a small drop of feces. After laparotomy, all mice were resuscitated by subcutaneous injection of normal saline (37°C, 50 ml/kg). The sham operation was performed with the same procedure but without ligation and puncture of the cecum.

Heart function detection

All mice were anesthetized by intraperitoneal administration of pentobarbital sodium 12 hours after CLP. The right carotid artery was exposed, from where a catheter was inserted into the left ventricle. A multi-channel data acquisition and processing system (RM6240BD, Chengdu Instrumeny) was utilized to monitor left ventricular systolic pressure (LVSP) and maximum rate of increase/decrease in left ventricular pressure ($\pm$ dp/dt$_{max}$).

Enzyme-linked immunosorbent assay (ELISA)

The myocardial homogenate was centrifuged, and the supernatant was collected. Tumor necrosis factor (TNF)-α, interleukin (IL)-6, and IL-1β levels were measured using ELISA kits. Creatine kinase-MB (CK-MB, E006-1-1) and cardiac troponin I (cTnI, H149-2) content in serum were measured. All kits were purchased from Nanjing Jiancheng Bioengineering Institute.

HE staining

The myocardial tissue of mice was fixed with 4% paraformaldehyde, embedded in paraffin, and cut into 4 μm slices. The slices were deparaffinized with xylene, infiltrated with gradient alcohol, and stained with HE. At last, the tissue structure was observed microscopically.

Table 1. RT-qPCR primer sequences

Genes	Primer sequence (5'–3')
GAPDH	Forward: 5'-ATGGGGAAGGTGAAGGTCG-3'
	Reverse: 5'-TTACTCCTTGGAGGCCATGTG-3'
U6	Forward: 5'-CTCGCTTCGGCAGCACATATACT-3'

	Reverse: 5'- TCACCGCTCTTGGCCGTCACA -3'
OXSR1	Forward: 5'- AAAGACGTTTGTTGGCACCC -3'
	Reverse: 5'- GCCCCTGTGGCTAGTTCAAT -3'

Real-time reverse transcriptase-polymerase chain reaction (RT-qPCR)

Total RNA in mouse myocardial tissue and human serum samples was isolated using TRIZOL RNA extraction reagent (Invitrogen, USA). PrimerScript real-time kit (TAKARA, Japan) was applied for reverse transcription. Finally, RT-qPCR was detected by SYBR Premix Ex Taq TM II reagent and ABI PRISM 7000 (Applied Biosystems, USA). Using U6 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as internal references for miRNA and mRNA, respectively, relative gene expression was calculated by $2^{-\Delta\Delta Ct}$. The primer sequence was shown in Table 1.

Western blot

Total protein in the myocardial homogenate was extracted using a protein extraction kit (Beyotime, China), and later a bicinchoninic acid kit (Nanjing Jiancheng Bioengineering Institute) was utilized to determine the protein concentration. Next, the protein was loaded for electrophoresis, and protein gel was transferred to a polyvinylidene fluoride membrane (Millipore, USA), which was sealed with 0.1% Tween-20 in Tris-buffered saline (5% skim milk) at room temperature for 1 hour, and later combined with the primary antibody p-NF-κB p65 (ab86299, Abcam), NF-κB p65 (#8242, Cell Signaling), OXSR1 (H00009943-M09, Abnova), and GAPDH (ab181602, Abcam) overnight at 4°C. Next, the membrane was incubated with horseradish peroxidase-conjugated goat anti-rabbit immunoglobulin G (ab205718, Abcam) to evaluate protein immunoreactivity. The density of

Figure 1. circROCK1 is highly expressed in sepsis.
Note: RT-qPCR to detect circROCK1 expression in the serum of normal subjects and patients with sepsis. The data were expressed as mean ± S.D., and the Student's t-test was applied.

protein bands was analyzed by Image-Pro Plus version 6.0 (Media Cybernetics, USA).

Dual luciferase reporter experiment

The circROCK1 or OXSR1 3'untranslated region sequence containing miR-96-5p binding site was inserted into the pmirGLO vector (Promega, USA), and the wild type (WT) luciferase reporter plasmids were named circROCK1-WT and OXSR1-WT. After the binding sites were mutated, mutant type (MUT) luciferase plasmids (circROCK1-MUT and OXSR1-MUT) were constructed. HEK293 cells were transplanted into 48-well plates at 3×10^4 cells/well and transfected with 2 μL of plasmids and 100 nM miR-96-5p mimic or mimic-NC (GenePharma, China). After 48-hour transfection, the dual luciferase reporter system (Promega; E1910) was utilized to detect firefly and renilla luciferase activities.

Data analysis

Values expressed as mean ± standard deviation (S.D.) were analyzed by GraphPad Prism software 8.01 (GraphPad Software, USA). The Student's t-test was applied to compare two groups. Spearman correlation analysis examined the relationship between circROCK1 and the clinicopathological characteristics of septic patients. $*P<0.05$ was considered statistically significant.

Table 2. Clinicopathological characteristics of subjects

Parameters	Healthy subjects (n = 37)	Septic patients (n = 63)
Age (years)	57.64±6.27	53.78±4.93
Gender (male/female)	male (14)/female (23)	male (39)/female (24)*
BMI (kg/m²)	21.27±0.79	20.98±1.07

Note: Scr: serum creatinine; WBC: white blood cells; CRP: C-reactive protein; PCT: procalcitonin; SOFA: sequential organ failure assessment. Data expressed as mean ±S.D., combined with student's *t*-test and spearman correlation analysis.

RESULTS

Clinical and pathological characteristics of subjects

37 healthy subjects (14 males, 23 females, average age: 57.64±6.27 years old) and 63 septic patients (39 males, 24 females, average age: 53.78±4.93 years old) were recruited. The clinicopathological characteristics of the two groups were detailed in Table 2. There were no significant differences in age or BMI between healthy subjects and sepsis patients. There were significant differences in gender, Scr, albumin, white blood cells, CRP, and PCT.

circROCK1 is highly expressed in sepsis and is related to sepsis clinicopathology

circROCK1 in sepsis was examined. circROCK1 expression in the serum of septic patients was higher than that in healthy subjects (Fig. 1). The clinicopathological

Figure 3. Silencing miR-96-5p promotes myocardial injury in septic mice.
Note: (**A**) RT-qPCR to detect serum miR-96-5p expression in healthy subjects and septic patients; (**B**) RT-qPCR to detect miR-96-5p expression; (**C**) Mice cardiac function indexes LVSP, LVEDP, +dp/dt$_{max}$, and -dp/dt$_{max}$ as well as serum cTnI and CK-MB levels; (**D**) HE staining of mice myocardial tissue; (**E**) ELISA to detect TNF-α, IL-1β, and IL-6 levels in mice myocardial tissue; (**F**) Western blot to detect phosphorylated NF-κB expression in mice myocardial tissues; the data were expressed as mean ± S.D. (n=6) and compared by Student's *t*-test. In comparison with the NC antagomir group, $^{\&}P<0.05$.

relationship between circROCK1 and sepsis was subsequently examined. circROCK1 was positively correlated with Scr, CRP, PTC, and SOFA scores in sepsis (Table 3).

Silencing circROCK1 improved myocardial injury in septic mice

A CLP mouse model was established to further examine the role of circROCK1 in sepsis. First, the survival rate of CLP mice within 48 hours was evaluated. The survival rate of CLP mice within 48 hours after surgery was 41.2%, while the mice in the Sham group did not die (Fig. 2A). After CLP, circROCK1 expression in the myocardial tissue of mice was elevated; after sh-circROCK1 injection, circROCK1 expression was reversed (Fig. 2B). Later the cardiac function of the mice was checked. After CLP, LVSP and +dp/dt$_{max}$ were reduced, while -dp/dt$_{max}$, LVEDP, cTnI, and CK-MB were elevated. After sh-circROCK1 injection, the changes in the above indicators were reversed (Fig. 2C). HE staining revealed that myocardial necrosis and interstitial

edema appeared in the myocardial tissue of CLP mice, and these pathological changes were attenuated after silencing circROCK1 (Fig. 2D). Additionally, CLP surgery elevated inflammatory factors TNF-α, IL-1β, and IL-6 levels in the myocardial tissue of mice. After silencing circROCK1, inflammatory factor levels were reduced (Fig. 2E). Western blot results implied that CLP elevated phosphorylated NF-κB expression in mouse myocardial tissue. After silencing circROCK1, phosphorylated NF-κB expression was reduced (Fig. 2F). Based on these findings, silencing circROCK1 improves myocardial injury in septic mice.

Silencing miR-96-5p promoted myocardial injury in septic mice

In this work, miR-96-5p was under-expressed in the serum of septic patients (Fig. 3A). Subsequently, miR-96-5p in CLP mice was down-regulated by injection of miR-96-5p antagomir (Fig. 3B). Next, the impact of miR-96-5p on myocardial injury in septic mice was examined. After down-regulating miR-96-5p, LVSP and

Figure 4. circROCK1 acts as a miR-96-5p sponge in sepsis to mediate OXSR1 expression.
Note: (**A**) RT-qPCR to detect miR-96-5p expression in mice myocardial tissues; (**B**) http://starbase.sysu.edu.cn/ to query circROCK1 and miR-96-5p potential binding sites; (**C**) Dual luciferase reporter experiment to verify the targeting relationship between circROCK1 and miR-96-5p; (**D**) RT-qPCR and western blot to detect OXSR1 expression in mice myocardial tissue; (**E**) http://starbase.sysu.edu.cn/ to query OXSR1 and miR-96-5p potential binding sites; (**F**) Dual luciferase reporter experiment to confirm the targeting relationship between miR-96-5p and OXSR1; (**G**) RT-qPCR and western blot to examine OXSR1 expression mice myocardial tissues; data were expressed as mean ± S.D. (n=6) and compared by student's t-test. In comparison with the Sham group, * $P<0.05$; in comparison with the sh-NC group, ^$P<0.05$; in comparison with the NC antagomir group, &$P<0.05$; in comparison with the mimic NC group, #$P<0.05$.

+dp/dt$_{max}$ decreased, whereas -dp/dt$_{max}$, LVEDP, cTnI, and CK-MB elevated in CLP mice (Fig. 3C). HE staining indicated that down-regulating miR-96-5p aggravated myocardial necrosis and edema in CLP mice (Fig. 3D). Additionally, down-regulating miR-96-5p further elevated inflammatory factors TNF-α, IL-1β, and IL-6 in the myocardial tissue of CLP mice and promoted phosphorylated NF-κB expression (Figs. 3E, F).

circROCK1 acted as a miR-96-5p sponge in sepsis to mediate ROCK1 expression

After silencing circROCK1, miR-96-5p expression in CLP mice was elevated (Fig. 4A). It is speculated that circROCK1 is available to target miR-96-5p expression. CircROCK1 and miR-96-5p have a targeting relationship on http://starbase.sysu.edu.cn/ (Fig. 4B). Next, a dual luciferase reporter experiment was conducted to further examine the targeting relationship between circROCK1 and miR-96-5p. WT-circROCK1 reduced the luciferase activity in the miR-96-5p mimic group, whereas MUT-circROCK1 had no impact (Fig. 4C). This indicates that circROCK1 competitively binds miR-96-5p in sepsis. OXSR1 has been found to be highly expressed in sepsis and has an important relationship with sepsis development. In this work, OXSR1 expression was elevated in septic patients compared with healthy controls as well as in CLP mouse myocardial tissue compared with the Sham group. After down-regulating miR-96-5p, OXSR1 expression was further elevated (Fig. 4D). Given that, OXSR1 may be a potential target gene of miR-96-

5p. On the http://starbase.sysu.edu.cn/, it was found that OXSR1 and miR-96-5p had potential binding sites (Fig. 4E). Based on dual-luciferase findings, WT-OXSR1 could reduce miR-96-5p luciferase activity, while MUT-OXSR1 had no impact on it (Fig. 4F). Additionally, silencing circROCK1 can inhibit OXSR1 expression in the myocardial tissue of CLP mice (Fig. 4G). These findings indicate that OXSR1 is the target gene of miR-96-5p and is regulated by circROCK1.

DISCUSSION

In recent years, sepsis incidence has risen year by year, but the specific mechanism that affects septic organ injury is still not clear (Font *et al.*, 2020; L'Heureux *et al.*, 2020). In this work, our team found that circROCK1 was highly expressed in the serum of septic patients and indicated a positive correlation with Scr, CRP, PTC, and SOFA scores in sepsis. Additionally, knocking down circROCK1 improved septic myocardial injury by enhancing myocardial contractility, reducing myocardial tissue necrosis and edema, as well as inhibiting the activation of NF-κB signaling pathway and downstream inflammatory factor expression. In terms of mechanism, circROCK1 silencing can ameliorate myocardial injury in sepsis mainly through competitive binding of miR-96-5p-mediated OXSR1 expression.

The CLP mouse model has been widely applied in basic research on sepsis. After CLP, the mice presented myocardial inhibition and inflammatory injury, mainly

including decreased LVSP and +dp/dt$_{max}$ and elevated -dp/dt$_{max}$, LVEDP, cTnI, CK-MB, and inflammatory factors. These findings are in line with previous studies (Gao *et al.,* 2021; Liu *et al.,* 2020), revealing that CLP is available to induce severe myocardial dysfunction.

Various circRNAs can regulate inflammatory responses in sepsis, which is vital for understanding sepsis inflammation development. For example, circ_0114428 regulates sepsis-induced renal inflammatory injury by targeting miR-495-3p/cereblon axis (He *et al.,* 2021). The circRNA circVMA21 improves lipopolysaccharide-induced acute kidney injury by targeting the miR-199a-5p/Neuropilin-1 axis in sepsis (Li *et al.,* 2021). This work found for the first time that circROCK1 can reduce septic myocardial tissue inflammation mainly by inhibiting NF-κB phosphorylation. NF-κB is an essential inflammatory signaling pathway, which acts in the process of cellular inflammation and immune response (Lawrence 2009; Pflug & Sitcheran, 2020).

Organ failure is a common feature of sepsis (Joffre *et al.,* 2020; Black *et al.,* 2020). In recent years, studying the role of circRNA in protecting cardiac function has become a research hotspot. Recently, Qiu and others (Qiu *et al.,* 2021) found that circHIPK3 regulates cardiomyocyte autophagy and apoptosis stimulated by hypoxia/reoxygenation via miR-20b-5p/autophagy related 7 axis. Additionally, Cheng and others (Cheng *et al.,* 2020) found that circular RNA POSTN promotes myocardial infarction-induced myocardial injury and cardiac remodeling through regulating miR-96-5p/Bcl-2/adenovirus E1B 19kDa interacting protein 3 axis. In our research, knocking down circROCK1 improved myocardial function and inflammatory injury in septic mice. It is worth noting that circROCK1 has been found to be highly expressed in septic lung tissue, so we speculate that circRNA also has a similar impact on sepsis and other organ failures.

In further research on the mechanism, based on the bioinformatics website and dual luciferase reporter system, circROCK1 was directly bound to miR-96-5p to elevate OXSR1 expression. miR-96-5p regulates the NF-κB signaling pathway to reduce the severe response of neonatal sepsis (Chen *et al.,* 2020), which is the same as our findings. Furthermore, miR-96-5p also improved myocardial function in septic mice. This may be because miR-96-5p can reduce the release of systemic inflammatory cytokines in septic mice. OXSR1 is an essential immunomodulator in the body, which is differentially expressed in cancer, hypertension (Frame *et al.,* 2019; Puleo *et al.,* 2020), as well as neurological diseases (Frame *et al.,* 2019). A recent report revealed that overexpressing OXSR1 can improve acute kidney injury induced by sepsis (Qin *et al.,* 2019). Previous studies have shown that abnormal expression of the miR-96-5p/OXSR1 axis plays an important role in acute lung injury (Wu *et al.,* 2022). This suggests that the miR-96-5p/OXSR1 axis may also be involved in other organ injuries induced by sepsis, such as liver and intestine. We speculate that OSXR1 is also involved in the process of septic organ injury. This needs to be explored in subsequent studies. In this article, OXSR1 was also highly expressed in sepsis-induced myocardial injury.

In conclusion, our findings show that circROCK1 is highly expressed in sepsis and is correlated with clinicopathological characteristics. In terms of mechanism, circROCK1 promotes septic myocardial dysfunction by acting as a miR-96-5p sponge to mediate OXSR1 expression.

Timosaponin AIII attenuates precocious puberty in mice through downregulating the hypothalamic-pituitary-gonadal axis

Lili Zhou[1]✉, Yaoquan Ren[2], Dongmei Li[2], Weiwei Zhou[2], Chengke Li[1], Qiang Wang[1] and Xiangzheng Yang[1]

[1]Pediatrics Department, Beijing University of Chinese Medicine Shenzhen Hospital at Longgang, Shenzhen, China; [2]Pediatrics Department, Gansu Provincial Hospital of Traditional Chinese Medicine, Lanzhou, China

Precocious puberty (PP) has increasingly become a social concern. This study aimed to investigate the effect of timosaponin AIII (TAIII) on the precocious puberty and its possible mechanisms in mice. Four groups of mice consisting of controls that received saline or TAI-II, a model that received leptin to induce precocious puberty (PP), and leptin+TAIII (the leptin model treated with TAIII) were used to determine the effect of TAIII on PP. Pathological and cytological examinations were conducted to investigate the signs and onset of PP and the development of reproductive organs. The level of serum luteinizing hormone (LH), follicle stimulating hormone (FSH) and estradiol (E2) were determined using enzyme-linked immunosorbent assay (ELISA). The expression of genes related to the hypothalamic-pituitary-gonadal axis (HPGA) was assessed using qRT-PCR and Western blotting. Bone mineral density (BMD) was determined using high resolution peripheral quantitative computed tomography. In mice treated with leptin, earlier vaginal opening and estrus were observed, as well as the increased ovarian and uterine weight, total uterine cross-sectional size, number of corpora lutea, and elevated serum sex hormone levels and HPGA expression. On the other hand, TAIII treatment delayed the vaginal opening and vaginal estrus to 32.1 and 37.5 days after birth, and delayed the development of reproductive organs, leading to significantly smaller uterus and ovary size, less corpora lutea and low BMD ($P<0.05$). In addition, the serum levels of LH, FSH and E2 were significantly reduced ($P<0.05$) and so was the expression of HPGA and leptin genes ($P<0.05$). Our experimental data demonstrated that TAIII has activity against leptin-induced PP activity and may attenuate PP by reducing reproductive hormones and deactivating the hypothalamic-pituitary-gonadal axis through downregulating leptin expression.

INTRODUCTION

Precocious puberty (PP) is a growth and developmental disorder that manifests as early onset of secondary sexual characteristics, occurring before the age of 8 and 9 years in girls and boys (Bradley et al., 2020; Yang et al., 2021). The incidence of precocious puberty is growing and the age of puberty onset gradually decreases, largely due to the change of lifestyles (Kim et al., 2015). Clinical signs such as premature breast and pubic hair development, together with determination of bone age, pelvic echography and hormone tests are among the routine procedures to diagnose central (gonadotropin-releasing hormone (GnRH)-dependent) PP (CPP) and peripheral (GnRH-independent) PP (PPP) (Antoniazzi & Zamboni, 2004; Neely & Crossen, 2014). Due to the early onset of puberty, children with PP develop earlier and grow shorter, due to shorter time of bone growth and subsequently shorter stature (Censani et al., 2019) because the activation of the hypothalamic-pituitary-gonadal axis (HPGA) results in the release of gonadotropins that induces the development of puberty and promotes bone maturation (Cheuiche et al., 2021). In addition, PP can cause a series of psychological and physiological problems, which may also be associated with diseases, obesity, overweight and other environmental factors (Chae et al., 2021; Sitruk-Ware et al., 1986). At the molecular level, PP has been found to up- and down-regulate hundreds of proteins that potentially impact numerous metabolic pathways (Wang et al., 2021). In recent years, the age of PP onset trends to decrease and PP has become an important social issue, particularly for girls, who have the condition 10 times more often than boys, and their families (Cesario & Hughes, 2007).

Long-acting gonadotropin-releasing hormone analogs have revolutionized the treatment of CPP, resulting in the stabilization of pubertal progression, a reduced growth velocity, and a decreased bone age advancement (Cheuiche et al., 2021). However, questions remain regarding their optimal use in CPP and other conditions. Although most cases of precocious sexual maturation are gonadotropin-dependent and currently assumed to be idiopathic, there are mutations in genes involved in pubertal development, such as MKRN3 and DLK1, which may require different treatment options. Additional studies are needed to address key areas related to the psychosocial effects of CPP and their alterations due to the use of gonadotropin-releasing hormone analogs (Carel et al., 2009).

In East Asia, herbal medicines are used for the treatment of PP (Liu et al., 2016). Traditional Chinese medicine Zhimu is made from the roots of *Anemar-*

rhena asphodeloides and is an important member of the herbal medicines that have activity against PP. For example, Zhibaidihuang decoction made with *A. asphodeloides*, *Rehmannia glutinosa*, *Cornus officinalis*, peony bark, yam, *Poria cocos* and *Alisma orientalis* was found to alleviate PP by reducing the levels of serum hormone FSH, LH and E_2 (Xu & Qiu, 2007; Yu *et al.*, 2014). Sarsasapogenin, a steroidal sapogenin, is a main active ingredient in Zhimu (Bao *et al.*, 2007) and was found to have anti-PP activity through inhibiting the HPGA (Hu *et al.*, 2020a). In addition, pharmacological studies have shown that sarsasapogenin also has activities against thrombosis, Alzheimer's disease, tumor, inflammation, and depression (Han *et al.*, 2018; Wang *et al.*, 2014). Timosaponin AIII (TAIII), a triterpenoid, is also a main ingredient in *A. asphodeloides* extract with a number of pharmacological activities (Lin *et al.*, 2020). However, little is known about its activity against PP although decoctions made with *A. asphodeloides* are shown to be effective to attenuate PP (Xu & Qiu, 2007; Yu *et al.*, 2014).

The aim of this study was to investigate the therapeutic effect of TAIII on PP and its possible mechanisms by measuring serum sex hormone levels and expression of KISS1/GPR54 genes in mouse model of PP.

MATERIALS AND METHODS

Animals and treatments

Female C57BL mice, female, aged 2 weeks and weighing 12±1.1g, were purchased from the Laboratory Animal Center, Yanjiang Biotech, Shanghai, China. The animals were housed in groups of three in plastic box cages kept in pathogen-free animal rooms at 25°C and 42% humidity with 12-h light (06:00–18:00) and dark (18:00–06:00) cycles and *ad libitum* access to chow and drinking water. At the completion of experiments, mice were euthanized by carbon dioxide asphyxiation and tissues were isolated for subsequent analysis. Carbon dioxide was supplied at a flow rate of 20% of the cage volume per minute (5L/min). The death after exposure to carbon dioxide was confirmed after careful assessment of cardiac arrest. The study was carried out in compliance with the ARRIVE guidelines. The animal experimental protocols procedures were approved by the Institutional Animal Care and Use Committee of Beijing University of Chinese Medicine Shenzhen Hospital, Shenzhen, China.

The animals were randomly divided into controls (saline and TAIII), model (leptin), and TAIII (leptin+TAIII) groups with 16 mice in each group. At the age of 20 days, the mice were subcutaneously injected daily with leptin at 2 µg/g body weight (cat. no. 177404-21-6, Guangjian Pharmaceuticals, Shenzhen, China) in 100 µl saline with 0.1% DMSO i.p. at 09:00–10:00 hours during the light cycle as described previously (Ahima *et al.*, 1997) (model) and additionally TAIII at 10 µg (100 µl) per g body weight (cat.no. HY-N0810, MedChemExpress LLC, Shanghai, China) was administered to mice by gavage (TAIII group). Before use, TAIII was dissolved in 0.1% DMSO to 10 µg/µl to keep as a stock solution and stored at −20°C. Controls were injected with 100 µl saline or TAIII containing 0.1% DMSO. From the age of 25 days, the vaginal opening (VO) was checked daily. For the mice with VO, vaginal smear was checked every morning and the onset of vaginal estrus (VE) was determined as described previously (Nelson *et al.*, 1990).

Detection of serum hormone levels

Blood samples were collected from the abdominal aorta, and centrifuged at 4°C to obtain serum, which was stored at –20°C before analysis. Serum LH (ab72838, 1:2000), FSH (ab21011, 1:2000) and E_2 (ab100969, 1:2000) levels were determined using ELISA kits according to the supplier's instructions (abcam, Shanghai, China) with a Accuris SmartReader 96 (Labrepco, PA, USA). All assessments were repeated three times.

Pathological examination

The uterus and ovary samples were immediately isolated after the last blood samples were taken. The uterus and ovaries were isolated, weighed and fixed in 10% formalin, embedded in paraffin, sectioned and stained with hematoxylin-eosin (HE). To measure the size of uterus and ovary, the sections were pictured at 40× magnification, the edge of uterine was traced and grided with 100×100 point-grid using CAST software (v.2.0). The numbers of points falling on the cross section of the whole uterus and endometrium were counted and used to calculate the area through the built-in area conversion system in the software.

Bone densitometry

The tibias of the right hind limb were isolated and fixed in in 70% ethanol after removing the surrounding tissue. The tibial samples were longitudinally scanned using high resolution peripheral quantitative computed tomography (HR-pQCT) to display the morphology of the proximal tibia. HR-pQCT scans were performed 3.0 mm and 12.0 mm below the epiphysis line for determination of the cancellous and compact bone density.

qRT-PCR

Total RNA was extracted using Beyozol reagent (cat. no. R0011, Beyotime, Beijing China) from the hypothalamus tissues isolated from the brain according to the supplier's instructions and quantified suing a UV spectrophotometer. The RNA was converted to cDNA using BeyoRT first strand cDNA kit (cat. no. D7166, Beyotime). Real-time PCR amplification and quantification were carried out using BeyoFast SYBR Green One-Step qRT-PCR Kit (cat. no. D7268s, Beyotime) on the ProFlex™ PCR Systems (Thermo Fisher, USA). The cycle parameters consisted of initial denaturation at 96°C for 10 min, followed by 45 cycles of denaturation at 95°C for 10 s, annealing at 55°C for 15 s, and extension at 60°C for 60 s. β-actin gene was used as the internal standard, the $2^{-\Delta\Delta Ct}$ method was used to calculate the relative expression level of genes (Livak & Schmittgen, 2001). Primers for the PCR were synthesized at Huada Gene Inc., Shanghai and the sequences were:

All reactions were repeated three times.

Western blot

Western blot analysis was performed to assess the expression of the KISS1 and GRP54 genes. The brain tissues were lysed in RIPA buffer (Thermo Fisher Scientific, USA) with protease inhibitors according to the supplier's instructions. Proteins in the lysates were quantitated using BAC protein quantification kit (Thermo Fisher Scientific) according to manufacturer's instructions. After boiling at 100°C for 5 min, 50 µg denatured proteins were subjected to each lane of 12% polyacrylamide gel electrophoresis (SDS-PAGE), and transferred to PVDF membranes. The KISS1 and GRP54 proteins were detected by incubating the membranes with antibodies against KISS1 (ab226786, 1:1500, Abcam, US), GRP54 (ab108606, 1500, Abcam), GnRH (ab281844, 1:1500, Abcam), GnRHR (ab183079, 1:1500, Abcam), leptin (ab219260, 1:1200, Abcam) and β-actin (as internal reference, ab179467, 1:1500, Abcam) and horseradish peroxidase conjugated IgG (H + L) (ZB-2301, 1:2000, ZSbio, Beijing). The immunoreactive bands were visualized using chemiluminescent substrate (ab5801, Abcam) in the dark according to the supplier's protocols and quantified using Quantity one (v4.62) analysis software (General Electric, UK).

Statistical analysis

Microsoft Excel (IBM, USA) with statistical add-in was used for statistical analysis of experimental data. The measurement data were compared among and between groups were conducted using one-way analysis of variance (AVONA) and t-test, respectively, and the data were expressed as mean ± standard deviation (m ± S.D.). P<0.05 was regarded as statistically significant.

RESULTS

TAIII postpones VO and VE

From day 25, all mice were checked for VO. For controls (saline or TAIII containing 0.1% DMSO-treated mice), VO occurred similarly at 32.4±1.96 and 32.6±1.86 days after birth. In leptin-treated mice, VO occurred at 29.47±1.26 days, which was significantly earlier than in controls (P<0.05). The VO occurred at 32.1.8±2.26 days in mice receiving leptin+TAIII, which was significantly later than for those receiving leptin treatment alone (P<0.05), suggesting that TAIII postpones leptin-induced

PP. Similarly, VE occurred earlier in leptin-treated mice (34.8±2.74) as compared with controls (38.0±2.61 and 37.5±2.22) and was delayed in leptin+TAIII-treated mice (37.5±2.47) as compared with leptin-treated mice (Fig. 1). Leptin+TAIII-treated mice looked and behaved normally as compared with saline-, TAIII- and leptin-treated mice, during the experimental period.

TAIII delays sexual development

No difference was observed between the controls (saline or TAIII alone) in sexual development. Compared with the controls, leptin facilitated the development of ovaries and uterus, resulting in increased weight and size of these organs (P<0.05, Table 1). However, treatment with TAIII hindered this effect, as the sizes of ovaries and uterus were significantly reduced (P<0.05, Table 1), with lower ovarian weight (18.8 vs 22.4mg), uterine weight (27.8 vs 40.3mg), smaller total uterine cross-sectional area (0.65 vs 1.05 mm²) and smaller endometrial cross-sectional area (0.35 vs 0.55 mm²) as compared with leptin-treated mice (P<0.01, Table 1), although they were still larger than in the controls. Leptin treatment also resulted in the early development of corpora lutea, while leptin+TAIII treatments significantly reduced the number of corpora lutea as compared to the leptin-treated mice (P<0.01, Table 1).

TAIII reduces BMD

Bone development was similar between the controls (saline or TAIII alone) (Table 2). After leptin treatment, mice had significantly higher BMD, TBD and CBD as compared with controls (Table 2). TAIII treatment sig-

Figure 1. Onset of puberty in leptin-, saline- and TAIII-treated female mice.
The mice were weaned at 21 d, housed in groups of three under 12 h light (06:00–18:00) and dark (18:00–06:00) cycles, and allowed ad libitum access to chow and water. They were injected with recombinant mouse leptin, 2 µg/g body weight, saline vehicle, 100 µl i.p., or leptin plus TAIII, 10 µg/g body weight once a day at 10:00–11:00 hours until day 42. n=15 per group.

Table 2. Bone mineral density, trabecular bone density and cortical bone density in mice treated with leptin and TAIII.

Group	No. animals	Bone mineral density (mg/cm^2)	Trabecular bone density (mg/cm^2)	Cortical bone density (mg/cm^2)
Control (saline)	6	340.5±2.21	180.5±1.24	540.5±4.14
Control (TAIII)	6	342.5±2.21	183.5±1.54	537.5±3.24
Leptin	6	410.5±3.23*	230.1±1.94*	680.5±5.04*
Leptin+TAIII	6	380.2±1.11#	210.8±2.11#	650.2±3.31

Data were presented as mean ± standard deviation. *and #$P<0.05$ compared to controls (saline and TAIII) and leptin treatment, respectively, using one-way ANOVA.

Table 3. Serum luteinizing hormone (LH), follicle stimulating hormone (FSH) and estradiol (E$_2$) levels in mice treated with leptin and TAIII.

Group	No. animals	LH (ng/ml)	FSH (ng/ml)	E$_2$ (pg/ml)
Control (saline)	6	5.8±0.91	22.4±3.91	25.2±2.6
TAIII	6	5.7±0.61	21.4±3.56	24.7±2.4
Leptin	6	12.4±1.21*	39.3±4.99*	55.7±7.6*
Leptin+TAIII	6	7.8±0.81#	27.8±3.01#	±4.3 #

Data were presented as mean ± standard deviation. *and #$P<0.05$ compared to controls (saline and TAIII) and leptin treatment, respectively, using one-way ANOVA.

nificantly decreased BMD, TBD but not CBD in leptin-treated mice (Table 2).

TAIII reduces LH, FSH and E$_2$ levels

Next, we investigated the changes of several serum hormones that are related to PP development. The results showed that LH, FSH and E$_2$ levels were similar between controls (saline or TAIII alone) (Table 3). However, compared with the controls, the hormone levels were increased significantly after leptin treatment ($P<0.01$, Table 3). On other hand, TAIII administration reduced the levels of these hormones significantly as compared with leptin-treated mice ($P<0.01$, Table 3), although they were still higher than the controls.

TAIII downregulates the expression of KISS1, GPR54, GnRH and GnRHR

qRT-PCR and Western blot analyses showed that the expression of KISS1, GPR54, GnRH and GnRHR at both mRNA and protein levels was significantly upregulated in leptin treated mice (Fig. 2) but not in TAIII treated mice, as compared with control mice (saline-treated). Leptin+TAIII treatment significantly downregulated the expression of the four genes compared to leptin treatment (Fig. 2).

TAIII downregulates the expression of leptin

Since leptin is involved in GnRH secretion from hypothalamic neurons (Burcelin *et al.*, 2003), we assessed leptin gene expression in brain tissue. qRT-PCR and Western blot analysis showed that both mRNA and protein levels of leptin were not affected by either TAIII or leptin treatment, as compared with saline treatment (Fig. 3). However, both mRNA and protein levels of leptin were significantly reduced in leptin-treated mice after TAIII treatment (Fig. 3) the control, TAIII- or leptin-alone treated mice.

DISCUSSION

PP is a developmental disorder in children caused by early activation and hyperfunction of the HPGA axis.

Our experimental data showed that leptin could induce PP in mice, manifesting with earlier VO and VE and increased BMD. TAIII delayed leptin-induced sexual development acceleration, as evidenced by reduced sex hormone production and decreased expression of the genes encoding HPGA components: KISS1, GPR54, GnRH and GnRHR. TAIII also reduced BMD, TBD, and leptin expression in the leptin-treated mice. These findings indicate that TAIII is one of the active ingredients in *A. asphodeloides* preparations that confers anti-PP activity.

Puberty is a complex developmental process, which is affected by a variety of genetic and endocrine factors. To investigate the therapeutic effect of TAIII, we constructed murine model of PP using leptin and measured the progress of sexual maturation using several indexes such as VO, VE and BMD. VO and VE are external signs of the initiation of female sexual development, and are also used as the criteria for judging the onset of puberty (Zhou & Li, 2014). After leptin treatment, VO and VE were accelerated, and BMD was increased, as compared with the controls (saline or TAIII). Furthermore, pathological and biochemical analysis showed that the ovarian and uterus development was enhanced and serum hormone levels were increased in the leptin-treated mice as compared with control, confirming that the leptin treatment induced PP in mice. This is consistent with the results obtained in a previous study showing that leptin could facilitate the onset of puberty in female mice (Ahima *et al.*, 1997). On other hand, TAIII treatment delayed VO and VE, reduced BMD and delayed the sexual organ developments in the leptin-treated mice, indicating that TAIII attenuates leptin-induced PP. The crude preparations of *A. asphodeloides* are used as herbal medicine for PP (Xu & Qiu, 2007; Zhou & Li, 2014), it would be interesting to investigate whether this purified compound from *A. asphodeloides* is also able to alleviate PP in humans. Recent study shows that leptin communicates metabolic information with the brain neurons that control reproduction using GABAergic circuitry, resulting in releasing of GnRH from hypothalamic neurons (Burcelin *et al.*, 2003) and puberty onset (Egan *et al.*, 2017). In rats, the model of PP is established using da-

nazol, a drug that can rapidly activate the HPGA leading to increased expression of KISS1 and GRP45 and onset of PP (Park *et al.*, 2021).

To further investigate the mechanisms underlying TAIII-mediated anti-PP activity, we profiled the changes of several serum hormones that are related to PP. In females, LH and FSH are synthesized in the anterior pituitary gland and the levels of LH and FSH exhibit rhythmic changes throughout the menstrual or estrous cycle and have an important influence on development of puberty, gonads, and reproductive function. Premature secretion of LH and FSH leads to the early gonad activation and development of secondary sexual traits (Coss, 2018). E_2 is a steroid hormone secreted in the ovaries and is involved in the regulation of the estrous and menstrual reproductive cycles in female (Park *et al.*, 2006; Siemieniuch *et al.*, 2010). E_2 receptors are distributed in the uterus, breast and ovary. They function to promote the maturation of sexual organs (Hewitt & Korach, 2018). Earlier secretion of E_2 and other sex hormones acceler-

ate bone maturation, resulting in shortened bone growth cycle and reduced bone mineral density (Khosla & Monroe, 2018; Manolagas *et al.*, 2002). Therefore, LH, FSH, E_2 and GnRH stimulation test have been used as intuitive clinical indexes to diagnose PP (Yeh *et al.*, 2021).

Our data showed that LH, FSH and E_2 were increased following leptin treatment as compared to the controls, which is consistent with the symptoms of PP, and the increases observed in other PP models (Park *et al.*, 2021). However, after TAIII treatment, the levels of LH, FSH and E_2 in leptin-treated mice were decreased significantly, suggesting that TAIII is able to modulate the synthesis and/or secretion of these hormones, although the exact mechanisms of this modulation remain unclear. In parallel with the hormone levels, the signs of sexual development in leptin-treated mice, such as ovarian and uterus weight and size, and corpora lutea number, were reduced after TAIII treatment, further conforming that TAIII has activity against puberty onset. While hormones have been shown to play important role in sexual (Park *et*

al., 2006; Siemieniuch et al., 2010; Miyakoshi, 2004) and bone development (Miyakoshi, 2004; Olney, 2003), the causal relationship between the reduced hormone levels, reproductive organ development and bone development needs to be further investigated to better understand the model of action of TAIII.

The hypothalamus secretes GnRH, which triggers the anterior pituitary to release FSH and LH that act on the gonads (ovaries) to secrete E2, forming the HPGA axis (Lockett et al., 1977). KISS1 was discovered as a novel human malignant melanoma metastasis-suppressor gene in melanoma cells on chromosome 6 (Lee et al., 1996). KISS1 expression is significantly upregulated in pubertal rats (Kuohung & Kaiser, 2006) and may be induced by estrogenic mycotoxin (Yang et al., 2016). GPR54 is a member of G protein-coupled receptors in the rhodopsin family and is expressed in brain regions (pons, midbrain, thalamus, hypothalamus, hippocampus, amygdala, cortex, frontal cortex, and striatum), as well as in peripheral regions (liver and intestine) (Lee et al., 1999). Although the actual role of the KISS-1/GPR54 system in the timing of puberty onset remains unexplored, the activation of the gonadotrophic axis at puberty represents the final point of a complex sex developmental cascade for reproductive capacity. KISS1 and its receptor GPR54 gene are important for puberty onset. The levels of KISS1 and GPR54 mRNA in the thalamus are elevated at puberty onset and they could stimulate GnRH neurons to trigger various pathways engaged in the onset of puberty (Kuohung & Kaiser, 2006). In PP rat, serum sex hormone concentrations are closely related to GnRH mRNA levels, while the synthesis and release of GnRH and GnRHR are regulated by KISS-1/GPR54. Early activation of KiSS1/GPR54 could activate the production of GnRH in the neurons, and subsequently the HPGA axis, resulting in accelerated sexual development (Dedes, 2012; Song et al., 2017). Our data showed that mRNA and protein expression of KISS1 and GPR54, as well as

GnRH and GnRHR, in serum, was significantly upregulated after the leptin treatment, which was reversed by concomitant TAIII treatment. In rat model of PP, increased KISS1 and GPR54 expression was also observed following danazol treatment. However, GPR54 expression was not affected by sarsasapogenin, another active ingredient from *A. asphodeloides*, although it has anti-PP activity (Hu et al., 2020b). Apparently, the molecular mechanism of action of sarsasapogenin is different from the mechanism of action of TAIII, which downregulated KISS1 and GPR54 expression elevated by leptin treatment, suggesting that TAIII may exert anti-PP activity through the KISS1/GPR54 system.

As an adipocyte-derived hormone, leptin stimulates the secretion of gonadotropins from the pituitary and hence play important roles in pubertal development and maintenance of reproductive function (Dehpour et al., 1976; Tezuka et al., 2002). It regulates development and is a permissive factor for the initiation of human puberty, but not the only stimulator of puberty initiation (Terasawa & Fernandez, 2001). The difference in body fat quantity can affect leptin concentration to regulate the expression of genes related to obesity (Hu et al., 2001). Through informing brain centers about the amount of fat stored in the body, leptin exerts various regulatory functions especially associated with energy intake and metabolism, including controlling the activity of the hypothalamic-pituitary-adrenal (HPA) axis (Roubos et al., 2012). Our analysis showed that after TAIII treatment, leptin mRNA and protein levels were reduced in the brain of leptin-treated mice. This might generate signals leading to reduced HPGA activities, including decreased KiSS1, GPR54, GnRH and GnRHR expression, and consequently reduced serum hormone levels, reduced BMD, and postponed PP (Antoniazzi & Zamboni, 2004). However, the impact of TAIII on leptin level in the blood was not assessed and should be investigated further. It is also noted that leptin protein level in the brain remained unchanged in leptin-treated mice compared to untreated mice. The exact reasons for this are unclear. It is likely that the subcutaneously injected leptin might need leptin receptor as a transporter to enter the brain via choroid plexus (Lynn et al., 1996) due to the blood-brain barrier, or it might be diluted/partially degraded after injection. While leptin treatment was reported to cause PP (Ahima et al., 1997), which is confirmed in the present study, no increase in brain leptin level observed in the leptin-treated mice suggests that leptin may signal outside of the brain to regulate gene expression in the brain indirectly.

Our assessment showed that endogenous leptin expression was only reduced in leptin and TAIII-treated animals, but not in control, TAIII, or leptin treated animals. There might be several mechanisms for this. TAIII might be bound/altered/activated by the injected leptin to downregulate the expression of leptin in the brain. Since the concentration of injected leptin was likely much higher than endogenous leptin in the blood (Odle et al., 2014), TAIII could act as concentration-dependent antagonist of leptin to inhibit the expression of leptin, resulting in differential outcomes in leptin-treated animals and untreated animals. This hypothesis should be further tested to verify the relationship between TAIII concentration and leptin expression level. For example, ligand-binding assays could be used to investigate the molecular interaction between TAIII and leptin to better explain the results observed in the present study.

Although TAIII has been shown to have multiple pharmacological targets, including VEGFR, XIAP,

BMI1, mTOR, NF-κB, COX-2 and MMPs, the way it impacts gene expression of these targets is still unclear (Lin *et al.*, 2020). It is possible that TAIII may bind to regulatory sequences or targeting microRNAs that subsequently impact the expression of the target genes. Ligand binding assays, immunoprecipitation, compound-target binding assays and *in silico* predictions of herbal compound target may be designed to gain insight on the physical interactions between the molecule and cellular targets for better exploration of its anti-PP activity.

Taken together, our work demonstrated that TAIII is an active ingredient of *A. asphodeloides* preparation that counteracts PP. It downregulates the expression of KISS1, GPR54, GnRH, GnRHR and leptin, reduces the levels of serum LH, FSH, E$_2$, and delays BMD and sexual development in leptin-induced PP murine models. However, since this is a single dose study with model animals, the optimal efficacy and dose for PP control have not been determined. The safety profiles of this compound need to be determined and the therapeutic effects need to be further verified in other animal models and eventually in human subjects in order to develop it into a clinically applicable agent. Meanwhile, chemical modifications or screening of analogs may be carried to improve the efficacy and safety of this compound for clinical use.

Quercetin inhibits the expression of *MYC* and *CYP2E1* and reduces oxidative stress in the myocardium of spontaneously hypertensive rats

Oksana Maksymchuk[1]✉, Angela Shysh[2] and Anna Kotliarova[2]

[1]Institute of Molecular Biology and Genetics, Department of Molecular Oncogenetics, National Academy of Sciences of Ukraine, Kyiv 03143, Ukraine; [2]Bogomoletz Institute of Physiology, Department of General and Molecular Pathophysiology, National Academy of Sciences of Ukraine, Kyiv 01024, Ukraine

Oxidative stress is one of the most important pathological processes in chronic heart failure caused by hypertension. These processes involve MYC-regulated mechanisms, including the induction of CYP2E1 as a potent prooxidant factor. In this work, we used qPCR, Western blot analysis, and biochemical markers of oxidative stress to investigate the ability of quercetin to inhibit oxidative stress by modulating MYC expression. We studied spontaneously hypertensive rats (SHRs) in which the onset of cardiac pathology was observed at least at 4 months of age and the development of pathology occurred during life up to 22 months of age. Wistar rats were used as normotensive controls. We observed overexpression of the transcription factor MYC (p=0.0024) in the myocardium of SHRs compared to normotensive controls, and an increased expression of MYC-target gene, *CYP2E1*, (p=0.0001) in the old SHR group compared to young SHRs. This probably contributed significantly to the development of oxidative stress in the cardiac tissue of old SHRs. We demonstrated that long-term treatment of old SHRs with quercetin resulted in dramatic inhibition of *MYC* (p=0.0000), and a significant decrease in CYP2E1 (p=0.0001) expression and CYP2E1 protein levels (p=0.0136). This probably contributed significantly to the decrease in lipid peroxidation (p=0.0000). Quercetin was also able to activate antioxidant activity, resulting in a significant improvement in the prooxidant-antioxidant balance in the heart. In turn, the elimination of oxidative stress could contribute to a decrease in blood pressure (p=0.0000) and relative heart weight (p=0.0071) in quercetin-treated old SHRs compared to the untreated old SHR group.

Keywords: CYP2E1, hypertension, MYC, myocardium, oxidative stress, quercetin

INTRODUCTION

Hypertension is one of the most common pathologies of the cardiovascular system, characterized by chronic high blood pressure. This is one of the main factors in the development of chronic heart failure (CHF). Hypertension leads to functional overload of the myocardium (Nolly *et al.*, 2015), which significantly increases the risk of arrhythmias, stroke, and myocardial infarction.

It is known that in cardiac pathologies, the expression of genes regulating energy metabolism in the myocardium changes significantly (Kodde *et al.*, 2007). This is favored by the strong activation of some transcription factors, including MYC (Ahuja *et al.*, 2010). MYC-mediated metabolic changes have been associated with the preservation of cardiac function under stressors (Ahuja *et al.*, 2010). MYC directly regulates glucose metabolism and mitochondrial biogenesis in cardiomyocytes and is an important regulator of energy metabolism in the heart. Activation of MYC has been shown to promote the development of myocardial hypertrophy and functional overload in response to pathological conditions (Ahuja *et al.*, 2010). In turn, increased expression of MYC causes the induction of transcription of many genes, including *CYP2E1* (cytochrome P450 2E1) (Guan *et al.*, 2019). CYP2E1 is one of the major sources of cellular (especially mitochondrial) reactive oxygen species (ROS). CYP2E1 is a potent prooxidant factor in the cell, an increase in its expression leads to an intensification of peroxide processes and the development of oxidative stress, resulting in oxidative damage to cellular structures, mainly biomembranes (Zhang *et al.*, 2011; Guan *et al.*, 2019). This affects the functionality of the plasma membrane (permeability, electrical conductivity, receptor function, etc.). Mitochondrial membrane damage contributes to the initiation of apoptosis (Zhang *et al.*, 2011). Moreover, *CYP2E1* is one of the genes that control mechanotransduction, mitochondrial energy metabolism, redox balance, and myocardial extracellular matrix function (Guan *et al.*, 2019). It has been shown that an increase in CYP2E1 contributes significantly to myocardial energy supply under overload and stress conditions. On the other hand, overexpression of CYP2E1 leads to the initiation of pathological mechanisms in the myocardium, including oxidative stress and stress-associated pathological processes (Guan *et al.*, 2019).

It has been shown that a diet enriched with quercetin has a beneficial effect on the cardiovascular system. Some molecular mechanisms of the cardioprotective effects of this bioflavonoid have already been described. In particular, quercetin may prevent the development

of cardiac hypertrophy, oxidative stress, etc. (Yan *et al.*, 2013; Ghafouri-Fard *et al.*, 2021). The positive cardioprotective properties of quercetin suggest that this bioflavonoid could be used for therapeutic purposes (Larson *et al.*, 2010; Patel *et al.*, 2018). Research into the detailed molecular mechanisms of action of quercetin remains important. This is necessary for the identification of new molecular targets for the treatment of various heart diseases. In this work, we investigated the effect of long-term consumption of quercetin on the expression levels of *MYC* (as an important transcription factor in cardiac pathology) and MYC-regulated *CYP2E1* (as a major factor for oxidative stress). Prooxidant and antioxidant processes were also investigated in the myocardium of spontaneously hypertensive rats (SHRs) as a model of hypertension in the elderly (Reckelhoff *et al.*, 2006).

MATERIAL AND METHODS

Animals

Adult male rats (Wistar – normotensive rats and SHRs – Spontaneously hypertensive rats) were provided by Bogomoletz Institute of Physiology NAS of Ukraine (Kyiv, Ukraine). Spontaneously hypertensive rats have been used as a well-established model for genetic hypertension and age-related left ventricle dysfunction. The study involved 20 animals, which were divided into four experimental groups: five young Wistar rats (aged 4 months), five young SHRs (aged 4 months), five old SHRs (aged 22 months), and five old SHRs (aged 22 months) treated with quercetin. The old SHRs were administered quercetin (≥95.0%, PhytoLab, Sigma-Aldrich, Germany) once daily in the morning via oral gavage at a dose of 50 mg/kg bw per day for 30 days. The group of young Wistar animals was used as a normotensive control. A noninvasive method of tail artery blood pressure measurement using the Sphygmomanometer S-2 ("HSE", Germany) was used. The experimental rats were decapitated at the end of the experiment under sodium pentobarbital anesthesia (60 mg/kg bw).

All manipulations of laboratory animals were performed in accordance with the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes (Strasbourg, 1986). The protocol was approved by the Local Committee on Bioethics (registration number: 0114U007233).

Oxidative stress markers

Levels of lipid peroxidation (LPO), catalase, and superoxide dismutase (SOD) in heart tissue were determined as previously described (Maksymchuk *et al.*, 2015). The level of LPO was determined in heart homogenates by assessing the level of malondialdehyde (MDA). Catalase activity in heart homogenates was measured by hydrogen peroxide (H_2O_2) degradation. SOD was determined using nicotinamide adenine dinucleotide and phenazine methosulfate reagents for the reduction of nitro-blue tetrazolium salt to blue-colored formazan. MDA values were expressed as µmol per milligram of protein. Enzyme activity values were expressed as U/mg protein (one unit of catalase activity means the amount of enzyme that degrades 1 µmol of H_2O_2 per minute, one unit of SOD activity – the amount of enzyme that oxidizes 1 nmol NADH per minute).

Determination of target gene expression levels by quantitative PCR (qPCR)

RNA isolation from rat heart tissue and cDNA synthesis were performed using the GeneJET RNA purification kit and the Maxima H Minus cDNA Synthesis master mix (ThermoSci), respectively. The qPCR was performed using 5x Hot FirePol EvaGreen qPCR Supermix (Solis Biodynes) according to the manufacturer's protocol. The specific primers were used in qPCR to quantify gene expression of *MYC* (forward primer: CAACGTCTTGGAACGTCAGA, reverse primer: CTCGCCGTTTCCTCAGTAAG) (Barathidasan *et al.*, 2013), *CYP2E1* (forward primer: TGAAAAAGCCAAG-GAACACC, reverse primer: TGTGCTGGTGGTCT-CAGTTC) and *GAPDH* (forward primer: CTACCCAC-GGCAAGTTCAAC, reverse primer: CCAGTAGACTC-CACGACATAC) (Cabiati *et al.*, 2012). *GAPDH* expression was used for normalization. Results are expressed in relative units.

Western blot analysis and protein measurement

Preparation of heart samples for Western blot analysis and measurement of CYP2E1 protein levels were performed as previously described (Maksymchuk *et al.*, 2015). CYP2E1 was detected using rabbit anti-CYP2E1 antibodies (Sigma-Aldrich, USA). GAPDH (loading control) was identified using mouse anti-GAPDH antibodies (Sigma-Aldrich, USA). After treatment of the membranes with secondary antibodies (Sigma-Aldrich, USA), chemiluminescence detection was performed according to the manufacturer's instructions. Western blots were visualized and calculated using the ChemiDoc XRS + system with Image Lab software (Bio-Rad, USA). Relative protein levels were calculated by comparing CYP2E1 levels with GAPDH levels and expressed as relative units.

Statistical analysis

Statistical analysis was performed using Status software (http://status-please.herokuapp.com). Data were tested for normal distribution using the Shapiro-Wilk test. The Tukey HSD test was used for multiple comparisons. Differences in means between groups were tested with the one-way ANOVA and the *t*-test. Statistically significant results were considered at $p < 0.05$. Results are expressed as mean ± standard deviation (S.D.).

RESULTS

Blood pressure and body weight of animals

In this work, we studied the physiological parameters of adult male Wistar and SHR rats. We showed that the average blood pressure in the group of young Wistar rats (Table 1) corresponded to physiologically normal values for age (Novelli *et al.*, 2007). Therefore, we defined this group of rats as a normotensive control group. We found a significant increase in blood pressure in young SHRs at 4 months of age (22%, $p = 0.0000$) compared to normotensive animals of the same age (Table 1). We also found an increase (42%, $p = 0.0021$) in relative heart weight in young hypertensive rats compared to young normotensive rats (Table 1). This could be one of the signs of cardiac hypertrophy that may develop in chronic hypertension (Kahan & Bergfeldt, 2005). We demonstrated that the parameters studied in the hypertensive animals increased, even more, when they reached the

Table 1. Physiological parameters of experimental animals

Animal groups	Blood pressure, mmHg	Body weight, g	Heart weight, g	Relative heart weight, %
young Wistar	129±4.2	353.4±10.19	0.839±0.034	0.237±0.015
young SHR	158±5.7*	270.6±18.35	0.912±0.133	0.337±0.047*
old SHR	185±6.1#	391.0±26.39	1.628±0.362	0.414±0.079

Values are means±S.D., n=5 rats in each group. *$p \leq 0.001$ compared to the Wistar group, #$p \leq 0.001$ compared to the young SHR group, •$p \leq 0.01$ compared to the old SHR group (One-way ANOVA)

Table 2. Oxidative stress markers in the heart of experimental animals

Animal groups	Catalase, U/mg	Superoxide dismutase, U/mg	Malondialdehyde, µmol/mg
young Wistar	96.37 ± 6.51	2.94 ± 0.27	5.9 ± 0.42
young SHR	68.94 ± 10.12*	2.07 ± 0.12*	8.64 ± 0.64*
old SHR	54.45 ± 9.34#	1.52 ± 0.14#	12.13 ± 0.87#
old SHR /Quercetin	107.32 ± 17.67•	2.93 ± 0.07•	8.68 ± 0.26•

Values are means ± S.D., n=5 rats in each group. *$p \leq 0.001$ compared to the Wistar group, #$p \leq 0.05$ compared to the young SHR group, •$p \leq 0.001$ compared to the old SHR group (One-way AOVA)

age of 22 months. We found an increase in blood pressure (17%, $p=0.0001$) and relative heart weight (23%, $p=0.0995$) in old SHRs compared to the group of young SHRs (Table 1).

Treatment of old hypertensive rats with quercetin resulted in a reduction in blood pressure (20%, $p=0.0000$) and relative heart weight (32%, $p=0.0071$) compared to untreated old SHRs. Thus, quercetin treatment contributed to the return of these indicators to the level of young SHRs (Table 1).

Oxidative stress markers in the heart of animals

It is well known that oxidative stress is one of the most important pathological processes in CHF caused by chronic hypertension (Rodrigo *et al.,* 2011). In this work, we found evidence of oxidative stress in the heart of SHRs. A significant decrease in the activities of the antioxidant enzymes catalase (29%, $p=0.0009$) and SOD (30%, $p=0.0002$) was observed in young SHRs compared to age-matched normotensive controls. At the same time, we found an increase in MDA content (45%, $p=0.0000$), which may indicate a dramatic intensification of peroxide processes (Table 2). It should be noted that significant changes in these parameters were observed in

the heart of the old hypertensive rats in comparison with the young SHR group: a decrease in the activities of the antioxidant enzymes (catalase, 21%, $p=0.0467$; SOD, 27%, $p=0.0002$) and an increase in MDA content (40%, $p=0.0001$) (Table 2).

Treatment of old hypertensive rats with quercetin significantly improved the prooxidant-antioxidant balance and caused an increase in the activity of antioxidant enzymes: catalase (1.9-fold, $p=0.0004$) and SOD (2-fold, $p=0.0000$). At the same time, the MDA level decreased by 29% ($p=0.0000$) compared to untreated old hypertensive animals (Table 2). It should be noted that the prooxidant-antioxidant balance also improved compared to the young SHR group (Table 2).

MYC expression level in the myocardium

It is well known that MYC controls transcriptional regulation of cardiac metabolism and mitochondrial biogenesis in response to pathological stress (Ahuja *et al.,* 2010). In this work, a large increase (8-fold, $p=0.0024$) in the expression of *MYC* was observed in the myocardium of young SHRs compared to the age-matched normotensive control (Fig. 1a). It should be noted that the expression of this transcription factor in hypertensive rats contin-

(**B**) Quantification of Western blotting results. *SHR y* – spontaneously hypertensive young rats, *SHR o* – spontaneously hypertensive old rats, *SHR o/Q* – spontaneously hypertensive old rats treated with quercetin, *Liver* – a total liver lysate (as a reference control). *p-values <0.05 were considered statistically significant, Student's t-test. Means ± S.D., n=4 in each group

ues to increase throughout life. We found that the expression of *MYC* was higher (1.9-fold, p=0.0106) in the myocardium of old SHRs than in the group of young SHRs (Fig. 1b).

Treatment of old SHRs with quercetin resulted in a significant decrease (8.7-fold, p=0.0000) in myocardial *MYC* expression compared to the group of untreated old SHRs (Fig. 1b). Thus, the expression of this transcription factor was much lower than in the group of young hypertensive rats (Fig. 1b).

CYP2E1 expression and protein levels in the myocardium

Since *CYP2E1* is under MYC-dependent transcriptional control, modulation of *MYC* could cause a change in CYP2E1 expression. We found a significant increase in *CYP2E1* gene expression (4.8-fold, p=0.0001) (Fig. 1c) as well as protein content (2.8-fold, p=0.0007) in the heart of old hypertensive rats compared to the young SHR group (Fig. 2).

Quercetin treatment resulted in a significant decrease in *CYP2E1* expression (4.9-fold, p=0.0001), which was accompanied by a decrease in protein content (2.2-fold, p=0.0136) in the heart of the old hypertensive rats compared to the group of untreated old SHRs (Fig. 1c and 2).

DISCUSSION

Despite modern optimal therapies, mortality of patients with cardiovascular pathology (coronary heart diseases, myocardial infarction etc.) caused by hypertension remains high. Detailed study of the pathogenesis of heart disease is necessary to prevent and correct pathological changes in the myocardium, improve the quality of life of patients, and prolong their lives. It is known that in a normal physiological state, mitochondrial fatty acid oxidation is the main source of energy production in the myocardium. In heart failure, the level of this oxidation often decreases, while glycolytic pathways become more prominent, ultimately leading to contractile dysfunction. Chronic hypertension has been shown to be one of the key factors in such pathological processes (Oh & Cho, 2020). In this work, we investigated the development of cardiac pathology using a model of spontaneously hypertensive rats. We found a steady increase in blood pressure even in young SHRs compared with normotensive animals of the same age and sex. An increase in relative heart weight was also noted in young SHRs, which may be a sign of cardiac hypertrophy. It is well known that chronic hypertension may contribute to the development of oxidative stress, one of the major pathological processes leading to structural and functional damage of the myocardium in the development of CHF (Rodrigo *et al.*, 2011; Mei *et al.*, 2015). We also found evidence of an imbalance between prooxidants and antioxidants, which may indicate the development of oxidative stress in the heart of young SHRs. Thus, the data obtained may indicate the onset of pathological processes in the heart of young hypertensive animals. These processes continued and are exacerbated during the life of the animals.

Significant metabolic changes have been shown to occur in the myocardium during hypertension-induced cardiac overload. Changes in the expression of key transcription factors (including MYC) that regulate metabolic genes in cardiomyocytes lead to transient adaptation of the myocardium to stress and also initiate pathological processes (Ahuja *et al.*, 2010; Guan *et al.*, 2019). We found strong activation of *MYC* expression in the myocardium of young hypertensive animals compared to normotensive controls. It should be noted that this activation further increased during life in hypertensive rats. It has been shown that *MYC* is expressed at a very low level in the adult heart under normal physiological conditions. However, in response to cardiac overload, the expression of *MYC* increases sharply (Xiao *et al.*, 2001). In particular, it has been shown that the expression of *MYC* was significantly increased in the myocardium of spontaneously hypertensive animals and was associated with cardiac hypertrophy and atherosclerosis (Negoro *et al.*, 1988). In our work, we also demonstrated an increase in *MYC* expression that was accompanied by an increase in relative heart weight. Such activation of MYC in adult myocardium was found to increase glucose uptake and utilization, reduce fatty acid oxidation by downregulat-

ing PPARα, and induce mitochondrial biogenesis. As a result, the function of the left ventricle remains normal despite hypertrophic changes (Ahuja *et al.,* 2010). Thus, in young hypertensive rats, we found evidence of pathological processes and a sharp increase in the expression of *MYC,* which persisted and increased until 22 months of age.

In turn, the increased expression of *MYC* may be a key factor in the induction of transcription of many genes, including *CYP2E1* in the myocardium (Guan *et al.,* 2019). We have demonstrated a significant increase in *CYP2E1* expression as well as protein content in the myocardium of old hypertensive animals compared to young SHRs. It has been reported that CYP2E1 expression levels may change significantly during the development of myocardial hypertrophy in various models of heart failure. Such an increase in CYP2E1 expression has previously been demonstrated in hypertension and acute myocardial injury, and a key factor might be the upregulation of MYC (Guan *et al.,* 2019). Clearly, increased expression of CYP2E1, a potent prooxidant factor, may be one of the most important reasons for the development of oxidative stress (Pang *et al.,* 2021) in the myocardium, for which we found evidence in our experiment. It has been shown previously that altered expression of CYP2E1 may be a marker of various pathophysiological factors and conditions in the myocardium. Increased expression of CYP2E1 plays several pathophysiological roles in the heart, including oxidative stress and apoptosis, as well as involvement in energy production and supply pathways to meet the increased energy demands of the heart under pathological conditions (Zhang *et al.,* 2011; Guan *et al.,* 2019). Therefore, an increase in CYP2E1 expression in the early stages of heart failure development may be an adaptation of the myocardium to the conditions of altered energy exchange pathways, ensuring the preservation of the contractile function of the heart. On the other hand, oxidative stress, which may be caused by increased CYP2E1 expression, is one of the crucial pathological mechanisms in the development of heart disease (Guan *et al.,* 2019; Pang *et al.,* 2021).

Thus, increased expression of *MYC* could lead to activation of CYP2E1 expression, which is associated with the development of oxidative stress and other pathological processes in the myocardium. We hypothesize that modulation of *MYC* expression level in the myocardium may help to inhibit the development of the above pathological processes (including oxidative stress) caused by hypertension. This conjecture was tested in our study. A natural agent such as quercetin was chosen as a modulatory agent because this agent has cardioprotective properties and can prevent the development of CYP2E1-induced oxidative stress (Larson *et al.,* 2010; Yan *et al.,* 2013; Maksymchuk *et al.,* 2017; Ghafouri-Fard *et al.,* 2021).

We found that treatment with quercetin resulted in a significant decrease in *MYC* expression in old SHRs compared to untreated old SHRs and young SHRs. This bioflavonoid has been shown to modulate multiple signaling pathways, including activation of PPAR (Yan *et al.,* 2013), resulting in downregulated MYC expression. In addition, quercetin has been found to directly inhibit the expression of MYC by binding to the regulatory region of the corresponding gene (Tawani *et al.,* 2017). It has been shown that inhibition of MYC can significantly inhibit myocardial hypertrophic growth (Ahuja *et al.,* 2010). In this work, we also showed a significant decrease in relative heart weight, which may be a consequence of the downregulation of this transcription factor. Since

MYC induces *CYP2E1* (Guan *et al.,* 2019), suppression of *MYC* could lead to a decrease in *CYP2E1* expression, which contributes to a decrease in CYP2E1 protein content in the heart. This is exactly the effect we observed in the myocardium of animals treated with quercetin. We also noted some normalization of the balance between pro- and antioxidants in the heart, i.e., a decrease in the level of LPO and an increase in the activity of antioxidant enzymes. A decrease in the expression of CYP2E1 (as a potent prooxidant factor) could lead to a decrease in LPO levels (Pang *et al.,* 2021). Moreover, the quercetin molecule can directly inhibit the activity of CYP2E1 by blocking the active site of the enzyme (Östlund *et al.,* 2017). At the same time, this bioflavonoid can scavenge radicals and activate the expression of antioxidants (de Lacerda Alexandre *et al.,* 2021). It also contributes to the antioxidant effect of quercetin in the myocardium. It is known that quercetin can lower blood pressure and hypertrophy by reducing the manifestations of oxidative stress (Larson *et al.,* 2010; de Lacerda Alexandre *et al.,* 2021). We observed a similar effect in old-treated hypertensive rats.

CONCLUSION

Oxidative stress is one of the most important pathological processes in chronic heart failure caused by hypertension. These processes involve MYC-regulated mechanisms, including the induction of CYP2E1 as a potent prooxidant factor. We observed overexpression of the transcription factor MYC in the myocardium of SHRs compared to normotensive controls, and an increased expression of the MYC-target gene, *CYP2E1,* in the old SHR group compared to young SHRs. This probably contributed significantly to the development of oxidative stress in the cardiac tissue of old SHRs. We demonstrated that long-term treatment of old SHRs with quercetin resulted in dramatic inhibition of *MYC,* and a significant decrease in CYP2E1 expression and CYP2E1 protein levels. This probably contributed significantly to the decrease in lipid peroxidation. Quercetin was also able to activate antioxidant activity, resulting in a significant improvement in the prooxidant-antioxidant balance in the heart. In turn, the elimination of oxidative stress could contribute to a decrease in blood pressure and relative heart weight in quercetin-treated old SHRs compared to the untreated old SHR group.

LncRNA MIR31HG promotes cell proliferation and invasive properties of the MCF-7 cell line by regulation of receptor-interacting serine-threonine kinase 4

Jingwei Tang, Xiaojing Zhang, Chunchun Chen, Binbin Wang, Yansong Chen, Hao Zhang, Mengxiang Qiao, Xianfu Liu, Wei Guo and Gongsheng Jin✉

Department of Surgical Oncology, the First Affiliated Hospital of Bengbu Medical College, Changhuai Road, Bengbu 233000, Anhui, China

LncRNA MIR31HG is involved in many types of cancers, while its roles in breast cancer are still unknown. The current study aimed to explore the function of lncRNA MIR31HG in breast cancer and the underlying mechanisms. Stable expression cell lines were constructed by using lentivirus particles. MTT assay was used to determine cell viability. Wound healing and Transwell assay were used to determine cell migration and invasion, respectively. The changes in biomarkers were determined by using qPR-PCT and Western blotting, respectively. BALB/c nude mice were used to generate a xenograft mouse model. MIR31HG regulated cell proliferation, migration and invasion in MCF7 cells. Besides, MIR31HG regulated N-Cadherin, Vimentin, and E-Cadherin. MIR31HG positively regulated receptor-interacting serine-threonine kinase 4 (RIPK4), as supported by the fact that knockdown of MIR31HG suppressed RIPK4, and the knockdown of RIPK4 did not affect MIR31HG. Additionally, we found that RIPK4 regulated cell proliferation, migration and invasion in MCF7 cells. The changes in RIPK4 regulated N-Cadherin, Vimentin, and E-Cadherin. Consistently, *in vivo* studies showed that the knockdown of MIR31HG or RIPK4 reduced tumor size in xenograft animal models. The roles of lncRNA MIR31HG in breast cancer were associated with its regulatory effects against RIPK4.

INTRODUCTION

Breast cancer is known as the most common cancer in women, which accounts for about 12.5% of all cancer cases in the world (Ferlay *et al.*, 2021; Lei *et al.*, 2021). Approximately 2.3 million newly diagnosed breast cancer cases were reported with around 685,000 breast cancer-related deaths in 2020 (Ferlay *et al.*, 2021; Lei *et al.*, 2021; Lima *et al.*, 2021). Breast cancer can be divided into non-invasive or pre-invasive (also termed intraductal carcinoma) and invasive types, where the invasive type accounts for 70~80% of all cases (Matsuno *et al.*, 2007; Sharma *et al.*, 2010). In patients with early stage breast cancer, a 99% of 5-year survival rate can be achieved in patients with localized non-metastasis breast cancer with proper treatment (Page, 2003; Sharma *et al.*, 2010). However, breast cancer can spread to other tissues including liver, lung, bone, and brain tissues. When tumor metastasis occurs, the 5-year survival rate is only 29% (Matsuno *et al.*, 2007; Page, 2003). Therefore, diagnosis of breast cancer in the early stage is crucial for the treatment of breast cancer and the improvement of the survival rate.

The roles of long non-coding RNAs (lncRNAs) have been implicated in many types of cancers such as lung cancer, hepatoma, colorectal cancer, breast cancer, etc. (Fang & Fullwood, 2016; Hauptman & Glavač, 2013). LncRNAs are involved in a series of cellular events such as cell proliferation, migration and invasion, and genetic stability, in part, by the regulation of various genes (Fang & Fullwood, 2016; Spizzo *et al.*, 2012). Moreover, lncRNAs are also known as functional transcripts, which are associated with tumor progression and metastasis (Spizzo *et al.*, 2012; Zhang *et al.*, 2013). Targeting lncRNAs becomes a promising strategy for cancer therapy (Zhang *et al.*, 2013). LncRNA microRNA-31 host gene (MIR31HG) was identified as an oncogene in twelve different types of cancers including bladder cancer, head and neck cancer, osteosarcoma, cervical cancer, gastric cancer, etc. (Wei *et al.*, 2022). Besides, the changes of MIR31HG can also be used as a prognosis biomarker for patients with digestive system cancer (Zhou *et al.*, 2020). However, it is still unclear whether MIR31HG is involved in breast cancer. Therefore, this study aims to determine the role of MIR31HG in breast cancer and its molecular mechanisms.

A receptor-interacting serine-threonine kinase (RIPK) 4 is known to be associated with epidermal homeostasis and development by the regulation of cell-cell adhesion (Oberbeck *et al.*, 2019; Xu *et al.*, 2020). It also acts as a transcriptional target of TP63 and plays important roles in transcriptional factor- nuclear factor kappa B (NF-κB) activation (Liu *et al.*, 2018; Xu *et al.*, 2020). Recently, the roles of RIPK4 in cancer have drawn much attention from scientists (Li *et al.*, 2021; Liu *et al.*, 2015; Liu *et al.*, 2021). In 2015, Liu and colleagues have reported that the RIPK4 can be used as a prognostic and diagnostic biomarker for patients with cervical cancer (Liu *et al.*, 2015). In 2021, Li and colleagues have found that RIPK4 regulates cell migration and metastasis in hepatoma by the regulation of signal transducer and activator of the transcription 3 (STAT3) signaling pathway (Li *et al.*, 2021). However, the roles of RIPK4 are still unknown. Herein,

the roles of MIR31HG in breast cancer *in vitro* and *in vivo* were clarified in our study.

MATERIALS AND METHODS

Antibody and reagents

Antibodies against Vimentin, E-Cadherin, N-Cadherin, and GADPH were obtained from Cell Signaling Technology (Danvers, MA). Antibodies against RIPK4 and Ki67 were obtained from Thermo Fisher Scientific (Waltham, MA). Predesigned shRNAs targeting MIR31HG and RIPK4, control shRNAs (shNC), and other chemicals were purchased from Sigma-Aldrich (St. Louis, MO).

Cell culture and cell viability

Breast cancer cell line MCF7 was purchased from the ATCC (Rockville, MD). The cells were cultured in recommended medium with 10% fetal bovine serum (FBS) and penicillin/streptomycin (100 U/ml) under 37°C with 95% humidity and 5% CO_2. MTT assay was used to determine cell viability. In brief, MTT solution (5 mg/mL, 10 μL) was added and incubated for another 2 h. Next, DMSO (100 μL) was used to dissolve the purple formazan crystal followed by shaking for 30 sec. Next, the plate was read under a wavelength of 570nm with a reference wavelength of 630 nm.

Construction of stable cell lines

To construct stable MIR31HG and RIPK4 knockdown cell lines, MCF7 cells were transfected with MIR31HG shRNA (Targeting sequence: GCTGCTGATGACGTAAAGT), RIPK4 shRNA (Targeting sequence: CGTTCGTTTCTCGTTGCCTAA) or empty vector (shNC) lentivirus as previously described. After 72 h, a medium containing puromycin (2 μg/mL) was added and incubated for another 72 h for the selection of the cells. To construct MIR31HG and RIPK4 overexpressing cell lines, pcDNA MIR31HG, pcDNA RIPK4, or empty plasmid containing shNC sequence was used to construct pLKO.1 plasmid followed by the generation of lentivirus. Puromycin (2 μg/mL) was used for the selection of stable overexpressing cell lines.

Cell invasion and wound healing assays

Cell invasion assay was determined by using Transwell chamber. In the upper chamber, the cells were seeded and cultured with a serum-free medium. In the lower chamber, a medium containing 10% FBS was added. After 72 h, cells that were in the lower chamber were stained. Five random fields were selected, and the number of cells were counted. In the wound healing assay, cells were seeded into a 6-well plate. When 80–90% confluence was observed, a sterile tip (1 mm width, 200 μL) was used to scratch the cell monolayer. After 72 h, cells were observed by using a microscope, and wound healing rate was calculated. The Transwell chamber was purchased from BD (Franklin Lakes, NJ, USA).

Western blotting assay

Protein samples were extracted from the cells by using cold RIPA buffer (1% phenylmethanesulfonyl fluoride) and qualified by using BCA assay. Protein samples were loaded on a 10% SDS page followed by transferring onto the PVDF membrane. After that, the membrane was blotted with 5% non-fat milk for 1 h at room temperature. The primary antibodies were added and incubated overnight at 4°C. After that, the secondary antibodies conjugated with HRP were added and blotted for another 2 h at room temperature. A chemiluminescence substrate was added, and the protein intensity was compared to the internal control GADPH.

qRT-PCR

Total RNAs were extracted by using the phenol-chloroform method. In this study, the sequences of primers were described below.

TAP-1 forward primer: 5'-GCCCACTACCACGT-CAAGAT-3', and reverse primer: 5'-TTCACCATG ATGTGCAGGAT-3'; MIR31HG forward primer: 5'-GTTTCTGGTCCTCATACCGTGTGGTT-3', and reverse primer: 5'-CTTGGAATGAATCCTCTGTC-CTCC-3'; GADPH forward primer: 5'-TCAACGAC-CACTTTGTCAAGCTCA-3', and reverse primer: 5'-GCTGGTGGTCCAGGGGTCTTACT-3'. A reverse transcription reaction was then performed by using real-time PCR kits (Takara Bio Inc, San Jose, CA).

MCF7 Xenograft animal model

BALB/c nude mice (age 4~6 weeks) were purchased from GemPharmatech (Nanjing, China) and kept in specific pathogen-free facilities. In this study, animal procedures were approved by the First Affiliated Hospital of Bengbu Medical College. Mice were subcutaneously injected with MCF7 cells (MIR31HG-KD, MIR31HG-OE, or MCF7) at a density of 5×10^6 cells, and tumor size was measured once a week in accordance with a formula: tumor volume=length×width^2/2.

Data analysis

The results were represented as means ± standard deviation (S.D.). A significant difference was obtained by using GraphPad prism 7 based on either one-way or two-way ANOVA test followed with a post hoc test. When a *p*-value was smaller than 0.05, the statistical significance was decided.

RESULTS

MIR31HG regulated cell proliferation in MCF7 cells

Our results showed an elevation of MIR31HG in MIR31HG-OE cells and a reduction of MIR31HG in the MIR31HG-KD cells, indicating the successful construction of MIR31HG stable cell lines (Fig. 1A). MTT assay showed that cell proliferation was significantly increased in the MIR31HG-KD cells, whereas cell proliferation was diminished in the MIR31HG-OE cells (Fig. 1B). Consistently, we found that Ki67 decreased in the MIR31HG-KD cells. Interestingly, the protein expressions of Ki67 were enhanced in the MIR31HG-OE cells (Fig. 1C).

MIR31HG regulated wound healing and cell invasion

The effects of MIR31HG on cell migration and invasion were then determined. We observed a decrease in the closure rate and a reduction in the invaded cell numbers in the MIR31HG-KD cells, whereas an elevation in closure rate and invaded cell numbers was observed in the MIR31HG-OE cells (Fig. 2A and B). Additionally, overexpression of MIR31HG enhanced the protein ex-

Figure 1. MIR31HG regulated the proliferation of MCF7 cells.

Figure 2. MIR31HG regulated the migration and invasion of MCF7 cells.
(**A**) A wound healing assay was used to determine the closure rate of control, MIR31HG-KD, and MIR31HG-OE MCF7 cells. (**B**) The invasion assay was used to determine the numbers of invaded cells in control, MIR31HG-KD, and MIR31HG-OE MCF7 cells. (**C–F**) Western blotting was used to determine the protein levels of EMT-related markers including N-Cadherin (**C and D**), Vimentin (**C and E**), and E-Cadherin (**C and F**) in control, MIR31HG-KD, and MIR31HG-OE MCF7 cells (n=3).

pressions of N-Cadherin and Vimentin, whereas knockdown of MIR31HG suppressed the protein expressions of N-Cadherin and Vimentin in MCF7 cells (Fig. 2C–E). Moreover, overexpression of MIR31HG suppressed the protein expressions of E-Cadherin, whereas knockdown of MIR31HG enhanced the protein expressions of E-Cadherin (Fig. 2C and F).

MIR31HG regulated the levels of RIPK4

We further determined the impact of MIR31HG on RIPK4 in MCF7 cells. An elevation of RIPK4 in the MIR31HG-KD cells, and a reduction of RIPK4 were observed in the MIR31HG-OE cells (Fig. 3A and B). Next, we successfully constructed RIPK-KO and RIPK-OE cells (Fig. 3D). Interestingly, no significant change of MIR31HG was found among RIPK-KO, RIPK-OE, and control MCF7 cells (Fig. 3C). We also found that a

reduction in RIPK4 in the RIPK-KO cells, whereas an elevation of RIPK4 was observed in the MIR31HG-OE cells both at the mRNA and protein levels (Fig. 3D and E). These results indicate that MIR31HG regulated the levels of RIPK4 in MCF7 cells.

RIPK4 mediated cell proliferation in breast cancer cells

We determined the effects of RIPK4 on cell proliferation. Our results showed that cell proliferation was enhanced in the MIR31HG-KD cells as compared to the MIR31HG-OE cells (Fig. 4A). Consistently, we found that Ki67 decreased in the MIR31HG-KD cells. Interestingly, Ki67 increased in the MIR31HG-OE cells (Fig. 4B).

Figure 3. MIR31HG regulated the levels of RIPK4 in MCF7 cells.
(**A–B**) Western blotting and qRT-PCR were used to determine the protein (**A**) and mRNA (**B**) levels of RIPK4 in control, MIR31HG-KD, and MIR31HG-OE MCF7 cells. Besides, (**C**) the mRNA levels of MIR31HG were determined in control, RIPK4 knockdown (KD), and RIPK4 overexpressing (OE) MCF7 cells. (**D–E**) The protein and mRNA levels of RIPK4 in control, RIPK4-KD, and RIPK4-OE MCF7 cells (n=3).

Figure 4. RIPK4 mediated the proliferation of breast cancer cells *in vitro*.
(**A**) MTT assay was used to determine cell viability of control, RIPK4-KD, and RIPK4-OE MCF7 cells (**B**) Western blotting was used to determine the protein levels of Ki67 in control, RIPK4-KD, and RIPK4-OE MCF7 cells (n=3).

RIPK4 regulated cell migration and invasion

Moreover, we investigated the impact of RIPK4 change on cell migration and invasion. A decrease in closure rate as well as a reduction in invaded cell numbers were observed in the RIPK4-KD cells, whereas both closure rate and invaded cell numbers were increased in RIPK4-OE cells (Fig. 5A and B). Additionally, overexpression of RIPK4 increased N-Cadherin and Vimentin, whereas knockdown of RIPK4 suppressed N-Cadherin and Vimentin (Fig. 5C-E). Moreover, overexpression of RIPK4 suppressed E-Cadherin, whereas knockdown of RIPK4 increased E-Cadherin (Fig. 5C and F).

Knockdown of MIR31HG or RIPK4 repressed MCF7 tumor growth in mice

To confirm the observations *in vitro*, we observed the effects of MIR31HG or RIPK4 knockdown on tumor growth in the animal cancer xenograft model. Interestingly, we found that tumor size was significantly reduced in the MIR31HG-KD and RIPK4-KD groups (Fig. 6A). The protein expressions of Ki67 were also significantly decreased in the MIR31HG-KD and RIPK4-KD groups (Fig. 6B). These results indicate that the knockdown MIR31HG or RIPK4 suppressed tumor growth *in vivo*. Next, we investigated the levels of Epithelial-to-mesenchymal transition (EMT)-related biomarkers. A reduction of N-Cadherin and Vimentin was observed in the MIR31HG-KD and RIPK4-KD group as compared to the control group (Fig. 6C–E). Besides, an elevation of E-Cadherin was observed in the MIR31HG-KD and RIPK4-KD group (Fig. 6F), suggesting the regulatory effects of MIR31HG and RIPK4 on EMT.

Figure 5. RIPK4 regulated the migration and invasion of MCF7 cells.
(**A**) A wound healing assay was used to determine the closure rate of control, RIPK4-KD, and RIPK4-OE MCF7 cells. (**B**) Invasion assay was used to count the numbers of the invaded cells of control, RIPK4-KD, and RIPK4-OE MCF7 cells. (**C–F**) Western blotting was used to determine the protein levels of EMT-related markers including N-Cadherin (**C and D**), Vimentin (**C and E**), and E-Cadherin (**C and F**) in control, RIPK4-KD and RIPK4-OE MCF7 cells (n=3).

Figure 6. Knockdown of MIR31HG or RIPK4 repressed MCF7 tumor growth in mice.
(**A**) Tumor size was measured in the xenograft mice of the control, MIR31HG-KD, and RIPK4-KD MCF7 group. (**B–F**) Western blotting was used to determine the protein levels of Ki67 (**C**), N-Cadherin (**D**), Vimentin (**E**), and E-Cadherin (**F**; n=5 mice).

DISCUSSION

This study revealed the roles of MIR31HG in the MCF7 breast cancer cell lines and breast cancer xeno-graft mouse model. MIR31HG promoted cancer growth by regulating a series of cellular events including cell proliferation, migration and invasion. Additionally, the roles of MIR31HG in breast cancer were associated

with its regulatory effects against EMT, as suggested by the changes in N-Cadherin, Vimentin, and E-Cadherin that were observed in these MIR31HG overexpressing or knockdown cell lines. Underlying mechanism studies identified RIPK4 as a downstream target of MIR31HG, as supported by MIR31HG positively regulating the levels of RIPK4, whereas knockdown of RIPK4 did not significantly affect MIR31HG. These results suggested that MIR31HG might serve as an oncogenic gene in breast cancer by its regulatory effects against RIPK4.

MIR31HG is involved in cancer occurrence and progression (Wei et al., 2022). Moreover, the alteration of MIR31HG is observed in twenty types of cancers (Wei et al., 2022). For instance, Zheng and colleagues reported that MIR31HG promotes cell proliferation and invasion in lung cancer (Zheng et al., 2019). The downregulation of MIR31HG is associated with the alternation of EMT in non-small cell lung cancer. In another study, the overexpression of MIR31HG is associated with a low overall survival rates and advanced tumor, node, and metastasis stage in patients with bladder cancer (Wu et al., 2019). More recently, Ko and colleagues demonstrated that the overexpression of MIR31HG is associated with poor disease-free survival rate in patients with pancreatic ductal adenocarcinoma (Ko et al., 2022). These results suggested the oncogenic roles of MIR31HG in cancer. However, it is still unclear whether MIR31HG promoted tumor growth in breast cancer. Herein, our study reported the roles of MIR31HG in breast cancer. Consistently, our results revealed that the overexpression of MIR31HG promoted cancer cell growth and invasion in MCF7 cells as well as tumor growth in the cancer xenograft mouse model.

EMT is frequently observed in breast tumor invasion and metastasis (Ye et al., 2017). Moreover, the activation of EMT is linked with drug resistance in breast cancer (Kotiyal & Bhattacharya, 2014). Previous studies indicated the regulatory effects of MIR31HG on EMT in many types of cancers (Zheng et al., 2019). For instance, MIR31HG is known to promote EMT in pancreatic cancer cells induced by the transforming growth factor β and to induce EMT phenotype in non-small lung cancer cells (Ko et al., 2022). Therefore, we explored whether the roles of MIR31HG in breast cancer were associated with EMT. Interestingly, our data suggested that overexpression of MIR31HG increased the protein levels of N-Cadherin and Vimentin, whereas changes in MIR31HG regulated these EMT-related biomarkers in MCF7 cells and breast tumor tissues.

The roles of MIR31HG in cancers are associated with its regulatory effects on various biological processes, signaling pathways, and proteins (Ko et al., 2022; Wei et al., 2022; Zheng et al., 2019). For instance, MIR31HG promotes non-small cell lung cancer growth, in part, by regulating Wnt/β-catenin signaling pathways (Zheng et al., 2019). Another study revealed that MIR31HG is upregulated in colorectal tumor tissues and associated with proteins relevant to glycolysis (ex. hexokinase 2 and glucose transporter 1) and angiogenesis (ex. vascular endothelial growth factor A and tissue inhibitor matrix metalloproteinase 1) (Wang et al., 2022). Wang and colleagues reported that MIR31HG promotes tumor growth in head and neck cancer via its regulation of hypoxia-inducible factor A and cyclin-dependent kinase inhibitor p21 (Wang et al., 2018). Our study found the role of MIR31HG in breast cancer, at least partly, by regulating RIPK4. Interestingly, we found RIPK4 served as a downstream target of MIR31HG, since changes in MIR31HG regulated the levels of RIPK4, whereas the

knockdown of RIPK4 did not significantly affect the levels of MIR31HG.

RIPK4 is involved in many types of cancers by affecting a series of biological functions and signaling transduction proteins (Li et al., 2021; Qi et al., 2018). For instance, Li and colleagues reported that RIPK4 inhibits hepatoma cancer cell invasion and metastasis by the regulation of STAT3 signaling pathways (Li et al., 2021). As an immune regulatory biomarker, the abnormal expressions of RIPK4 are observed in many types of cancers including gynecologic cancer, melanoma, cervical squamous cell carcinoma, etc. (Liu et al., 2015; Liu et al., 2021; Madej et al., 2021). Liu and colleagues observed that an elevation of RIPK4 in cervical squamous cell carcinoma is correlated to poor overall survival rate, and knockdown of RIPK4 suppresses cell migration and invasion (Liu et al., 2015). In this study, we identified RIPK4 as a downstream target of MIR31HG in breast cancer. RIPK4 regulated cell proliferation, invasion, and migration as well as EMT-related biomarkers. Consistently, in vivo studies showed that the knockdown of RIPK4 reduced tumor size in cancer xenograft animal models. These results suggested that targeting RIPK4 might be a good strategy for breast cancer therapy.

CONCLUSION

MIR31HG positively regulates cell proliferation, invasion and migration, and EMT. In addition, MIR31HG positively regulates RIPK4, as supported by the fact that changes in MIR31HG affect RIPK4, whereas RIPK4 knockdown does not affect MIR31HG. Consistently, in vivo studies showed that the knockdown of MIR31HG or RIPK4 reduces tumor size in tumor xenograft animal models. These data suggest that the roles of lncRNA MIR31HG in breast cancer are associated with its regulatory effects against RIPK4.

Comparative analysis of A¹ and A² allele detection efficiency for bovine *CSN2* gene by AS-PCR methods

Roman Kulibaba[1]✉, Mykola Sakhatskyi[1] and Yuriy Liashenko[2]

[1]National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine; [2]Institute of Animal Science, the National Academy of Agrarian Sciences of Ukraine, Kharkiv, Ukraine

This study was aimed at conducting a comparative analysis of the efficiency in genotyping cattle by beta-casein locus using the allele-specific PCR methods. The results of the study have demonstrated the necessity to optimize the protocol for the use of AS-PCR to detect alleles A¹ and A². It was found that the use of non-optimized PCR protocols led to the genotyping errors, manifested regarding beta-casein locus (*CSN2*). The impossibility of using the touchdown PCR as an optimization instrument for AS-PCR was proven. The elaborated typing protocols were used to study the genetic structure of the cattle populations of different breeds, reared in Ukraine – Ukrainian Red-and-White dairy, Ukrainian Black-and-White dairy (two populations), and Charolais. It was found that locus *CSN2* was polymorphic in all the cattle populations. The frequencies of allele A² varied within 0.34–0.91 depending on the population of the animals, which may be conditioned by the specificities in the selection work. No deviation from the Hardy-Weinberg equilibrium was found in any investigated population of cattle.

INTRODUCTION

The genetic structure analysis for the experimental populations of cattle is among the routine tasks of genetics and marker-associated selection in cattle breeding (Wakchaure *et al.*, 2015). However, along with such widely known qualitative trait loci as kappa casein, prolactin, beta-lactoglobulin, leptin, etc., related to the expression of productive traits of animals, in a few recent years, there has been a steady interest in the beta-casein gene, the allelic variants of which are related to the parameters of milk quality (Cieślińska *et al.*, 2019; Sebastiani *et al.*, 2022; Jiménez-Montenegro *et al.*, 2022). A¹ and A² belong to one of the best-studied and promising allele systems of beta-casein from the standpoint of applied genetics of cattle (Antonopoulos *et al.*, 2021). As shown in numerous studies, various forms of beta-casein are associated with a number of human pathological states which makes the *CSN2* gene a relevant research object

in the context of the production performance of different dairy cattle breeds (Summer *et al.*, 2020; Bisutti *et al.*, 2022; De Vitte *et al.*, 2022). Alleles A¹ and A² differ by the presence of a specific amino acid in position 67 of the beta-casein molecule (Sebastiani *et al.*, 2020). In the case of form A¹, it is histidine, and as for A² – proline (Thiruvengadam *et al.*, 2020). Different forms of protein (beta-casein) are determined by the mutation in the *CSN2* gene, in position 304 (GenBank, NM_181008) – by the presence of adenine for allele A¹ and cytosine for allele A² (Dai *et al.*, 2016; Kay *et al.*, 2021). The replacement of nitrogenous bases in DNA does not relate to the restriction site for endonucleases which necessitated the elaboration of alternative typing methods for alleles at the *CSN2* locus. One of the most common methods is ACRS-PCR (Artificially Created Restriction Site), using TaqI and DdeI as restriction endonucleases (Lien *et al.*, 1992; McLachlan, 2006). The alternative elaborated variant was found in the methods of allele-specific PCR (AS-PCR), real-time probes for PCR, etc. (Manga *et al.*, 2010; Rahimi *et al.*, 2015; Giglioti *et al.*, 2021; Ristanic *et al.*, 2022). Sequencing is conducted in some cases, but regardless of its efficiency, at this stage, it is not always reasonable for routine large-scale population studies (Dai *et al.*, 2016). The genotyping of cattle by alleles A¹ and A² at the beta-casein locus is conducted in different regions of the world which demonstrates the increasing interest in this problem (Zepeda-Batista *et al.*, 2015; Vougiouklaki *et al.*, 2020; Ivankovi´c *et al.*, 2021). In recent years, the interest in genotyping cattle from different breeds has been noted in Ukraine, which is confirmed by a number of publications (Ladyka *et al.*, 2020; Ladyka *et al.*, 2021).

The availability of rather a large spectrum of different typing methods for beta-casein alleles leads to the need for a comparative analysis of their efficiency, which is especially relevant if similar methodological approaches are applied. Compared to other methods of differentiating beta-casein alleles, allele-specific PCR is one of the most promising technologies due to its low cost, speed, and accuracy (Pabitra *et al.*, 2022). However, this matter has a number of additional complications, related to the specificities of conducting the amplification and analysis of genotyping results, which, considering the promising nature of using AS-PCR as the main instrument in large-scale studies, substantiates the need for the analysis of different critical constituents of the method.

The analysis of a number of publications demonstrated that in many instances of using the AS-PCR method for typing of *CSN2* alleles, the issues of PCR protocol optimizations are ignored during routine analyses (Ramkaran *et al.*, 2017; Raja *et al.*, 2021; Adoligbe *et al.*, 2022). However, the analysis shows that there is rather a high risk of inaccurate genotyping which, first of all, is caused

Table 1. The methods, primer nucleotide structure, and melting temperature.

	IGBpF (A[2])	cttccctgggcccatccc	64.6	

by the simple replication of the methods, described in the scientific literature. First and foremost, it is related to the specificities of amplification programs for different AS-PCR methods (Gaudet *et al.*, 2009). Inaccurate genotyping may lead to a false interpretation of the obtained genetic structure parameters of the experimental groups of animals which distorts the results of the population studies completely. In addition, the genotyping of the cattle individuals is one of the demanded commercial services for the tasks of further selection and for the purpose of obtaining A2 milk, which is an additional indication of the need for maximization of the accuracy and reproducibility of the typing procedure (Park *et al.*, 2021).

Therefore, the aim of our studies is to conduct a comparative analysis of the efficiency of cattle genotyping by beta-casein gene using the methods of allele-specific PCR.

MATERIAL AND METHODS

The studies were conducted in the Laboratory of Molecular and Genetic Studies at the Department of Animal Biology, the National University of Life and Environmental Sciences of Ukraine. To study the efficiency of genotyping by *CSN2* locus, the cows of the Ukrainian Black-and-White dairy breed were used as a model object.

DNA was extracted using the commercial set of reagents "DNA-sorb-B" (Amplisense, RF) according to the manufacturer's recommendations. Hair follicles were used as a source of biological material.

The genotyping of cattle was conducted using the methods of AS-PCR (as the methods under investigation) and ACRS-PCR (as a control method of genotyping).

The primers, presented in Table 1, were used for the amplification of exon 7 of the *CSN2* gene.

The following amplification program was used for the ACRS-PCR method: 1 cycle – denaturation at 94°C; 35 cycles – denaturation at 94°C, 30 s, annealing at 60°C, 30 s, elongation – 72°C, 30 s. The size of restriction fragments was 121 bp for allele A[1]; 86 and 35 bp for allele A[2].

Tm Calculator (Thermo Fisher Scientific) based on Allawi & SantaLucia's thermodynamics method (Allawi & SantaLucia, 1997) was used to calculate the temperatures of annealing primers.

In both cases of applying the AS-PCR method, the amplification protocol was optimized according to the following schemes:

The variations of the annealing temperature of primers (from 55°C to 68°C with 1°C interval).

The number of intermediate steps of the second stage of PCR (from two to ten with one step interval).

The duration of the intermediate steps of the second stage of PCR (from 15 to 120 s with 15 s. interval).

Touchdown PCR protocol (Korbie & Mattick, 2008).

PCR was conducted using MiniAmp™ Thermal Cycler (Thermo Fisher Scientific) and the commercial reagent kit "DreamTaq PCR Master Mix" (Thermo Scientific). The volume of the final reaction mixture was 10 μl. The final concentration of primers in the reaction mixture was 0.2 μM.

The electrophoretic separation of the amplification/restriction products involved the use of 3% agarose gel for the ACRS-PCR method and 2% – while using the allele-specific PCR.

The visualization of DNA fragments in the gel was conducted using ethidium bromide in the ultraviolet spectrum (312 nm). The molecular mass marker GeneRuler 50 bp (Thermo Scientific) was used to determine the size of the amplified/restriction fragments.

The object of the study was the populations of cows of different breeds, reared in Ukraine: Ukrainian Red-and-White dairy breed (n=38), Ukrainian Black-and-White dairy breed (two populations from different farms and regions of Ukraine – n=31 and n=100, respectively), Charolais (n=29).

The results of the individual genotyping of the animals were used to estimate the main genetic structure parameters: the frequencies of genotypes and alleles, observed (H_o) and expected (H_e) heterozygosity, the Wright's fixation index (F_{is}), the correspondence to the Hardy-Weinberg genetic equilibrium by the method of χ^2. The estimation of genetic structure parameters was conducted using Popgen32 Version 1.32 (Yeh *et al.*, 2000).

RESULTS AND DISCUSSIONS

The use of standard amplification programs for AS-PCR, described in the scientific literature, allowed for differentiating between alleles A[1] and A[2] of the beta-casein locus of cattle. To conduct the comparative analysis of the efficiency of genotyping the cattle by the beta-casein locus for the purpose of the amplification of the experimental fragment of *CSN2*, only the animals, homozygous by allele A[2] (A[2]A[2]) were used, whose genotype had previously been determined using the ACRS-PCR (DdeI) method (McLachlan, 2006). The variation in the temperature regimes (PCR parameters) led to a considerable change in the genotyping results. Figure 1 presents the electrophoregram for the amplification products of

Figure 1. Different PCR protocols for the amplification of *CSN2* fragment using the primers of AS-PCR 244 bp.
1–11, numbers of the samples; 4, 8, molecular mass marker GeneRuler 50 bp; 1–3, annealing temperature for oligonucleotides, 58°C; 5–7, annealing temperature for oligonucleotides, 62°C; 9–10, Touchdown PCR.

Figure 2. The results of typing the cattle individuals by AS-PCR 244 bp method using the optimized amplification protocol.
1, A¹A¹; 2, 7, A²A²; 3, 5, 6, A¹A², 4, molecular mass marker Gene-Ruler 50 bp.

the fragment of the *CSN2* gene using the AS-PCR 244 bp.

In the case of genotype A¹A¹, the electrophoregram shows the DNA fragment of 244 bp only in the well, corresponding to allele A¹, for genotype A²A² – only in the well, corresponding to allele A²; as for the heterozygous genotype, the amplified fragments are found in both wells. The use of different amplification programs led to significant variations in PCR efficiency. In this case, a critical moment is the selection of optimal parameters for amplification protocols of the experimental fragments. This variation can be implemented into the general program both *via* temperature and the introduction of the intermediate cycles. In our studies, we have used a wide spectrum of annealing temperatures – from 58 to 69°C (with one-degree interval), the Touchdown PCR method, and two additional cycles for the second stage of PCR, one of which was optimized for the annealing temperature for the first (forward) primer, and the other – for the second (reverse) one. The theoretical analysis of the annealing temperatures demonstrated the differences of several degrees between the used primers (under 4°C). The study results were used to set optimal temperatures for both inner cycles.

Figure 1 shows the results of applying three different PCR protocols for the amplification of *CSN2* fragment using primers for AS-PCR 244 bp. All the samples in the presented electrophoregram are related to genotype A²A², but the results of typing differ considerably.

The decrease in the annealing temperature below the minimal theoretically estimated temperature for primers (Table 1) leads to the reduction in the specificity of the method – allele A¹ is amplified in the samples (samples 1, 2, 6, 7). The maximal decrease in the annealing temperature values practically leads to the coincidence in the staining intensity for the amplified fragments of alleles A¹ and A². In its turn, the use of the Touchdown PCR method results in the amplification of all the possible variants of alleles in each sample (samples 9–11), which is a reason for their false interpretation as heterozygous individuals A¹A².

The use of the optimal values of the annealing temperature and the number of cycles allowed for a maximal decrease in the concentration of "unused" primers (to increase the amplification efficiency to the maximum), in case of preserving the high specificity of the reaction and in case of complete absence of non-specific PCR products. In this case, two cycles with different annealing temperatures are used: 67°C – 10 cycles; 65°C – 25 cycles. The final optimal protocol, which ensured the successful genotyping of the cattle, is as follows: 1 cycle – denaturation at 94°C for 5 min; 10 cycles – denaturation at 94°C for 30 s, annealing at 67°C for 30 s,

elongation at 72°C for 30 s; 25 cycles – denaturation at 94°C for 30 s, annealing at 65°C for 30 s, elongation at 72°C for 30 s.

However, even in the case of optimal parameters, some samples may still have the fragment, remarkable for the second allele, which may be explained by a close value of the annealing temperatures for allele-specific primers (IGBhF A¹ and IGBpF A²), as well as a number of additional potential factors – the differences in the values of the initial concentration of the DNA under analysis, the type of the used enzyme (different modified forms of Taq-polymerase), the concentrations of primers, etc. In this case, we used the primers in the concentration of 0.2 µM, which allowed obtaining the maximally vivid and unambiguous picture in each case of genotyping the animals of *Bos taurus* by *CSN2* locus. In general, when the method of allele-specific PCR is used, there is still a possibility for the amplification of the non-specific allele in a sufficiently wide range. If the luminosity intensity is insufficient regarding the second fragment, one can make a conclusion about the amplification of the non-specific allele (Fig. 1, samples 2 and 7). In the ideal system (under maximally possible amplification efficiency), the luminosity intensity of different fragments (A¹ and A²) in the case of heterozygous samples will be the same, as both variants are present in the initial DNA in the equivalent number. In case of the insufficient luminosity of one of the specific fragments, two assumptions are possible: either the phenomenon of non-specific amplification or the presence of inhibitors in a specific sample. Then the algorithm of targeted testing of "problematic" samples should be applied based on the alternative method (ACRS-PCR), which is actually ignored by different researchers. In addition to the above, it is reasonable to have regular "blind testing" of the samples using the alternative method (ACRS-PCR).

Regardless of the present difficulties, the application of the optimized (described above) PCR protocol ensured the successful genotyping for the animals of *Bos taurus* by alleles A¹ and A² (Fig. 2).

The results of the typing were entirely confirmed by the ACRS-PCR method (DdeI), the coincidence of geno-types, found by both methods, was 100%.

The application of the described methodological approaches allowed for obtaining similar results while using the AS-PCR 854 bp method as well. In this case, the optimal results, which ensure unambiguous identification of *CSN2* alleles, were also obtained using the two-stage PCR algorithm. The values of the annealing temperature for primers were considerably different from the ones, presented in other scientific works (Keating *et al.*, 2008; Rahimi *et al.*, 2015).

The best result was obtained using the following amplification program – the use of two cycles on the second stage

Table 2. The genetic structure parameters of different cattle populations.

Breed	Genotype frequency			Allele frequency		H_e	F_{is}	χ^2 test
	A^1A^1	A^1A^2	A^2A^2	A^1	A^2			
RW	0.13	0.61	0.26	0.43	0.57	0.49	−0.24	2.06
BW (pop 1)	0.42	0.48	0.1	0.66	0.34	0.45	−0.07	0.201
BW (pop 2)	0.12	0.49	0.39	0.37	0.63	0.47	−0.04	0.34
Charolais	0	0.17	0.83	0.09	0.91	0.16	−0.06	0.24

RW, Ukrainian Red-and-White dairy breed; BW (pop 1), Ukrainian Black-and-White dairy breed (Population 1); BW (pop 2), Ukrainian Black-and-White dairy breed (Population 2); He, expected heterozygosity; Fis, Wright's fixation index

of PCR with different annealing temperatures: 66°C − 10 cycles; 64°C − 25 cycles (Fig. 3). The final optimal protocol, which ensured the successful genotyping of the cattle, is as follows: 1 cycle – denaturation at 94°C for 5 min; 10 cycles – denaturation at 94°C for 30 s, annealing at 66°C for 30 s, elongation at 72°C for 30 s; 25 cycles – denaturation at 94°C for 30 s, annealing at 64°C for 30 s, elongation at 72°C for 30 s. The amplification was conducted without the final elongation stage (stage 3). The obtained results of typing are completely confirmed by the ACRS-PCR (DdeI) method and are in complete correlation with the results of using AS-PCR 244 bp. The coincidence of genotypes between all the used methods of typing was 100 %.

Therefore, the study results directly demonstrate the need for a thorough selection of amplification parameters while using the allele-specific PCR for the genotyping of cattle by beta-casein locus. The identity of the typing results for two different primer systems for AS-PCR demonstrates the commonality of the methodological approaches in solving the task of enhancing the specificity, reproducibility, and efficiency of amplifying alleles A^1 and A^2. The obtained results can be used for large-scale routine genotyping of individuals of different cattle breeds by allelic variants of the beta-casein gene.

The above-mentioned methodological approaches were used to determine the genetic structure parameters of the cattle population of different breeds, reared in Ukraine (Table 2).

The study results demonstrated that the beta-casein locus is related to polymorphous ones in all the experimental populations. The animals with all the possible genotypes were found in each experimental population except for Charolais.

The maximal value for allele A^2 frequency was found in the Charolais population, which may be determined by the fact of its origin. Charolais are meat cattle, so, taking into consideration the descent of allele A^1 from the European dairy cattle breeds, the minimal number of heterozygotes A^1A^2 in the population (5 out of 29) is absolutely reasonable. Homozygotes A^1A^1 are entirely absent in this population.

The analysis of the genetic structure of the populations of dairy cows shows the following picture: two populations of Ukrainian Black-and-White breed from different farms demonstrate significant differences regarding the values of allele frequencies. For instance, in population 2 there is a prevalence of allele A^2 frequency, while in population 1, the situation is diametrically opposite – there is a significant prevalence of allele A^1 frequency (practically two-fold). At the same time, the values of the observed (H_o) and expected (H_e) heterozygosity in both populations are very similar. The obtained study results allow for the assumption that the observed picture is related to the specificities of the selection work with this breed at each farm and to the degree of "Holsteinization", used in breeding to enhance the parameters of dairy performance of cattle. The study results confirm the data for the distribution of allelic frequencies obtained in the analysis of the Holsteinized Black-and-White cattle, reared in Latvia (Smiltina et al., 2018). This assumption is also indirectly confirmed by the actual presence of allele A^1 (with different frequency) in the populations of Holstein cattle in different regions of the world (Yamada et al., 2021; Ivankovi´c et al., 2021; Bisutti et al., 2022).

In its turn, the insignificant domination of allele A^2 frequency was noted for the population of the Ukrainian Red-and-White breed, with the two-fold prevalence of the number of homozygotes A^2A^2 over A^1A^1. The excess of heterozygous animals was also noted in this population of cows (24%). The data about the distribution of allelic frequencies in the populations of Black-and-White and Red-and-White dairy breeds are confirmed by the results of other authors obtained for these breeds in other countries (Ehrmann et al., 1997; Kamiński et al., 2006).

It should be noted that no deviation from the Hardy-Weinberg genetic equilibrium was found in any cattle population under study.

CONCLUSIONS

The application of the above-described methodological approaches to the optimization of PCR methods allows for efficient genotyping of the animals (A^1 and A^2 allele detection) on the background of current advantages of AS-PCR before the alternative variants – low material-technical and time expenditures under completely comparable efficiency.

To achieve the maximal efficiency of the amplification, it is recommended to use the modified PCR protocol, including the two-step second stage with the following values of the annealing temperatures for primers: for AS-PCR 244 bp – 67°C (10 cycles) and 65°C (25 cycles); for AS-PCR 854 bp – 66°C (10 cycles) and 64°C (25 cycles).

Figure 3. The results of typing the cattle individuals by AS-PCR 854 bp method using the optimized amplification protocol.
1, A^2A^2, 2, 4, A^1A^2, 5, A^1A^1, 3, molecular mass marker GeneRuler 50 bp.

The use of the touchdown PCR method as the instrument for optimization of AS-PCR protocols is not efficient for the primer systems under investigation and leads to genotyping mistakes.

To control the specificity of the amplification of the experimental *CSN2* gene fragment, it is recommended to use the alternative method (ACRS-PCR) via both so-called analyses of "problematic samples" and blind typing from the sampling frame.

Upregulation of miR-22 alleviates oxygen–glucose deprivation/reperfusion-induced injury by targeting Tiam1 in SH-SY5Y cells

Jiansong Yin#, Yu Wan#, Jing Wang and Mei Xue✉

Department of Neonatology, The Affiliated Changzhou No.2 People's Hospital of Nanjing Medical University, Changzhou 213200, Jiangsu, China

MicroRNA-22 (miR-22) has been reported to exert a neuroprotective effect. However, the specific role and mechanism of miR-22 in ischemia/reperfusion (I/R)-induced brain injury are still not known well. In this study, we evaluated whether miR-22 participates in I/R-induced neuronal injury and the potential mechanism by using an oxygen-glucose deprivation/reperfusion (OGD/R) model *in vitro*. Our results showed that miR-22 was significantly down-regulated in SH-SY5Y cells suffering from OGD/R. Up-regulation of miR-22 by its specific mimic could protect SH-SY5Y cells against OGD/R-induced injury. The luciferase reporter assay demonstrated that T-cell lymphoma invasion and metastasis 1 (Tiam1) was a direct target of miR-22. MiR-22 mimic obviously inhibited Tiam1 expression in OGD/R-exposed SH-SY5Y cells. Tiam1 siRNA could attenuate OGD/R-induced SH-SY5Y cell injury. In addition, Tiam1 siRNA reduced the activation of Ras-related C3 botulinum toxin substrate 1 (Rac1) in OGD/R-exposed SH-SY5Y cells, and up-regulation of Rac1 activity could attenuate the neuroprotective effect of miR-22 up-regulation. Furthermore, OGD/R exposure led to increased methylation of miR-22, and the demethylating agent 5-Aza-dC significantly up-regulated miR-22 expression and inhibited Tiam1 expression and Rac1 activation. Taken together, our results demonstrated that DNA methylation-mediated miR-22 down-regulation aggravated I/R-induced neuron injury by promoting the activation of Tiam1/Rac1 signals. Our findings provide a deeper understanding of I/R-induced brain injury and suggest that miR-22 may be a promising therapeutic target for this disease.

Keywords: miR-22, Tiam1, Rac1, neuronal injury

INTRODUCTION

Neuron dysfunction and/or death serves a pivotal function in the development and progression of brain-related diseases, such as Parkinson's disease, ischemic stroke and neonatal ischemic hypoxic brain damage (HIBD), which is caused by oxygen deprivation in the infant's brain (Khoshnam *et al.*, 2017; Koehn *et al.*, 2020; Liu *et al.*, 2020a; Salamon *et al.*, 2020). The neuronal cell was susceptible to injury or death by various pathophysiological factors (Khoshnam *et al.*, 2017; Koehn *et al.*, 2020; Liu *et al.*, 2020a; Salamon *et al.*, 2020). Ischemia is characterized by an insufficient oxygen supply and serves as the main cause of the aggravation of cerebral injury. The treatment for cerebral ischemia usually involves the restoration of blood flow as quickly as possible. However, this can entail secondary injury to the ischemic area, referred to as 'ischemia/reperfusion' (I/R) injury (Ryou and Mallet, 2018). However, the molecular mechanisms underlying I/R-induced neuronal injury are not entirely clear.

It is demonstrated that miRNAs played an important role in I/R-induced injury in various tissues, including brain tissue (Cai *et al.*, 2021; Duan *et al.*, 2019; Kuai *et al.*, 2021; Liu *et al.*, 2020b). Previous studies have reported that miR-22 played a protective role in myocardial injury (Du *et al.*, 2016; Zhang *et al.*, 2019). Up-regulation of miR-22 was shown to protect the cerebra against I/R injury (Wang *et al.*, 2020). A recent study discovered that mesenchymal stem cells-derived exosomes (MSC-exos) alleviated I/R-induced brain injury by transferring miR-22 to neurons (Zhang *et al.*, 2021b). Jiao *et al* reported that enhanced miR-22 expression reversed I/R-induced apoptosis in PC12 cells (Jiao *et al.*, 2020). These findings indicated that miR-22 might provide a potential neuroprotective effect. However, the neuroprotective mechanism of miR-22 in I/R-induced injury is far from fully elucidated.

Ras-related C3 botulinum toxin substrate 1 (Rac1), a Rho-related small GTPase, is ubiquitously expressed throughout the brain (Stankiewicz and Linseman, 2014). Rac1 has been implicated in oxygen-glucose deprivation (OGD)/reoxygenation (OGD/R)-induced pathways responsible for neuronal injury, neuronal degeneration, and cognitive dysfunction (Chen *et al.*, 2020; Li *et al.*, 2021). The precise spatial and temporal regulation of Rac1 activation depends on its upstream regulators, the guanine nucleotide exchange factors (GEFs) (Marei and Malliri, 2017). T-cell lymphoma invasion and metastasis 1 (Tiam1) is a Rac1-specific GEF, which is stimulated by N-methyl-D-aspartate (NMDA) receptor (NMDAR) activation in a Ca²⁺-dependent manner (Tolias *et al.*, 2005). Previous studies demonstrated that Tiam1-mediated Rac1 activation in hippocampal and cortical neurons mediates differential spine shrinkage in response to OGD (Blanco-Suarez *et al.*, 2014). However, whether Tiam1-mediated Rac1 activation is involved in OGD/R-induced neuronal injury remains unknown. Tiam1 was demonstrated to be a target gene of miR-22 in various cells (Li *et al.*, 2013; Li *et al.*, 2012) and endometrial Tiam1/Rac1 signal was shown to be negatively regulated by miR-22

(Ma *et al.*, 2015). Therefore, it is worthwhile to explore whether Tiam1/Rac1 signal is involved in protective effect of miR-22 against I/R-induced neuronal injury.

In vitro OGD/R is a widely accepted experimental model of *in vivo* I/R-induced neuronal injury (Zhang *et al.*, 2021a). In this study, we investigated the effect of miR-22 on I/R-induced neuronal injury and its mechanism by using an OGD/R model in SH-SY5Y cells. Our results showed that miR-22 was down-regulated in SH-SY5Y cells. Enforced miR-22 expression could inhibit Tiam1 expression and suppress Rac1 activation, thus contributing to SH-SY5Y cell protection against I/R-induced injury. Furthermore, we also found that methylation of the miR-22 gene promoter suppressed its expression in OGD/R-exposed SH-SY5Y cells.

MATERIALS AND METHODS

Cell culture and OGD/R induction

The SH-SY5Y human neuroblastoma cell line was purchased from Zhong Qiao Xin Zhou Biotechnology Co., Ltd (Shanghai, China). Cells were grown in MEM/F12 (1:1 mixture) supplemented with supplemented with 10% heat inactivated fetal bovine serum, 1% sodium pyruvate, 1% L-alanyl-L-glutamine, and 1% penicillin/streptomycin at 37°C in a humidified atmosphere with 5% CO_2. For neuronal differentiation, SH-SY5Y cells were cultured for 3 days in MEM/F12 medium containing 10 μM retinoic acid and 1% FBS, followed by culturing for a further 3 days with 50 ng/mL brain-derived neurotrophic factor and 2 mmol/L glutamine in MEM/F12 medium containing 1% FBS. For OGD/R induction, SH-SY5Y cells were cultured in glucose-free MEM/F12 under the conditions of 95% N_2, 5% CO_2 and 37°C for 4 h. Thereafter, the cells were then cultured in normal DMEM for 24 h of reoxygenation under normoxic condition. SH-SY5Y cells cultured in DMEM containing glucose under normoxic condition served as a control.

Cell transfection

The miR-22 mimic and its negative control, Tiam1 siRNA and control siRNA were purchased from Genepharma (Shanghai, China) and transfected into SH-SY5Y cells using lipofectamine 2000 (Invitrogen) according to the manufacturer's manual. The expression of target genes was determined after 24 h of transfection and cells were used in further experiments. Sequences of the miR-22 mimic, and its negative control (NC) were as follows: miR-22 sense, 5'-AAGCUGCCAGUUGAAGAACUGU-3' and antisense, 5'-AGUUCUUCAACUGGCAGCUUUU-3'; and NC sense, 5'-UUCUCCGAACGUGUCACGUTT-3' and antisense, 5'-ACGUGACACGUUCGGAGAATT-3'.Sequences of Tiam1 siRNA were as follows: GGCGAGCUUUAAGAAGAAATT (sense) and UUUCUUCUUAAAGCUCGCCGT (antisense). Scrambled siRNA was used as a negative control in all experiments.

CCK-8 assay

The cell viability of SH-SY5Y cells was measured by CCK-8 assay. SH-SY5Y cells were seeded into 96-well plates (5×10³/well) and treated as described in the text. At the end of treatment, CCK-8 solution (10 μL/well, Chemicon, Temecula, CA, USA) was added to the cultured cells for 2 h incubation at 37°C. The absorbance (OD) at 450 nm was measured using an ELx-800 microplate reader (Bio-TekInc., Winooski, VT, USA).

Hoechst staining

SH-SY5Y cells were seeded onto coverslips in 6-well plates (5×10³/well) and treated as described in the text. At the end of treatment, cells were fixed with 4% paraformaldehyde for 30 min, then stained with Hoechst 33258 (5 μg/mL) for 20 min at room temperature. After washing with PBS, the cells were observed and photographed under a fluorescence microscope.

Luciferase reporter assay

The wild-type Tiam1 3'-UTR and mutant-type Tiam1 3'-UTR were cloned into the pGL3 basic luciferase reporter vector (Promega, Madison, WI, USA). SH-SY5Y cells were transfected in 24-well plates with miR-22 agomir and WT Tiam1 3'-UTR or miR-22 agomir and Mut Tiam1 3'-UTR respectively using Lipofectamine 2000 (Invitrogen) according to the manufacturer's protocol. After 48 h of transfection, the cells were harvested, and the luciferase activity was measured using a Dual-Luciferase Reporter Gene Assay kit (Promega). Renilla luciferase activity was used to normalize the firefly luciferase intensity.

Western blot

At the end of treatment, total proteins were extracted from SH-SY5Y cells using RIPA lysis buffer (Beyotime Biotechnology, Shanghai, China). Proteins were separated by SDS-PAGE and transferred onto polyvinylidene fluoride (PVDF) membranes (Millipore, USA). After blocking with 5% milk for 1 h at room temperature, the membranes were incubated overnight at 4°C with primary antibodies specific to Tiam1, Rac1, Bcl-2, Bax, Bad and GAPDH (all 1:1000; Cell Signaling Technology, Danvers, MA, USA). The membranes were then incubated with secondary antibodies (1:2000, anti-rabbit; 1:5000, anti-mouse) at room temperature for 1 h. The blots were visualized with an enhanced chemiluminescence kit (Pierce; Thermo Fisher Scientific, Inc.). Image J software was used to analyze the band density.

Pull-Down Assay

Pull-down assay was used to detect Rac1 activity and performed as described previously (Stahle *et al.*, 2003). Briefly, after treatments, equal volumes of total cellular protein were incubated with GST-PBD beads captured on MagneGST glutathione particles (Promega, Madison, WI) for 1h at 4°C. The particles were then resuspended in SDS and subjected to immunoblotting analysis by using an anti-Rac1 antibody.

Lactate dehydrogenase (LDH) activity detection

At the end of treatment, the supernatants of SH-SY5Y cells were collected and the contents of LDH were measured by an LDH detection kit (Nanjing Jiancheng Bioengineering Institute, Jiangsu, China) according to the manufacturer's manual. Absorbance values were read at 450 nm using an ELx-800 microplate reader (Bio-TekInc., Winooski, VT, USA).

RT-qPCR

Total RNA was extracted from SH-SY5Y cells using RNAeasy™ Small RNA Isolation Kit (Beyotime,

Shanghai, China) according to the manufacturer's manual. cDNAs were synthesized using the OneStep PrimeScript miRNA cDNA Synthesis Kit (Takara Biotechnology, Dalian, China). Quantitative real-time PCR was performed with an ABI 7300 system (Applied Biosystems, USA) using BeyoFast™ SYBR Green qPCR Mix (Beyotime). The relative gene expression level of miR-22 was normalized to U6 and calculated using the $2^{-\Delta\Delta Ct}$ method. Primers used for RT-qPCR were listed as follows: U6 small nuclear RNA was used as internal reference, with upstream: 5'-GGAACAGAGAAGATTA GC-3', and downstream: 5'-TTGGAATCACGAATTCCG-3'.miR-22 upstream: 5'-TGACAACCGTTTTTGACTG-3' and downstream: 5'-TACTGTTTTGAAAATCGTT-3'.

Methylation specific PCR (MSP)

The genomic DNA was extracted and purified by the Genomic DNA Extraction Kit (TaKaRa, Dalian, China). Bisulfite treatment and conversion of DNA for methylation analysis were performed using the EZ-96 DNA Methylation Kit (Zymo Research, Irvine, CA, USA). The PCR reaction conditions were as follows: 98°C for 4 min, 40 cycles of 98°C for 30 s, 56°C for 30 s, and 72°C for 30 s, and then 72°C for 10 min. The PCR products were electrophoresed in 3% agarose gel.

Statistical analysis

SPSS 16.0 statistics software (SPSS, Chicago, IL) was used for statistical analysis. The data were presented as the mean ± standard deviation (S.D.). Significant differences were determined using One-way ANOVA. $P<0.05$ was considered statistically significant.

RESULTS

OGD/R down-regulated miR-22 expression, up-regulated Tiam1 expression and Rac1 activation in SH-SY5Y cells

As shown in Fig. 1A, the expression level of miR-22 was decreased time-dependently in SH-SY5Y cells after OGD/R treatment. The results of the western blot assay revealed that the expression level of Tiam1 was significantly increased after treatment for 12 h or 24 h with OGD/R (Fig. 1B). The activity of Rac1 was obviously increased, while the total Rac1 expression remained unchanged during OGD/R treatment (Fig. 1B).

Figure 1. The effects of OGD/R exposure on the activation of Rac1 and the expression levels of miR-22 and Tiam1 in SH-SY5Y cells.
SH-SY5Y cells were exposed to OGD/R for the indicated times, and then the expression level of miR-22 was detected by qRT-PCR (**A**), the expression levels of Tiam1 and Rac1 were measured by western blot, Rac1 activation (Rac1-GTP) was determined by pull-down assay and analyzed by western blot (**B**). **$P<0.01$ compared with 0 h group.

Up-regulation of miR-22 protected SH-SY5Y cells against OGD/R-induced injury

To elucidate the effect of miR-22 down-regulation on OGD/R-induced neuronal injury, SH-SY5Y cells were transfected with miR-22 mimic, which obviously up-regulated the expression level of miR-22 in OGD/R-exposed SH-SY5Y cells (Fig. 2A). CCK-8 assay showed that miR-22 mimic notably elevated the viability of SH-SY5Y cells under OGD/R condition (Fig. 2B). Hoechst staining showed that miR-22 mimic significantly reduced the number of apoptotic cells in OGD/R-exposed SH-SY5Y cells (Fig. 2C). In addition, OGD/R treatment significantly increased the expression levels of Bax and cleaved caspase-3, and reduced the expression level of Bcl-2 in SH-SY5Y cells (Fig. 2D). However, the expression levels of these proteins were notably reversed after treatment with miR-22 mimic in OGD/R-exposed SH-SY5Y cells (Fig. 2D). Furthermore, miR-22 mimic markedly reduced the content of LDH from OGD/R-exposed SH-SY5Y cells (Fig. 2E). These data indicated that up-regulation of miR-22 protected SH-SY5Y cells against OGD/R-induced injury.

MiR-22 alleviated OGD/R-induced injury by directly targeting Tiam1 in SH-SY5Y cells

To investigate the protective mechanism of miR-22, we analyzed its potential targets using TargetScan and

Figure 4. The effect of Rac1 V12 over-expression on the protective effect of miR-22 over-expression during OGD/R-induced injury.
(**A**) Rac1 activation was measured by pull-down assay in SH-SY5Y cells with negative control siRNA (si-NC) or Tiam1 siRNA (si-Tiam1) transfection under normal (control) or OGD/R conditions. (**B**) Rac1 activation was measured by pull down assay in SH-SY5Y cells with negative control mimic (mi-NC) or miR-22 mimic (miR-22) transfection under normal (control) or OGD/R conditions. (**C–E**) After transfection of empty plasmid (vector) or the plasmid containing constitutively active form of Rac1 (Rac1-V12) in mi-NC or miR-22 overexpressed SH-SY5Y cells, cell viability, the levels of apoptosis-related proteins and LDH release were determined by CCK-8 assay (C), western blot (D) and ELISA assay (E), respectively. $**P<0.01$ compared with control + si-NC group; $##P<0.01$ compared with OGD/R + si-NC group; $\&\&P<0.01$ compared with control + mi-NC group; $@@P<0.01$ compared with OGD/R + mi-NC group; ▲▲$P<0.01$ compared with vector + mi-NC group; ▼▼$P<0.01$ compared with vector + mi-22 group.

miRDB. Tiam1 was selected for further study as it was predicted to be a potential target of miR-22 by using the two software and was demonstrated to be involved in the regulation of hippocampal neuronal vulnerability to OGD/R (Blanco-Suarez *et al.*, 2014). The possible binding sites between miR-22 and Tiam1 were presented in Fig. 3A. Luciferase reporter assay illustrated that miR-22 mimic notably inhibited the luciferase activity of Tiam1 harboring wild type (WT) 3′UTR, but it had no effect on the luciferase activity of Tiam1 with a mutant type (Mut) 3′UTR (Fig. 3B). Moreover, OGD/R treatment led to a significant increased expression level of Tiam1, which was reversed by the miR-22 mimic (Fig. 3C). These data suggest that Tiam1 is a direct target of miR-22 under the OGD/R condition.

To examine whether Tiam1 is involved in the protective effect of miR-22, SH-SY5Y cells were transfected with Tiam1 siRNA, which markedly inhibited Tiam1 expression in OGD/R-exposed SH-SY5Y cells (Fig. 3D). OGD/R-induced up-regulation of Bax and cleaved caspase-3, and down-regulation of Bcl-2 were reversed by Tiam1 siRNA in SH-SY5Y cells (Fig. 3D). Tiam1 siRNA obviously increased the viability of SH-SY5Y cells under OGD/R condition (Fig. 3E). Tiam1 siRNA also significantly inhibited LDH release in OGD/R-exposed SH-SY5Y cells (Fig. 3F). The above data indicated that miR-

22 alleviated OGD/R-induced injury by directly targeting Tiam1 in SH-SY5Y cells.

Rac1 activation reversed the protective effect of miR-22 up-regulation on OGD/R-induced injury in SH-SY5Y cells

As Tiam1 is a specific guanine nucleotide-exchange factor (GEF) of Rac1, the involvement of Rac1 in the protective mechanism of miR-22 was then investigated. As shown in Fig. 4A, Tiam1 siRNA significantly inhibited OGD/R-induced Rac1 activation in SH-SY5Y cells. OGD/R-induced Rac1 activation was also inhibited by miR-22 mimic (Fig. 4B). MiR-22 overexpression significantly elevated cell viability, inhibited LDH release, Bax and cleaved caspase-3 expression, and up-regulates Bcl-2 expression in OGD/R-exposed SH-SY5Y cells (Fig. 4C-4E). However, these parameters were reversed by transfection of Rac1-V12, an active mutant of Rac1 (Fig. 4C-4E). These results suggested that Rac1 activation reversed the protective effect of miR-22 up-regulation on OGD/R-induced injury in SH-SY5Y cells.

Methylation of the miR-22 gene promoter suppressed its expression in SH-SY5Y cells under OGD/R condition

To investigate the underlying mechanism of miR-22 down-regulation in SH-SY5Y cells after OGD/R expo-

Figure 5. Methylation of the miR-22 gene promoter inhibited miR-22 expression under OGD/R condition.
(**A**) The methylation level of miR-22 in OGD/R-exposed SH-SY5Y cells with or without 5-Aza-dC (5AdC) treatment was analyzed by MSP analysis. (**B**) The expression level of miR-22 in OGD/R-exposed SH-SY5Y cells with or without 5-Aza-dC (5AdC) treatment was examined by RT-qPCR. (**C**) The level of Tiam1 expression and Rac1 activation in OGD/R-exposed SH-SY5Y cells with or without 5-Aza-dC (5AdC) treatment were determined by western blot and pull down assay, respectively. **$P<0.01$ compared with control group; ##$P<0.01$ compared with OGD/R group.

Figure 6. Schematic illustration of OGD/R-induced SH-SY5Y cell injury *via* the miR-22/Tiam1/Rac1 signaling pathway.

sure, the methylation level of the miR-22 gene promoter was measured. As shown in Fig. 5A, OGD/R exposure led to increased methylation of miR-22, which was reversed by treatment with 5-Aza-dC, a demethylating agent. 5-Aza-dC treatment also obviously up-regulated the level of miR-22 in OGD/R-exposed SH-SY5Y cells (Fig. 5B). Moreover, the increased Tiam1 expression and Rac1 activation in OGD/R-exposed SH-SY5Y cells were significantly inhibited by 5-Aza-dC treatment (Fig. 5C). These results suggested that methylation of the miR-22 gene promoter suppressed its expression in SH-SY5Y cells under OGD/R condition.

DISCUSSION

MicroRNAs have been demonstrated to work as critical factors in various brain injuries (Song *et al.*, 2019; Suofu *et al.*, 2020; Zhao *et al.*, 2020). Previous studies have indicated that up-regulation of miR-22 could protect neuron against I/R-induced injury (Wang *et al.*, 2020). Recently, MSC-exos-derived miR-22 was shown to attenuate I/R-induced brain (Zhang *et al.*, 2021b). However, the specific mechanism of miR-22 in I/R-induced neuronal injury is far from clear nowadays. In this study, we constructed an OGD/R model of SH-SY5Y cells and found that the level of miR-22 was decreased. Up-regulation of miR-22 could protect SH-SY5Y cells against OGD/R-induced injury. Our results suggest that miR-22 plays a protective role in OGD/R-induced neuronal injury.

The potential neuroprotective mechanism of miR-22 was then explored by searching for its target gene with targetscan and miRDB. Our results showed that the expression of Tiam1 was negatively correlated with miR-22 and was a potential target of miR-22. Tiam1 was demonstrated to be the target of miR-22 in several types of cells, such as NK/T cells, colon cancer cells and ovarian cancer cells (Huang *et al.*, 2016; Li *et al.*, 2013; Li *et al.*,

2012). In the present study, luciferase report assay and western blot assay indicated that Tiam1 is a direct target of miR-22 in OGD/R-exposed SH-SY5Y cells. Furthermore, Tiam1 siRNA could obviously attenuate OGD/R-evoked injury in SH-SY5Y cells. These results suggested that miR-22 overexpression alleviated OGD/R-induced injury by directly targeting Tiam1 in SH-SY5Y cells. MiR-22 was shown to exert its neuroprotective function by regulating PI3K/AKT signaling pathway in cerebral I/R rats (Wang *et al.*, 2020). Jiao *et al.* (Jiao *et al.*, 2020) reported that miR-22 protects PC12 cells from OGD/R-evoked injury by targeting the p53 upregulated modulator of apoptosis (PUMA). Recently, it is demonstrated that MSC-exos-derived miR-22 attenuated OGD/R-evoked injury by inhibiting KDM6B expression in rat primary cortical neurons (Zhang *et al.*, 2021b). These findings, together with our results, indicated that miR-22 exerts neuroprotective effects by different downstream targets, which depend on cell type. It will be interesting to determine whether the reported targets of miR-22 are involved in our system and their crosstalk with Tiam1.

Tiam1 is known best as a specific GEF for Rac1 activation (Chapelle *et al.*, 2020; Kurdi *et al.*, 2016; Yue *et al.*, 2021). Previous studies showed that Tiam1 mediates an OGD-induced increase in Rac1 activity in hippocampal neurons (Blanco-Suarez *et al.*, 2014; Smith *et al.*, 2017). Furthermore, Rac1 activation was demonstrated to play an important role in I/R-induced injury in different tissues, including brain tissue (Chen *et al.*, 2020; Li *et al.*, 2017; Liang *et al.*, 2018; Liu *et al.*, 2019; Su *et al.*, 2019). Therefore, we speculated that miR-22 exerts its neuroprotective function by inhibiting Tiam1-mdiated Rac1 activation. Our results showed that Rac1 activity was obviously increased in OGD/R-exposed SH-SY5Y cells. Tiam1 siRNA and miR-22 angomir could markedly inhibit OGD/R-induced Rac1 activation. Moreover, Rac1-V12, an active mutant of Rac1, could significantly attenuate the inhibitory effect of miR-22 up-regulation on OGD/R-evoked injury. These data indicated that miR-22 exerts its neuroprotective function on OGD/R-evoked injury by inhibiting Tiam1-mdiated Rac1 activation in SH-SY5Y cells.

The key factors that reduced miR-22 expression in our system were then investigated. It is demonstrated that the CpG island methylation in promoter regions is key to miRNAs expression (Chhabra, 2015; Glaich *et al.*,

2019). Moreover, DNA-methylation was shown to play an important role in I/R-induced brain jury (Deng *et al.*, 2019; Jin *et al.*, 2021; Tang and Zhuang, 2019; Zeng *et al.*, 2020). Thus, we investigated whether the decreased miR-22 expression in OGD/R-exposed SH-SY5Y cells is due to DNA-methylation in its promoter. Our results showed that the methylation level of the CpG island in the miR-22 promoter was significantly increased after OGD/R exposure. 5-Aza-dC treatment could obviously up-regulated miR-22 expression in OGD/R-exposed SH-SY5Y cells. Furthermore, Tiam1 expression and Rac1 activity were significantly inhibited by 5-Aza-dC treatment in OGD/R-exposed SH-SY5Y cells. These results suggested that DNA-methylation in OGD/R-exposed SH-SY5Y cells led to a decreased miR-22 expression and increased Tiam1 expression and Rac1 activation, thereby promoting neuronal injury.

In conclusion, our study demonstrated that DNA-methylation of miR-22 causes miR-22 down-regulation, which results in Tiam1 up-regulation and Rac1 activation in OGD/R-exposed SH-SY5Y cells, therefore leading to cell injury (Fig. 6). MiR-22 up-regulation plays a neuroprotective role in OGD/R-exposed SH-SY5Y cells, which is partly via directly targeting Tiam1 to inhibit Rac1 activation. Although additional *in vivo* studies are needed to verify our findings, our study provides a new insight into the protective effects of miR-22 against I/R-induced brain injury and warrants further study of DNA methylation-mediated silencing of miR-22 may serve as a potential therapeutic strategy for I/R-induced brain injury.

Circ-Sirt1 promotes osteoblast differentiation by activating Sirt1 and Wnt/β-catenin pathway

Yuanli Li[1], Junlan Nie[2], Qing Wu[1], Xin Yang[1] and Ping Jiang[1]✉

[1]Department of Orthopedics, Affiliated Hospital of North Sichuang Medical College, Sichuan, 637000, P. R. China; [2]Department of Operating Room, Affiliated Hospital of North Sichuang Medical College, Sichuan, 637000, P. R. China

Osteoporosis, a bone disease common in the elderly, results in bone loss and damage to bone microstructure. Sirtuin 1 (Sirt1), belongs to Sirtuin family, is involved in regulating bone quality. Circ-Sirt1 is one of the transcripts of Sirt1 host gene. Here, the involvement of circ-Sirt1 was determined in bone disease for the first time, proposing that circ-Sirt1 can activate the Wnt/β-catenin pathway to promote osteogenesis differentiation. This study was aimed to elucidate the potential function of Circ-Sirt1 and Sirt1 regulatory loop in the differentiation of bone marrow mesenchymal stem cells (BMSCs). The differentiation of bone marrow mesenchymal stem cells was detected by ALP, alizarin red staining and qPCR. The dual luciferase reporter assay was applied to reveal the interaction between RNAs. The result showed that Sirt1 promoted osteogenic differentiation of BMSCs. Circ-Sirt1, derived from Sirt1, acted as miR-132 and miR-212 sponge, and up-regulated the expression of Sirt1. Furthermore, Sirt1-mediated circ-Sirt1 promoted osteogenic differentiation. Finally, we unveiled that Circ-Sirt1 facilitates osteogenic differentiation by activating the Wnt/β-catenin pathway. In conclusion, our data suggested that Circ-Sirt1 elevates osteogenic differentiation *via* miR-132/212/Sirt1 and Wnt/β-catenin pathway.

INTRODUCTION

Osteoporosis is a systemic bone disease which has serious complications in elderly people especially elderly females. It is caused by functional disproportion between osteoblasts and osteoclasts (Liu *et al.*, 2020; Zhang *et al.*, 2020). Osteoblasts, responsible for bone formation, are not terminally differentiated. However, these osteoblasts can eventually differentiate into osteocytes through physiological activities such as proliferation, secretion of protein, and calcification (Chen *et al.*, 2019; Chu *et al.*, 2020). Inhibition of the growth and physiological activities of osteoblasts can cause numerous bone diseases, including osteoporosis, osteoarthritis, rheumatoid arthritis and osteogenesis imperfecta (Dadras *et al.*, 2020; Edwards *et al.*, 2013). Therefore, clarifying the regulatory mechanism of osteoblast differentiation and proliferation may pos-

sibly provide novel and effective treatment strategies for osteoporosis.

Sirt1 is a nicotinamide adenine dinucleotide (NAD+) dependent class 3 histone deacetylases which has been demonstrated as regulating lifespan in several model organisms (Koga *et al.*, 2015). Sirt1 plays an important role in the physiological activities of bone tissue. It has been revealed that Sirt1 regulates SOX2 to maintain the self-renewal and pluripotency of BMSCs (Yoon *et al.*, 2014). Whereas, another study reported that Sirt1 knockout mice shows a low bone mass phenotype, but the specific signaling pathway has not been elucidated (Feng *et al.*, 2016). Wnt is a type of secreted protein that is rich in cysteine. It is well known that Wnt/β-catenin signaling pathway affects the differentiation balance of BMSCs in bone tissue. Meanwhile, it is also established that Sirt1 is involved in TNF-α-stimulated osteogenic differentiation of human Dental pulp stem cells (DPSCs) through Wnt/β-catenin signal (Zainabadi *et al.*, 2017). As core target of cellular aging, energy metabolism and bone metabolism, Sirt1 is known to play significant role in the pathogenesis of osteoporosis. In this study, we sought to investigate the function and mechanism of Sirt1 in regulating BMSCs differentiation.

Recently, the role of non-coding RNA in osteoporosis has been gradually discovered. Circular RNA (CircRNA) is a new type of non-coding RNA that has regulatory abnormalities in a variety of cancers, frequently involving different carcinogenic processes (Lou *et al.*, 2020). CircRNA is a covalent closed loop structure formed by back-splicing of pre-mRNA without 5' and 3' ends (Salzman *et al.*, 2013).

With comparison of linear exosomes, the high stability of them is manifested *in vivo* with main existing in the cytoplasm and classification of exosomes (Li *et al.*, 2018) Previous studies have affirmed the typical modulation of homologous mRNAs via circRNAs as nuclear transcriptional regulators, platforms for RNA-binding proteins, or cytoplasmic microRNA sponges (Li *et al.*, 2015). Using the CircBase database, it was found that Sirt1 host gene may produce 11 circRNAs. However, the function and mechanism of circRNA derived from the Sirt1 host gene is still unclear in the bone related diseases, and the role of Circ-Sirt1 in the regulation of Wnt/β-catenin signaling pathway has not been fully explored.

In this study, it was found that Circ-Sirt1 derived from the Sirt1 gene promotes the expression of Sirt1 by competing with miR-132/212, and activates the Wnt/β-catenin signaling pathway to accelerate the differentiation of bone marrow mesenchymal stem cells. Therefore, Circ-Sirt1 may serve as a new biomarker and therapeutic target in bone related diseases.

MATERIAL AND METHODS

Cell culture and treatment

BMSCs (Riken Cell Bank, cell line RCB2154, Tsukuba, Japan) were cultured in α-MEM medium supplemented with 10% fetal bovine serum (FBS, Gibco, USA) and 100 U/ml penicillin, and 100 mg/ml streptomycin sulfate, under 5% CO_2 and 37°C. Ascorbic acid (50 mg/mL), dexamethasone (0.1 mg/mL) and sodium glycerophosphate (10 mM) (Sigma-Aldrich, St. Louis, MI) were applied in the culture medium to stimulate the differentiation of osteoblasts.

RNA extraction and qPCR detection

Total RNA was extracted from BMSCs using TRNzol reagent (TIANGEN Biotech, Beijing, China) according to the manufacturer's instructions. Reverse transcription kit (TIANGEN Biotech, Beijing, China) was applied to generate cDNA from total RNA. RNA concentration was determined by NanoDrop spectrophotometer (TIANGEN Biotech, Beijing, China). Real-time qPCR was conducted by using FastFire qPCR PreMix (TIANGEN Biotech, Beijing, China). Primer sequences used in this study were listed in Table 1.

ALP activity and ALP staining

To detect the osteogenic differentiation, BMSCs were cultured in osteogenic differentiation induction medium for 21 days. ALP activity was determined using an Alkaline Phosphatase Assay Kit (Beyotime, Beijing, China) by following the manufacturer's instructions.

Alizarin red staining

First, the osteogenic differentiation was induced in BMSCs for 21 days, which were then fixed the cells with 4% paraformaldehyde, and stained with 1% Alizarin Red S (Beyotime, Beijing, China) for 30 minutes. After

washing with PBS for 3 times, the cells were visualized, and images were captured under an inverted microscope (Olympus Corporation, Japan). The alizarin red staining was quantified using Image J.

Luciferase reporter assay

The 3'UTR of circ-Sirt1 or Sirt1 containing miR-132 or miR-212 binding sites was amplified by PCR, cloned into the pgl3 promoter vector of Xba I (circ-Sirt1 WT or Sirt1 WT), The mutant sequence was cloned into pgl3 promoter vector to construct circ-Sirt1 MUT or Sirt1 MUT. Twenty-four hours before transfection, cells were trypsinized ($2×10^5$ cells/mL) and then plated on 24-well plates. The above plasmids together with Renilla (pRLTK) plasmid, miR-132 mimics, miR-212 mimics, negative control (NC) mimics plasmids were transfected into cells using Lipofectamine 2000 (Invitrogen). After 6 h, the medium was replaced with serum-containing medium, and 48 h after transfection, cells were collected to detect dual-luciferase activity using dual-luciferase assay system (Promega, USA). The relative luciferase activity was calculated from the ratio of firefly to Renilla luciferase signals.

RNA pull down assay

The MagCapture™ RNA Pull Down Kit (whatman, England) was applied for RNA pull-down assay. In brief, BMSCs were washed with precooled PBS, and then incubated with beads and biotinylated miR-132/212 probes for 1 hour. Western blot analysis was used to detect proteins.

Western Blot

Total protein was extracted from BMSCs using RIPA buffer containing 1mM Phenylmethylsulfonyl fluoride (PMSF). BCA kit (Beyotime, Beijing, China) was applied to determine protein concentration. The protein was separated using SDS-PAGE (10% or 12%), and then transferred to PVDF membrane (Millipore, Danvers, MA, USA), and then incubated with primary antibodies Sirt1 (1:1000; ab110304; Abcam), β-catenin (1:1000; ab32572; Abcam), Lamib B1 (1:1000; ab16048; Abcam), β-Tubulin (1:1000; ab6046; Abcam) at 4°C overnight. Later, membranes were washed, and incubated with respective secondary antibodies HRP (anti-rabbit IgG, 1:5000, Cell Signaling Technology, Inc., MA, USA). Finally, the membranes were exposed using ECL system (Beyotime, Beijing, China), and protein bands were analyzed using Quantity One software.

Statistical analyses

Data were analyzed with Graphpad Prism 8 software and expressed as mean ± S.D. One-way ANOVA followed up with a post hoc test was performed for multiple group comparisons. T test was used for comparison between the two groups. $P<0.05$ was considered as statistically significant.

RESULT

Sirt1 promotes BMSCs differentiation

Firstly, it was observed that the mRNA expression of Sirt1 was gradually increased during the differentiation of BMSCs (Fig. 1A), indicating that Sirt1 might play vital role in the differentiation of BMSCs. To evaluate the function of Sirt1 in BMSCs, pcDNA3.1-Sirt1 was used to over-ex-

Figure 1. Sirt1 promotes BMSCs differentiation.
(**A**) The relative expression of Sirt1 in the differentiation of BMSCs was detected by qRT-PCR on the 3rd, 6th and 12th day. (**B**) The qRT-PCR was used to detect the overexpression efficiency 24 hours after Sirt1 transfection. (**C**) After overexpression of Sirt1 for 24 hours, the relative activities of alkaline phosphatase in BMSCs were measured with the ALP kit. (**D**) Sirt1 was overexpressed in BMSCs for 24 hours and stained with ALP. (**E**) After overexpression of Sirt1 in BMSCs, qRT-PCR was used to detect the mRNA levels of Runx2, OCN and OPN. (**F**) Sirt1 overexpressed in BMSCs for 24 hours was stained with alizarin red. All results are expressed as mean ± S.D., n=3. *$P<0.05$, **$P<0.01$

press Sirt1 (Fig. 1B). Interestingly, over-expression of Sirt1 apparently increased ALP activity and ALP staining intensity in BMSCs as shown in Fig.1C-D. Moreover, osteogenic markers Runx2, OCN and OPN were obviously elevated *via* upregulation of Sirt1 (Fig. 1E). Alizarin red staining showed that BMSCs overexpressing Sirt1 was more likely to develop calcified nodules (Fig. 1F). These data indicated that Sirt1 facilitated osteoblastic differentiation in BMSCs. To study the effect of Sirt1 on Wnt/β-catenin signaling pathway, Western Blot experiment found that β-catenin in

cytoplasm and nucleus was also detected after knockdown of Sirt1, affirming that β-catenin in cytoplasm was elevated, while in nucleus was reduced. To further confirm that Sirt1 promoted the nuclear translocation of β-catenin, immunofluorescence experiments was conducted, finding that the immunocytochemical strength of β-catenin in the nucleus of si-Sirt1 group was declined. In short, Sirt1 activates the Wnt/βcatenin pathway to facilitate the nuclear translocation of β-catenin during the osteogenic differentiation of BMSCs (Attached Fig. 1B, C), suggesting that Sirt1 accelerates

Figure 2. Sirt1 is the direct target of miR-132/212.

osteogenic differentiation of BMSCs through the Wnt/β catenin pathway.

MiR-132/212 binds to Sirt1 in BMSCs

Next, the binding of upstream miRNAs to Sirt1 was explored. The relative expression of miR-132/212 was decreased during osteogenic differentiation of BMSCs in a time-dependent manner (Fig. 2A–B). Then, miR-132/212 mimics was used to increase the expression of miR-132/212 in BMSCs (Fig. 2C). In order to further investigate the interaction of miR-132/212 and Sirt1, miR-132/212 mimics or mimics-NC was co-transfected with wt-Luc-Sirt1 or mut-Luc-Sirt1 in BMSCs. Our results showed that overexpression of miR-132/212 can clearly inhibit the luciferase activity of Sirt-WT, while overexpression of miR-132/212 had no effect on the relative luciferase activity of Sirt1-MUT in BMSCs (Fig. 2D–E). In addition, RNA pull down assay showed that biotinylated miR-132/212-WT clearly pull down the Sirt1 mRNA, while miR-132/212-MUT did not (Fig. 2F). Finally, it was revealed that miR-123/212 up-regulation apparently reduced the expression of Sirt1 (Fig. 2G). Thus, it was concluded that miR-132/212 reduced the expression of Sirt1 by directly targeting the Sirt1 3'UTR.

MiR-132/212 is sponged by circ-Sirt1 in BMSCs

It was previously reported that miR-132 and miR-212 are sponged by circ-Sirt1 in vascular smooth muscle cells (VSMCs) (Kong *et al.*, 2019). The detection for circRNAs candidates from Sirt1 host genes in the human genome was conducted. Meanwhile, the identification of three circRNAs (hsa_circ_0093883, hsa_circ_0093887, hsa_circ_0093890) from Sirt1 host genes was exposed in human BMSCs (attached Fig. 1A). The up-regulation of Sirt1 *via* circ-Sirt1 was assured in BMSCs by sponging miR-132/212. As shown in Fig. 3A, it was found the elevation of circ-Sirt1 during osteogenic differentiation of BMSCs in a time-dependent manner. It was further determined that the ectopic expression of miR-132/212 reduced the relative luciferase activity of circ-Sirt1-WT,

while Sirt1 overexpression further enhanced it. Whereas, similar experimental conditions had not affected the relative luciferase activity of MUT-circ-Sirt1 (Fig. 3B–C). RNA pull down assay manifested that circ-Sirt1 was clearly pulled down *via* biotinylated miR-132/212-WT, while not affected *via* miR-132/212-MUT (Fig. 3D). Taken together, these results indicated that miR-132/212 was sponged by circ-Sirt1 in BMSCs.

Sirt1 plays an essential role in circ-Sirt1-promoted osteoblastic differentiation

To further examine the effect of Sirt1 in circ-Sirt1 dependent BMSCs differentiation, sh-Sirt1 was applied to transfect BMSCs. Our results showed that silencing of Sirt1 reduced the stimulatory effects of up-regulatory circ-Sirt1 on ALP activity and staining intensity as shown in Fig. 4A–B. Moreover, silencing of Sirt1 also restored the expression of Runx2, OCN and OPN upregulation as induced by circ-Sirt1 upregulation (Fig. 4C–E). These data suggested that Sirt1 played an essential role in the BMSC differentiation as regulated by circ-Sirt1.

Circ-Sirt1 promotes BMSCs differentiation by activating Wnt/β-catenin pathway

Finally, it was investigated whether the Wnt/β-catenin pathway mediated circ-Sirt1 dependent BMSCs differentiation, finding that β-catenin was apparently declined via silencing of circ-Sirt1 in the nucleus, while an opposite trend manifested in the cytoplasm (Fig. 5A). The detection results of TOP/FOP Flash showed that silencing of circ-Sirt1 obviously reduced the TOP luciferase activity in BMSCs (Fig. 5B), indicating that silencing circ-Sirt1 inhibited Wnt/β-catenin pathway. Finally, it was found that WIF-1 (Wnt/β-catenin pathway inhibitor) treatment obviously reduced the stimulatory effects of circ-Sirt1 upregulation on osteogenic differentiation of BMSCs in Fig. 5C–H. In summary, these results indicated that circ-Sirt1 up-regulates Sirt1 through miR-132/212, and activates Wnt/β-catenin pathway to promote BMSCs differentiation.

Figure 4. Sirt1 is essential in Circ-Sirt1-induced BMSC differentiation.
(**A, B**) The ALP activity and ALP staining of BMSCs were detected 24 hours after transfection of circ-Sirt1 and sh-Sirt1. (**C–E**) The mRNA levels of osteogenic differentiation marker were detected 24 hours after transfection of circ-Sirt1 and sh-Sirt1. All results are expressed as mean ± S.D., n=3. *$P<0.05$, **$P<0.01$.

DISSCUSSION

In this study, it was uncovered that Circ-Sirt1 promoted osteoblast differentiation by activating Sirt1 and Wnt/β-catenin pathway (Fig. 6). It has been determined that Sirt1 is widely involved in the physiological activities of bone tissue, and the biological functions of bone cells (Qu *et al.*, 2020). Inhibition of Sirt1 accelerates the acetylation and ubiquitination of SOX2, and represses the osteogenic differentiation of BMSCs. In current study, the

(**A**) Relative expression of nuclear β-catenin and cytoplasm β-catenin were detected by Western blot 24 hours after transfection of sh-circ-Sirt1 in BMSCs. (**B**) The relative activity of TOP and FOP luciferase were detected 24 hours after transfection of sh-circ-Sirt1 in BMSCs. (**C–D**) ALP activity and ALP staining were detected in BMSCs treated with circ-Sirt1 and WIF-1 for 24 hours. E. Alizarin red was detected in BMSCs treated with circ-Sirt1 and WIF-1 for 24 hours. (**F–H**) The mRNA levels of osteogenic differentiation marker were detected in BMSCs treated with circ-Sirt1 and WIF-1 for 24 hours. All results are expressed as mean ± S.D., n=3. *$P<0.05$, **$P<0.01$.

Figure 6. Schematic diagram of circ-Sirt1 activating Wnt/β catenin signaling pathway through direct and indirect mechanisms

role and molecular mechanism of Sirt1 was explored in BMSCs differentiation, affirming that Sirt1 was elevated with BMSCs differentiation. Moreover, miR-132 and miR-212 restrain the Sirt1 dependent BMSCs differentiation.

Increasing evidence showed that host genes can be regulated by circRNA which are formed by non-classical splicing. For example, circGFRA1 regulates GFRA1 in breast cancer by sponging miR-34a (Bai *et al.*, 2018). Similarly, CircFBLIM1 promotes HCC progression by sponging miR-346 (He *et al.*, 2017). It has been studied that Circ-Sirt1 enhances Sirt1 expression through sequence-specific interaction with miR-132/212 binding in Vascular smooth muscle cells. Therefore, the study was aimed to investigate if Circ-Sirt1, spliced from Sirt1, could sponge miR-132/212 to up-regulate Sirt1 in BMSCs. Sirt1 and miR-132/212 have been closely associated with human aging and Alzheimer's disease (Hernandez *et al.*, 2016).However, the function of miR-132/212 in osteoporosis remains ambiguous. In this study, it was confirmed that circ-Sirt1 can sponge miR-132/212 as the ceRNA of Sirt1. Circ-Sirt1 promoted BMSCs differentiation, and the silencing of Sirt1 inhibited the stimulatory effects of circ-Sirt1 on the differentiation of BMSCs.

Previous studies reported that Sirt1 could trigger the Wnt/β-catenin pathway (Hwang *et al.*, 2015). β-catenin, the core molecule of Wnt/β-catenin pathway, is widely implicated with osteoblast differentiation and proliferation (Feng *et al.*, 2020). demonstrated that microRNA-378 inhibits osteogenesis and bone formation damage of BMSC by inactivating the Wnt/β-catenin signaling pathway (Wang *et al.*, 2021). Whereas, miR-130a-3p regulates Wnt/β-catenin pathway to induce osteogenic differentiation among adipose stem cells (Yang *et al.*, 2020). Additionally, a study has manifested the participation of Sirt1 in osteoblast differentiation through Wnt/β-catenin signaling in endodontic stem cells. . The first detection of β-catenin in cytoplasm and nucleus in this study was conducted after Sirt1 knockdown, affirming up-regulation of β-catenin in cytoplasm and decline in nucleus. Furthermore, the promotion of the nuclear translocation of β-catenin via Sirt1 was determined. Moreover, elevation of β-catenin in the cytoplasm and reduction in the nucleus via down-regulation of circ-Sirt1 were founded. Briefly, our experimental results demonstrated that circ-Sirt1 elevates BMSCs differentiation by activating Wnt/β-catenin signaling pathway.

In summary, our study demonstrated that circ-Sirt1 up-regulates Sirt1 as a sponge for miR-132/212, and activates the Wnt/β-catenin pathway to promote osteoblastic differentiation of BMSCs, suggesting that circ-Sirt1 may be associated with bone formation. Circ-Sirt1 activates the Wnt/βcatenin signaling pathway through direct and indirect mechanisms, respectively. However, the direct and indirect effects of circ-Sirt1 are performed on Wnt/β catenin signaling pathway, and of them which is

the main way remains to be further studied. The possible application of circ-Sirt1 in clinic needs further study. Clinical samples and in vivo experiments will be further explored with the permission of experimental conditions later.Overall, these findings provide novel directions and insights into potential osteoporosis therapeutics.

MicroRNA-221-3p promotes post-burn HUVEC proliferation, migration, and angiogenesis by regulating CDKN1B

Kun Miao, Fei Xie and JinGui Lin✉

Department of Hand and Foot Microsurgery, Fuzhou Second Hospital Affiliated to Xiamen University, Fuzhou City, Fujian Province, 350000, China

Background and objective: Previous studies have shown that miR-221-3p plays an important role in vascular remodeling, but it is unclear whether it contributes to angiogenesis after burn injury. The purpose of this study was to investigate the effect of miR-221-3p on angiogenesis in HUVECs after burn injury and to reveal its underlying molecular mechanism. **Methods**: The burn HUVECs model was established by heat treatment. Plasmid or oligonucleotide transfection altered the expression of miR-221-3p and CDKN1B in HUVECs. MTT, colony formation, Transwell, flow cytometry, and tube formation experiments were applied to assess the proliferation, migration, apoptosis, cell cycle, and tube formation capacity of HUVECs. miR-221-3p, CDKN1B, Ki-67, and PCNA expression was assessed by RT-qPCR or Western blot. The dual-luciferase reporter assay verified the targeting relationship between miR-221-3p and CDKN1B. **Results**: miR-221-3p was lowly expressed and CDKN1B was highly expressed in burn HUVECs. Overexpression of miR-221-3p promoted the proliferation, migration, and tube formation ability of burn HUVECs and inhibited apoptosis and the proportion of cells in the G0/G1 phase, whereas overexpression of CDKN1B had the opposite effect. Knockdown of miR-221-3p further inhibited the angiogenic capacity of burn HUVECs, but this effect was reversed by knockdown of CDKN1B. Mechanistically, miR-221-3p targeted CDKN1B. **Conclusion**: miR-221-3p improves the angiogenesis of burn HUVECs by targeting CDKN1B expression, and the miR-221-3p/CDKN1B axis may serve as a potential molecular target for future burn therapy.

INTRODUCTION

Burn is one of the top ten causes of death in the world, killing more than 200 000 patients each year. In addition to a significant economic burden, burn injuries have a higher risk of developing mental illness (Haagsma *et al.*, 2016). Severe burn injuries can affect various organs and systems of the body, and their severity is related to the surface area and depth of burn throughout the body, but even relatively minor burn injury can still be life-threatening and life-altering (Kanitakis *et al.*, 2011). The core problem of burn injury is the loss of vascular integrity, the destruction of physiological barriers, and the edema caused by increased interstitial pressure (Edgar *et al.*, 2011). One of the key points of burn injury treatment is to maintain the blood volume, supply blood to the organs, and accelerate the exchange of skin and important nutrients, such as oxygen (Gelfand, Donelan, and Burke 1983). Vascular damage caused by burn injury can easily cause tissue edema around the wound or even systemic (van Baar *et al.*, 2006). Therefore, post-burn angiogenesis is an important factor for a good outcome of the disease.

MicroRNA (miRNA) is a class of conservative non-coding microRNA molecules consisting of about 22 nucleotides, which can regulate gene expression (Johnson *et al.*, 2019). With the development of next-generation sequencing technology, the research on the function and mechanism of miRNA has become increasingly in-depth, and there are also more studies on miRNA targeting mRNA in the treatment of vascular-related diseases. For example, miR-342-3p/-5p has significant anti-inflammatory and pro-angiogenic effects when targeting pannexin-2 down-regulation (Ray *et al.*, 2020); miR-210 can inhibit the apoptosis of arteriosclerotic occlusive vascular endothelial cells through JAK-STAT (Yue *et al.*, 2019) and miR-125b can limit the formation of the vascular lumen through translation inhibition of VE-cadherin (Muramatsu *et al.*, 2013). This study focused on a miRNA with an important role in vascular remodeling, named miR-221-3p. miR-221-3p has also been studied to mediate vascular remodeling in perivascular adipose tissue-derived extracellular vesicles (Li *et al.*, 2019) and regulate the dysfunction of diabetic retinal microangiopathy (Wang *et al.*, 2020). However, it is unclear whether miR-221-3p plays a role in vascular remodeling after burn injury.

Preliminary experiments found that miR-221-3p was abnormally low expressed in the serum of burn injury patients. It was speculated that miR-221-3p may have a similar role in the process of vascular remodeling after burn injury. Therefore, this work focused on exploring the effects of miR-221-3p on the proliferation, migration, tube formation, apoptosis, and cell cycle of HU-

VECs in the burn environment, and revealed its potential downstream molecular mechanisms.

MATERIALS AND METHODS

Serum from burn injury patients

Ten burn injury patients (burns area ≥50%) in Fuzhou Second Hospital Affiliated to Xiamen University were enrolled, including 6 males and 4 females, aged 18–55 years. Venous blood (10 mL) was collected within 24 h before regular anti-shock treatment and centrifuged at 4°C to obtain the supernatant which was then stored at –80°C. Normal serum from 10 healthy volunteers was recruited as a control group. This study was approved by the Ethics Committee of Fuzhou Second Hospital Affiliated to Xiamen University (ethical number: 2015061129s), and written informed consent was obtained from all participants.

Heat treatment

HUVECs (BeNA, Beijing, China) were identified by STR typing. HUVECs were seeded in Petri dishes for 48 h, harvested into 15 ml centrifuge tubes, and immersed in a circulating water bath at 52°C for 3 min. The cells in the control group were placed in a 37°C water bath for 3 min. Heat-treated cells were re-seeded in Petri dishes and further incubated at 37°C. Cells were then harvested after 6 h of heat treatment.

Cell culture and transfection

Heat-treated HUVECs were grown to 80% confluence in an endothelial cell culture medium (Sciencell, USA) with 5% fetal bovine serum, 0.05% penicillin-streptomycin (Thermo Fisher Scientific, USA). Then, HUVECs were detached with 0.25% trypsin, added with a culture medium to terminate the detachment, and prepared for a cell suspension (1×10^5 cells/mL). Flow cytometry confirmed the positive expression of CD31 and VWF in the purchased HUVECs (Supplementary Fig. 1 at https://ojs.ptbioch.edu.pl/index.php/abp/).

HUVECs with a cell density of 1×10^5 cell/mL were inoculated into 96-well plates (100 µL/well), and 10% fetal bovine serum (Thermo Fisher) was added and incubated for 24 h. miR-221-3p-mimic, miR-221-3p-inhibitor, mimic/inhibitor-negative control (mimic/inhibitor-NC), small interfering RNA (siRNA) targeting CDKN1B (si-CDKN1B), si-NC, PCDNA-CDKN1B, and pcDNA 3.1 were purchased from Shanghai GenePharma. The reagent was transfected into HUVECs instantaneously according to the manufacturer's instructions for Lipofectamine 2000 (Thermo Fisher). After incubation for 48 h, the transfection efficiency was detected by RT-qPCR and western blot.

MTT method

After transfection, every 4×10^4 HUVECs in each well on the 96-well plates were combined with 20 µL of MTT solution (Sigma, USA) at 0 h, 24 h, 48 h, and 96 h. Then, the samples were further cultured for 3 h, centrifuged at 4°C for 15 min, and dissolved by adding 150 µL of dimethyl sulfoxide solution (Sigma). Finally, optical density $(OD)_{490}$ nm was measured (Zhang et al., 2022).

Colony formation method

HUVECs were cultured at 700 cells/well on the 6-well plates with the culture medium changed every 3 days. The culture was terminated when macroscopic clonal clusters appeared. Then, colonies were fixed with 4% paraformaldehyde (Leagene, Beijing, China) at 1 mL/well for 40 min, stained with crystal violet solution (Leagene) at 1 mL/well for 20 min, and counted (Zhang et al., 2021).

Transwell experiment

A total of 2×10^4 HUVECs suspended in a serum-free DMEM (Thermo Fisher Scientific) were added to the upper chamber of the transwell plate, and 800 µL of endothelial cell culture medium and 10% fetal bovine serum were added to the lower chamber. HUVECs after 48-h culture were dyed with crystal violet solution for 20 min and counted under a microscope (Wang et al., 2022).

Flow cytometry detection

Apoptosis was assessed according to Annexin V-FITC Apoptosis Detection Kit (ThermoFisher, USA). The log-phase growing HUVECs were digested with EDTA-free trypsin, washed once with pre-cooled PBS, centrifuged at low speed for 15 min at 4°C, and centrifuged once again. After discarding the supernatant, 5 µL of Annexin V-FITC and PI were added for 10 min, and finally, 500 µL of Annexin V binding buffer was supplemented to detect cell apoptosis by flow cytometry (He et al., 2021).

Cell cycle was assessed by the Propidium Iodide Flow Cytometry Kit (Abcam, USA). HUVECs were first digested with trypsin to obtain a single cell suspension, fixed with 66% ethanol for 2 h at 4°C, and centrifuged at $500\times g$ for 5 min. The cell pellet was resuspended in prepared 1×PI+RNase Staining solution for 20 min at 37°C in the dark and loaded into a flow cytometer.

RT-qPCR detection

Total RNA was extracted with Trizol reagent (Thermo Fisher Scientific), reverse-transcribed into cDNA with the reverse transcription kit (Thermo Fisher Scientific). All primers were synthesized by Sangon (Shanghai, China). Taking U6 and GAPDH as the internal references, miR-221-3p and CDKN1B expression was calculated by the $2^{-\Delta\Delta CT}$ method (Miao et al., 2020).

Western blot

Protein lysates were harvested by adding RIPA (Merck, Germany) and the concentration was examined by a BCA kit (Enzyme-Linked Biotechnology, Shanghai, China). Proteins were separated by protein electrophoresis on sodium dodecyl sulfate-polyacrylamide gel (Thermo Fisher Scientific) and transferred to PVDF membranes for reaction with CDKN1B (1:1000, sc-1641), Ki67 (1:1000, ab92742), PCNA (1:1000, sc-56) and GAPDH (1:1000, ab8245), together with goat anti-rabbit secondary antibody (1:5000, 7074). ECL solution (GlpBio, USA)-developed bands were tested to analyze the gray value (Lu & Huang, 2021).

Luciferase reporter gene assay

Prediction from the website https://starbase.sysu.edu.cn shows that miR-221-3p has a binding site for CDKN1B. Wild-type and mutant CDKN1B sequences containing the miR-221-3p binding site were cloned into the PGL4 luciferase reporter vector (Promega). The above luciferase reporter vector and miR-221-3p mimic and mimic-NC were then co-transfected into HUVECs using Lipofectamine 2000 (Invitrogen). The cells were collected 48 h after trans-

fection, and the luciferase activity was detected according to the instructions of the luciferase activity detection kit (Promega). Renilla luciferase activity was considered as a reference for signal intensity (Dong *et al.*, 2021).

In vitro HUVECs tube formation model

Matrigel (Merck, Germany) was added to the center of the μ-slide well plate and left for 15 min. Cell suspension (50 μL, 3×10^4/mL) was centrifuged, washed twice with serum-free DMEM, and centrifuged again. Cells were resuspended in 50 μL endothelial cell culture medium (containing 10% burns serum or 10% control serum) and added to μ-slide well plates. Images were taken in 5 fields of view 6 h later and analyzed by Image-pro Plus 6.0 software (Stefanini *et al.*, 2009).

Statistical analysis

All data were analyzed using SPSS 21.0. Data were presented as mean ± standard deviation (S.D.). Two groups were compared by Student's *t*-test while multiple groups were compared by One-way ANOVA. All functional experiments were run in triplicate. Results were plotted using GraphPad Prism 7.0 software. *P*<0.05 indicated statistical significance.

RESULTS

Abnormally low expression of miR-221-3p in burn environment

miR-221-3p Expression was decreased in the serum of burn injury patients (Fig. 1A). Subsequently, miR-221-3p expression was found to be reduced in heat-treated HUVECs (Fig. 1B).

Overexpression of miR-221-3p restores the angiogenic capacity of burn-injured HUVECs

miR-221-3p-mimic Was transfected into burn-injured HUVECs. miR-221-3p-mimic promoted miR-221-3p ex-

Figure 1. miR-221-3p and CDKN1B signatures in HUVECs
(**A**) RT-qPCR to detect miR-221-3p in the serum of healthy subjects and burns patients; (**B**) RT-qPCR to detect miR-221-3p in the normal and heat-treated HUVECs. Data are presented as mean ± S.D. *P*<0.05.

pression in burn-injured HUVECs (Fig. 2A). MTT assay and colony formation assays showed that heat treatment inhibited the proliferation and clonogenic ability of HUVECs, while overexpression of miR-221-3p alleviated this phenomenon (Fig. 2B, C). Transwell assay indicated that heat treatment inhibited the migration ability of HUVECs, whereas the migration ability of HUVECs was increased after overexpression of miR-221-3p (Fig. 2D). Western blot reported that heat treatment decreased the expression of the proliferation proteins Ki-67 and PCNA in HUVECs, whereas overexpression of miR-221-3p prevented this change (Fig. 2E, F). Flow cytometry demonstrated that heat treatment increased the apoptotic rate of HUVECs and arrested cells in G0/G1 phase, while overexpression of miR-221-3p alleviated this phenomenon (Fig. 2G, H). Tube formation experiments manifested that heat treatment reduced the angiogenic capacity of HUVECs, but overexpression of miR-221-3p increased tube formation in HUVECs (Fig. 2I).

Targeted regulation of CDKN1B by miR-221-3p

Subsequently, the potential downstream target genes of miR-221-3p were explored. miRNAs can often bind to the 3' UTR of mRNA to regulate their expression (Yang *et al.*, 2021). Through the bioinformatics prediction website https://starbase.sysu.edu.cn, it was found that miR-221-3p had a binding site with CDKN1B (Fig. 3A). The luciferase reporter gene assay

Figure 2. Overexpression of miR-221-3p restores the angiogenic capacity of burn-injured HUVECs
miR-221-3p-mimic was transfected into burn-injured HUVECs to upregulate miR-221-3p. (**A**) RT-qPCR to detect miR-221-3p in HUVECs; (**B**) MTT assay to detect the proliferation of HUVECs; (**C**) Clone formation assay to evaluate the clonogenic ability of HUVECs; (**D**) Transwell assay to detect the migration of HUVECs; (**E–F**) Western blot to measure Ki-67 and PCNA; (**G–H**) Flow cytometry to determine apoptosis and cell cycle; (**I**) Tube formation assay to assess the tube-forming ability of HUVECs; data are expressed as mean ± S.D. *P*<0.05.

Figure 3. Targeted regulation of CDKN1B by miR-221-3p
(**A**) The binding region of miR-221-3p and CDKN1B on https://starbase.sysu.edu.cn; (**B**) Luciferase activity of cells after co-transfection; (**C**) RT-qPCR and Western blot to detect CDKN1B in burn-injured HUVECs; (**D**) RT-qPCR and Western blot to detect the effect of overexpression of miR-221-3p on CDKN1B expression; data are expressed as mean ± S.D. *$P<0.05$.

results verified the binding relationship between the two. The co-transfection of WT-CDKN1B and miR-221-3p-mimic reduced luciferase activity, but that of MUT-CDKN1B and miR-221-3p-mimic had no effect on luciferase activity (Fig. 3B). In burn-injured HUVECs, an abnormal increase in CDKN1B expression (Fig. 3C) was determined. Furthermore, overexpression of miR-221-3p suppressed CDKN1B expression (Fig. 3D).

Overexpression of CDKN1B enhances the inhibitory effect of burn on HUVECs angiogenesis

Subsequently, pcDNA-CDKN1B was transfected into burn-injured HUVECs to explore the role of CDKN1B. pcDNA-CDKN1B increased CDKN1B expression in HUVECs (Fig. 4A). Functional experiments verified that overexpression of CDKN1B further inhibited the proliferation and colony ability of burn-injured HUVECs, decreased the number of migrating cells, suppressed Ki-67 and PCNA protein expression, promoted cell apoptosis, blocked cells at G0/G1 phase, and reduced the number of tube formations (Fig. 4B–I).

miR-221-3p Targets CDKN1B expression to improve angiogenesis in burn-injured HUVECs

A functional rescue experiment was implemented to probe the regulatory role of the miR-221-3p/CDKN1B axis in burn-injured HUVECs. The transfection designs were as follows: Inhibitor-NC+si-NC, miR-221-3p-inhibitor+si-NC and miR-221-3p-inhibitor + si-CDKN1B. The results presented that miR-221-3p inhibitor promoted CDKN1B expression, while si-CDKN1B reversed this effect (Fig. 5A). Functional experiments manifested that after transfection of miR-221-3p-inhibitor, cell proliferation and cloning abilities were attenuated (Fig. 5B, C), the number of migrating cells was reduced (Fig. 5D), and Ki67 and PCNA protein expressions were reduced (Fig. 5E, F), the apoptotic rate was promoted, cells in G0/G1 phase were increased (Fig. 5G, H), and tube-forming ability was impaired (Fig. 5I), and these effects were reversed by knockdown of CDKN1B.

DISCUSSION

Burn injury damages the body caused by thermal exposure, radiation, and chemical or electrical contact, which

Figure 4. Overexpression of CDKN1B enhances the inhibitory effect of burn on HUVECs angiogenesis

miR-221-3p-inhibitor and si-CDKN1B were co-transfected into burn-injured HUVECs (**A**) RT-qPCR and Western blot to detect CDKN1B in HUVECs; (**B**) MTT assay to detect the proliferation of HUVECs; (**C**) Clone formation assay to evaluate the clonogenic ability of HUVECs; (**D**) Transwell assay to detect the migration of HUVECs; (**E–F**) Western blot to measure Ki-67 and PCNA; (**G–H**) Flow cytometry to determine apoptosis and cell cycle; (**I**) Tube formation assay to assess the tube-forming ability of HUVECs; data are expressed as mean ± S.D. $*P<0.05$.

induce activation of peripheral nerve fibers, initiating a sustained hypersensitivity response to thermal and mechanical stimuli (Laycock *et al.,* 2013). The consequences of burns are severe, with a high mortality rate and common in low- and middle-income countries (Atwell *et al.,* 2020). With the development of science and technology, there have been many studies on gene technology treatment for burn injury (Zhang *et al.,* 2021). Bioinformatics analysis has identified 43 miRNAs as potential regulators of early burn injury response among which miR-212-3p is down-regulated in dermal interstitial fluid (Foessl *et al.,* 2021). In addition to post-burns pain management, psychological counseling, scar healing, etc., post-burns angiogenesis is the basis of many burn treatment principles (Eyuboglu *et al.,* 2018). The physiological basis of tissue edema and body fluid extravasation after burn injury is the change of vascular permeability which is one of the main manifestations of vascular endothelial cell damage (Tian *et al.,* 2015).

Belonging to miRNAs family which affects physiological processes (Amponsah *et al.,* 2017), miR-221 is located in the p11.3 region of the X chromosome and is involved in the physiological regulation of hematopoiesis and angiogenesis (Liu *et al.,* 2009). In vascular endothelial cells, miR-221 acts on CDKN1B and PI3KR1 and inhibits endothelial cell biological functions (Celic *et al.,* 2017). In human aortic endothelial cells, miR-221-3p carries the ability to block the production of peroxisome proliferator-activated receptor λ coactivator 1α, leading to mitochondrial dysfunction and apoptosis (Xue *et al.,* 2015). The present study found that miR-221-3p has a positive role in vascular remodeling after burn injury. Overexpression of miR-221-3p promoted the proliferation of HUVECs by reducing the ratio of HUVECs in the G0/G1 phase, thereby mediating HUVECs migration and tube formation, which will benefit the angiogenic capacity of HUVECs in the burn environment. Cell cycle changes are important for the proliferation of HUVECs. When cells are arrested in the G0/G1 phase, the proliferation of HUVECs is inhibited and their tube-forming ability is

reduced (Cota Teixeira *et al.,* 2019; Zhang *et al.,* 2013). Several studies have demonstrated the role of miRNAs in regulating the cell cycle and proliferation of HUVECs, such as miRNAs including miR-182-5p (Su *et al.,* 2021), miR-20b (Dong *et al.,* 2020). This study speculated that the regulation of miR-221-3p on the cell cycle of HUVECs will affect the ability of vascular remodeling, and the effect of miR-221-3p on the cell cycle of HUVECs needs to be further explored in subsequent studies.

CDKN1B is located on chromosome 12p 13 and has a promoting regulatory role in tumors (Kim *et al.,* 2015), such as osteosarcoma (Gao *et al.,* 2022). As a downstream target gene of miR-221, CDKN1B can promote the proliferation of vascular smooth muscle cells in the neovascular intima (Medina *et al.,* 2008). MiR-221-3p/CDKN1B axis can regulate the proliferation and cell cycle of HUVECs after burn injury, and further influence cellular migration and tube formation ability. It is worth noting that this study only validated the role of the miR-221-3p/CDKN1B axis in angiogenesis in an *in vitro* model and could be explored in future animal burn injury models. In addition, there are few reports on the regulatory mechanism of ncRNAs in burn injury, and the regulatory mechanism of ncRNAs is crucial in vascular remodeling, skin recovery and other processes. Therefore, it is necessary to further explore the changes and mechanisms of ncRNAs in burn injury.

In conclusion, this work confirmed that miR-221-3p affects the proliferation, migration, cell cycle, apoptosis, and tube formation of burn-injured HUVECs by regulating CDKN1B. MiR-221-3p/CDKN1B axis may be of interest in future burn treatments.

MALAT-1 regulates the AML progression by promoting the m6A modification of ZEB1

Jing Jin, Leihua Fu, Pan Hong and Weiying Feng✉

Department of Hematology, Shaoxing People's Hospital, Shaoxing City, Zhejiang Province, China

Metastasis-associated lung adenocarcinoma transcript 1 (MALAT-1) is abnormally upregulated in various human cancers. However, the role of MALAT-1 in acute myeloid leukemia (AML) remains unclear. This study investigated the expression and function of MALAT-1 in AML. MTT assay was used to determine cell viability, qRT-PCR was applied to determine the RNA levels. Western blot was performed to detect the protein expression. Flow cytometry was conducted to measure cell apoptosis. RNA pull-down assay was carried out to detect the interaction between MALAT-1 and METTL14. RNA FISH assay was performed to determine the localization of MALAT-1 and METTL14 in AML cells. Our results have revealed the key role of MEEL14 and m6A modification in AML. Besides, MALAT-1 was significantly up-regulated in AML patients. MALAT-1 knockdown inhibited the proliferation, migration and invasion of AML cells, and induced cell apoptosis; additionally, MALAT-1 binding to METTL14 promoted the m6A modification of ZEB1. Besides, ZEB1 overexpression partially reversed the effect of MALAT-1 knockdown on the cellular functions of AML cells. Taken together, MALAT-1 promoted the aggressiveness of AML through regulating m6A modification of ZEB1.

INTRODUCTION

Acute myeloid leukemia (AML) is a malignant disease of myeloid hematopoietic stem/progenitor cells (Cai & Levine, 2019). Before maturation, leukemic cells abnormally proliferate and accumulate in bone marrow and blood, causing loss of hematopoietic function (Acheampong et al., 2018; Mueller et al., 2018). AML is highly popular among adults, accounting for more than 30 percents of all leukemia cases worldwide (Zimta et al., 2019). Current studies have shown that chromosome abnormalities, uncontrolled gene expression, and non-coding RNA such as long non-coding RNAs (lncRNAs) could promote acute myeloid leukemia (Mer et al., 2018; Wang et al., 2019). Clinically, the AML recuperation rate is less than 45%, while 50% relapse and the late survival rate is only at about 10% (Pan et al., 2017). Because of the poor prognosis of AML, it is of great importance to identify new markers and therapeutic targets for AML.

LncRNA is a category of transcripts larger than 200bp and lacks protein-coding function (Yang et al., 2019). Recent studies have illustrated the crucial roles of the lncRNAs in cell proliferation, survival, apoptosis, and differentiation (Ferre et al., 2016; Ju et al., 2019). However, most lncRNAs underlying mechanisms are yet to be studied. The lncRNA MALAT-1 is involved in the development of various tumors (Zhang et al., 2017; Liu et al., 2019; He et al., 2019). Previous studies have confirmed that the overexpression of MALAT-1 can promote the invasion and migration of lung cancer, cervical cancer, and ovarian cancer (Xia et al., 2018; Guo et al., 2018; Yu et al., 2019). It is also an essential marker for the early prognosis of lung adenocarcinoma, gastrointestinal cancer, and B-cell lymphomas (Li et al., 2016; Xu et al., 2018). However, the underlying mechanism of MALAT-1 in AML is not clear.

N6-methyladenosine (m6A) is the most accustomed mRNA modification; this modification affects all steps of RNA metabolism (Yu et al., 2018). Emerged evidence showed that m6A is involved in cancer progression and proliferation; it is also engaged in cancer stem cells' maintenance and differentiation (Sun et al., 2019). However, the mechanism of m6A in AML remains to be studied.

The zinc finger E-box binding homeobox 1 (ZEB1) leads to epithelial-mesenchymal transition (EMT) and confers properties of 'stemness', such as self-renewal in cancer. ZEB1 is involved in myogenesis (Postigo & Dean, 1999), neuronal development and differentiation (Wang et al., 2019;), gastrulation (Funahashi et al., 1993), and T fine cell development (Higashi et al., 1997). Copious evidence suggests that ZEB1 regulates stem cell self-renewal in cancer (Brabletz & Brabletz, 2010). Although ZEB1 is a renowned regulator of the expression of different stem cell/cancer-related transcription factors such as BMI1, KLF4, and SOX2, the deletion of ZEB1 promotes cell differentiation during the development of embryonic CNS (Singh et al., 2016) and skeletal muscle (Li et al., 2017). The comprehensive role of ZEB1 in normal stem cell progression remains unclear.

In the present study, we explored the underlying mechanism of MALAT-1 in AML. We found that the expression of MALAT-1 was significantly up-regulated in AML patients, and MALAT-1 promoted the m6A modification of ZEB1 through binding with METTL14, thereby promoting the proliferation and inhibiting the apoptosis of AML cells.

MATERIALS AND METHODS

Patient samples

40 AML patients and 40 healthy controls were recruited from Ningbo First Hospital. Among the AML patients, male: 26, female:14; age: 35.21 ± 6.14; physical activity state score, 0-1: 27, 2-4: 13; Type, M1: 3; M2: 5; M3: 11; M4: 13; M5: 6; M6: 2. The peripheral blood was collected and stored in liquid nitrogen immediately until needed. The patients who received chemotherapy or radiotherapy were excluded from this study. This study was approved by the Research Ethics Committee of Ningbo First Hospital20190126, January 26th, 2019, and each patient has signed an informed consent form.

Cell culture and transfection

The human bone marrow stromal cell line HS-5 and human AML cell lines HL60 and THP-1 were obtained from the Cell Bank of the Chinese Academy of Science (Shanghai, China). All cells were maintained in RPMI-1640 medium (Hyclone, Logan, UT, USA) and were supplemented with 10% fetal bovine serum (FBS, Hao Yang Bio) in a humidified atmosphere of 5% CO_2 at $37°C$. The MALAT-1 overexpression plasmids, si-MALAT1, si-METTL14, and ZEB1 overexpression plasmids were synthesized by GenePharma (Shanghai, China). Lipofectamine 2000 (Invitrogen, USA) was used for cell transfection following the manufacturers' instructions.

Quantitative real-time RCR (qRT-PCR)

The RNA was extracted from HS-5, HL60, and THP-1 cells using TRIzol reagent (nitrogen source). The cDNA was synthesized using a reverse-transcription kit (TRAGEN). The real-time quantitative PCR was conducted on 20ng of cDNA by SYBR Green mixture (Shanghai Yisheng) and GAPDH was used as an internal control. The primer sequences are as follows:
MALAT1:
Forward 5'-AGGCGTTGTGCGTAGAGGA-3',
reverse 5'-GGATTTTTACCAACCACTCGC-3';
ZEB1:
Forward 5'-GATGATGAATGCGAGTCAGATGC-3',
reverse 5'-ACAGCAGTGTCTTGTTGTTGT-3'.

MTT assay

MTT assay was used to determine the HL60 and THP-1 cells' viability. 1×10^4 cells were seeded into 96-well plates. Next, we added 16 μL/well MTT solution (5 mg/mL, Sigma) and incubated for 4 h at $37°C$. The cell viability was determined by a microplate reader (Bio-Tek, Winooski, USA) at 570 nm.

Cell apoptosis assay

Annexin V-FITC Apoptosis Detection kit (YEASEN, Shanghai) was used to evaluate cell apoptosis. In brief, after treating HL60 and THP-1 cells for 72h, the cells were washed using PBS; Then, the cells were mixed with the binding buffer, Annexin V-FITC and propidium iodide (PI) and were incubated in dark for 15 min. The apoptotic rates were determined using flow cytometry (BD).

Transwell

The transwell assay was performed to detect the cell invasion, while transwell without Matrigel was performed to analyze the cell migration. About 0.6 mL Complete medium was added into lower chambers. Then, the cells were added into the upper chambers. After incubating for 48 h, the non-migrated and non-invaded cells were removed with a swab. The 4% paraformaldehyde was used to immobilize the cells on the bottom surface and 0.1% crystal violet was used to stain the cells. A light microscope was used to observe the cells.

RNA FISH

The RNA FISH probe for MALAT1 and METTL14 was purchased from Biosearch Technologies (Novato, CA, USA) and used to visualize RNA in the interchromatin granule clusters. Hybridizations were performed according to the manufacturer's instructions. Briefly, slides were hybridized overnight with 50 pmol probe in 20 μl hybridization buffer, washed in RNAse-free PBS, dehydrated in ethanol, post-fixed in 1% paraformaldehyde (Life Technologies, Darmstadt, Germany) in PBS, and treated for 2 min with 0.1% Triton-X100 (Serva, Heidelberg, Germany).

RNA immunoprecipitation

RNA experiments were performed using a Magna RIP RNA-Binding Protein Immunoprecipitation Kit (Millipore, USA) according to the manufacturer's instructions.

Western blotting

HL60 and THP-1 cells were placed in an ice-cold lysis buffer for 30 min (Beyotime). The supernatants were collected by centrifugation at 14 000 r/min for 20 min at $4°C$. Protein concentration was calculated with a BCA Kit (Pierce, USA). Then the protein was separated with 10% SDS-PAGE and transferred onto PVDF membranes. Afterwards, the membranes were blocked in 5% non-fat milk; next, the membranes were incubated with primary antibodies: anti-ZEB1 (1:1 000), anti-METTL14 (1:1 000), and anti-METTL3 (1:1 000) (Boster Biological Technology, China) overnight at $4°C$. On the next day, the membranes were incubated with the HRP-labeled secondary antibodies (Abcam, Shanghai) and treated with BeyoECL Plus (Beyotime, China). The bands were visualized using CC-D camera (Bio-Rad, USA).

RNA pull-down

RNA pull-down assay was performed to confirm whether METTL14 or METTL3 can be pulled down by MALAT-1 in HL60 and THP-1 cells. The biotin-labeled METTL14 and METTL3 were transcribed with the Biotin RNA Labeling Mix (Roche) and T7 RNA polymerase (Roche). After 2d of transfection, cells were lysed and then mixed with biotin-labeled METTL14 and METTL3 and streptavidin agarose magnetic beads at $4°C$ for 1 h. Western blot was used to detect the protein levels of the retrieved Ago2.

Statistical analysis

Data were analyzed using SPSS17.0 software (SPSS, Inc.) and expressed as mean $\pm$ S.D. One-way ANOVA followed by Duncan's post hoc test was used to evaluate the differences among groups. The differences between the two groups were analyzed by Student's t-test. $P<0.05$ was defined as significant.

Figure 1. MALAT1 was upregulated in AML patients and AML cell lines.
(**A**) The expression of MALAT1 in serum samples from AML patients and healthy volunteers. (**B**) The expression of MALAT1 in AML in the human bone marrow stromal cell line HS-5 and human AML cell lines HL60 and THP-1. **$P<0.01$ *vs* HS-5.

RESULTS

lnc-MALAT-1 was up-regulated in AML patients and cells

Firstly, we collected serum samples from 40 healthy participants and 40 AML patients, and then examined the expression of MALAT-1 in serum by RT-qPCR method. The expression level of MALAT-1 in the serum of patients with AML was significantly higher than normal controls ($P<0.05$; Fig. 1A). It was consistent with in vitro assay, the expression of MALAT-1 in HL60 and THP-1 cells were significantly increased compared with HS-5 cells ($P<0.05$; Fig. 1B).

MALAT-1 knockdown inhibited proliferation of AML cells

To explore the role of MALAT-1 in AML, HL60, and THP-1 cells were transfected with si-MALAT-1 or MALAT-1 overexpression plasmids, and then we examined the effects of MALAT-1 on cell proliferation. Results, in Fig. 2A, revealed that compared with the si-NC group the expression of MALAT-1 was significantly reduced after transfection with si-MALAT1. Compared with the vector group, the expression of MALAT-1 was remarkably promoted after transfection with MALAT1 overexpression plasmids ($P<0.01$). As shown in Fig. 2B–C, knockdown of MALAT-1 significantly suppressed the cell viability of HL60 and THP-1, whereas overexpression MALAT-1 remarkably promoted the AML cell viability ($P<0.05$).

Figure 3. Effects of MALAT1 knockdown on apoptosis of AML cells.
After HL60 and THP-1 cells were transfected with si-MALAT1 or MALAT1 for 48 h, cell apoptosis (**A–B**), migration (**C**) and invasion (**D**) were evaluated by flow cytometry assay. **$P<0.01$. ***$P<0.001$.

MALAT-1 knockdown promoted AML cells apoptosis

To further explore the function of MALAT-1 in AML, after HL60 and THP-1 cells transfection with si-MALAT-1 or MALAT-1 overexpression plasmids, we examined the effects of MALAT-1 on cell apoptosis, migration, and invasion. Flow cytometry results showed that compared with the si-NC group, the apoptosis of HL60 and THP-1 cells was significantly increased in si-MALAT1 group ($P<0.05$; Fig. 3A–B). Besides, the results of Transwell exhibited that compared with the si-NC group, the migration and invasion abilities of the HL60 and THP-1 cells were significantly decreased in

Figure 2. Effects of MALAT1 on proliferation of AML cells.
(**A**) After AML cells were transfected with si-MALAT1 or MALAT1 for 48 h, the transfection efficiency was evaluated by qRT-PCR. (**B and C**) MTT assay was conducted to determine cell proliferation in HL60, and THP-1 cells transfected with si-MALAT1 or MALAT1. **$P<0.01$.

Figure 4. MALAT1 bound with METTL14 in AML cells.
(**A**) RNA pull-down assay. (**B**) RNA immunoprecipitation assay. (**C**) MALAT1 and METTL14 location detecting by RNA FISH in AML cells.

the si-MALAT1 group (P<0.05; Fig. 3C–D). These data revealed that MALAT1 knockdown promoted AML cell apoptosis and inhibited AML cell migration and invasion.

METTL14 bound with MALAT-1

m6A Modification affects almost all steps of RNA metabolism, including lncRNA. Therefore, RNA pull-down assay, RIP experiment, and RNA FISH were used to verify whether m6A binds with MALAT-1. The results of the RNA pull-down assay verified the interaction between MALAT-1 and METTL14 (Fig. 4A). Furthermore, METTL14 directly bound with MALAT-1 (Fig. 4B). Similarly, RNA FISH results also confirmed the mutual binding of MALAT-1 and METTL14 (Fig. 4C). Taken together, these data confirmed that METTL14 bound with MALAT-1.

MALAT-1 regulated m6A modification of ZEB1

Previous research has shown that mRNA translation is regulated by lncRNA and m6A modification. Therefore, we explored the effects of MALAT-1 and m6A modification on ZEB1 expression. In Fig. 5A, ZEB1 produced significant m6A methylation modification in both AML cells, compared with the control group.

MALAT-1 knockdown remarkably reduced the enrichments of ZEB1 in HL60 and THP-1 cells (P<0.05; Fig. 5B). As shown in Fig. 5C, overexpression of MALAT-1 significantly promoted the enrichments of ZEB1 compared with the control group. However, these changes would be partly reversed in the MALAT-1+si-METTL14 group (P<0.05; Fig. 5C). After transfection with MALAT-1 overexpression plasmids or si-METTL14, we detected the expression of ZEB1 in AML cells. Results showed that the expression levels of ZEB1 were promoted by MALAT-1 overexpression plasmids, compared with the control group. The expression levels of ZEB1 were significantly reduced by MALAT-1+si-METTL14 compared with the MALAT-1+si-NC group (P<0.05; Fig. 5C). As shown in Fig. 5D, after transfection with MALAT-1 overexpression plasmids, the stability of ZEB1 expression was promoted, compared with the vector+si-NC group, which was partly reversed by si-METTL14 (Fig. 5D). Overexpressed MALAT-1 promoted the protein expression of ZEB1 compared with the vector+si-NC group, while the protein expression of ZEB1 was decreased in the MALAT-1+si-METTL14 group compared with the MALAT-1+si-NC group (P<0.05; Fig. 5E).

Figure 5. Effects of MALAT1 and METTL14 on ZEB1.
(**A**) ZEB1 produces m6A modification in AML cells. (**B**) After AML cells were transfected with si-MALAT1, the enrichment of ZEB1 was evaluated by qRT-PCR. (**C**) After AML cells were transfected with MALAT1 or si-METTL14, the enrichment and expression of ZEB1 was evaluated by qRT-PCR. (**D**) The stability of ZEB1. (**E**) The protein expression of ZEB1. **P<0.01.

Overexpression ZEB1 alleviated the effects of MALAT-1 knockdown on cellular function AML cells

To further explore the role of MALAT-1 and ZEB1, a rescue experiment was conducted in AML cells. As presented in Fig 6A, MALAT-1 knockdown significantly reduced the expression of ZEB1 compared with the vector+si-NC group, the expression levels of ZEB1 were promoted by ZEB1 overexpression plasmids compared with si-MALAT-1+si-NC group ($P<0.05$; Fig. 6A). Knockdown MALAT-1 significantly reduced cell viability of HL60 and THP-1 cells, whereas overexpression of ZEB1 remarkably reversed the effect of MALAT-1 knockdown ($P<0.05$; Fig. 6B). Knockdown of MALAT-1 significantly induced the apoptosis of HL60 and THP-1 cells, whereas overexpression of ZEB1 reversed the effect of MALAT-1 knockdown ($P<0.05$; Fig. 6C). What is more, knockdown of MALAT-1 significantly decreased the migration and invasion of the HL60 and THP-1 cells, whereas overexpressed ZEB1 remarkably reversed the effect of MALAT-1 knockdown on the migration and invasion of AML cells ($P<0.05$; Fig. 6D–E).

DISCUSSION

In this study, MALAT-1 was significantly upregulated in patients compared with the healthy control group. Besides, MALAT-1 knockdown inhibited HL60 and THP-1 cells' proliferation, migration, and invasion abilities, and promoted the apoptosis of HL60 and THP-1 cells.

Figure 6. Knockdown ZEB1 reversed the effect of MALAT1 on AML cells.
(**A**) After AML cells were transfected with MALAT1 or si-ZEB1 for 48 h, the expression of ZEB1 was detected by qRT-PCR. (**B**) MTT assay was conducted to determine cell proliferation in HL60, and THP-1 cells transfected with MALAT1 or si-ZEB1. (**C**) After HL60 and THP-1 cells were transfected with MALAT1 or si-ZEB1 for 48 h, cell apoptosis was evaluated by flow cytometry assay. (**D–E**) After HL60 and THP-1 cells were transfected with MALAT1 or si-ZEB1 for 48 h, Transwell assay was performed to detect the migration and invasion. *$P<0.05$, **$P<0.01$.

Moreover, MALAT-1 promoted m6A methylation modification of ZEB1 by binding with METTL14, thereby enhancing the proliferation, migration, and invasion ability of AML cells.

MALAT-1 is a highly methylated LncRNA that is often abnormally upregulated in human cancer tissues (YiRen et al., 2017; Shen et al., 2019). Recently, abnormal expression of MALAT-1 can be a diagnostic marker for multiple myeloma at early stage (Hu et al., 2018). Additionally, the abnormally high expression of lncRNA-MALAT-1 was associated with the poor prognosis of AML patients (Huang et al., 2017). However, MALAT-1 knockout enhances cytarabine chemosensitivity of AML cells (Hu et al., 2019). These findings suggest that MALAT-1 may function as an oncogene in AML. In this study, MALAT-1 was up-regulated in AML clinical samples and cells. Moreover, knockdown of MALAT-1 reduced AML cells' viability, migration, and invasion, and induced cells' apoptosis, which is a key "player" in the occurrence and development of AML. Nevertheless, the underlying molecular mechanisms remain unclear.

The m6A methylation modification mediates the 0.3–0.5% adenosine modification in human cell mRNA, and the main complexes responsible for the m6A modification of mRNAs are METTL3 and METTL14 (Ianniello et al., 2019). The study found that METTL14 was overexpressed in AML, which was consistent with previous studies (Vu et al., 2017; Barbieri et al., 2017). Overexpression of METTL14 promotes the proliferation of AML cells, while knockout of METTL14 promotes AML cell apoptosis (Weng et al., 2018). Barbieri et al. reveal that METTL14 is a crucial gene regulating the survival of AML cells (Barbieri et al., 2017). METTL3/METTL14 methylation complex can promote the development of AML and maintain leukemia stem cells (Weng et al., 2018). These results prove the oncogenic role of METTL14 in AML. In this study, MALAT-1 bound with methyltransferase METTL14, which suggests the possibility of m6A modification in AML cells.

ZEB1 is the primary regulator of EMT-related signal pathways related to cancer stem cells' growth, survival, and metastasis. For example, up-regulating ZEB1 improves the migration ability of HCC cells (Wang et al., 2020). ZEB1 is highly expressed in AML patients and can be a marker for early diagnosis and prognosis of AML (Shousha et al., 2019). However, ZEB1 knockout reduces the invasiveness of leukemia stem cells (Stavropoulou et al., 2016). However, the reason that ZEB1 was overexpressed in AML cells is still unclear. In this study, we found that ZEB1 was rich in m6A level in AML cells. Additionally, MALAT-1 interacted with METTL14 to promote m6A modification of ZEB1, which induced the up-regulation of ZEB1 in AML cells. Besides, overexpression of ZEB1 promoted proliferation, migration, and invasion, and suppressed the apoptosis of AML cells.

In conclusion, MALAT-1 was overexpressed in AML. MALAT-1 bound with METTL14 to promote the m6A modification of ZEB1, which promoted the proliferation, migration, and invasion of AML cells. This might provide a new effective therapeutic strategy for the treatment of AML.

Declarations

Data Availability Statement. The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions. All authors participated in the design, interpretation of the studies, and analysis of the data, and review of the manuscript; LHF and PH conducted the experiments; JJ wrote the manuscript; WYF provided the idea.

CD36 is a type 2 cell surface scavenger receptor expressed in various tissues. In macrophages, CD36 recognizes oxidized low-density lipoprotein (ox-LDL), which promotes the formation of foam cells, the first step toward an atherosclerotic arterial lesion. CD36 possesses a variety of posttranslational modifications, among them N-glycosylation and O-GlcNAc modification. Some of the roles of these modifications on CD36 are known, such as N-linked glycosylation, which provides proper folding and trafficking to the plasma membrane in the human embryonic kidney. This study aimed to determine whether variations in the availability of UDP-GlcNAc could impact Rab-5-mediated endocytic trafficking and, therefore, the cellular localization of CD36. These preliminary results suggest that the availability of the substrate UDP-GlcNAc, modulated in response to treatment with Thiamet G (TMG), OSMI-1 (O-GlcNAcylation enzymes modulators) or Azaserine (HBP modulator), influences the localization of CD36 in J774 macrophages, and the endocytic trafficking as evidenced by the regulatory protein Rab-5, between the plasma membrane and the cytoplasm.

KEYWORDS

CD36 localization, O-GlcNAcylation, hexosamine biosynthetic pathway, vesicular traffic, environment of cells

Introduction

Human CD36 is a class B scavenger receptor localized to the plasma membrane that is widely expressed in immune cells like macrophages, monocytes, dendritic cells and subsets of T and B cells, and non-immune cells, such as platelets, immature erythrocytes adipocytes, myocytes, specialized epithelial cells, and microvascular endothelial cells. Its ligands include endogenously derived ligands such as apoptotic cells, cholesterol esters, fatty acids, oxidatively modified lipoproteins, glycated proteins, and amyloid-forming peptides (Luiken et al., 2016; Chen et al., 2022). Similarly, CD36 is a pattern recognition receptor for molecular patterns presented by various pathogens on phagocytic cells, binds, and mediates phagocytosis (Patel et al., 2004; Baranova et al., 2008; Silverstein and Febbraio, 2009).

The endocytic system of eukaryotic cells embraces a complex network of membrane compartments, each of which fulfills a specific set of tasks in cargo sorting, distribution, and catabolism (Barbero et al., 2002). Rab GTPases organize the endocytic pathway into a mosaic of biochemically and functionally distinct membrane domains; they are involved in vesicle trafficking and endocytic and exocytic processes (Rink et al., 2005). Rab5 recruits different effector proteins that oligomerize within a membrane domain enriched in PI(3)P (Christoforidis et al., 1999). Rab5, Rab4, and Rab11 occupy distinct membrane domains that are sequentially traversed by recycling cargo. Cargo destined for degradation is first internalized into Rab5 domains in early endosomes (Yuan and Song, 2020) and later appears in Rab7 domains in late endosomes (Mukhopadhyay et al., 1997).

Short-term (minutes) regulation of cellular fatty acid uptake rate occurs by reversible intracellular recycling (vesicular traffic) of CD36 from an endosomal storage compartment to the plasma membrane. Long-term regulation of cellular fatty acid uptake occurs via changes in CD36 gene transcription, mediated, among others, by fatty acid-induced PPAR activation, HIF-1, and C/EBPα (Glatz and Luiken, 2018). CD36 expression is regulated at both the transcriptional and posttranslational levels; the regulation differs between different cell types. Post-translational modifications (PTMs) modulate partner-to-partner interactions and are responsible for protein function. A single PTM or a combination of PTMs modifies the local conformation of a region or domains of a protein and offers different interaction surfaces. Therefore, a protein can interact with many partners, changing its localization, stability, interaction with other partners, and, ultimately, its activities (Vercoutter-Edouart et al., 2015). The evidence concerning PTMs of CD36 suggests that these modifications impact protein function in a tissue-specific way; for more details, see the reviews (Shu et al., 2022; J.J; Luiken et al., 2016).

In addition, CD36 is heavily N-linked glycosylated (Mori et al., 2012), which is the cause for the increase in molecular mass to 88 kDa. N-glycosylation of membrane and secretory proteins impacts proper folding and trafficking to the plasma membrane and enhances their stability (Hoosdally et al., 2009). N-glycosylation occurs in the endoplasmic reticulum (ER) and refers to the attachment of the oligosaccharide N-acetylglucosamine (GlcNAc) to the side chain of Asparagine (Asn) through a β-1N linkage of a protein molecule—N-glycans impact the structure and function of some eukaryotic proteins (Reily et al., 2019). The endoplasmic reticulum and the Golgi apparatus synthesize glycolipids, glycoproteins, and glycans utilizing UDP-GlcNAc, which is synthesized through the Hexosamine Biosynthetic Pathway (HBP).

A small portion of UDP-GlcNAc acts as a versatile substrate pool for reversible post-translational modifications known as O-GlcNAc. This process, which occurs in the cytoplasm, mitochondria, and nucleus, shares common features with phosphorylation. O-GlcNAcylation and phosphorylation target serine or threonine residues, leading to a dynamic interplay as they compete for the same or adjacent sites (Leney et al., 2017). Furthermore, O-GlcNAcylation engages in intricate crosstalk with other PTMs, such as acetylation, methylation, ubiquitination, and proteolysis, offering a myriad of combinations that give rise to diverse protein isoforms in the human proteome (Leutert et al., 2021). Moreover, protein O-GlcNAcylation is very sensitive to the availability of uridine di-phospho-N-acetylglucosamine, the GlcNAc donor for O-GlcNAcylation, and a downstream metabolite of glucose; therefore, O-GlcNAcylation is often referred to as a nutrient sensor in cells (Hardivillé and Hart, 2014). A single N-acetylglucosamine group is attached to the serine and threonine residues of target proteins by O-GlcNAc transferase. In contrast, the enzyme O-GlcNAcase manages the removal of this group (Fisi et al., 2017) (Figure 1). OGT interacts with several intracellular proteins and O-GlcNAcylation to modify proteins associated with various human diseases such as cancer, neurodegenerative and cardiovascular diseases (Nie and Yi, 2019). Rescue metabolites such as glucosamine and N-acetylglucosamine are used to modulate flux through the hexosamine pathway, and pharmacological agents or anti-metabolites have been used to alter activity and/or substrate for research purposes or therapeutic benefit. Since GFAT1 catalyzes the main step in the *de novo* synthesis of HBP, many studies have used inhibitors of this enzyme, which are mainly glutamine analogs as cytotoxic antimetabolites of glutamine, Azaserine is used to study glutamine-dependent metabolic pathways (Van Cura et al., 2023). OSMI-1 has been identified as a permeable Hogt inhibitor. OSMI-1 binds to the active site of hOGT and inhibits the enzyme with an IC50 value of 2.7 μM *in vitro* (Ju Kim, 2020). On the other hand, Thiamet G is a stable sugar-based inhibitor of the OGA enzyme with excellent inhibitory efficacy (Ki = 21 nM) and good selectivity over human lysosomal β-hexosaminidase (Liu et al., 2017). The effect of glycosylations on the CD36 protein is unclear, but our study shows preliminary

FIGURE 1

The Hexosamine Biosynthetic Pathway (HBP) and O-GlcNAcylation. Fed for glucose and glucosamine, UDP-GlcNAc, the final product of HBP, which is involved in the synthesis of glycoproteins and proteoglycans, integrates multiple metabolic pathways and has long been considered an important nutrient signaling pathway, L-glutamine: D-fructose-6-phosphate amidotransferase (GFAT) is the rate-limiting enzyme of HBP, and the regulation of HBP flux via small-molecule inhibitors of GFAT is limited to the glutamine analogs Azaserine, or OSMI-1 which inhibit the O-GlcNAc transferase, responsible for using UDP-GlcNAc to modify proteins with O-GlcNAc. TMG inhibits the hexosaminidase O-GlcNAcase, which removes O-GlcNAc from proteins.

results on the localization of CD36 in response to UDP-GlcNAc levels, using HBP pathway and O-GlcNAcylation modulators.

Materials and methods

Cell culture

The J774.2 mouse bone marrow-derived macrophage cell line was maintained. In RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS) and 1% antibiotic penicillin-streptomycin at 37°C in 5% CO2.

Western blot

J774 macrophages were cultured in 6-well plates (9.6 cm^2), at 1.2×10^6 cells to confluence for 1, 8, and 12 h in RPMI 1640 medium supplemented with 1% FBS, in the presence or absence of 10 μM of TMG (SML0244 Sigma), 50 μM OSMI-1 (SML1621 Sigma) or 0.5 μM Azaserine (A4142 Sigma). The concentrations of the HBP modulators were taken from the following references: OSMI-1 (Ortiz-Meoz et al., 2015), Azaserine (Rajapakse et al., 2009), and TMG (Wani et al., 2017). Cells were then washed with ice-cold PBS and lysed with buffer 50 mM Tris–HCl (pH 8), 137 mM NaCl, 10% (v/v) glycerol, 1% (v/v) Triton, 50 mM NaF, 10 mM disodium β-glycerophosphate, 1 mM Na$_3$VO$_4$, and protease inhibitor cocktail tablets (ROCHE) supplemented with 100 μM PUGNAc (A7229 Sigma) and 4 μM TMG (SML0244 Sigma), to preserve the O-GlcNAcylation state of the proteins during the extraction procedure. The quantification of protein content was determined using the BCA Protein Assay Kit (Thermo Scientific™ 23225), according to the manufacturer's instructions. Forty μg of total protein was resolved by a 10% reduction SDS-PAGE using Tris-Glycine gels and transferred to

nitrocellulose membranes (GE Healthcare) at constant amperage (10 V for 14 h). The transfer efficiency and equal loading were verified using Ponceau red staining (17435103 Thermo Scientific). Membranes were first saturated for 60 min with 5% (m/v) nonfat dry milk in Tris-buffered saline (TBS)-Tween buffer [15 mM Tris·HCl, 140 mM NaCl, and 0.05% Tween 20 (vol/vol), pH 8.0]. We used mouse monoclonal anti-O-GlcNAc (RL2, ab2739) at a dilution of 1:1,000, and rabbit polyclonal anti-β-actin (4,967 Cell Signaling) at a dilution of 1:1,000 was used as a loading control. After incubation with appropriate antibodies, the bands were visualized using enhanced chemiluminescence reagents (ECL Select, Amersham) and detected with a chemiluminescence ImageQuant™ 500.

Signal density quantification by ImageJ

All western blots were performed independently in triplicate. The obtained images were analyzed by ImageJ software. First, they were converted to 8-bit format, then each "O-GlcNAc protein profile was individually selected and circumscribed with the rectangular ROI selection and "gels" function, followed by quantification of the peak area of the obtained histograms. For more details on the configuration of "gel analyzer options," see supplementary materials. Data were acquired as arbitrary area values, and the differences in the expression between groups were normalized to β-actin. All data are presented as the means ± standard deviation for all performed repetitions. Statistically significant differences among three or more groups were analyzed by one-way analysis of variance, followed by Tukey's *post hoc* analysis. *, **, ***, $p < 0.05$, $p < 0.001$, $p < 0.0001$, respectively, ns non-significant.

Immunofluorescence

J774 cells were grown on a Chamber Slide System (Thermo Fisher Scientific) for 12 h in 1% FBS in the absence or presence of TMG [10 μM], OSMI-1 [50 μM], or Azaserine [0.5 μM]. Cells were washed with Phosphate-buffered saline (PBS), fixed with 4% cold methanol for 20 min, and then washed with PBS. Non-specific binding sites were blocked with IgG-free 2% bovine serum albumin (BSA, Thermo Fisher Scientific) for 30 min at room temperature. Slides were washed and incubated with primary antibody (anti-CD36) diluted 1:200 in PBS with 1% albumin overnight at 4°C in a humidity chamber. Slides were washed with TBS and incubated with a second primary antibody (anti-O-GlcNAc) diluted 1:100, and Rab-5 (E6N8S Cell Signaling) diluted 1:100, for 90 min in a dark humidity chamber. Then, the chambers were washed with PBS 3 times for 5 min. We

incubated the secondary antibodies (Alexa 488-conjugated anti-mouse and Alexa 594-conjugated anti-rabbit) diluted 1:100 at room temperature for 60 min in a dark humidity chamber. Slides were washed, stained, and sealed with Fluoroshield with DAPI-mounting medium (Sigma-Aldrich) and coverslipped. Images were obtained with a Cytation 5 imaging reader.

Signal fluorescence quantification by ImageJ

First, images were converted to 16 bits and freehand selected to draw on the circumference of the cells; 10 cells were randomly selected per image in 4 independent experiments. The "measure" function was used to obtain an average fluorescence intensity. Statistically significant differences between groups were analyzed by one-way analysis of variance, followed by Tukey's *post hoc* analysis. *, **, ***, $p < 0.05$, $p < 0.001$, $p < 0.0001$, respectively, ns non-significant.

Signal fluorescence colocalization by ImageJ

Images were converted to 8-bit and analyzed with the JACoP plug-in of the ImageJ software (2006.02.01). The JACoP colocalization plug-in primarily uses statistics to assess the relationship between fluorescence intensities (Bolte and Cordelières, 2006), using Pearson correlation coefficients that measure the strength of the linear relationship between two variables, the gray values of fluorescence intensity pixels of green and red image pairs, this is mostly done using correlation coefficients that measure the strength of the linear relationship between two variables, in this case the gray values of fluorescence intensity pixels of green and red image pairs. Subsequently, statistically significant differences between groups were analyzed by one-way analysis of variance, followed by Tukey's *post hoc* analysis. *, **, ***, $p < 0.05$, $p < 0.001$, $p < 0.0001$, respectively, ns non-significant.

Results

O-GlcNAcylation protein levels respond according to the time treatment with modulators

To analyze the effect of TMG, OSMI-1, and Azaserine on the levels of O-GlcNAcylated proteins, we treated J774 macrophages in the presence of 10 μM TMG as the optimal dose, 50 μM OSMI-1, or 0.5 μm Azaserine, the signal detected in the blot was

FIGURE 2
Western Blots of the profile of O-GlcNAcylated proteins in J774 macrophages. **(A)** O-GlcNAc profile in cells without stimulation (control), in the presence or absence of TMG (10 μM), OSMI-1 (50 μM), or Azaserine (0.5 μM), during 1, 8 and 12 h. We incubated Western Blots with anti-O-GlcNAc and anti-actin (as a loading control). **(B)** The effect of TMG, OSMI-1, and Azaserine treatment on O-GlcNAc/actin protein expression is observed. Graphs represent the means ±3 independent experiments. Statistical analysis was performed using a one-way analysis of variance followed by Tukey's *post hoc* test. *, **, ***, $p < 0.05$, $p < 0.001$, $p < 0.0001$, respectively, ns non-significant.

measured by densitometry (Figure 2A), shows O-GlcNAc profile proteins in response to treatments; we noticed that when J774 cells were treated with TMG at 8 and 12 h, they had a tendency to exhibit more O-GlcNAcylation compared to the control. OSMI-1 and Azaserine did not show variations between treatment times, otherwise a better response was observed at 12 h of TMG treatment; after these results, we decided to perform the next experiments at 12 h.

CD36 protein colocalization with O-GlcNAc and Rab-5

To explore the effects of TMG, OSMI-1, and Azaserine treatment on the cellular distribution of CD36, J774 cells were examined using immunofluorescence, and we evaluated the colocalization using Pearson correlation with the JACoP plug-in of the ImageJ software. In control cells, CD36 and Rab-5 show a large distribution in intracellular compartments. The increase in UDP-GlcNAc availability under TMG treatment shows a wide distribution to intracellular compartments and areas with increased staining of CD36, which colocalizes with Rab-5, located near the plasma membrane (yellow arrows). Treatment with the OSMI-1 and Azaserine generated a redistribution of CD36 from the cytoplasm to the surface (white arrows). CD36 and Rab-5 colocalization showed a significant decrease in Pearson correlation after treatment with OSMI-1 and Azaserine ($p < 0.05$) (see supplementary materials). These results suggest that CD36 trafficking is sensitive to the environmental status of UDP-GlcNAc.

Discussion

To evaluate the effect of modulators TMG, OSMI-1, and Azaserine on O-GlcNAc protein levels, we treated J774 macrophages. The effects of increased/decreased O-GlcNAcylation levels, depending on the treatment with the aforementioned modulators, were evaluated using an anti-O-GlcNAc antibody (Rl2). The treatment with OSMI-1 and Azaserine demonstrated a non-significant reduction of O-GlcNAcylated proteins, because their formation depends on the availability of UDP-GlcNAc as a substrate (Rajapakse et al., 2009; Olivier-Van Stichelen et al., 2012; Chiaradonna et al., 2018).

An increase in global O-GlcNAcylation levels was observed when J774 cells were treated with TMG, for 8 and 12 h (Figure 2). Immunofluorescence staining showed significant changes in the mean fluorescence intensity of O-GlcNAcylation after Azaserine treatment ($p < 0.0001$), and we observed a tendency to decrease O-GlcNAcylation after treatment with OSMI-1. We significantly increased O-GlcNAcylation levels by applying TMG treatment ($p < 0.0001$) (Figures 3A, B). These results confirm the function of the modulators. CD36 and O-GlcNAc showed high correlation rates with the control, and we detected no changes between the treatments compared to the control (Figure 3C).

Subsequently, we evaluated whether the availability of UDP-GlcNAc could impact the localization of CD36. We assessed the localization of CD36 by immunofluorescence; J774 macrophages were treated with TMG, OSMI-1, and Azaserine for 12 h. Under

FIGURE 3

CD36 protein colocalization with O-GlcNAc and Rab-5. Macrophages were cultured with RPMI medium either in the presence or absence of TMG, OSMI-1, or Azaserine for 12 h and processed for immunofluorescence, as described in the materials and methods section. **(A)** Representative images of immunofluorescence staining for O-GlcNAc (green), CD36 (red), and merged with cell nuclei (blue). **(B)** Histograms represent the means $\pm$ SE from four independent experiments of mean fluorescence intensity of O-GlcNAcylation levels (green), with different treatments of TMG, OSMI-1, and Azaserine for 12 h. **(C)** The graph represents the means $\pm$ SE from four independent experiments to measure the Pearson correlation of CD36 and O-GlcNAc colocalization, using the JACoP plug-in of the ImageJ software. **(D)** Representative images of immunofluorescence staining for cell nuclei (blue), Rab-5 (green), and CD36 (red), merged with DAPI and Rab-5/CD36. **(E)** Bar graphs represent the means $\pm$ SE from four independent experiments of Pearson correlation of Rab-5/CD36 colocalization using the JACoP plug-in in ImageJ. * Significant as compared with untreated controls ($p < 0.05$), using ANOVA followed by Tukey's *post hoc* test, *, **, ***, $p < 0.05$, $p < 0.001$, $p < 0.0001$, respectively, ns; non-.significant.

basal conditions, a wide and even distribution of CD36 was observed, both in the cytoplasm and in the plasma membrane. Proteins bound to the Rab-5 antibody were observed predominantly close to the plasma membrane (yellow arrows) and still present in the cytoplasm, probably in intracellular vesicles. When macrophages were treated with TMG, CD36 was observed to be increased in specific areas close to the plasma membrane (blue arrows), although we obtained non-

significant changes compared to control, in colocalization results. On the other hand, after OSMI-1 treatment, CD36 and Rab-5 tended to redistribute close to the plasma membrane (white and green arrows, respectively). Treatment with Azaserine also redistributed CD36 (red arrows) and Rab-5 (purple arrows) to the plasma membrane (Figure 3D). The colocalization between CD36 and Rab-5 showed a significant decrease with OSMI-1 and Azaserine treatment (Figure 3E).

One study suggested that the N-glycosylations present in CD36 are responsible for the increase of CD36 to the membrane and the β-oxidation of oleate in rat hearts after treatment with N-acetylglucosamine (feeder of the hexosamine pathway), which would therefore increase the levels of UDP-GlcNAc favoring the levels of N-glycosylation (Lauzier et al., 2011). Alternatively, another modification involved in the recruitment of CD36 to the plasma membrane may be O-GlcNAc, as demonstrated by Laczy, when perfusing mouse hearts with N-acetylglucosamine, where the binding of CD36 to OGT was increased, improving fatty acid absorption (Laczy et al., 2011). Our results suggest that the O-GlcNAc modification may play a role in the recruitment of CD36 to the macrophage membrane following treatment with TMG. TMG inhibits the OGA enzyme, thereby increasing O-GlcNAcylation levels. After this treatment, CD36 is predominantly found near the plasma membrane predominantly, after this treatment.

There is evidence that both N-glycosylation and O-GlcNAc modification can contribute to the regulation of membrane trafficking. These modifications depend on the concentration of UDP-GlcNAc, generated by the HBP, through the intervention of several metabolites, such as glucose, glutamine, ATP, and Acetyl-CoA, depending on the environmental conditions, which are increasingly considered central regulators that affect cellular physiology (Bond and Hanover, 2015). The control of membrane trafficking can result from the direct modification of the receptor with O-GlcNAc or through the O-GlcNAcylation of other proteins that regulate endocytic trafficking processes, for example, modifying coat proteins involved in membrane fusion and fission (Guo et al., 2014), or proteins involved in clathrin-mediated endocytosis (Guo et al., 2014; Rahmani et al., 2019).

The decrease in colocalization suggests a redistribution of CD36 close to the plasma membrane after OSMI-1 and Azaserine treatment. This evidence also suggests that CD36 localization may be influenced by the nutrient availability of the cell, which determines the level of UDP-GlcNAc through the flux of the HBP. As mentioned, there are many examples that demonstrate the regulation of membrane trafficking through post-translational modifications; however, much remains to be discovered about the details of these mechanisms. One study that evaluated the impact of O-GlcNAc levels on cellular metabolism and energy homeostasis involved AMPK, a heterotrimeric complex signaling protein with many targets that regulate a wide range of cellular processes. AMPK upregulates catabolism, inactivates anabolism, and modulates endocytic traffic (Li and Chen, 2019). AMPK phosphorylation increases and ameliorates autophagic flux after inhibiting O-GlcNAcylation. Jin L et al. suggest that O-GlcNAcylation behaves like a regulator of AMPK activity (Jin et al., 2020).

Pathogen recognition, antigen presentation, and macrophage homeostasis are mediated by various receptors, including mannose and scavenger receptors. It has been reported that these receptors co-localize with Rab5 (Mukherjee et al., 2002), and IL-4/PGE2 stimulation significantly increases the expression of the mannose receptor, Rab5, and the Rab5 GEF Rin in mouse bone marrow-derived macrophages (Wainszelbaum et al., 2006). The recycling of CD36 from endosomes to the plasma membrane and *vice versa* is regulated by different families of proteins, adapter proteins (Scales et al., 1999), and Rab-GTPases, which regulate the binding of coat proteins to CD36-enriched areas, leading to the generation of a vesicle that moves through the filaments of the cytoskeleton to its target membrane (Glatz and Luiken, 2018). The Ras superfamily of GTPases is extensively modified by posttranslational modifications like prenylation, phosphorylation, and ubiquitination (Shinde and Maddika, 2018), which facilitate their membrane attachment and determine their subcellular localization and function; phosphorylation could trap the GDP-bound Rab either in the cytosol or at the membrane (Konstantinopoulos et al., 2007). In Hep3B cells, hyper O-GlcNAc modification regulates Rab3A, which attenuates the tumor suppressor effect of Rab3A on hepatocellular carcinoma (HCC) metastasis (Wu et al., 2018). Rab11, another traffic membrane regulator, is also modified by O-GlcNAc (Zhong et al., 2015). The evidence above suggests that glycosylations influence vesicular traffic by directly modifying membrane receptors like CD36 and impacting proteins involved in vesicular traffic, like Rab proteins.

The structure and function of receptors and vesicular trafficking regulatory proteins are mediated by modifications such as glycosylation, that are sensitive to metabolic conditions and impact different physiological contexts, health, and disease. The complexity of glycosylation on CD36 needs to be supported by further research. The structural variation presented by N-glycans is regulated by the modulation in the expression profile and activity of glycosyltransferases and glycosidases, leading to specific N-glycosylation structures in each cell type (Croset et al., 2012; Butler and Spearman, 2014). Direct glycosylation or phosphorylation of glycosyltransferases promotes their activity (Agrawal et al., 2014). Furthermore, glycosyltransferases and glycosidases and/or the availability of their specific substrates also modulate the glycosylation profile (Paneque et al., 2023). Then, the modulation of N-glycosylation is regulated at the transcriptional and post-translational levels and by the availability of substrates, revealing the complexity of regulating N-glycosylation (Esmail and Manolson, 2021). Nutrient availability regulates cellular O-GlcNAcylation levels by determining the amount of UDP-GlcNAc and modulating the

levels of OGT, OGA, and their respective adapter proteins and substrates. Similarly, the activity of the OGT enzyme is regulated by the nutritional conditions of the cell. In response to systemic changes in the metabolic state (through hormonal signals) (Yang and Qian, 2017), specific adapter proteins intervene to O-GlcNAcylate a specific substrate, leading to the activation of key cellular pathways, such as suppression of anabolism, stimulation of gluconeogenesis and ketogenesis, and activation of thermogenesis (Yang and Qian, 2017). This study modified the availability of a single substrate, UDP-GlcNAc, a variable within a complex network that regulates glycosylations. Further investigation using CD36 mutants at specific glycosylation sites may provide more compelling results for understanding its biological effects in folding, maturation, trafficking, secretion, and function.

These results are intended to set a pattern to continue discovering the impact of glycosylations on macrophage functions related to CD36. There are some questions to be addressed, such as whether aberrant modification of these glycosylations could uniquely influence localization, similarly influence inflammatory functions and lipid uptake, or disrupt the physiological conditions of macrophages. Our results suggest that UDP-GlcNAc is available for influx into CD36 and Rab-5 redistribution between the cytoplasm and cell surface.

Limitations of the study

1. Dependence on Specific Modulators: The conclusions of this study rely heavily on the effects of specific chemical modulators (Thiamet G, OSMI-1, and Azaserine) on the HBP. The observed responses may be specific to these compounds and may not fully represent the natural physiological regulation of O-GlcNAcylation. Hence, gene manipulations of OGT, OGA, GFAT, and CD36, will be required in addition to the use of agonists/antagonists of CD36.
2. *In vitro* Model: While the J774 macrophage cell line is a valuable tool, it limits the applicability of the findings to *in vivo* systems, where the cellular environment and interactions are more complex. The results obtained *in vitro* may not fully translate to *in vivo* contexts due to differences in the cellular microenvironment and systemic factors, underscoring the need for further research in this area.
3. Single Time-Point Analysis: Although necessary, the study's focus on specific time points (e.g., 12 h post-treatment) to assess the effects of modulation on protein O-GlcNAcylation and localization may miss transient changes and dynamic processes at other time intervals. A more comprehensive time-point analysis could provide a more nuanced understanding of these processes.
4. Limitations of Quantitative Analysis: The methods used to quantify O-GlcNAcylation levels and protein localization, such as densitometry of Western blots and fluorescence intensity measurements in immunofluorescence, have

inherent limitations in precision and reproducibility. These methods are heavily dependent on the linearity and sensitivity of the detection systems and may not accurately reflect subtle changes in O-GlcNAcylation or protein distribution. Other loading controls, such as β-tubulin or clathrin, may be considered in future studies.
5. Lack of Direct Evidence for Mechanistic Pathways: While the study discusses the potential mechanisms by which O-GlcNAcylation affects protein function and localization, it needs more direct experimental evidence linking specific O-GlcNAcylation changes to observed functional outcomes. Molecular studies or genetic interventions that directly alter O-GlcNAcylation sites on CD36 may provide more conclusive evidence of causality.
6. Generalizability of Findings: The findings are derived from a single type of immune cell (macrophages) and may not be generalizable to other cell types involved in the immune response, such as T cells, B cells, or dendritic cells, which may have different O-GlcNAcylation dynamics and functional responses.

Data availability statement

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

Ethics statement

Ethical approval was not required for the studies on animals in accordance with the local legislation and institutional requirements because only commercially available established cell lines were used.

Author contributions

Conceptualization and experimental procedures, KJL-R and YP-C, experimental procedures, E-RH; supervision and critical revision, EZ, and YP-C; critical revision of the manuscript, RS-M, AM-R, RT-R, LA-F, B-FR, SP-C, and AEA-M.

Funding

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgments

We thank the Biochemistry Department of Universidad Nacional Autónoma de México, Mexico City, Mexico, for their technical support.

Sensing antibody functions with a novel CCR8-responsive engineered cell

Jianyu Hao[1], Yitong Lv[1], Xufeng Xiao[2], Lidan Li[3]* and Changyuan Yu[1]*

[1]College of Life Science and Technology, Beijing University of Chemical Technology, Beijing, China, [2]Jiangsu Key Laboratory of Phylogenomics and Comparative Genomics, Jiangsu Normal University, Xuzhou, China, [3]National Clinical Research Center for Infectious Diseases, Shenzhen Third People's Hospital, The Second Affiliated Hospital of Southern University of Science and Technology, Shenzhen, China

Human chemokine receptor 8 (CCR8) is a promising drug target for immunotherapy of cancer and autoimmune diseases. Monoclonal antibody-based CCR8 targeted treatment shows significant inhibition in tumor growth. The inhibition of CCR8 results in the improvement of antitumor immunity and patient survival rates by regulating tumor-resident regulatory T cells. Recently monoclonal antibody drug development targeting CCR8 has become a research hotspot, which also promotes the advancement of antibody evaluation methods. Therefore, we constructed a novel engineered customized cell line HEK293-cAMP-biosensor-CCR8 combined with CCR8 and a cAMP-biosensor reporter. It can be used for the detection of anti-CCR8 antibody functions like specificity and biological activity, in addition to the detection of antibody-dependent cell-mediated cytotoxicity and antibody-dependent-cellular-phagocytosis. We obtained a new CCR8 mAb 22H9 and successfully verified its biological activities with HEK293-cAMP-biosensor-CCR8. Our reporter cell line has high sensitivity and specificity, and also offers a rapid kinetic detection platform for evaluating anti-CCR8 antibody functions.

KEYWORDS

monoclonal antibody, CCR8, engineered cell line, functional evaluation, HEK293-cAMP-biosensor-CCR8

Introduction

Chemokine (C-C motif) receptor 8 (CCR8) is a chemokine receptor principally expressed on regulatory T cells (Treg) (Miller et al., 1990; Vila-Caballer et al., 2019). CCR8 is preferentially expressed in lymphoid organs and participates in the recruitment of Tregs and Th2 cells to inflammatory and tumor sites (Miller et al., 1990; Zingoni et al., 1998; Gombert et al., 2005). CCR8 is a promising drug target for immunotherapy of cancer and autoimmune diseases. Compared to normal tissues, CCR8 is upregulated in rectal cancer, melanoma, gastric cancer, metastatic brain cancer, and metastatic liver cancer, especially in Tregs cells of breast cancer (Agarwal et al., 2013; Cao et al., 2016; Saito

et al., 2017; Hughes and Nibbs, 2018; Kuehnemuth et al., 2018; Li et al., 2018; Wiedemann et al., 2019). More than 30% of Tregs are activated in the presence of CCL1(Chemokine (C-C motif) ligand 1) in human peripheral blood cells causing the expression of CCR8 upregulation (Yeh et al., 2015; Barsheshet et al., 2017; Xu et al., 2017). In recent years, monoclonal antibodies have been successfully developed as targeted therapies for various inflammatory diseases and cancers (Weiner et al., 2010; Scott et al., 2012; Grilo and Mantalaris, 2019). Tregs with CCR8 were found to be sensitive to the effects of monoclonal antibodies (mAbs), which may have a significant impact on the immune response (García-Domínguez et al., 2021). Many CCR8 monoclonal antibodies have been produced by hybridomas to explore their biological function and cancer immunotherapy (Villarreal et al., 2018).

Various assays were performed to evaluate the properties of the antibody. The biological activities could be measured by Enzyme-linked immunosorbent assay (ELISA) (Suárez et al., 2016).

The biological functions of mAbs could be measured by ELISA (Xiao and Isaacs, 2012; Waritani et al., 2017). Western blot is a widely used analytical technique in molecular biology and immunogenetics that detects specific proteins or antibodies, which was used to detect the biological function, thermal stability, and purity of antibodies (Mahmood and Yang, 2012; Ma et al., 2019).

However, these approaches are time- and solvent-consuming and often involve several complicated procedures. BIAcore could be utilized to indicate the retention of antigen binding and specificity, but it requires costly instrumentation and specialized reagents (Hutchinson, 1995). In this study, we developed a novel CCR8 response engineered cell to achieve rapid dynamic detection of antibody specificity and biological activity. First, we constructed a cAMP signaling pathway regulated by G protein-coupled receptors in HEK293 cells by lentiviral infection. The anti-CCR8 antibodies regulate the level of intracellular cAMP after binding to cell surface receptors, which characterizes the specificity and biological activity of anti-CCR8 antibodies. Compared with ELISA and complex flow cytometers, the operation of the experiment becomes more convenient with the CCR8 response engineered cell sensing system. Our detection platform can be completed in 6 h and dynamically evaluates intracellular cAMP levels. Our reporter cell line has high sensitivity and specificity and also offers a rapid kinetic detection platform for evaluating antibody functions.

Materials and methods

All of the oligonucleotides used in this work were synthesized by Genewiz. (Suzhou, China). Forskolin was obtained from MedChemExpress (Shanghai, China). jetPRIME was from Polyplus (Franch) and CCL1 was purchased from R&D

Systems (Minnesota, United States). SP2/0 and HEK293T were purchased from Procell (Hubei, China). The engineered cell lines, Jurkat-NFAT-Luc2-CD16a-V158, Jurkat-NFAT-Luc2-CD32a-V158, BXPC-3-CCR8, CHO-K1-cyno-CCR8, CHO-K1-CCR8 and HEK293T-CCR8 used in this work were constructed in our previous research.

Construction of the HEK293-cAMP-biosensor-CCR8

The DNA coding sequences for CCR8 and cAMP biosensors were cloned into the vector pLVX to generate the pLVX-IRES-hyg-cAMP-22F and pLVX-EF1a-IRES-puro-CCR8 vectors. Lentiviral particles were produced in HEK293T cells by transient co-transfection with the helper plasmids PSPAX2 and PMD2G using jetPRIME. HEK293T was cultured in RPMI1640 supplemented with 10% fetal bovine serum and incubated at 37°C in a humidified atmosphere of 5% CO_2/95% air for 48 h. The virus was collected and concentrated after 12 h and resuspended in a medium to obtain the lentiviral particles. The method of lentiviral infection was used to gradually integrate the foreign genes cAMP-biosensor and CCR8 into the target cell HEK293T. HEK293T-cAMP-biosensor-CCR8 was cultured in RPMI1640 medium supplemented with 9 µg/mL Puromycin, 100 µg/mL Hygromycin B and 10% fetal bovine serum and incubated at 37°C in a humidified atmosphere of 5% CO_2/95% air. After antibiotic killing, gene overexpression efficiencies were verified by Glosensor cAMP and flow cytometer.

Validation of the HEK293-cAMP-biosensor-CCR8

Cells were collected after digestion with 0.25% trypsin-EDTA and seeded at a density of 20,000 cells per well in a 96-well opaque assay plate. These cells were cultured in a CO_2-independent medium supplemented with Glosensor cAMP Reagent and 10% fetal bovine serum and incubated at 37°C in a humidified atmosphere of 5% CO_2/95% air for 2 h. 0.1 mL of CCL1 (1 ng/mL) was added to the assay plate and incubated in dark conditions for 0.5 h. After adding 0.01 mL of Forskolin (1 µM), luminescence signals were measured using the BMG CLARIO star.

Flow cytometry (FACS)

Homogenous cells of HEK293-cAMP-Biosensor-CCR8 were collected after digestion with 0.25% trypsin-EDTA and seeded at a density of 20,000 cells per well in a 96-well assay plate. PE Anti-human CD198 antibody was added at 1 µg/mL

FIGURE 1
Illustration of the engineering customized cell line HEK293-cAMP-biosensor-CCR8.

and the cells were incubated at 4°C in dark conditions for 1 h with Anti-human-CD198 (CCR8). After cleaning with PBS, data were acquired with a flow cytometer (Luminex Corporation, Inc.) and analyzed using FlowJo.

Antibody validation by enzyme-linked immunosorbent assay (ELISA)

BXPC-3-CCR8 cells were collected after digestion with 0.25% trypsin-EDTA and seeded at a density of 20,000 cells per well in a 96-well assay plate. After the cells were fixed and washed with PBS, the 22H9 antibody was added at a 10-fold dilution of 20 μg/mL as the starting concentration. Mouse serum (971) was used as a positive control, and the unrelated antibody IgG isotype was used as a negative control. HRP-conjugated anti-mouse IgG was incubated as a secondary antibody. ELISA signals were measured using the TMB Substrate Reagent Set (BD Bioscience, San Diego, United States).

Antibody-dependent cell-mediated cytotoxicity (ADCC) and antibody-dependent-cellular-phagocytosis (ADCP) assays

Cells were collected after digestion with 0.25% trypsin-EDTA and seeded at a density of 10,000 cells per well in a 96-well opaque assay plate and then co-cultured with Jurkat-NFAT-Luc2-CD16a V158 and Jurkat-NFAT-Luc2-CD32a V158. 22H9 was added at a maximum concentration of 10 μg/mL at a 10x dilution and incubated

for 6 h, followed by the addition of 50 μL luciferase substrate; luminescence signals were measured using the BMG CLARIO star.

Results and discussion

As shown in Figure 1, the DNA coding sequences for CCR8 and the cAMP biosensor were cloned into the pLVX vector. Lentiviral particles were produced in HEK-293T cells by transient co-transfection with the helper plasmids PSPAX2 and PMD2G using jetPRIME. Lentiviral infection was employed to gradually integrate the foreign genes encoding the cAMP biosensor and CCR8 into the target HEK293 cells. CCR8 is currently recognized as the sole receptor for CCL1 (Korbecki et al., 2020). Upon binding and activation of CCR8 by CCL1, intracellular Gαi proteins are recruited. These Gαi proteins inhibit the activation of adenylate cyclase (AC), leading to a decrease in intracellular cAMP levels (Wang et al., 2020). Antibodies that specifically bind to CCR8 can hinder the activation of CCR8 by CCL1, resulting in an increase in intracellular cAMP concentrations. Intracellular cAMP concentrations can serve as an indicator of antibody bioactivity.

Forskolin, a potent activator of AC, is known to increase the production of intracellular cAMP (Alasbahi and Melzig, 2012; Sapio et al., 2017). First, the cAMP biosensor vector was transfected into HEK-293 cells. To confirm the successful construction of the HEK293-cAMP-biosensor cell line, Forskolin was utilized to stimulate intracellular cAMP production, and its concentration was measured using the Glosensor cAMP reagent. As the concentration of Forskolin

FIGURE 2
Construction of a model for kinetic detection of the HEK293-cAMP-biosensor-CCR8 reporter cell line. **(A)** Activation of forskolin on the HEK293-cAMP-Biosensor. The intracellular cAMP levels display a dose-dependent increase as the concentration of Forskolin also increases. The Y-axis "Fold" represents the multiple of the dosing group versus the blank group. **(B)** Flow cytometry measurements of CCR8 mAb binding on the homogeneous cell clone HEK293-cAMP-Biosensor-CCR8 1B1 reporter cell line. **(C,D)** Kinetics of the HEK293-cAMP-Biosensor-CCR8 reporter cell line upon treatment with different concentrations of Forskolin. The cAMP signal value progressively increases as the concentration of Forskolin also increases. **(E,F)** Kinetics of intracellular cAMP levels in the HEK293-cAMP-Biosensor-CCR8 reporter cell line treated with different concentrations of CCL1 and Forskolin (1 μM). The cAMP signal value gradually decreases as the concentration of CCL1 increases.

increased, intracellular cAMP levels also increased, indicating the successful establishment of the HEK293-cAMP-biosensor cell line (Figure 2A). Single-cell clones were generated for the HEK293-cAMP-biosensor-CCR8 cells. The expression of CCR8 in the target cells was verified by flow cytometry analysis (Supplementary Figure S2). Based on the results of flow cytometry and functional assays, the homogeneous cell clone 1B1 was selected for further experiments. Flow cytometry analysis showed a single peak, indicating specific binding of the CCR8 monoclonal antibody to cell surface CCR8 expression (Figure 2B). A 30-min kinetic assay was performed to examine the cAMP signaling pathways in the cells (Figure 2C; Supplementary Figure S1A), and the data from the 10-minute time point were chosen for analysis (Figure 2D). With increasing concentrations of Forskolin, the intracellular cAMP levels exhibited a corresponding increase. These results suggested the successful construction of the HEK293-cAMP-biosensor-CCR8 reporter cell line. Furthermore, based on the findings in Figures 2A, D, forskolin concentration of 1 μM was selected for the subsequent experiments. CCL1 was added at a concentration of 200 ng/mL, at a 10x dilution with nine test concentrations. After incubation in the dark for 0.5 h, kinetic detection was performed using 1 μM Forskolin (Figures 2E, F;

Supplementary Figure S1B). This established a kinetic detection platform capable of measuring intracellular cAMP levels.

A total of 10 female Balb/c mice, aged 6–8 weeks, were immunized by injecting CCR8 mRNA (10 μg/mouse) into the inner thigh muscle of the hind leg. Antibody titers in the blood were assessed by tail cutting (Supplementary Figure S3). Splenocytes were then electrofused with SP2/0 cells to generate a hybridoma cell line. Flow cytometry and enzyme-linked immunosorbent assay (ELISA) were employed to evaluate the binding activity of the monoclonal hybridoma cell supernatant (Supplementary Figures S4, S5). The optimal antibody, 22H9, was selected for further experiments.

The functionality of the new anti-CCR8 antibody, 22H9, was assessed using the HEK293-cAMP-biosensor-CCR8 reporter cell line. In this system, varying concentrations of 22H9, CCL1, and Forskolin were co-incubated to observe the kinetics (Figure 3A; Supplementary Figure S1C). The results indicated that the HEK293-cAMP-biosensor-CCR8 reporter system exhibited remarkable sensitivity, even at low antibody concentrations. As the antibody concentration increased, the inhibitory effect of CCL1 on the cAMP signaling pathway decreased, leading to an increase in the induction factor (Figure 3B). We hypothesized that

Demonstration of the specificity and biological activity of the 22H9 antibody. **(A)** Binding of the 22H9 antibody to HEK293T-CCR8 by flow cytometry. **(B)** Binding of the 22H9 antibody to HEK293T-CCR8 by ELISA. **(C)** Antibody blocking the binding of CCL1 to HEK293-cAMP-Biosensor-CCR8.

this antibody binds to the CCR8 receptor on the cell surface and effectively blocks the activation of the chemokine CCL1. To evaluate the ADCC and ADCP activity of 22H9, we utilized the Jurkat-NFAT-Luc2-CD16a-V158 and Jurkat-NFAT-Luc2-CD32a-V158 reporter cell lines, respectively. As depicted in Figures 3C, D, the anti-CCR8 antibody 22H9 bound to its target on the surface of the HEK293-cAMP-biosensor-

CCR8 cells, thereby activating ADCC and ADCP. The luminescence intensity increased with higher antibody concentrations, allowing the detection of the biological activity of 22H9. Our engineered cell line proves useful for evaluating antibody activity.

Typically, antibody binding activity is assessed using flow cytometry or ELISA. In the case of the new anti-CCR8

antibody 22H9, its binding capacity was characterized by measuring fluorescence values. The EC50 values, as determined by flow cytometry (Figure 4A) and ELISA (Figure 4B), were 0.0218 µg/mL and 0.236 µg/mL, respectively. However, these methods are time-consuming, require the use of solvents, and involve several complicated steps. Alternatively, the binding activity of antibodies can be evaluated using the HEK293-cAMP-biosensor-CCR8 reporter system. In this system, 22H9 binds to CCR8, blocking the binding activity of CCL1. Upon the addition of forskolin, luminescence increases. Different concentrations of the antibody elicit different responses, with an EC50 value of 0.0332 µg/mL (Figure 4C). Compared to traditional methods using an inherent Luciferase reporter gene system, the reporter cell system developed in this study exhibits high sensitivity and can effectively characterize the specificity of anti-CCR8 antibodies.

Conclusion

In summary, we have successfully constructed a reporter cell line that regulates the cAMP signaling pathway through the CCR8 protein receptor. The anti-CCR8 antibody can specifically bind to the cell surface G protein-coupled receptor CCR8 to block the binding of the chemokine CCL1 to CCR8. The specificity and biological activity of antibodies are demonstrated by intracellular cAMP levels. In this study, we constructed reporter cell lines to provide a rapid dynamic detection platform for the specificity and biological activity of CCR8 antibodies.

Effects of Baimuxinol on the inflammation and oxidative stress of LPS-induced RAW264.7 macrophages *via* regulating the NF-κB/IκBα and Nrf2/ARE signaling pathway

Yan Chen[1], Nan Chen[1], Jing Wang[2] and Shuqing Li[1]✉

[1]Department of critical care, Taizhou Hospital of traditional Chinese medicine, Taizhou, Jiangsu, China; [2]Department of emergency, Taizhou Hospital of traditional Chinese medicine, Taizhou, Jiangsu, China

Baimuxinol (BAI) is a sesquiterpenoid compound isolated from agarwood. This study aimed to investigate the specific mechanism of BAI on the inflammation as well as oxidative stress of RAW264.7 cells induced by lipopolysaccharide (LPS). The proliferation and cell viability were detected with EdU and MTT assay. The levels of inflammatory factors and antioxidant-related indexes were determined with corresponding kits. The qRT-PCR and western blot assays were performed to detect the expression of the related genes. We found that compared with the control group, cell viability and proliferation of the RAW264.7 cells was increased in the LPS group, while it was decreased in the BAI groups. In addition, in the LPS group, the contents of TNF-α, IL-1β, IL-6, ROS, MDA, PC and 8-OHdG were increased, the activities of T-SOD and CAT were decreased in comparison with the control group. It was reversed after BAI treatment. Finally, we confirmed that the NF-κB/IκBα signaling pathway is inhibited and the Nrf2/ARE signaling pathway is activated after BAI treatment. BAI relieved inflammation and oxidative stress of RAW264.7 macrophages induced by LPS through regulating the NF-κB/IκBα and Nrf2/ARE signaling pathway, which provided a novel insight for the therapy of sepsis.

INTRODUCTION

Sepsis is a systemic inflammatory response syndrome, which refers to organ dysfunction caused by host response disorder. It is a serious life-threatening disease, not only has a high incidence rate and mortality but also takes up a lot of medical resources (Arefian *et al.*, 2017). In 2016, the global medical community redefined sepsis, pointing out that sepsis is a fatal organ dysfunction due to the infection (Singer *et al.*, 2016). At present, despite the advances in antibiotic therapy (Alhashem *et al.*, 2017), mechanical therapy (Zampieri *et al.*, 2017), maintaining blood glucose balance (Dellinger *et al.*, 2008) and other treatment methods, severe sepsis is still the main cause of death. In addition, in the process of an inflammatory response, macrophages recognize pathogen/injury-related molecular patterns such as lipopolysaccharide (LPS) through toll-like receptor 4 (TLR4) and other pattern recognition receptors expressed on their cell membrane and then activate downstream signaling pathways, such as NF-κb and MAPKs (Lancaster *et al.*, 2018). Many studies have confirmed that NF-κB is closely related to inflammation (McDaniel *et al.*, 2016; Zaidi *et al.*, 2018). The p65/p50 NF-κB usually binds to IκBα and exists in the cytoplasm (McDaniel *et al.*, 2016). In response to an inflammatory reaction, IκBα will be phosphorylated and isolated from the NF-κB subunit. Free NF-κB transported to the nucleus and acted as a transcription factor, eventually leads to the secretion of inflammatory factors such as IL-6, IL-1β and TNF-α (Liang *et al.*, 2018).

Additionally, there is the interaction between inflammatory response and oxidative stress, the role of oxidative stress in uncontrolled inflammatory diseases has been gradually concerned (Tian *et al.*, 2017). Oxidative stress refers to the imbalance of the redox system in the body under the attack of harmful stimulating factors. Excessive reactive oxygen species (ROS) destroy the antioxidant function and lead to the inflammatory response (Newsholme *et al.*, 2018; Forrester *et al.*, 2018). Studies have found that Nrf2/ARE signaling pathway is closely related to oxidative stress in sepsis (Li *et al.*, 2018). When oxidative stress occurs, Nrf2 will enter into the nucleus and interact with ARE to regulate the levels of downstream antioxidant genes, including heme oxygenase-1 (HO-1), catalase (CAT) and superoxide dismutase (SOD). Therefore, up-regulation of Nrf2 expression and activation of ARE-related antioxidant protein can improve oxygenation, inhibit oxidative stress response and alleviate sepsis injury(Wu *et al.*, 2020).

Eaglewood, also known as Aquilaria Sinensis (Lour.) Spreng. is a famous traditional Chinese medicine in China. It has the functions of Xiangqi Zhitong, Wenzhong Zhou, Naqi Pingchuan. Clinically, it is commonly used in the treatment of chest and abdominal distension and pain, stomach cold and vomiting hiccup, kidney deficiency and dyspnea, etc. The main active components of Eaglewood are 2-(2-phenylmethyl) chromones and sesquiterpenes. Many studies have found eaglewood extract has anti-inflammatory and antioxidant effects (Zhou *et al.*, 2008; Lin *et al.*, 2013). Baimuxinol (BAI) is a sesquiterpenoid compound isolated from agarwood. However, as far as we know, there are very limited studies on the pharmacological effects of BAI.

Therefore, in the present study, we aimed to explore the effects of BAI on the proliferation and levels of inflammatory factors and antioxidant-related indexes of RAW264.7 cells stimulated by LPS. We hypothesized that BAI may alleviate LPS induced inflammation and oxidative stress *via* regulating the NF-κB/IκBα and Nrf2/ARE signaling pathway.

MATERIAL AND METHOD

Cell culture

RAW264.7 cells from leukemic mice were provided by the cell bank of Shanghai Chinese Academy of Sciences and cultured in high glucose DMEM medium containing 20% fetal bovine serum. 1% penicillin-streptomycin double-antibody was added to the medium. Then the cells were digested with 0.25% trypsin EDTA, passaged in 1:2, and cultured in a 5% CO_2 incubator at 37°C.

Groups

The cells were divided into Control group (CON), Lipopolysaccharide group (LPS, cultured with 50 mg/L LPS), Low baimuxinol group (L+BAI, cultured with 50 mg/L LPS+10 nM baimuxinol), Middle baimuxinol group (M+BAI, cultured with 50 mg/L LPS+50 nM baimuxinol), High baimuxinol group (H+BAI, cultured with 50 mg/L LPS+100 nM baimuxinol). Then the cells were cultured in a 5% CO_2 incubator at 37°C for 24 hours.

MTT

The cells were placed into 96-well plates (2×10^4 cells/well). The MTT reagent was added to the cells after incubation for 24 h. Then the cells were cultured with dimethyl sulfoxide. Finally, the absorbance was measured at 490 nm by a microplate reader.

5-ethynyl-2-deoxyuridine (EdU) Assay

The trypsin was added to the logarithmic phase cells, and resuspended in a complete medium to obtain cell suspensions, then the cells were placed into a 96-well plate (2×10^4 cells/well) and cultured at 37°C in an atmosphere of 5% CO_2, with the cell concentration adjusted to 2000 cells/well. The proliferation ability was measured with a Cell-Light EdU DNA Cell Proliferation Kit (RiboBio, Guangzhou, China) according to the instructions of the manufacturer.

Determination of inflammatory factors antioxidant related indexes

The contents of tumor necrosis factor α (TNF-α), interleukin 1β (IL-1β), interleukin 6 (IL-6), malondialdehyde (MDA), 8-hydroxy-2'-deoxyguanosine (8-OHdG), protein carbonyl (PC) and ROS, and CAT and total superoxide dismutase (T-SOD) activities of the cells were determined by the corresponding kits provided by Nanjing Jiangcheng Bioengineering Institute (Nanjing, China).

Quantitative real-time polymerase chain reaction (qRT-PCR)

The RNA was extracted with TRIzol® (Thermo Fisher Scientific, MA, USA). The transcript RT Kit (TIANGEN Biotech, Beijing, China) was conducted to reverse the RNA to cDNA. The mRNA expressions of the target genes were determined with a miScript SYBR Green PCR Kit (Qiagen, Germany) on a 7900 Real-Time PCR System. Reaction conditions: 95°C, 30 s; 95°C, 5 s, 40 cycles; 60°C, 30 s; 95°C, 15 s; 60°C, 30; 95°C, 15 s. The $2^{-\Delta\Delta Ct}$ method was performed to analyze the relative mRNA expressions. GAPDH was selected as the housekeeping gene. The primers used for qPCR were as follows: IL-6, For: TCCAGTTGCCTTCTTGGGAC, Rev: AGA-CAGGTCTGTTGGGAGTG; IL-1β, For: GAAATGCCACCTTTTGACAGTG and Rev: TG-GATGCTCTCATCAGGACAG; TNF-α, For: AGC-CGATGGGTTGTACCTTG, Rev: ATAGCAAATCG-GCTGACGGT.

Western blot

The protein of the cells was lysed with RIPA buffer (Beyotime Biotechnology), and the concentration was detected using the BCA method (Beyotime Biotechnology). The protein samples (give concentration=20μg) were separated by 12% SDS-PAGE, transferred to the PVDF membrane (Millipore) and blocked in TBS (50 mmol/l Tris-HCL [PH7.6], 150mmol/l NaCl) containing 0.1% Tween-20 (TBS-T) and 5% non-fat milk powder for 2 hr. Then the PVDF membranes were incubated with the primary antibody (Nrf2, 1:1000 dilution; HO-1, 1:1000 dilution; NF-κB, 1:1000 dilution; p-NF-κB, 1:1000 dilution; IκBα, 1:1000 dilution; p-IκBα, 1:1000 dilution;GAPDH, 1:500 dilution; Abcam Trading Co. Ltd., Shanghai) at 4°C overnight. The incubation product was further incubated with a secondary antibody (1:2000 dilution) for 1.5h. Finally, the blot was colored with ECL, and then exposed by LAS4000 chemiluminescence imaging analyzer for gray analysis.

Statistical analysis

All data were expressed as mean ± S.D. SPSS22.0 software was performed for statistical analyses. One way analysis of variance (ANOVA) with a Tukey's post hoc test was used for comparison among groups. $P<0.05$ indicated significant difference.

RESULTS

BAI suppressed the viability of the RAW264.7 cells

First, we determined the effect of BAI on the viability of the RAW264.7 cells. The molecular structure of CEP was shown in Fig. 1A. Compared with the CON group, the viability of the cells in the LPS group was significantly increased. After BAI treatment, the viability of the cells was dramatically decreased (Fig. 1B). In addition, the proliferation of the cells was significantly increased after LPS treatment and BAI inhibited the growth of the cells in a dose-dependent manner (Fig. 1C–D).

BAI decreased the levels of inflammatory factors in the RAW264.7 cells

To accurately explore the role of the BAI on the inflammatory response. We analyzed the TNF-α, IL-1β and IL-6 levels of the cells. As shown in Fig. 2, in the LPS group, the levels of TNF-α, IL-1β and IL-6 were markedly up-regulated in comparison with the CON group. In comparison with the LPS group, the TNF-α, IL-1β and IL-6 levels were markedly decreased in L-BAI, M-BAI and H-BAI groups in a dose-dependent manner.

Figure 3. Role of BAI in the antioxidant function of RAW264.7 cells induced by LPS.
(**A**) The levels of 8-OHdG (**A**), MDA (**B**), PC (**C**), ROS (**D**), CAT (**E**) and T-SOD (**F**) in RAW264.7 cell was detected after LPS and BAI treatment. Notes: Control, normal cells; LPS, normal cells + 50 mg/L LPS; L+BAI, normal cells + 50 mg/L LPS+10 nM baimuxinol; M+BAI, normal cells + 50 mg/L LPS+50 nM baimuxinol; H+BAI, normal cells + 50 mg/L LPS+100 nM baimuxinol. **P<0.01, ***P<0.001, *vs.* control group; #*P*<0.05, ##*P*<0.01, ###*P*<0.001 *vs.* LPS group.

Figure 4. Role of BAI in the mRNA levels of inflammatory factors and NF-κB/IκBα signaling pathway in RAW264.7 cells induced by LPS.
(**A**) The mRNA expressions of TNF-α, IL-1β and IL-6 were measured with qRT-PCR. (**B–D**) The protein expressions of p-NF-κB, NF-κB, p-IκBα and IκBα were detected with western blot. Notes: Control, normal cells; LPS, normal cells + 50 mg/L LPS; L+BAI, normal cells + 50 mg/L LPS+10 nM baimuxinol; M+BAI, normal cells + 50 mg/L LPS+50 nM baimuxinol; H+BAI, normal cells + 50 mg/L LPS+100 nM baimuxinol. **$P<0.01$, ***$P<0.001$, vs. control group; #$P<0.05$, ##$P<0.01$ vs. LPS group.

BAI relieved the oxidative stress of the RAW264.7 cells

Subsequently, we explore the effects of BAI on the antioxidant capacity of the RAW264.7 cells. As shown in Fig. 3, in the LPS group, the concentrations of the ROS, MDA, PC and 8-OHdG were dramatically up-regulated, and the T-SOD and CAT activities were significantly down-regulated in comparison with the control group. BAI reversed the effects of LPS on the levels of ROS, MDA, PC, 8-OHdG, T-SOD and CAT in a dose-dependent manner.

BAI suppressed the NF-κB/IκBα signaling pathway

Next, we analyzed the role of BAI in mRNA expressions of inflammatory factors and NF-κB/IκBα signal-

Figure 5. Role of BAI in the Nrf2/ARE signaling pathway in RAW264.7 cells induced by LPS.
(**A**) The mRNA expressions of Nrf2, HO-1, CAT and SOD1 were detected by qRT-PCR. (**B–D**) The protein expressions of Nrf2 and HO-1 were measured by western blot. Notes: Control, normal cells; LPS, normal cells + 50 mg/L LPS; L+BAI, normal cells + 50 mg/L LPS+10 nM baimuxinol; M+BAI, normal cells + 50 mg/L LPS+50 nM baimuxinol; H+BAI, normal cells + 50 mg/L LPS+100 nM baimuxinol. ***$P<0.001$, vs. control group; #$P<0.05$, ##$P<0.01$, ###$P<0.001$ vs. LPS group.

ing pathway. In the LPS group. the mRNA expressions of TNF-α, IL-1β and IL-6 were markedly up-regulated in comparison with the control group. Compared with the LPS group, the TNF-α, IL-1β and IL-6 mRNA expressions were markedly down-regulated in L-BAI, M-BAI and H-BAI groups in a dose-dependent manner (Fig. 4A). In addition, in comparison with the control group, the protein expressions of p-NF-κB and p-IκBα in the LPS group were markedly up-regulated. BAI treatment significantly down-regulated the protein expressions of p-NF-κB and p-IκBα in a dose-dependent manner (Fig. 4B–D).

BAI suppressed the Nrf2/ARE signaling pathway

Finally, the role of BAI in the Nrf2/ARE signaling pathway was explored. We found the mRNA expressions of Nrf2, HO-1, CAT and SOD1 were significantly decreased after LPS treatment, while BAI significantly increased the Nrf2, HO-1, CAT and SOD1 mRNA expressions in a dose-dependent manner (Fig. 5A). Additionally, the protein expressions of Nrf2 and HO-1 were increased in the LPS group in comparison with the control group. BAI markedly up-regulated the protein expressions of Nrf2 and HO-1 (Fig. 5B–D).

DISCUSSION

At present, the theory of uncontrolled inflammatory response and oxidative stress are major factors for the pathogenesis of sepsis. In the current study, we found BAI can reverse the excessive proliferation of RAW264.7 cells caused by LPS. Additionally, BAI could relieve inflammation and oxidative stress by regulating the NF-κB/IκBα and Nrf2/ARE signaling pathway.

Macrophages is one of the main cells that participated in inflammation. Stimulated by LPS, macrophages could induce the secretion of inflammatory factors, such as IL-1β, IL-6, TNF-α and so on, and then produce a clinical inflammatory response (Cotran et al., 1999). Excessive inflammation is the major factor in many chronic diseases, including autoimmune diseases and neurodegenerative diseases. Therefore, inhibition of excessive inflammatory response is an effective method for the therapy of chronic diseases (Tabas et al., 2013). TNF-α and IL-1β are the initiating factors in inflammatory mediators cascade reaction (Johnson et al., 2015). Among them, TNF-α is a pro-inflammatory cytokine in regulating immune cells. It can induce fever and apoptosis by producing IL-1β and IL-6 and then induce inflammation. The abnormal content of TNF-α leads to the occurrence of many diseases(Wang et al., 2020; Yosefifard et al., 2019; Johnson et al., 2015). IL-6 is a multifunctional cytokine that regulates immune, inflammatory and other physiological processes (Unver et al., 2018). The expression of IL-6 is positively regulated by LPS and IL-1β. In the present study, we confirmed that BAI decreases the production and mRNA expression of LPS induced pro-inflammatory cytokines (TNF-α, IL-1β and IL-6) in a dose-dependent manner, suggesting BAI has potential anti-inflammatory activity. Previous studies have confirmed that eaglewood or its extract has an anti-inflammatory function. Lin and coworkers found that the ethanol extract of eaglewood leaf has an obvious anti-inflammatory effect on capillary dilation, hyperpermeability, exudation and edema in the early stage of inflammation (Lin et al., 2013). Wu et al. showed that the extract of eaglewood can inhibit inflammation by down-regulating the expression of COX-2 and iNOS in the immune sig-

nal pathway (Wu et al., 2012). These results were similar to ours and indicated that the extract of eaglewood has an effective anti-inflammatory effect. Therefore, we speculate that BAI, a sesquiterpenoid isolated from eaglewood, maybe a key anti-inflammatory compound.

To further explore the mechanism of BAI, we analyzed the protein expression of the NF-κB/IκBα signaling pathway. NF-κB is critically the control center to regulate inflammatory response (Tak et al., 2001). NF-κB usually binds to IκB in cells in the form of inactive complexes. Once IκB is degraded, NF-κB dimer will transfer to the nucleus and start the transcription of the target gene. A previous study has confirmed that NF-κB can mediate the proliferation, differentiation and production of inflammatory factors of various immune cells(Hayden et al., 2011). In this study, the proliferation ability of the cells was dramatically promoted by LPS, and after treatment of BAI, the over-proliferation of macrophages RAW264.7 was decreased. In addition, we found that LPS activates the NF-κB/IκBα signaling pathway and BAI inhibited it in a dose-dependent manner. Our findings indicated that the inhibitory effect of BAI on overproliferation may be realized by NF-κB/IκBα inhibiting signal pathway. However, the specific mechanism needs to be further explored.

In addition, ROS is an important product of oxidative stress. When the body or cells are stimulated by endogenous or exogenous harmful substances, the antioxidant capacity will be destroyed, which results in a large amount of accumulated ROS and other oxides. Excessive ROS induces cell damage and promotes the occurrence of inflammatory reactions (Bae et al., 2017). On the other hand, inflammatory cells release many active substances in the inflammatory site, which will also lead to the aggravation of oxidative stress (Kumar et al., 2018). In sepsis, a large number of pro-inflammatory factors and the host's anti-inflammatory factors are released to induce the production of ROS, which leads to the imbalance of oxidation-reduction state in the body, causes oxidative stress reaction, and finally damages tissue cells and organ systems (Prauchner et al., 2017). Previous studies have shown that various plant extracts can relieve oxidative damage in sepsis, such as curcumin (Zhong et al., 2016) resveratrol (Aydin et al., 2016), etc. In the current study, we also confirmed that BAI reduces the excess ROS induced by LPS. Furthermore, excessive ROS can lead to protein, lipid and DNA damage (Aitken, 2017), which was also be confirmed in this study that the MDA, PC and 8-OHdG levels are increased after LPS treatment. It implied that the cells lipid peroxidation, protein and DNA damage occur in the cells. It is worth noting that all these are relieved after BAI treatment. Nrf2/ARE signaling pathway is one of the most important protection systems against oxidative stress. When cells are exposed to oxidative stress, Nrf2 is recognized and combined with the DNA motif (GCTGAGTCA) on ARE, which starts the transcription of antioxidant genes, and then leads to the expression of antioxidants and related enzymes, such as HO-1 (Shaw et al., 2020). Interestingly, we demonstrated that expressions of Nrf2 and HO-1 are up-regulated after BAI treatment, which indicated that BAI may improve the antioxidant function via the Nrf2/ARE signaling pathway.

To sum up, our results confirmed that BAI can effectively alleviate the inflammatory response and oxidative stress induced by LPS through regulating the NF-κB/IκBα and Nrf2/ARE signaling pathway. However, there are some limitations in this paper, such as we do not have in vivo experiments for validation because the con-

ditions do not permit. Also we hope to validate it on multiple cells in future studies. In conclusion, this study is the first to confirm that BAI has antioxidant and anti-inflammatory functions. Our findings provide a theoretical basis for the clinical application of eaglewood and a new method for the treatment of sepsis.

miRNA-301 As a molecule promoting necrotizing enterocolitis by inducing inflammation

Dajun Zou, Fude Hu, Qili Zhou and Xiaoqing Xu✉

Department of Pediatric Surgery, Affiliated Hospital of Chengde Medical College, 36 Nanyingzi Street, Chengde, Hebei, 067000. P.R. China

Objective: Necrotizing enterocolitis (NEC) is a devastating inflammatory disease with high morbidity and mortality, mainly affecting premature infants. This study aimed to explore the role of miRNA-301a in the pathogenesis of NEC. **Methods**: The differentially expressed miRNAs and mRNAs were screened by collating RNA-Seq data from the GEO database of intestinal tissue samples. The differential miRNA-mRNAs regulatory network was constructed based on functional enrichment analysis. Newborn BALB/c mice were used to establish the NEC model. Haematoxylin and eosin staining was used to assess intestinal damage. The levels of IL-8 and TNF-α in mouse serum were evaluated by ELISA. qRT-PCR was used to detect the expression of miRNA-301a in intestinal tissues. **Results**: Bioinformatics analysis showed that miRNA-301a was involved in intestinal lesions. Intestinal tissue damage was reduced and serum levels of the inflammatory cytokines IL-8 and TNF-α were lower in NEC model mice treated with miRNA-301a antagonists. The level of miRNA-301a in intestinal tissues of NEC model mice was significantly higher than in the control group and miRNA-301a antagonists treated group. **Conclusion**: miRNA-301a plays an important role in the pathogenesis of NEC by promoting inflammation, and is a potential therapeutic target of NEC.

Abbreviations: IBD, inflammatory bowel disease; NEC, necrotizing enterocolitis

INTRODUCTION

Despite decades of studies on necrotizing enterocolitis (NEC), NEC continues to be the most prevalent surgical condition that crises the lives of newborns (Meister *et al.*, 2020). Among very low birth weight infants, the prevalence of NEC ranges from 5% to 10%, and more than 50% of patients with NEC require surgery. Furthermore, the mortality rate of NEC treated by surgery ranges from 30% to 50% (Flahive *et al.*, 2020; Bell *et al.*, 2021). Hence, it is urgent to explore effective and reliable biomarkers for early identification of infants at risk of progression to improve the prognosis of NEC.

MicroRNAs (miRNAs) are a family of highly conserved RNAs, ranging in size from 19 to 24 nucleotides, and regulate the 3'-untranslated region of target mRNA transcripts (Chen *et al.*, 2013). In recent years, substantial progress has been achieved in understanding the role of diverse miRNAs in human diseases, including NEC (Cai *et al.*, 2022; Donda *et al.*, 2022). MiRNA-124 has been identified to facilitate NEC by targeting ROCK1 and promoting inflammatory cell infiltration in intestinal cells (Yin *et al.*, 2019). The increased expression of miRNA-141-3p could attenuate NEC damage to intestinal tissues by targeting MNX1 (Chen *et al.*, 2020). In addition, miRNA-301a facilitated intestinal mucosal inflammation by inducing IL-17A and TNF-α in inflammatory bowel disease (IBD) and colorectal cancer (He *et al.*, 2016). However, the role of miRNA-301a in NEC remains unclear.

In this study, a miRNA-mRNA regulatory network was successfully established by bioinformatics analysis and key miRNAs were screened based on this network. Next, a neonatal mouse NEC model was successfully established and the expression of miRNA-301a in the intestinal tissues and the levels of inflammatory factors TNF-α and IL-8 in the serum of mice were examined.

MATERIALS AND METHODS

Source of sample

MRNA and miRNA microarray data of intestinal tissue samples were gathered from GEO Datasets. GSE115513 includes 31 normal and 30 diseased intestinal tissue samples. GSE184093 includes 9 normal and 9 diseased intestinal tissue samples. The datasets were analysed by using PERL 5.30.2 (https://www.PERL.org/). The two datasets were sorted in the order of normal and experimental groups to acquire mRNA and miRNA data.

Differentially expressed miRNAs and mRNAs

The differentially expressed miRNAs and mRNAs were filtered by using the LIMMA package in the R software (https://rstudio.com/, version 3.6.2). The filtering criteria were set as |log2(fold change)|>1 and FDR (False Discovery Rate) <0.05. The "pheatmap" in R (3.6.2) was then applied to create differential volcano maps of the filtered differentially expressed mRNAs and miRNAs, respectively.

Identification of miRNA targets and construction of miRNA-mRNA regulatory network

The target genes of 222 differential miRNAs were predicted by using the gene function analysis tool FunRich (3.1.3) (http://www.funrich.org/). The differentially expressed mRNAs were crossed with the target genes of the miRNAs to generate the shared mRNAs and corresponding miRNAs, and the regulatory network was visualised using Cytoscape (3.7.2) (https://cytoscape.org/re-

lease_notes_3_7_2.html) to produce the miRNA-mRNA regulatory network.

GO and KEGG enrichment analyses

To further elucidate the biological functions of target genes in the regulatory network, GO (https://geneontology.org/docs/go-enrichment-analysis/) and KEGG enrichment analyses (https://www.genome.jp/kegg/pathway.html) of differential mRNAs were conducted with a screening condition of $p<0.05$ and $q<0.05$ and all outcomes were presented as bar graphs using the Bioconductor plugin in R software (Gao et al., 2018).

Mice

Seventy-five newborn and pathogen-free BALB/c mice (7–10 days old) were obtained from the Animal Research Centre of Chengde Medical College (Chengde, China). All mice were housed at 28–30°C and 45–65% humidity for 12 hours on a light/dark cycle. This study was approved by the Animal Care and Use Committee of the Affiliated Hospital of Chengde Medical College (Approved No. 000134, date 2020-6-17). Mice were randomized into three groups (n=25 mice per group): the NEC group, the control group, and the NEC+anti-miRNA-301a group.

Neonatal mouse NEC model

The neonatal mouse NEC model was established as described previously (Nolan et al., 2021). Mice in the NEC and NEC+anti-miRNA-301a groups (n=25) were fed Esbilac puppy formulae, which was complemented by bacteria cultured from the faeces of infants with severe NEC (12.5 µl of faecal slurry in 1 ml of formula). Briefly, a syringe filled with formulae was attached to a peripherally inserted central catheter (PICC) line. Next, the PICC line was gently introduced into the mouse's stomach by using forceps. Then the formulae were slowly dispensed into the stomach, and the PICC line was slowly withdrawn from the oral cavity (Nolan et al., 2021). Mice were fed every 3 hours and after 3 feeds were placed under $5\% \ O_2 + 95\% \ N_2$ for 10 minutes of stress to induce NEC. The feeding volume was 0.1 ml and gradually increased to 0.25 ml. The animals were sacrificed by decapitation on Day 5. For NEC+anti-miRNA-301a group, the mice were orally administered miRNA-301a antagonist (sequence mGmCmUmUmUmGmAmCmAmAmUmAmCmUmAmUmUmGmCmAmCmUmG, Genecreate LTD, Wuhan, China) following the manufacturer's manual once a day, starting at the beginning of NEC induction (Day 0) and continuing to Day 5.

Haematoxylin and eosin (H&E) staining

The intestinal tissues were dissected and washed with PBS at 4°C and fixed with 4% paraformaldehyde, paraffin-embedded, sectioned at 5 µm and stained with hematoxylin and eosin (H&E). The intestinal damage was analysed under a microscope with a 40x lens by two independent pathologists, who scored it double-blind according to published criteria (Zhang et al., 2020).

MiRNA/mRNA isolation and reverse transcription

According to the manufacturer's instructions, TRIzol reagent (Invitrogen) was used to isolate total RNA from the intestinal tissues of the mice. Total RNA (2

Figure 1. Volcanic map of differentially expressed miRNAs (orange represents upregulated miRNAs, blue represents downregulated miRNAs, and black represents miRNAs without a significant difference in expression).

Figure 2. Volcanic map of differentially expressed mRNAs (orange represents upregulated mRNAs, blue represents downregulated mRNAs, and black represents miRNAs without a significant difference in expression).

µg) was used to generate cDNA by utilizing the Prime Script RT reagent kit (Takara, Tokyo, Japan).

qRT-PCR

QRT-PCR was undertaken by using SYBR Premix Ex Taq II (Perfect Real Time) (Takara, Tokyo, Japan). The gene-specific primers were purchased from Applied Biosystems (Foster City, CA, USA) with following sequences: U6: 5'-CTCGCTTCGGCAGCACA-3' and 5'-AACGCTTCACGAATTTGCGT-3', miRNA-301a: 5'-GGCAGTGCAATAGTATTGT-3' and 5'-TGGTGTCGTGGAGTCG-3'. U6 was used as an internal control for miR-301a expression. All experiments were in triplicates.

Figure 3. The miRNA-mRNA regulatory network (ellipses represent mRNAs, squares represent miRNAs, orange represents upregulated expression, blue represents downregulated expression, and connected lines represent targeted relationships).

ELISA

Serum was taken from all groups of mice. Paired ELISA kits for IL-8 and TNF-α (all from Enzyme Linked Biotechnology Co., Ltd., Shanghai, China) were used to evaluate the concentrations of IL-8 and TNF-α in the serum of the mice from each group. The optical density (OD) values of each well were recorded at 450 nm by a microplate reader.

Statistical analysis

Data were analysed by using SPSS 25.0 statistical software and expressed as mean ± standard deviation. The differences were considered to be statistically significant at $p < 0.05$.

RESULTS

Differentially expressed miRNAs and mRNAs

After processing the dataset, a total of 222 differential miRNAs were screened, of which 172 miRNAs were highly expressed and 50 miRNAs were lowly expressed. Similarly, we obtained 2584 differential mRNAs, of which 1155 mRNAs were up-regulated and 1429 mR-

Figure 4. GO enrichment analysis of differentially expressed mRNAs.

Figure 5. KEGG enrichment analysis of differentially expressed mRNAs.

NAs were down-regulated. The volcanoes of the differential miRNAs and mRNAs were subsequently mapped using R software (Figs 1 and 2).

Construction of miRNA-mRNA network and functional enrichment analysis

The FunRich (3.1.3) was used to predict the target genes of 222 differential miRNAs and a total of 2908 target genes were identified. The miRNA-mRNA regulatory network was then mapped using Cytoscape software (Fig. 3). The regulatory network showed that miRNA-301a regulated a greater number of mRNAs. We performed GO and KEGG enrichment analysis on 2584 different mRNAs using R language with $p<0.05$ and $q<0.05$ as screening conditions (Figs 4 and 5).

miRNA-301a antagonist reduced histological damage in NEC mice

We successfully established the NEC model using a previously published protocol (Nolan *et al.*, 2021) (Fig. 6A). During the experiments, two mice died both in the control and in NEC+anti-miRNA-301a groups, while three mice died in the NEC group. The difference in mortality among the three groups was not statistically significant ($p>0.05$). At the end of the experiments, the intestinal tissues of the mice in the NEC group showed a bluish-black colour compared to those of the mice in the control group. However, after treatment with the miRNA-301a antagonist, the degree of intestinal tissue necrosis in mice was significantly reduced (Fig. 6B).

The average histological score of the mice in the NEC group was 3.12±0.72, while the scores of the control

(**C**) H&E staining was used to evaluate the severity of tissue damage in different groups of mice (n=5) Mann-Whitney U-test. ***$p<0.001$. (**D**) Representative histological images of the terminal ileum in different groups of mice. Scale bar: 10 μm.

Figure 7. Inhibition of miRNA-301a reduced serum levels of inflammatory factors in NEC mice (n=5)
(**A**) Serum levels of IL-8 in different groups of mice. (**B**) Serum levels of TNF-α in different groups of mice. (**C**) Expression levels of miRNA-301a in intestinal tissues of different groups of mice. All experiments were in triplicates. ***$p < 0.001$.

group were typically <2 points ($p < 0.05$). After treatment with miRNA-301a antagonist, the average histological score was 1.78±0.60, and the inflammation grade was significantly reduced ($p < 0.05$; Fig. 6C, D).

miRNA-301a antagonist reduced serum levels of IL-8 and TNF-α in NEC mice

The serum level of IL-8 was 13.95±1.05 pg/ml in the control group and 59.93±6.41 pg/ml in the NEC group ($p < 0.05$). However, posttreatment with the miRNA-301a antagonist reduced IL-8 level to 26.23±1.22 pg/ml ($p < 0.05$ compared to the NEC group; Fig. 7A).

Furthermore, the serum level of TNF-α was 94.16±3.92 and 197.04±16.19 in the control and NEC groups ($p < 0.05$), respectively, and was 111.51±8.62 in mice that received miRNA-301a antagonist treatment ($p < 0.05$ compared to the NEC group; Fig. 7B).

In addition, qRT-PCR showed that the expression level of miRNA-301a increased in the intestinal tissues of the NEC group ($p < 0.05$ compared to the control group), but decreased in NEC mice treated with miRNA-301a antagonist ($p < 0.05$ compared to the NEC group; Fig. 7C).

DISCUSSION

NEC is the main catastrophic cause of death in surviving premature infants. The pathogenesis of NEC as well as potential strategies for NEC prevention and treatment remain elusive, although it is evident that the inflammatory cascade plays an important role in the development of NEC (Niño *et al.,* 2016; Liu *et al.,* 2019). In this study, we successfully established an NEC mouse model to explore the role of miRNA-301a in the pathogenesis of NEC, and we proved the association between high expression of miRNA-301a and increased severity of NEC. In addition, our study revealed that high expression of miRNA-301a promoted the release of inflammatory factors IL-8 and TNF-α.

Numerous studies have proven that non-encoding RNAs regulate inflammation through a variety of pathways (Zhou *et al.,* 2021; Yang & Ge, 2018). miRNA-301a was highly expressed in peripheral blood mononuclear cells and inflamed mucosa of patients with active IBD and may promote TNF-α production by targeting SNIP1, ultimately facilitating the pathogenesis of IBD (He *et al.,* 2016). miRNA-301a also inhibited the expression of BTG1, thereby reducing the integrity of the epithelium, promoting inflammation of the mouse colon and stimulating tumorigenesis (He *et al.,* 2017). In this

study we found that the pathological inflammation of the mouse intestinal tissue was reduced after we treated NEC mice with miRNA-301a antagonist, indicating that miRNA-301a plays an important role in the inflammatory progression of NEC.

For newborns with NEC, IL-8, IL-10, and TNF-α can be used as biomarkers for early diagnosis (Seliga-Siwecka & Kornacka, 2013). Combined analysis of IFN-γ-inducible protein 10 and TNF-α showed a specificity of 80% and a sensitivity of 90% (Weissenbacher *et al.,* 2013). In this study, we focused on TNF-α and IL-8, and found that the serum levels of inflammatory cytokines IL-8 and TNF-α were reduced after we treated NEC mice with miRNA-301a antagonist, suggesting that miRNA-301a may be a potential therapeutic target for NEC. In future studies, we need to examine other pro-inflammatory interleukins such as IL-1, IL-6 and IL-10 (Fu *et al.,* 2023).

Studies have shown that microRNAs play an important role in energy metabolism, immune regulation, homeostasis, cell apoptosis, cell proliferation and differentiation (Qi *et al.,* 2022; Zhong *et al.,* 2018; Zhang *et al.,* 2022; Liu *et al.,* 2022; Dai *et al.,* 2022; Chen *et al.,* 2021). Interference with these key cell functions can lead to an increase in apoptosis and inflammation and a decrease in repair capacity, which may be crucial in the pathogenesis of NEC (Premkumar *et al.,* 2014; Ng *et al.,* 2015). To further explore the potential mechanism of miRNA-301a in promoting NEC, we need to identify target genes of miRNA-301a that medicate the effects of miRNA-301a on cell proliferation, apoptosis, inflammation, mentalism and autophagy involved in the progression of NEC.

In conclusion, although further studies are necessary to confirm the role of miRNA-301a in MEC, our results provide the first evidence that miRNA-301a plays an important role in the pathogenesis of NEC by promoting inflammation, and is a potential therapeutic target of NEC.

Cytokine IL6, but not IL-1β, TNF-α and NF-κB is increased in paediatric cancer patients

Anna Synakiewicz[1]✉, Anna Stanislawska Sachadyn[2], Anna Owczarzak[3], Malgorzata Skuza[4] and Teresa Stachowicz-Stencel[1]

Cytokines are responsible for maintaining homeostasis as cell growth, differentiation, migration and apoptosis mediators. They play a pivotal role in immune responses to inflammatory reactions. In oncological diseases, the cross-talk between cells of the immunological system and cells of the tumour microenvironment is led by cytokines. Also, the overproduction of cytokines may change the tumour microenvironment and stimulate tumour development and growth. To test whether pro-inflammatory cytokines or associated with them transcription factor levels are changed in a group of 53 paediatric cancer patients, serum levels of IL-1β, IL-6, TNF-α and NF-κB were assessed and compared to measures in 25 healthy controls. Increased levels of IL-6 were found among patients in active oncological treatment (P=0.002) but not among patients whose treatment was completed. Our data suggest that IL6, but not IL-1β, TNF-α and NF-κB, is elevated as a result of the immune response in the microenvironment around the tumour and in blood cancers, among patients who were not infected at the time of blood collection. Thus, IL6 levels might serve as a potential biomarker of oncohematological diseases.

INTRODUCTION

Cytokines are intercellular protein mediators which regulate many processes, including cell growth, differentiation, migration and apoptosis. They play a crucial role in immune responses to inflammatory reactions and, generally, are responsible for maintaining homeostasis. In the case of a healthy person, they are present locally in tissues or body fluids in relatively small amounts. High activity in low concentrations is a characteristic feature in certain pathological states.

These molecules are produced by many types of cells and may cause numerous reactions. Inversely, various groups of cytokines may play the same role. In addition, the source of cytokines may affect its final response, and even cause the opposite effect.

Cytokines create a complicated network of stimulation and inhibition processes (Jansen *et al.*, 2022). Interleukins (ILs) were the first described growth and differentiation regulators expressed by leukocytes. With further studies, other factors were discovered in terms of cytokines, and it is now known that there are more than 50 interleukins and additional proteins (Brocker *et al.*, 2010). Interleukins are divided according to their origin and functions, specifically to pro-inflammatory, proangiogenic, chemotactic or hematopoietic. Specific surface receptors are necessary for proper cytokine effect by increasing or decreasing its influence on cell metabolism.

The role of cytokines in malignant proliferation is widely studied. It is well known that the neoplastic process is associated with uncontrolled cell division and disturbances in metabolic regulation. Cancer cells are much better consumers of nutritional substances than normal tissue components due to their rapid growth. It includes amino acids, lipids, protein or glucose metabolism and its influence on the tumour microenvironment. The expression of adipose triglyceride lipase (ATGL) may be downregulated in some cancers and may be associated with glycolytic processes typical for most malignant tumours (Pan *et al.*, 2013).

Moreover, tumour cells may adapt by metabolic reprogramming (Tang *et al.*, 2021). Rapidly growing tumour mass requires new blood vessels, and angiogenesis takes place. But it is insufficient, and hypoxia is another process in this situation. Tumour cells use more likely energy from aerobic glycolysis and glutaminolysis or fatty acids, which is known as Warburg effect. Such a process may be connected with oncogene activation such as Myc, Ras, or inactivation of the p53 suppressor gene and some metabolic damage (Koppenol *et al*, 2011; Cairns *et al.*, 2011). All these processes influence signal transmission and have an impact on immunometabolism in cancer. Cytokines play a role as mediators between cells of the immunological system and cells of the tumour microenvironment. Cancer cell – intrinsic and extrinsic signalling is needed for progression and invasion of the neoplastic process (Briukhovetska D *et al.*, 2021).

Cytokines play different roles in uninhibited proliferation processes, such as paracrine and autocrine factors, proangiogenic agents, survival factors of neoplastic cells

and other elements that affect invasiveness and distant metastasis formation.

The role of the immune system, and thus the influence of cytokines in malignancies, cannot be overestimated. Inflammation, primarily chronic, and oxidative stress mediate different kinds of malignancies. Most of the studies on that correlation were collected from colon cancer patients who primarily have Crohn's disease (Monteleone *et al.*, 2012; Klampfer L, 2011; Borowczak *et al.*, 2022). Pro-inflammatory cytokines, such as IL-1β, IL-6 or TNF-α play a key role in proliferative diseases, and their overproduction may change the tumour microenvironment and stimulate tumour development. Also, activation of transcription factors such as NF-ϰB is involved in various cellular processes in neoplasms. This factor can inhibit apoptosis as well as enhance angiogenesis. Thus, it may play a role in developing both haematological neoplasms and solid tumours.

We have attempted to answer the question if changes in the level of the determined substances can serve as an early marker of neoplastic disease or be a prognostic marker of the outcome.

MATERIALS AND METHODS

Patients

Paediatric cancer patients, including patients with haematological malignancies and solid tumours, who were diagnosed and treated in the Department of Paediatrics, Haematology and Oncology, Medical University of Gdansk, Poland, were enrolled in the study. Twenty-five patients, between 1 and 18 years of age (mean age 8.04 years, median age six years), were during treatment, and twenty-eight patients, between 3 and 18 years of age (mean age 9.79 years, median age eleven years) were after treatment.

Inclusion criteria

We included children between 1 month and 18 years of age with confirmed neoplastic disease. The patients showed no signs of infection.

Control group

Twenty-five healthy children were recruited during routine medical checkup (14 males and 11 females), aged between 3 and 17 years (mean age 12.24 years, median age 14 years).

Laboratory analysis

Peripheral blood was collected from the patients during and after successful treatment; the average duration of treatment was about two years.

Measurements of IL-1β, IL-6 and TNF-α were assessed using R&D Systems Quantikine ELISA Kits (Minneapolis, MN, USA) and NF-ϰB using Nuclear Factor Kb P65 (NFKB P65), ELISA Kit (My BioSource, San Diego CA, USA). All assays were performed according to the procedure provided by the manufacturer. All analyses were performed in the laboratory of the Department of Clinical Nutrition Medical University of Gdansk, Poland.

Statistical analyses

The Wilcoxon rank-sum test was used to assess differences in subjects' age (years) and in levels of NF-ϰB (μmol/L), TNF-α (pg/mL), IL-6 (pg/mL) and IL-1β (pg/mL) between patients before treatment, patients during treatment, patients after treatment and healthy controls. The distributions of NF-ϰB, TNF-α, IL-6 and IL-1β were skewed as assessed by Kolmogorov-Smirnov test. Tests were two-tailed, and P-values ≤ 0.05 were considered statistically significant. Means and standard deviations, medians and 25th–75th percentiles were given for continuous variables. Statistical analyses were calculated using SAS 9.4 (NC, USA). XLStat (Addinsoft) programme was used to generate plots.

RESULTS

The study population consisted of 25 patients during treatment, 28 patients after treatment and 25 healthy controls (Table 1). Those groups did not differ significantly in age at the time of blood collection. A slightly

*Wilcoxon ranked-sum test; [1]patients during treatment *vs.* patients after treatment; [2]patients during treatment *vs.* controls; [3]patients after treatment *vs.* controls; # two outling values: 2.49, 6.08 pg/mL were removed from analyses

higher proportion of males were included in each group; males constituted 68% of patients, 57.14% of survivors and 56% of healthy subjects. More patients than survivors were diagnosed with acute lymphoblastic leukaemia (32% *vs.* 10.71%), while more survivors were diagnosed with neuroblastoma (50% *vs* 8%). Among survivors, two patients were diagnosed with Wilms tumour; one person was diagnosed with retinoblastoma. Among patients, two were diagnosed with osteosarcoma and two with Langerhans cell histiocytosis.

Levels of IL-1β, IL-6 or TNF-α and NF-κB were measured in blood samples collected from a healthy control group and pediatric oncological patients during treatment and post-treatment. Significantly higher levels of IL-6 were observed in the patients during active oncological treatment compared to both the control group and survivors (P=0.002, P=0.0002, respectively), as presented in Table 2, Figure 1. IL-6 levels in the post-treatment group were comparable to those in the control group (P=0.563). The mean value of IL-6 was 6.34±4.13 pg/mL among patients during active oncological treatment versus 2.75±3.45 pg/mL among healthy controls and 2.32±2.55 pg/mL among survivors.

In other parameters, such dependencies were not observed (Table 2, Fig. 1).

DISCUSSION

Pediatric cancer patients constitute a particular group of patients, mainly due to the low incidence rate of this disease in children. Neoplasms type, both haematological and solid tumours, also differ from those in the adult population. Observations regarding the interleukin impact in children concern mainly IL-2 regarding its modulating effect on the immune system and the anti-tumour response promotion through lymphocyte activation and their differentiation in progressing or metastatic patients (Schwinger *et al.*, 2005). It is well known that chronic inflammation concomitant with oxidative stress boosts tumour development, especially the skin, lung, colorectal or hepatocellular carcinoma (Bruni *et al.*, 2020).

Pro-inflammatory cytokines such as IL-1β, IL-6 or TNF-α, which were under investigation in the present study, and NF-κB, are crucial for metabolic homeostasis.

Figure 1. Levels of NF-κB, TNF-α, IL-6, IL-1β from patients before or after treatment and healthy controls.

They are secreted by healthy cells, but their overproduction may lead to neoplastic transformation. Also, neoplastic cells derived from fibroblasts and macrophages also release IL-1, IL-6, TNF-α, that serve as source of paracrine factors (Bingle *et al.*, 2002; Kunz-Schughart & Knuechel, 2002).

Among many cytokines present in pediatric oncology patients' sera, the ones determined by the authors seem to have a particular impact on the neoplastic process. The distinctive histology of childhood cancers makes it difficult to predict the behaviour of individual molecules, in contrast to the adult population where the inflammatory component of the neoplastic process has been relatively well studied (Dranoff, 2004; Greten et al. 2019; Mantovani et al., 2019).

The tumour microenvironment (TME), which in addition to cancer cells, also contains cancer-associated fibroblasts (CAFs), pericytes, endothelial cells, and immune cells, plays a significant role in tumour proliferation and progression processes. Pro-inflammatory cytokines serve as mediators in these actions (Christofi et al., 2019).

Our pediatric oncological patients showed significant differences in IL-6 levels during active treatment. Importantly, IL-6 values achieved those observed in the control group after the end of treatment. IL-6 is a multitasked substance. Its essential role is associated with the inflammatory response and active participation in the immunological processes. It may also be secreted by TME and cause further tumour development and progression (von Felbert et al., 2005). Interleukin- 6 has a pro-oncogenic function as it may activate carcinogenesis. It is one of the mediators of cytokine release syndrome. IL-6 signals to cells through two opposite pathways. The classic pathway is anti-inflammatory and takes part in repair processes. The trans-signaling pathway promotes inflammation and may contribute to the progression of many diseases, including cancer (Kumari et al., 2016). The classic pathway is based on transmembrane IL-6Rα receptors on a cell surface. The trans pathway occurs in the cells capable of expressing the gp130 protein.

IL-6 induces angiogenesis via the vascular endothelial growth factor. The elevated serum level of IL-6 in patients with colon and breast cancer or melanoma patients is a poor prognostic factor (Ma et al., 2017; Kucera et al., 2015). Furthermore, prostate cancer patients showed higher levels of this cytokine compared to a healthy control group. Moreover, it positively correlated with a higher Gleason score (Siemińska et al., 2015). In metastatic prostate cancer patients, the serum level of IL-6 was higher than in patients with localized disease; hence it may serve as a prognostic factor (Michalaki et al., 2004).

Similarly, in breast ductal carcinoma patients, Ma et al. (2017) demonstrated that elevated serum IL-6 levels positively correlated with more advanced disease stages and metastases to lymph nodes. Additionally, the authors noticed high levels of IL-6 in ER+ or HER2+ tumours in contrast to those with ER- or HER2 negative. In high-risk neuroblastoma pediatric patients, Egler and others (Egler et al., 2021) showed increased IL-6 levels in their serum and bone marrow. The researchers analyzed the link between the levels of inter alia, IL-6 and the genetic polymorphism of this interleukin. Such results may suggest that particular interleukins could serve as potential cancer biomarkers.

Interleukin-1 was initially considered as a pro-inflammatory factor, which plays an essential role in severe systemic infections, but its part in the activation and stimulation of other cytokine secretion or prostaglandin production suggests that it should be considered in a broader aspect (Razavi et al., 2015). It is also known that IL-1 may be partially involved in tumour promotion and could be responsible for metastasis. It develops via different mechanisms, such as matrix metalloproteinases expression, or affects the excretion of VEGF, IL-6, IL-8 or TNF-α by the surrounding tissues (Konishi et al., 2005, Dinarello, 1996). Anti-inflammatory mechanisms are enhanced by interleukin-1 via the release of e.g., IL-6 (Mantovani et al., 2019). Interleukin-1β belongs to the IL-1 family and is one of the structural components of IL-1. The other two are IL-1α and the IL-1 receptor antagonist. More importantly, IL-1β is initially produced by macrophages as a pro-protein and then converted into IL-1 ß with the use of caspase-1 (Teufel et al., 2022). Both alarmins, IL-1β and IL-1α, may serve as promotors of carcinogenic mediators: nitric oxide and reactive oxygen species (ROS) (Mantovani et al., 2019). Interleukin-1ß activates macrophages, suppresses NK function, and inhibits CD8+ lymphocytes by inducing neutrophils. The final effect is the production of pro-tumorigenic factors (Zhang et al., 2020). Its role in cancer transformation and progression was observed in colon and prostate cancer patients, whose sera showed elevated levels of this factor (Hai et al., 2016; Saylor et al., 2012). Studies of human cancer cells from ovarian, breast, lung carcinoma, sarcoma and melanoma have shown that they are capable of producing or up-regulating Interleukin-1β (Elaraj et al., 2006). Barrera and others (Barrera et al., 2018) showed that elevated IL-1β serum concentrations in lung cancer patients positively correlated with a high percentage of myeloid-derived suppressor cells and were associated with worse prognosis and poor survival. Also, studies carried out on mice demonstrated an increased sera level of IL-1β and IL-6 following carcinogen administration (Narayan et al., 2012). In our study, we did not observe increased values of IL-1β in our patients' sera, either during or after treatment, compared to the control group.

Another cytokine, tumour necrosis factor-α (TNF-α), also called cachexin, is of interest to those who study substances involved in developing various cancer types. It is mainly produced by macrophages (also TAMs- tumour associated macrophages) and monocytes, but also lymphocytes T, mast cells, fibroblasts and adipocytes. TNF-α is a part of the TNF superfamily, which also includes ligands and their receptors. When combined, most of them activate the nuclear transcription factor kappa (NF-κB) (Ware, 2008). Other signalling pathways for this factor are MAPK (mitogen-activated protein kinase) and the apoptosis signalling pathway. It is thought that cachexin may be both an anti-tumour and a pro-tumorigenic agent, depending on the dose (Dobrzycka et al., 2009). There are reports of a direct effect on the stimulation of neoplastic transformation by inducing cell proliferation and transformation (Wang et al, 2008).

Increased TNF-α levels are related to a higher stage of cancer (Zhou et al., 2014; Esquivel-Velazquez et al., 2015). In metastatic prostate cancer patients who started hormonal therapy, elevated serum TNF-α levels are associated with a worse course of the disease and a worse prognosis (Sharma et al., 2014). The researchers are not unanimous. Some authors showed lower serum TNF-α levels in colorectal cancer patients compared to the control group; others did not find it at all (Godos et al., 2017; Abe Vincente et al., 2014). It was found that high levels of this cytokine are associated with stage III and IV colorectal cancer (Obeed et al., 2014). Additional studies focused on the association between TNF-α serum levels and the risk of colon cancer development or polymorphism of the gene encoding TNF-α versus cancer development risk. No correlation was found (Joshi et al., 2014; Miao et al., 2018). However, Ma and others (Ma et al., 2017) indicated a correlation between serum concentrations of TNF-α, IL-6 and IL-8 and higher stages

of advancement (III-stage breast ductal carcinoma) and metastases to lymph nodes. We did not find any dependence for TNF-α in pediatric cancer patients compared to the control group, regardless of the treatment period.

Nuclear factor kappa B (NF-κB) constitutes a family of transcription factors which lead some important signaling pathways that might control cell differentiation, proliferation and angiogenesis during tumorigenesis (Taniguchi, 2018). The dysregulation of NF-κB is an essential contributor to the development of cancers and their progression or relapse. It is regarded as a potential therapeutic target for patients with neoplastic diseases. An NF-κB-inducing kinase (NIK), encoded by the gene *MAP3K14* is acclaimed as the central kinase controlling non-canonical NF-κB activation (Haselager, 2022). This NF-κB pathway is activated upon stimulation of the BAFF receptor, CD40, receptor activator of NF-κB or the lymphotoxin ß receptor. It accounts for the recruitment of TRAF2/3 to the receptor, resulting in the accumulation of NIK protein levels (Xiao *et al.*, 2001). NIK plays a regulatory role in the process of inflammation. Loss of NIK is associated with severe immune defects, whereas NIK overexpression is observed in inflammatory diseases and malignancies. For this reason, targeting NIK and the non-canonical NF-κB pathway may display a therapeutic potential in various diseases (Fei *et al.*, 2020; Jang *et al.*, 2020). NFκB1 is a subunit of NF-κB. An aberrant activation of the latter is associated with cancer pathogenesis. The nuclear factor kappa B 1 (NFκB1, p105/p50) is a potential target gene of miR-497. It has been reported that NFκB1 plays various roles in the development and progression of cancers. On the other hand, NFκB1 may act as a tumour suppressor in some gastrointestinal cancers (hepatocellular carcinoma, gastric cancer) (Chen *et al.*, 2022).

CONCLUSIONS

A significant increase in IL-6 in patients during oncological treatment and its absence after successful treatment may be helpful in monitoring the disease and may become an early biomarker of the neoplastic process in combination with other substances. The research carried out, and the results achieved indicate a certain important role of the tested substances in the process of oncogenesis and proliferation in oncohematological diseases in children. Further investigations are needed, including more potential biomarkers and patients with failure to check the course and level changes.

All the procedures performed in the study involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards – the study project of the study was approved by the Ethical Committee of the Medical University of Gdansk, Poland (NKBBN/868/2019).

Informed consent was obtained from the parents and patients over 16 years old.

Declaration

The authors declare that there are no conflicts of interest.

There have been substantial advances in HIV research over the past three decades, but we are still far from our goal of eliminating HIV-1 infection entirely. Numerous ever-evolving antigens are produced as a result of HIV-1's genetic variability. Developing an effective vaccination is challenging because of the structural properties of the viral envelope glycoprotein that obscure conserved receptor-binding sites and the presence of carbohydrate moieties that prevent antibodies from reaching potential epitopes. To work on an HIV-specific vaccine, this study identified 5 HIV-surface proteins, from the literature, to screen potential epitopes and construct an mRNA vaccine. A wide range of immunological-informatics techniques were utilized to develop a construct that efficiently stimulated cellular and humoral immune responses. The vaccine was produced with 31 epitopes, a TLR4 agonist termed RpfE that acts as an adjuvant, secretion boosters, subcellular trafficking structures, and linkers. It was determined that this suggested vaccine would cover 98.9 percent of the population, making it widely available. We, furthermore, carried out an immunological simulation of the vaccine illustrating the active and stable responses from innate and adaptive immune cells, the memory cells remained active for up to 350 days after vaccine injection, whereas the antigen was excreted from the body within 24 hours. Docking performed with TLR-4 and TLR-3 showed significant interaction with –11.9 kcal/mol and –18.2 kcal/mol^{-1} respectively. Molecular dynamics simulations further validated the vaccine's stability, with a dissociation constant of 1.7E-11 for the TLR3-vaccine complex and 5.8E-11 for the TLR4-vaccine complex. Lastly, codon optimization was carried out to guarantee that the designed mRNA construct would be translated into the host successfully. This vaccine adaptation, if tested *in-vitro*, would be efficacious and potent as predicted.

Keywords: HIV-1, clinical trials, mutagenesis, membrane proteins, immune stimulation.

INTRODUCTION

AIDS or acquired immunodeficiency syndrome is caused by a very notorious virus called HIV or human immunodeficiency virus. It directly attacks and affects the immune system of the host and makes it vulnerable and susceptible to many diseases (Del Amo *et al.*, 2020). The HIV consists of two strains namely HIV-1 and HIV-2 both having two RNA strands, 15 different viral proteins and could also contain a few proteins from the last host from which it is transferred (Jewell *et al.*, 2020). All these components are encapsulated by a lipid bilayer membrane. It can be transferred via blood or saliva but not by mere contact. In general, it is transferred through sexual contact, sharing needles or blood transfusion. It can also be transferred to the baby from the mother through breastfeeding (Cooper *et al.*, 2020). HIV-1 is transferred into the host more rapidly and is found all over the world. This infectious virus was first reported on June 5, 1981 in Los Angeles (Finlayson *et al.*, 2019). By the second month of 1983, the Centers for Disease Control in the United States reported that approximately 1000 people were HIV positive (Kanny *et al.*, 2019; Sullivan *et al.*, 2021). Although it was first reported in the United States, it had a greater impact in Africa. Nine countries in Africa had one-third of the world's HIV infection (Lancet HIV, 2020; Ssentongo *et al.*, 2021).

For a long time now, Antiretroviral therapy or ART has been considered the best possible measure for controlling HIV (Jiang *et al.*, 2020). It basically consists of a combination of drugs which are prescribed to infected patients to be taken on daily. This therapy does not cure the viral infection but helps the infected persons to live a comparatively longer and healthier life (Chen, 2019). The virus basically destroys the CD4$^+$ T cells which are responsible for fighting off different infections and diseases. The medication basically works by reducing the amount of HIV in the body (Suryawanshi *et al.*, 2018). The virus is not completely eliminated by them but the reduced number gives the body a chance to regrow CD4$^+$ T cells and fight off the infections and keep the body healthy (Nami *et al.*, 2019). Another approach to cure HIV is to produce a suitable vaccine. To date, many vaccines have been developed by different research institutions but none of them have been successful enough to be prescribed for mass treatment (Yoshida *et al.*, 2021). All of them had notable demerits due to which they failed the early trial stages. Also, the new approaches to HIV vaccine production were recently leveraged by SARS-Cov 2 response so, the dire need for successful vaccine production remains (Karim *et al.*, 2021).

The sequence variability of HIV is one of the primary underlying reasons why an HIV vaccine is not yet commercially available on a worldwide basis (Vasavi *et al.*, 2019; Fenwick *et al.*, 2019). There are up to 20% differ-

ences between the strains of HIV in terms of proteins that are largely conserved, and there are up to 35% differences between the strains in terms of the outer envelope. Additionally, there is a wide variety of ways in which the virus might spread (Akbari *et al.*, 2021). Due to the fact that it can be introduced into the body by sexual contact or the intravenous route, the virus can spread fast throughout the body; nevertheless, it typically takes between one and two weeks for the virus to colonize healthy cell populations (Ng'uni *et al.*, 2020). The first form of vaccination, also known as the conventional method, involves the use of complete organisms, which might provoke allergic reactions due to the presence of big antigens in the body (Abdulla *et al.*, 2019). Any new epidemic could emerge at any time in the future, just like SARS COV-2 did. The development of an mRNA vaccination that incorporates epitopes from a variety of conserved and membrane proteins is one strategy that can be implemented to reduce the severity of allergic reactions (Andrabi *et al.*, 2018; Naveed *et al.*, 2023a; Naveed *et al.*, 2023b).

The fundamental objective of this study was to design an in-silico technique for the construction of an mRNA-based peptide-based immunization that was based on antigenic proteins derived from HIV-1 (Liang *et al.*, 2023). This was illustrated in Figure 1. (A). (Larijani *et al.*, 2018; Muttaqin *et al.*, 2021). Using a number of approaches, it was possible to make predictions about autoimmune disease as well as B cell, CTL, and HTL epitopes and then confirm these predictions. The construct of the vaccine was made by combining each epitope with several linkers and various adjuvants. RpfE was used as an adjuvant, and other aspects of the vaccine, including its population coverage, antigenicity, allergenicity, and toxicity, were investigated. Both the secondary and tertiary structures of the vaccine had been predicted. In addition, the TLR-3 and TLR-4 molecular docking systems were included in the vaccine construct. Simulations using molecular dynamics confirmed that the vaccine does not lose its effectiveness over time.

MATERIALS AND METHODS

The pipeline of the methodology is described in Fig. 1A.

Viral Proteins Sequence Retrieval

The complete Genome of the Human Immunodeficiency Virus (HIV) was obtained from National Centre for Biotechnology Information Database (NCBI) under Accession number: MN692147.1. The proteins of HIV that were selected based on the previously reported data from UniProt with accession numbers: K0J9R5, Q01804, Q9QBZ6, P04585, 0.5886.

Evaluation and Analysis of Proteins

In order to determine the antigenicity of viral proteins, we utilized the Vaxijen 2.0 internet server. The threshold value was set at 0.4 so that it would be more specific. We utilized a technique called AllerTop to determine whether or not proteins were allergenic (https://www.ddgpharmfac.net/Vaxijen/Vaxijen/Vaxijen.html) and AllerTop v2 is used for determining allergenicity (https://www.ddgpharm.net/AllerTOP/method.html).

Physiochemical Analysis

Using the ExPASy Protpram tool (https://www.expasy.org/resources/protpram), the physiochemical properties of a chosen protein, including its theoretical PI, amino acids composition, instability index, *in-vitro* and *in-vivo* half-life, aliphatic index, molecular weight, and most important grand average of hydropathicity (GRAVY), were investigated.

B-Cell Epitope Prediction

For the prediction of B-cell epitopes, the IEDB Linear Epitope Prediction Tool version 2.0 was utilized, and its default settings were left alone. It makes use of complicated algorithms that are based on the architecture of antigen-antibody proteins. It was put to use in an accessibility examination of the surface.

CTL and HTL Epitope Prediction

IEDB was utilized in order to make a prediction regarding the T-cell epitopes. When a sequence is supplied in FASTA format, various build-in IEDB tools are used to create MHC-I and MHC-II epitopes. It was decided that humans would serve as the host species. All alleles with length 9 were chosen for further study. As the output format, an XHTML table was utilized, and all of the other parameters and choices were left in their default states. (http://tools.iedb.org/mhcii/).

Evaluation of Epitopes

The antigenicity, allergenicity, and toxicity of each single epitope were assessed. We used the VaxiJen antigen server (http://www.ddg-pharmfac.net/Vaxijen/VaxiJen/VaxiJen.html) to assess antigenicity. In an alignment-free

Figure 1. (A) Flow Chart of Diagram of Vaccine Design, (B) Flow Diagram of Vaccine Construct from N-terminal to C-terminal.

method, the physicochemical characteristics of epitopes form the basis for the prediction. For this experiment, bacteria with a cutoff of 0.5 were used. AllerTop V.2.0 (http://www.ddg-pharmfac.net/AllerTOP) was used for epitope analysis due to its user-friendly interface and comprehensive database. The parameters were left in their default states (Naveed *et al.*, 2022b). Finally, epitope toxicity was quantified using the ToxinPred (https://webs.iiitd.edu.in/raghava/txnpred/multisubmit.php) site for toxicity analysis. For further study, only antigenic, non-toxic, and allergy-free epitopes have been selected.

Resemblance with Human Proteins

Using the BLASTp program (https://blast.ncbi.nlm.nih.gov/Blast.cgi?PAGE=Proteins), all of the predicted peptides were analyzed in relation to the protein database for Homo sapiens (Taxid:9606). If the E-value is more than 0.05, then all of the peptides in the vaccine are evaluated as potential non-homologous peptides.

Population Coverage Calculation

Population Coverage for vaccine design aimed at targeting T-lymphocyte epitopes and associated MHCI and MHCII alleles can be calculated using the IEDB database (http://tools.iedb.org/population/). This number is based on how many different MHC alleles the construct's epitopes are able to identify. This is because there is a wide range in MHC-allele distribution across different regions and peoples.

Construct of the proposed vaccine

The construct of the vaccine is shown in Fig. 1B. Each anticipated epitope was joined together using one of three linkers: AAY, KK, or GPGPG. These linkers are necessary for separating and isolating different functional domains. They are tough, bendable, and easy to cut. Resuscitation-promoting factor (RpfE) was utilized as an adjuvant in order to boost the adaptive immune response. The mRNA vaccine needs to have a Kozak sequence, which consists of an ORF start codon and a stop codon. In addition, two structures were added to the construct: first, the tissue plasminogen activator (tPA) secretory signal sequence (UniProt ID: P00750) in the 5' region of the construct. Once translated, epitopes can be secreted from cells with the help of this signal sequence. Second, the mRNA vaccine's 3' locus end contains an MHC I-targeting domain (MITD; UniProt ID: Q8WV92).

Evaluation of Vaccine Protein

Antigenicity was analyzed by the Vaxigen v2.0 and for allergenicity we used AllerTop. ToxinPred was used for toxicity analysis. Solubility analysis with the help of SoLpro was done to determine the purity of a substance. ExPasy-Protparam Tool was used for physiochemical properties analysis.

Peptide Secondary and Tertiary Structure Prediction

Secondary and tertiary structures were analyzed by the PsiPred and TsRosseta respectively to explore multi-epitope vaccine. The tertiary structure was assessed using Tr Rosetta (https://yanglab.nankaledu.en/trRosetta/).

mRNA Vaccine Secondary Structure Prediction

Predicting the secondary structure of the mRNA vaccine with the help of the RNAfold tool (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAfold.cgi). It

makes use of McCaskill's technique to determine the secondary structure with the lowest free energy (MFE). This method was used to determine the minimum free energy (MFE) of a structure, as well as the MFE of a centroid secondary structure.

Refinement and Validation of tertiary structure

The vaccine's structure was refined using the Galaxy-Refine server. This involved, first, the rebuilding and re-packing of sidechains, and second, the relaxation of the structure using molecular dynamics simulation processes. (http://galaxy.seoklab.org/). Multiple servers were used to verify the accuracy of the 3D structure based on references. To begin, RAMPAGE (Ramachandran Plot Assessment) was utilized. After that, PROCHECK was utilized to verify the building's integrity. (https://bip.weizmann.ac.il/toolhox/structure/validation.htm).

Analysis of Conformation B-Cells Epitope Prediction

New conformational B-cell epitopes can be stimulated by the protein's tertiary structure. Estimates of discontinuous B-cell epitopes in the protein structure were generated using ElliPro, a web-based service (http://tools.iedb.org/ellipro/). Ellipro benefits from the 3D model's geometric properties. When compared to other known strategies for predicting discontinuous B-cell epitopes, ElliPro has the greatest AUC value of 0.732 for the protein model.

Docking Analysis

Peptide vaccines with either toll-like receptor 4 (TLR-4) (PDB ID: 3FXI) or TLR-3 (PDB ID: 3FXI) (PDB ID: 1ZIW) To dock 3D structures on the ClusPro server, we employed the PIPER docking method. Both TLR4 and TLR3 were blocked by a RpfE adjuvant. It is possible that this server will produce numerous models using various scoring mechanisms. Free binding energy (G), dissociation constant (Kd), and percentages of charged and polar amino acids on the non-interacting surface were calculated by receptor-ligand 3D interaction using the PRODIGYY tool on the HADDOCK website (https://haddock.science.uu.nl/).

Evaluation of Binding Energies

T cells and MHC alleles underwent a molecular docking simulation to determine their binding affinities. RCSB's PDB database was queried for the tertiary structure of MHC alleles. PyMol was used to visualize the structures, and the Swiss-PDB viewer was employed to reduce power consumption. Epitopes were folded into 3D structures using the PEP-FOLD 3.5 server, and energy was conserved by viewing the structures in the Swiss-PDB viewer. The docking and binding affinity computations were performed on the Cluspro 2.0 server. Additional visualization and analysis were performed using PyMol and Discovery Studio.

Molecular Dynamics Simulations

iMods online was used for molecular dynamics simulations. It studies the molecule and interaction on the basis of torsion angles. It was utilized for the analysis of RMSD values, co-variance among residues, eigenvalue of interacting residues and distortion of structure. It was utilized to discover the stability of the complex.

Table 1. List of Proteins selected Previous Literature

No.	Protein	Uniprot ID	Antigenicity	Function	Location
1	Envelope glycoprotein gp160	K0J9R5	0.5767	Host-Virus Interaction	Surface Protein
2	OTU domain-containing protein 4	Q01804	0.5	Pathogenesis and Innate Immune Response	Cytoplasmic Protein
3	Gag polyprotein	Q9QBZ6	0.58	Virion Assembly	Cell Membrane
4	Gag-Pol polyprotein	P04585	0.6778	Virion Assembly and Lipid Anchor to Host	cell membrane
5	Tat- Protein	Q76PP9	0.5886	Receptor Binding to Host	Cytoplasmic Protein

Codon Optimization and Expression Analysis of Proposed Vaccine

The codon of the vaccine was optimized to ensure that the peptide vaccine construct was produced efficiently in human cells. This was achieved with the help of the GenSmart Codon Optimization software (http://www.genscript.com/). In order to determine whether or not a product is of high quality, GenScript uses Rare Codon Analysis (http://www.genscript.com/) (GS). How well mRNA is expressed and translated is quantified by the Codon Adaptation Index (CAI). The sequence was back-translated using the backtranseq software EMBOSS 6.0.1 so that the mRNA protein could be expressed in the expression vector. after then, the Java Codon Adaptation Tool was used for codon optimization (JCAT). As an expression vector, we employed the pub18 gene from E. coli. SnapGene used in-silico PCR for construct amplification.

Immune Simulation

C-ImmSim was used to verify the immune response. It uses an immune epitope and interaction with the help of a position-specific scoring matrix (PSSM). All the procedure was done at default parameters. (https://kraken.iac.rm.cnr.it/C-IMMSIM)

RESULTS

Protein sequence Retrieval

The FASTA format of amino acids of Human immunodeficiency virus 1 proteins that are present on the surface or on transmembrane having accession number CCA61241.1, QEE91975.1, Q9QBZ6.2, NP_057849.4, UED13371.1 respectively, were obtained from the NCBI database. The function and cellular localization of the shortlisted proteins are given in Table 1.

B-cell Epitope Predictions

IEDB Linear Epitope Prediction v2.0 was used to predict the B cell epitopes. At first, 25 epitopes were predicted which were then filtered out on the basis of the antigenicity and allergenicity. At the end, only 8 epitopes were selected for the vaccine construct as shown in Table 2.

CTL or HTL Epitopes and their Evaluation

T-cell Epitopes are of two types: MHC-I and MHC-II. These epitopes are predicted or selected on the basis of the value of IC50. Those epitopes with values lower than 200 are selected.. The lower the ic50, the high the binding affinity of the epitope is. For this whole dataset of the HLA alleles are selected. A total of 40,419 MHC Class I Epitopes were predicted and out of them, only 8 were selected on the basis of their antigenicity and their allergenicity. A total of 18,279 MHC Class II Epitopes were predicted and out of them, only 15 were selected on the basis of their antigenicity and their allergenicity. The shortlisted MHC I and II epitopes are shown in Table 2.

Interaction between Epitopes and MHC-alleles

In total, there are 23 T-lymphocyte epitopes and 120 MHC-alleles. As can be seen in Table 4, whereas some epitopes only recognize a single MHC allele, others can detect as many as seventeen different alleles. We selected 5 epitopes that matched up with certain MHC alleles for further molecular docking study. The ClusPro 2.0 server docking results are shown in Table 4 as energy affinities. With an MHC allele (HLA-A*32:01) and its associated epitope, the YALFYKLDIV region displays the highest binding affinity (–9.2 kcal/mol). As can be seen in Figs 2A and 2B, as a result, epitopes bind competently to the MHC-allele binding fork. As can be seen in Fig. 3, we also assessed every potential interaction between the targeted epitope and allele residues.

Proposal for a Vaccine Construct

The proposed design of the vaccine construct is like the following:

The antigenicity score of the constructed vaccine is 0.7056 at a threshold of 0.5. The overall allergenicity of

Figure 2. Docking visualization between the epitope AG-FRQYRAASIQVGN and its corresponding MHC allele (HLA-DRB1*01:01) using the PyMol software: (A) Surface View (B) Cartoon View.

the vaccine is predicted as non-allergen. This shows that the construct is a good vaccine candidate.

Physiochemical Properties of Vaccine

To determine the antigenicity, allergenicity, toxicity, and soluble nature of a construct, scientists can use programs like VaxiJen, ANTIGENpro, AllerTOP, Toxin-Pred, and SolPro. The results showed that the vaccine met all of the criteria for an effective vaccine: it was anigenic, non-allergenic, non-toxic, and water-soluble. Table 5 displays the results of using the ExPasy ProtParam service to establish the physiochemical profile of the construct. Based on the vaccine's known physiochemical properties, it was projected that the construct would be thermally stable. Due to the GRAVY value being -0.357, it may be concluded that the vaccine is hydrophilic. These results indicate that the mRNA vaccine design is a promising potential vaccination candidate.

Prediction of Population Coverage

Combining all 120 alleles of the matching 23 epitopes on MHC-I and MHC-II, the IEDB population coverage technique was able to estimate that the human population would be protected against all known pathogens. Eventually, global vaccination rates would reach about 98.9 percent.

Immune Simulation of Vaccine

We used three vaccinations to kick off the immune response (see Fig. 4). Both the second and third options performed better than the first. After antigen suppression, immunoglobulin levels were high, and it was discovered that more IgM than IgG was being produced. This increase may be indicative of the formation of immunological memory following antigen exposure. B-cell isotype persistence across time reveals the existence of memory cells within the B-cell population. It's also true that more CTL and HTL cells were produced as a direct consequence of memory formation. Furthermore, macrophage activity rose while dendritic cell activity remained unchanged. IFN- and IL-2 levels also went up. There is a rise in both innate immunity and the number of epithelial cells, which play a role in innate immunity.

mRNA Vaccine Prediction for secondary structure

The mRNA vaccine's structure was inferred using the RNAfold website. The free energy of the structures was also computed using this site. As a starting point, we took the codons that were optimized for usage in the vaccine. As shown in Fig. 5F, the mRNA vaccine had a minimum free energy of -930.20 kcal/mol during pro-

duction, and the energy of its secondary centroid structure was -700.67 kcal/mol. The results indicate that the mRNA structure will be stable.

Secondary and tertiary structures of the mRNA vaccine

We used the PSIPRED server to try and guess the secondary structure of the vaccine. Figure 5A depicts the structure, which is composed mostly of alpha helices.

To learn about the vaccine's tertiary structure, we used the Tr Rosetta server (see Fig. 5B). The PROCHECK service was then used to confirm the structure's stereochemical accuracy. Figure 5C's Ramachandran plot shows that 98.3% of residues were located in the recommended zones, 1.6% in the additional allowance zone, and 0.2% in the prohibited allowance zone. The vaccine has an overall quality factor of 92.64211, which is

Table 4. Molecular Docking of T-Lymphocytes epitopes with corresponding MHC alleles and their Binding affinity

quite high. The tertiary protein model is very consistent, as predicted by the ProSA-web server, which yielded a negative Z-score of -6.01.

Conformational B-cell epitopes Prediction

For the purpose of locating B-cell conformational epitopes, a server named ElliPro was used to execute vaccination model folding. Eleven discontinuous conformational B-cell epitopes were forecast using this method. Figure 6 reveals that the anticipated score for the 285

residues for secondary and tertiary models of conformational cell Epitopes ranges from 0.512 to 0.883.

Molecular Docking

The probable connections between the construction and TLR-4 and TLR-3 receptors were verified using ClusPro software for molecular docking. Additionally, we used the PRODIGY website to analyze the binding affinities and dissociation constants at 37°C for the more

Figure 9. Optimized Vaccine Cloned in PUC18 Vector

of 2.5E-07. PDBsum was used to analyze the vaccine's enhanced interaction with TLR-3 and TLR-4 receptors.

Molecular Simulation of Vaccine

When exposing the Vaccine-TLR3 and Vaccine-TLR4 complexes to the iMOD server, molecular dynamic simulation analysis was performed. Vaccine deformable loci and amino acids with coiled forms are both shown by peaks in the deformability graph. NMA (normal mode analysis) is a computational tool for studying protein adaptability. As can be seen in Figs 7C and 8B, the B-factor graph represents the complex's connection to the Normal Mode Analysis and PDB areas. The eigenvalues of the docked complexes are displayed in Figures 7D and 7D, respectively. Figures 7E and 8E demonstrate the

clustered component of each complex. As a benchmark, we relied on the adjuvant docked complex.

There was a difference in binding affinity of −18.2 kcal/mol⁻¹ between the TLR3-Vaccine complex and the control. At 25 degrees Celsius, the complex dissociation constant for Vaccine-TLR3 was 1.7E-11, while the value for the control was 1.1E-06. The binding affinity for the TLR4-Vaccine complex was −11.9 kcal/mol⁻¹, while it was only −9.0 kcal/mol⁻¹ for the control. Vaccine-TLR4 had a complex dissoiation constant at 25°C of 5.8E-11, significantly higher than the control's value

interactions between amino acid duplets in the dynamical area as a covariance matrix, where the red part denotes correlated residues, the white part for anti-correlated residues, and the blue part for non-correlated residues.

Codon Adaptation and In-silico Cloning

JCat which is a codon adaptation tool was used to optimize the vaccine construct codon to get maximum protein expression. The optimized codon (Fig. 9) sequence has 70% GC Content. The optimized codon sequence was inserted into PUC18 Vector to make a recombinant plasmid which is then amplified through In-silico PCR using SnapGene software.

DISCUSSION

Vaccination against a particular disease not only protects individuals from contracting the illness but also results in an overall improvement in the health of the population, cuts down on the spread of the disease, and is very cost-efficient. However, the process of immunization calls for a significant investment of time and money while it is still in the developmental stage. In this context, the contribution of specialists is absolutely essential. Because of advances in technology and the accessibility of various bioinformatics tools, it is now possible to save costs while simultaneously reducing the amount of time spent. Analyses of the pathogen on the genomic and proteomic levels are being carried out in order to create vaccinations (Pandey et al., 2018). The goal of this research is to decrease the amount of viral material that is bound to virus particles and transferred to human cells by focusing on the outer-membrane and transmembrane proteins. The investigation of the secondary and tertiary structure has been demonstrated to offer a highly antigenic potential for the development of vaccines. Based on the allergenicity and antigenicity report of the vaccine, this study demonstrates, in general, the potential of this in silico produced vaccine targeting the gp160 in membrane and trans-membrane.

As a result of advancements in the clinical research field, we are now able to choose and target histocompatibility complex (MHC) T-cells that have the most interaction with human leukocyte antigen (HLA) scheme using computational biology. Alternatively, we can choose to use B-cells as the source of vaccine design. This option is available to us. In the beginning, it is necessary for us to get all of the databases and software that are available for all of the nucleocapsid and trans-membrane epitopes that are feasible on the protein. The IEDB database was selected for the epitope prediction of B-cells because it can predict antigenicity in two different methods. The cutoff score for antigenicity has been set to 5.0. On the other hand, we identified T-cell epitopes by screening them first to find those with an IC50 value of less than 200, which ensures that they are highly active against the targeted protein. After that, the epitopes are combined with MHC Class-I and MHC Class-II Class, and then the two classes are separated for screening (Naveed et al. 2023c).

Vaxijen v2.0 may be used to calculate the antigenic characteristics of B and T cells, as well as the ACC of peptides based on their physiochemical parameters. Those with levels more than the limit are considered antigens in nature. This antigenic epitope should be safe in its natural condition, so that it does not cause

problems when employed as an immune response (Cong et al., 2023). We also assess vaccine allergenicity since vaccine allergenicity is the greatest impediment to advancement in the field of vaccine development. Both classes' MHC have shown a high degree of conservation over the world, resulting in an increase in the proportion of the HIV patient population protected by peptide vaccines (Meron-Sudai et al., 2023).

Following the acquisition of all necessary criteria, the process of vaccine manufacturing will involve the selection of 8 epitopes from MHC Class-I T-cells, 8 epitopes from B-cells, and 15 epitopes from MHC Class-I T-cells as the subunits (Naveed et al., 2022c). The vaccine demonstrates a growing response of the vaccination in the identification of pathogens and activation of the immune system, immune-reactivity is one of the features that adjuvants like 50S ribosomal protein L7/LI2 are used to boost. In the first stages of the production of multiple epitope vaccines, linkers are utilized for the purpose of fusing B-cell and T-cell epitopes together. Linkers such as EAAAK, CPGPG, KK and AAY were incorporated between the critical predicted epitopes in order to produce a viable vaccine with the highest antigenicity possible.

The generated protein sequence has been subjected to bioinformatic analysis as well as immunologic testing, both of which have concluded that it does not include any allergenic or poisonous components. GalaxyRefine was utilized in order to refine the 3D structure of the chimeric vaccine, which resulted in the acquisition of the desired features (Al Tbeishat, 2022). RAMPAGE, also known as the Ramachandran Plot, demonstrates that a possible vaccination candidate possesses suitable characteristics. According to the findings, the majority of the residues are located in favorable areas, while just a few residues were found in regions that were considered to be outliers (Naveed et al., 2022e).

This demonstrates that the quality of the desired model can be considered acceptable. Clustpro2.0 is utilized in the Docking process, which displays the most promising models of the vaccine-receptor complex by bringing them into close proximity to the reference structure. A simulation using molecular dynamics was carried out, with the goal of emulating the natural behavior of our dynamic system (Naveed et al., 2022d). The docked complex of the vaccine construct of viral gp160 protein and CD4 receptor of the host should that the computational vaccination model of human immunodeficiency virus has the potential to combat Autoimmune Deficiency Syndrome.

The primary emphasis of this research was on the development of an in-silico strategy for the design of an mRNA peptide-based vaccination based on HIV-1 antigenic proteins (Shabani et al., 2022). Using immunoinformatic methods, the advised mRNA vaccine was tested for stability, thermostability, antigenicity, lack of allergenicity, and hydrophilicity. The ability of the vaccine to establish memory cells upon exposure, as well as to produce chemokines that increase B-cell response and humoral response, was verified using molecular simulation after three doses were administered (Naveed et al., 2022a). Macrophages, dendritic cells, and the Simson index were markers for the development of memory cells. Finally, it was determined that the manufactured vaccine shows promise as a potential candidate for use in the prevention of Human Immunodeficiency syndrome infections.

CONCLUSION

Humanity has faced significant scientific, medical, and moral challenges due to HIV/AIDS since its discovery in 1983. The results of this investigation indicate that the vaccine design has both desirable physicochemical properties and immune responses against HIV-1. Using a variety of immune-informatics techniques or methodologies, it was discovered that this immunization will activate an immunological response against HIV-1 in the host. Our results were supported by the immunological response that the vaccine elicited, as measured by Immune Stimulation. Accordingly, this construct is suggested for use as a potential subject for in vitro and in vivo studies against *S. marcescens*, employing a wide variety of serological assays to elicit a reaction. By developing a reliable vaccine, this study aids the global effort to wipe out HIV.

Prevalence of circulating antibodies against hemagglutinin of influenza viruses in epidemic season 2021/2022 in Poland

Katarzyna Kondratiuk[1], Ewelina Hallmann[1]*, Karol Szymański[1], Katarzyna Łuniewska[1], Anna Poznańska[2] and Lidia B. Brydak[1]

[1]Laboratory of Influenza Viruses and Respiratory Viruses, Department of Virology, National Institute of Public Health NIH—National Research Institute, Warsaw, Poland, [2]Department of Population Health Monitoring and Analysis, National Institute of Public Health NIH—National Research Institute, Warsaw, Poland

The aim of the study was to determine the level of anti-hemagglutinin antibodies in the serum of patients during the 2021/2022 epidemic season in Poland. A total of 700 sera samples were tested, divided according to the age of the patients into 7 age groups: 0−4 years of age, 5−9 years of age, 10−14 years of age, 15−25 years of age, 26−44 years of age, 45−64 years of age and ≥65 years of age, 100 samples were collected from each age group. Anti-hemagglutinin antibody levels was determined using the haemagglutination inhibition assay (OZHA). The results obtained confirm the presence of anti-hemagglutinin antibodies for the antigens A/Victoria/2570/2019 (H1N1) pdm09, A/Cambodia/e0826360/2020 (H3N2), B/Washington/02/2019 and B/Phuket/3073/2013 recommended by World Health Organization (WHO) for the 2021/2022 epidemic season. The analysis of the results shows differences in the levels of individual anti-hemagglutinin antibodies in the considered age groups. In view of very low percentage of the vaccinated population in Poland, which was 6.90% in the 2021/2022 epidemic season, the results obtained in the study would have to be interpreted as the immune system response in patients after a previous influenza virus infection.

KEYWORDS

influenza, hemagglutinin antibodies, protection rate, GMT, serum financial support

Introduction

Influenza is a significant public health threat both in Poland and around the world. It is an acute infectious respiratory viral disease caused by influenza viruses classified into four types: A, B, C, and D. Influenza A virus infects not only humans, but also horses, pigs, aquatic mammals (such as seals, whales), and birds. The influenza B virus only infects humans, while the influenza C virus infects humans and pigs. In contrast, the influenza D virus has so far been detected in pigs and cattle (Ducatez et al., 2015; Gliński and Żmuda, 2022). Human infection with influenza D has not been observed (Wu and Wilson, 2020). This classification is based on antigenic differences between the main proteins of the

virion, i.e., the M protein and the NP nucleoprotein. These types differ epidemiologically (Brydak, 2008). Influenza epidemics are caused by both influenza A (A/H3N2/and A/H1N1/pdm09) and influenza B (B/Yamagata and B/Victoria) lineages, but only influenza A viruses can cause a pandemic and dramatically increase hospitalizations and deaths from post-flu complications (Frey et al., 2023). In most cases, the influenza C virus causes only mild symptoms after infection.

Seasonal influenza mainly occurs during the colder months in regions with temperate climates. Human-to-human transmission of the influenza virus occurs through inhalation of infectious respiratory particles when an infected person coughs or sneezes. There is also evidence that the influenza virus can be transmitted by talking or breathing, that is by transmitting small respiratory particles. The incubation period of the influenza virus is usually 24–48 h. An infected patient is contagious even one to 2 days before the onset of influenza symptoms and for five to 7 days after the onset of symptoms. Infected children and persons taking immunosuppressive drugs may show prolonged secretion of the influenza virus (Gaitonde et al., 2019).

The influenza A virus particle, which deceptively resembles a chestnut with protruding spikes, has a lipid envelope originating from the plasma membrane of the host cell. Two surface proteins are anchored in it: hemagglutinin (HA) and neuraminidase (NA). Hemagglutinin is responsible for the adsorption of the influenza virus into the cell, while neuraminidase is responsible for the release of viruses from the host cells. It is estimated that there are approximately 400 HA spikes and 100 NA spikes per influenza A and B virus particle. The structure of the influenza virus genome is segmented. Influenza A and B viruses are characterized by having 8 viral RNA segments, while the influenza C virus has only 7 viral RNA segments. Influenza C viruses have only one type of spike in the lipid envelope, which serves as hemagglutinin and neuraminidase. The organization of the influenza A virus genome in the form of segments allows for reassortment, which is an important mechanism for the formation of diverse strains (Gliński and Żmuda, 2022). Thus, the influenza A virus is characterized by high antigenic variability, and based on differences in surface antigens, 11 subtypes conditioned by neuraminidase–NA (N1-N11) and 18 subtypes conditioned by hemagglutinin–HA (H1-H18) are distinguished (Brydak, 2008; Wierzbicka-Woś et al., 2015). Pandemic influenza strains arise as a result of antigenic shift and may include avian-derived hemagglutinin (HA) subtypes (such as H5, H7, and H9) or porcine hemagglutinin variants (H1, H2, and H3) which, by acquiring further adaptive mutations, become capable of human-to-human transmission of infection (Bouvier and Palese, 2008; Taubenberger and Kash, 2010; Khalenkov et al., 2023). Vaccination against influenza is the most effective preventive measure. Influenza vaccines reduce the risk of being affected by influenza and prevent the development of serious complications. They also play an important role in

pandemic preparedness plans around the world (Frey et al., 2023).

However, in order to be effective, it requires constant and thorough worldwide supervision and timely updates of the formulation of the influenza vaccine (Khalenkov et al., 2023). Influenza virus infections, like many other infections, induce an immune response in the infected body, reducing or even cessating virus replication and formation of so-called immunological memory in the patient, protecting against subsequent infection. However, this optimistic scenario is hampered by the fact that the influenza A virus is characterized by high antigenic variability and constant mutations. This significantly impedes the formation of memory and immune response, while facilitating the transmission of infections between sick and healthy population (Wierzbicka-Woś et al., 2015). Antigenic drift (antigenic shift) is a consequence of point mutation of genes in the replication of influenza viruses, leading to changes in amino acid sequences that alter antigenic sites in epitopes. New variants and annual influenza epidemics are the result of antigenic changes in the H and N glycoproteins of the virus. This results in the inability to develop a universal formulation of the vaccine and the need to change the composition of influenza vaccines every season (Shao et al., 2017; Gliński and Żmuda, 2022). Anti-hemagglutinin antibodies are characterized by a relatively short persistence in blood serum (Allwinn et al., 2013). Due to all these reasons, seasonal influenza vaccinations are extremely important, contributing to an increase in resistance to influenza infections of the general population, and thus reducing the risk of post-influenza complications and death.

The aim of this study was to determine the level of anti-hemagglutinin antibodies in the sera of persons in different age groups during the 2021/2022 epidemic season in Poland.

Materials and methods

The study material consisted of 700 sera collected by employees of 16 Provincial Sanitary and Epidemiological Stations in Poland, in accordance with the World Health Organization (WHO) recommendations. Samples were collected at voivodeship sanitary and epidemiological stations (VSES) in Poland, between 1st October 2021 and 31st September of 2022. The serum samples were divided into 7 groups according to the age of the patients: 0–4 years of age, 5–9 years of age, 10–14 years of age, 15–25 years of age, 26–44 years of age, 45–64 years old and ≥65 years of age, 100 samples collected from each age group (the number of samples from each voivodeship was not the same). Prior to testing, serum samples were stored at −80°C. Prior the testing sera were selected and checked for haemolysis in sample. If noticed, sample was discarded.

TABLE 1 Influenza virus strains used for the hemagglutination inhibition assay (HAI) in the 2021/2022 epidemic season.

Epidemic season 2021/2022		
Influenza virus strains	A/H1N1/pdm09	A/Victoria/2570/2019 (H1N1)pdm09-like virus
	A/H3N2/	A/Cambodia/e0826360/2020 (H3N2)-like virus
	B Victoria lineage	B/Washington/02/2019 (B/Victoria lineage)-like virus
	B Yamagata lineage	B/Phuket/3073/2013 (B/Yamagata lineage)-like virus

All viruses were obtained from World Influenza Centre at Francis Crick Institute, London, and then propagated in the amniotic cavity on 11- days old chicken embryos in Influenza Virus Research Department, National Influenza Center at the National Institute of Public Health NIH-National Research Institute (NIPH NIH-NRI), in accordance with WHO recommendations (WHO, 2011). The eggs were incubated as follows: for H3N2 and H1N1 viruses (2 days at 37°C); and for influenza B viruses (3 days at 35°C). Then titer of each virus was determined. Labelled vials containing viruses were stored at −80°C upon using in research (WHO, 2011).

The study used antigens for the 2021/2022 epidemic season recommended by WHO (Table 1).

The level of anti-hemagglutinin antibodies was determined by hemagglutination inhibition assay (HAI). The haemagglutination inhibition assay (OZHA) was performed using 8 hemagglutination units of the virus. The sera were inactivated prior to testing according to adopted standards (Tyrell and Horsfall et al., 1952; WHO, 2011). Necessary viruses with high titer were selected to be used in this test. Solution of titer 1:8 from each of the virus was prepared. For example, for virus titer 1:64, suspension of the virus was diluted 8 times. For 1:16—two Times. After preparing all necessary solution, they were stored in 4°C upon adding them on the plates.

PBS and Alsever's solution needed for the OZHA test are prepared in–house. In this study V-bottom, clear, microtitration plates were used.

For OZHA test are used chicken red blood cells. Blood cells delivered to the laboratory were suspended in Alsever's solution. By centrifugation at a speed of 1200 RPM for 10 min, a concentrate of packed blood cells was obtained and used in further research.

Each of the sera was treated with Receptor Destroying Enzyme (RDE) (Thermo Fisher Scientific) for 16 h at 37°C prior to the hemaggluti-nation inhibition test. After this step, to inac-tivate the enzyme, the mixture was incubated at 56°C for 30 min.

In OZHA test, a serial dilution of each of the sera was made in PBS. Then, the prepared solution of the virus, which has titer of 1:8 was added to each well on the plate. After virus addition, the plate was incubated for 15 min at room temperature. After incubation, 50 μL of blood cell solution was added. Readings were taken after 30 min of incubation at room temper-ature, then the results were read.

The analysis of the test results of the study was based on the following parameters: geometric mean titer (GMT) of the anti-hemagglutinin antibody in the tested sera and the protection rate (percentage of people with anti-hemagglutinin antibodies at a level ≥1:40 that appeared after the administration of an influenza vaccine or during the previous infection by the influenza virus) (Brydak, 2008; WHO, 2011; Krammer, 2019). This is the value of anti-hemagglutinin antibody titers, which is considered a protective value (Brydak, 2008).

Statistical analysis

The test chi-square was used to compare age groups regarding the categorical variables (prevalence of anti-hemagglutinin antibodies and reaching their protective titer). The Kruskal-Wallis test was applied to compare the titer distribution between seven age groups, and the Mann-Whitney U test was used for two. The significance level for all the tests was assumed to amount to 0.05. The calculations were executed with the SPSS 12.0 PL.

Results

The analysis of the obtained results shows that antibodies against A/Victoria/2570/2019 (H1N1) pdm09 were present in 332 people (47.4% of the studied patients). The largest number of tested patients—649 persons (92.7% of all subjects)—had antibodies against A/Cambodia/e0826360/2020 (H3N2). The smallest number of tested patients had antibodies against B/Washington/02/2019 (B/Victoria lineage), it was 288 patients (41.1% of subjects). Antibodies against B/Phuket/3073/2013 (B/Yamagata lineage) were present in the sera of 534 patients (76.3% of all tested sera).

Figures 1, 2 show the percentage of patients in individual age groups that had antibodies against a particular influenza virus.

Using the chi-square test, it was found that statistically significant differences in the number (and therefore percentage) of those with antibodies between the tested sera of patients from all seven age groups apply to all four types of antibodies for the following types and subtypes of influenza viruses:

FIGURE 1
The presence of antibodies in the serum of patients aged 0−4 years, 5−9 years of age and 10−14 years of age in the 2021/2022 epidemic season.

FIGURE 2
The presence of antibodies in the serum of patients aged 15−25, 26−44, 45−64, and 65+ years of age in the 2021/2022 epidemic season.

- For the H1 subtype: $p < 0.001$, the percentage of those with antibodies ranged from 5% in the 10–14-year-old group to 90% in the 15–25-year-old group;
- For the H3 subtype: $p = 0.024$, the percentage of those with antibodies ranged from 87% in the 0–4 years old group to 99% in the 45–64 years old group;
- For the B/Victoria line (B/Washington): $p < 0.001$, the percentage of those with antibodies ranged from 3% in the group of 10–14 years old to 93% in the group of 65 years and over;
- For the B/Yamagata line (B/Phuket): $p < 0.001$, the percentage of those with antibodies ranged from 26% in the 5–9 years old group to 95% in the 15–25 years old group.

In Figure 3 shows the geometric mean titers of anti-hemagglutinin antibodies in the sera of patients according to age groups in the 2021/2022 epidemic season in Poland (Figure 1).

Based on the obtained test results, the highest GMT values for hemagglutinin A/H1 were found in patients in the youngest patients' age group 0–4 years old (GMT = 54.3). Lower GMT values for hemagglutinin A/H1 were obtained in the 5–9 age group (GMT = 46.5). In the remaining age groups, GMT values for hemagglutinin A/H1 were comparable, with the lowest value in the age group of 26–44 years (GMT = 20.0).

The highest GMT values for hemagglutinin A/H3 was recorded in the age groups 10–14 years (GMT = 181.0) and 26–44 years (GMT = 180.0). Lower values were found in the age

FIGURE 3
Geometric mean titers of anti-haemagglutinin antibodies (GMT) in the epidemic season 2021/2022 in age groups in Poland.

group of the youngest children aged 5–9 (GMT = 151.6), in patients aged 45–64 years (GMT = 139.1) and in the youngest patients' age group 0–4 years old (GMT = 103.2). In the remaining patients, the GMT values for hemagglutinin A/H3 remained at a similar level: in the oldest patients over 65 years of age was 39.4 and in patients aged 15–25 was 30.3.

In the case of type B/Washington/02/2019, the highest GMT value was reported in the 10–14 age group (GMT = 31.7). In the remaining age groups, GMT values were as follows: ≥65 years old (GMT = 30.6), 26–44 years old (GMT = 28.0), 0–4 years old (GMT = 27.5), 5–9 years old (GMT = 25.7), 15–25 years old (GMT = 20.9), 45–64 years old (GMT = 16.9).

According to the analyzed data for type B/Phuket/3073/2013, the highest geometric mean antibody titers was reported for the youngest patients aged 0–4 years (GMT = 81.5). The age group 26–44 had a similar GMT value (GMT = 67.0). For the remaining age groups, the GMT values were: 10–14 years old (GMT = 46.2), ≥65 years old (GMT = 30.4), 5–9 years old (GMT = 29.0), 45–64 years old (GMT = 25.3), 15–25 years old (GMT = 22.0).

In neither age group the geometric mean titer of all of anti-hemagglutinin antibodies (H1, H3, B/Washington/02/2019 and B/Phuket/3073/2013) was not ≥ 40. In two age groups 15–25 and 65+, the average level of none of the antibodies reached 40. Only in the case of the youngest patients aged 0–4 years, the geometric mean titer of three anti-hemagglutinin antibodies (H1, H3 and B/Phuket/3073/2013) was ≥40. GMT values were respectively: for H3 GMT = 103.2, for B/Phuket/3073/2013 GMT = 81.5, for H1 GMT = 54.3, respectively.

Statistical analysis performed using the Kruskal-Wallis test showed that for all types of antibodies, the difference in their titer between all seven age groups was statistically significant ($p <$ 0.001 in all cases).

- For the H1 subtype: antibodies found in 332 persons, the mean GMT = 37.0, the lowest antibody level in the group of 26–44 years old (GMT = 20.0), the highest in the group of 0–4 years old–GMT = 54.3 (p < 0.001);
- For the H3 subtype: antibodies found in 649 persons, the mean GMT = 97.1, the lowest antibody level in the group of 15–25 years old (GMT = 30.3), the highest in the group of 10–14 years old–GMT = 181.0 (p < 0.001);
- For the B/Victoria line (B/Washington): antibodies found in 288 persons, the mean GMT = 25.2, the lowest antibody level in the group of 45–64 years (GMT = 16.9), the highest in the group of 10–14 years–GMT = 31.8 (p < 0.001);
- For the B/Yamagata (B/Phuket) line: antibodies found in 534 persons, the mean GMT = 38.9, the lowest antibody level in the 15–25 years old group (GMT = 22.0), the highest in the 0–4 years old group–GMT = 81.5 (p < 0.001).

Figure 4 shows the percentage of cases with a protective anti-hemagglutinin antibody titer (%), i.e., ≥40, in the 2021–2022 epidemic season, in different age groups.

Studies on the effectiveness of influenza vaccination show that the protective coefficient should reach different values depending on the age of the patient in order to achieve the desired effect of vaccination effectiveness. According to the

FIGURE 4
Percentage of cases with a protective titer of anti-haemagglutinin antibodies (%) in the 2021/2022 epidemic season in different age groups.

criteria of the CPMP (Committee for Proprietary Medicinal Products) of the European Agency for the Evaluation of Medicinal Products (EMEA) and the Commission of the European Communities regarding the harmonization of requirements for influenza vaccination, parameters such as the mean increase in anti-HA antibody titers (MFI), the protective factor and the response rate, measured approximately 3 weeks after vaccination should be taken into account when assessing the serological response to this vaccination. Depending on the age of the patient these values vary (Commission of the European Communities, 1991; Committee for Proprietary Medicinal Products, 1997).

Comparing the results of the protective coefficient results for all hemagglutinins, the highest protective coefficient values were obtained for hemagglutinin H3 and B/Yamagata (B/Phuket) line. The conducted analyzes of the value of the protective coefficient indicate that in the age group of 0–4, 5–9, 10–14, 26–44 and 45–64 years values above 70% and 60% for the 65+ age group have been recorded. These values were obtained only for the above mentioned subtypes. In other cases, the protection rate did not reach the recommended protection level. The highest value of protective coefficient was recorded for hemagglutinin H3. These data correspond to the low level of vaccination of the population in Poland in the 2021/2022 epidemic season (according to data from the Influenza Research Institute, National Influenza Centre).

For all antibody types, there is a statistically significant difference in protective coefficients between all seven age groups, as was demonstrated with the use of the chi-square test.

- For the H1 subtype: 200 subjects had antibodies with titers of ≥ 40, the protective coefficient was 29%, the statistical significance of differences between age groups was $p < 0.001$, the protective coefficients in age groups ranged from 4% in the group of 10–14 years old to 62% in the group of 0–4 years old;

- For the H3 subtype: 532 subjects had antibodies with titers ≥ 40, the protective coefficient was 76%, the statistical significance of differences between age groups was $p < 0.001$, the protective coefficients in age groups ranged from 35% in the group of 15–25 years old to 90% in groups of 10–14 years old and 45–64 years old;

- For the B/Victoria line (B/Washington): 108 subjects had antibodies with titers ≥ 40, the protective coefficient was 15%, statistical significance of differences between age groups was $p < 0.001$, protective coefficients in age groups from 2% in the group 10–14 years old to 38% in the group 65 years old and over;

- For the B/Yamagata (B/Phuket) line: 308 subjects had antibodies with titers ≥ 40, the protective coefficient was 44%, statistical significance of differences between age groups was $p < 0.001$, protective coefficients in age groups from 13% in groups of 5–9 years old and 15–25 years old to 72% in the 0–4 years old group.

Distributions of antibody levels among the tested sera of children (300 subjects aged 0–14) and adults (400 subjects aged over 14) show clear differences:

- For the H1 subtype: in adults, antibody titer values ranged from 0 to 640, quartiles (Q1/Q2—median/Q3): 0/0 (median)/20; in children values ranged from 0 to 160, quartile: 0/0 (median)/40; the difference in distributions is statistically significant (p = 0.002), as determined using the Mann-Whitney U test; the percentages of adults and children with antibodies are similar—45% vs. 50%, the difference is not statistically significant, as determined by the chi-square test; the mean level of antibodies in subjects who have them is significantly higher among children (49.8 vs. 29.1, p < 0.001), as shown by the Mann-Whitney U test; as expected (in both compared groups a similar percentage of subjects have antibodies, and their titers are clearly higher in younger ones), children reach the protective level significantly more often (38% vs. 22%; p < 0.001);

- For the H3 subtype: in both age groups, antibody titer values ranged from 0 to 640; quartile among adults: 20/80 (median)/160, higher among children 80/160 (median)/320; the difference in distributions is statistically significant (p < 0.001)—Mann-Whitney U test; presence of antibodies against H3 is common, 96% in adults and 89% in children, however the difference is statistically significant ($p = 0.001$, chi-square test); the mean level of antibodies (in people who have them) is significantly higher in children (142.0 vs 74.4; $p < 0.001$—Mann-Whitney U test); children are also a group that achieves the protective level significantly more often (86% vs. 69%; $p < 0.001$);

- For the B/Victoria line (B/Washington): in adults, antibody titer values ranged from 0 to 640, quartile: 0/10 (median)/20; in children, antibody titer values ranged from 0 to 160, quartile 0/0 (median)/0; the difference is statistically significant ($p < 0.001$)—Mann-Whitney U test; 63% of adults and only 13% of children had antibodies against B/Washington, the difference is statistically significant ($p < 0.001$, chi-square test); unlike other antibodies, there is no difference in their mean level in children (27.3) and adults (24.9)—as before, we only count subjects with antibodies; as expected (antibodies in adults are present much more often, and their average titer in both groups is similar), adults reach the protective level significantly more often (22% vs. 6%; $p < 0.001$);

- For the B/Yamagata (B/Phuket) line: in both age groups, antibody titer values ranged from 0 to 640; quartile in adults: 10/20 (median)/40, and in children 0/40/80; difference in distributions bordering on statistical significance ($p = 0.053$)—Mann-Whitney U test; 89% of adults and 59% of children had antibodies against B/Phuket, the difference is statistically significant ($p < 0.001$, chi-square test); the mean level of antibodies (in subjects with antibodies) is significantly higher in children (54.8 vs 32.7; $p < 0.001$—Mann-Whitney U test). The frequency of reaching the protective level is higher among children under 14 years of age (51% vs. 39%, $p = 0.001$).

Discussion

The analysis of the study results indicates that antibodies against all four influenza viruses included in the influenza vaccine in the 2021/2022 influenza season were detected in the tested sera of patients from all age groups. Due to the very low vaccination rate of general population in Poland, which in the 2021/2022 epidemic season, despite recommendations and solid, multi-threaded educational campaigns, was estimated at only 6.90% (Grohskopf et al., 2021; NIPH NIH-NRI, 2023) the results obtained in the study should be interpreted as a response of the immune system in patients after a previous infection caused by the influenza virus. The detection of anti-hemagglutinin antibodies in the patient's blood serum may indicate a past infection with influenza viruses or the fact that the patient has been vaccinated against influenza. Immunity after vaccination against influenza usually appears approximately 10–14 days after receiving the vaccine and lasts for approximately 6–12 months, i.e., during one epidemic season, which usually covers period from October to March. For this reason, and because the influenza virus is subject to rapid antigenic changes, seasonal influenza vaccination is extremely important. Vaccination is the most effective preventive measure against influenza infection, mitigating the course of the disease and preventing post-influenza complications, which may be very serious, including complications with death threat. This may not only apply to people in high-risk groups.

Comparing the antigenic composition of the influenza vaccine in effect in the Northern Hemisphere in the 2021/2022 epidemic season and in the 2020/2021 epidemic season, it can be noted that in both epidemic seasons the same antigens for type B influenza viruses were present: B/Washington/02/2019 (B/Victoria lineage)-like virus and B/Phuket/3073/2013 (B/Yamagata lineage)-like virus. In these two epidemic seasons, only the antigens for influenza A viruses mutated, both for the influenza virus of the A/H1N1/pdm09 subtype and for the A/H3N2/virus. The influenza B/Phuket/3073/2013 (B/Yamagata lineage)-like virus antigen has been included in the influenza vaccine recommended for the Northern Hemisphere for several consecutive epidemic seasons. Despite this, this virus reached a protective level only in one age group among the analyzed samples–among the youngest children under 4 years of age (72%).

It is considered necessary to vaccinate 70%–80% of the population to achieve community immunity. It is assumed that the titer of anti-hemagglutinin antibodies in blood sera at a level of ≥1:40 protects against influenza virus infection. The effectiveness of vaccinations in older people is lower than in young people. After vaccination, most young people achieve this

titer, while in the group of older people only ¼ do (Carrat and Valleron, 1994; Glathe and Langer, 1995; Brydak, 2008).

Emerging infectious diseases pose a serious threat to global health security, as exemplified by the recent COVID-19 pandemic. Seasonal influenza virus infections, millions of cases registered every epidemic season and thousands of deaths due to post-influenza complications around the world, as well as the threat of another influenza pandemic and cases of human infection with avian influenza viruses in the past make the fight against influenza one of the public health priorities. Effective control of the threats posed by this disease depends, among others, on effective supervision. A worrying but unfortunately common phenomenon among the society is the disregard of the early symptoms of the disease in particular, when influenza is often confused with the common cold. In many cases, this significantly hinders or completely prevents effective antiviral therapy. Referring to the diagnosis of the influenza virus, the serious consequences resulting from the incorrect diagnosis of symptoms and the implementation of unjustified antibiotic therapy are also worth mentioning. The arising problem is antibiotic resistance, i.e., the lack of sensitivity of bacteria to antibiotics. Due to frequent complications, antibiotic therapy is implemented as part of medical prophylaxis, despite the fact that it is widely known that antibiotics are not used in the prevention of viral infections. The trend of increasing drug resistance of microorganisms, which has been observed in recent years, may lead to a very difficult situation, which is the exhaustion of therapeutic options against infections. The use of antibiotics should therefore be justified by appropriate tests.

Fast and effective diagnosis of patients suspected of having influenza may allow for the earliest possible implementation of treatment and bring about both health-related and economic benefits.

Conclusion

Based on the assessment of the level of anti-hemagglutinin antibodies in sera collected from patients in seven age groups during the 2021/2022 epidemic season in Poland, the following conclusions can be drawn:

- The study results confirmed the circulation in the population of four antigens of influenza virus strains included in the influenza vaccine for the 2021/2022 epidemic season: A/Victoria/2570/2019 (H1N1) pdm09-like virus, A/Cambodia/e0826360/2020 (H3N2)-like virus, B/Washington/02/2019 (B/Victoria lineage)-like virus and B/Phuket/3073/2013 (B/Yamagata lineage)-like virus.
- Adult patients (of over 14 years of age) had antibodies against hemagglutinin of influenza viruses more often than

children (of under 14 years of age) (with the exception of antibodies against A/Victoria/2570/2019 (H1N1) pdm09—here, the level of antibodies in patients from the two above groups was at a similar level).
- Among the tested subjects with antibodies, their titer is on average higher in children under 14 years of age (the exception being antibodies against B/Washington/02/2019 (B/Victoria lineage)—here the level of antibodies in both adult patients over 14 years of age and in children was at a similar level).
- Tested children aged 0–14 years more often achieved a protective level (anti-hemagglutinin antibody titer ≥40) in case of antibodies against A/Victoria/2570/2019 (H1N1) pdm09, A/Cambodia/e0826360/2020 (H3N2) and B/Phuket/3073/2013 (B/Yamagata lineage); the protective level against B/Washington/02/2019 (B/Victoria lineage) was more often achieved by adults over 14 years of age (while as many as 87% of children under 14 years of age did not have anti-hemagglutinin antibodies at all).
- The low percentage of vaccinated persons in particular age groups may indicate that the level of protection obtained may have been the result of a past infection caused by influenza viruses.

Data availability statement

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

Ethics statement

Ethical review and approval were waived for this study due to the National Influenza Centre (NIC) cooperating with Voivodship Sanitary Epidemiological Stations (VSES), within the WHO's Global Influenza Surveillance And Response System (GISRS). VSES collected samples from patients during the epidemic season. The studies were conducted in accordance with the local legislation and institutional requirements. The human samples used in this study were provided by VSES. Written informed consent to participate in this study was not required from the participants or the participants' legal guardians/next of kin in accordance with the national legislation and the institutional requirements. Written informed consent was not obtained from the individual(s), nor the minor(s)' legal guardian/next of kin, for the publication of any potentially identifiable images or data included in this article because samples were collected by VSES. All documents regarding patients and their consent, belongs to VSES.

Contemporary scientific discussions are increasingly focusing on *Akkermansia muciniphila* due to its complex influence on intestinal physiology. This article provides a comprehensive analysis of the various effects *Akkermansia muciniphila* has on intestinal inflammation, while also exploring its potential associations with obesity and cardiovascular diseases. A systematic literature search was conducted using PubMed, Google Scholar, and ResearchGate with the following keywords: *Akkermansia muciniphila*, obesity, cardiovascular risk, and inflammatory bowel diseases. The aim of our mini-review was to examine the impact of *Akkermansia* bacteria on the intestines, cardiovascular system, and its relationship with obesity. Through a detailed review of current literature, the article seeks to elucidate the complex interactions of *Akkermansia muciniphila* within the human body, highlighting its potential contributions to health improvement and medical interventions. Research indicates that *Akkermansia muciniphila* positively correlates with maintaining intestinal health, modulating the cardiovascular system, and aiding in weight management. However, the number of studies available is small, and the effects of *Akkermansia muciniphila* on human health require further research.

KEYWORDS

Akkermansia muciniphila, cardiovascular diseases, inflammation, obesity, microbiota

Introduction

In recent years, the microbiome has emerged as a key player in influencing various aspects of human health. Among the myriad of microorganisms inhabiting the human gut, *Akkermansia muciniphila*, isolated from feces and named in 2004 by a group of Dutch scientists, led by professor Willem M. de Vos and PhD. Muriel Derrien has gained considerable attention for its potential role in shaping our overall wellbeing. This microscopic bacterium is particularly intriguing due to its distinctive ability to thrive on mucin, a key component of the protective mucus layer lining the intestines. As research continues to unveil the intricate relationship between *Akkermansia muciniphila* and human health, its profound impact on inflammation within the gastrointestinal tract and the broader implications for cardiovascular health have become subjects of intense scientific exploration (Derrien et al., 2010). This article delves into the multifaceted influence of *Akkermansia muciniphila* on the inflammatory processes within the intestines and its consequential effects on the obesity and cardiovascular system (Figure 1).

Due to the frequent occurrence of diseases such as obesity and cardiovascular diseases, it is important to prevent them through various options, as well as to support available treatments. Modulation of the gut microbiome may be one of the potential possibilities. Therefore, the aim of our mini review was to examine the impact of *Akkermansia* bacteria on the effects on the intestines, cardiovascular system and the relationship with the obesity.

Methods

A systematic literature search was conducted using the PubMed, Google Scholar and ResearchGate with the following keywords: *Akkermansia muciniphila*, obesity, cardiovascular risk, inflammatory bowel diseases. We found 24 trials included studies on humans and animals in 2007–2023 years regarding *A. muciniphila's* impact on the intestines, cardiovascular risk and obesity. 11 of them were rejected because they did not meet the criteria for an observational or interventional study.

Characteristics of *Akkermansia muciniphila*

A. muciniphila is an anaerobic, gram-negative rod, representing the sole bacterium from the Verrucomicrobiales family in the human body (Derrien et al., 2010). It colonizes the mucosal layer of the crypts in the colon and rectum. Devoid of spore-forming capabilities and independent motility, this bacterium specializes in the degradation of mucins - glycoprotein conjugates produced by epithelial cells to ensure their proper functioning. Elevated production of these proteins, integral to mucosal integrity, correlates with an increased likelihood of colorectal cancer, particularly involving the MUC-1 protein (Nath and Mukherjee, 2014).

FIGURE 1
The scheme of *Akkermansia muciniphila* impact on health.

A. muciniphila makes its presence in the human gut as early as the first year of life, acquired from maternal milk, constituting approximately 1%–3% of the bacterial population (Collado et al., 2007). Its levels are diminished in individuals with overweight or obesity, and they exhibit an inverse correlation with age (Collado et al., 2007; Dao et al., 2016; Dao et al., 2019). Preliminary studies conducted on a group of nine individuals during Ramadan, simulating intermittent fasting conditions, unequivocally indicate a significant rise in the quantity of *A. muciniphila* in the gut during intermittent fasting (Dao et al., 2016; Dao et al., 2019; Mousavi et al., 2022). Crucially, research on a cohort of patients who underwent bariatric surgery did not confirm a similar increase in *A. muciniphila* levels despite the requisite dietary changes, suggesting that the surge in *A. muciniphila* is specific to intermittent fasting rather than a dietary shift (Dao et al., 2016; Dao et al., 2019). However, further studies on a larger sample size are essential for validation. Although there is no evidence supporting the influence of diet on *A. muciniphila* levels, other factors come into play such as metformin, a first-line medication for type 2 diabetes, which has been found to statistically positively correlate with *A. muciniphila* levels in the gut (Shin et al., 2014).

A. muciniphila is categorized into four phenotypic groups, AmI to AmIV (Becken et al., 2021). The most extensively studied strain and widely available as a probiotic is the pasteurized MucT strain, belonging to the AmI group. Despite initial assumptions of being strictly anaerobic, *A. muciniphila* has demonstrated adaptability to aerobic environments. Even low oxygen concentrations can promote its growth, as evidenced by studies on various strains of the bacterium. Strains belonging to AmII exhibit relatively good tolerance to aerobic conditions, with a survival rate of 60% after 24 h, whereas AmIV strains display very low survival at 0.01% under the same conditions after only 12 h (Becken et al., 2021). *A. muciniphila* also participates in the transformation of cobalamin precursors (Cbi) into cobalamin (vitamin B12), although it cannot synthesize it *de novo* (Mok et al., 2020). To date, there is no evidence supporting the possibility of human infection by *A. muciniphila* with research indicating the absence of negative effects associated with the administration of this bacteria (Depommier et al., 2019).

Cardiovascular impact of *Akkermansia muciniphila*

Akkermansia muciniphila significantly reduces local inflammation of the vascular endothelium, leading to atherosclerosis. An approximately 2.4-fold increase in the quantity of *A. muciniphila* results in a 72.59% decrease in C-reactive protein (CRP) levels, measured by a highly sensitive method (Shin et al., 2014). Studies on mice in 2016 demonstrated that in mice fed a high-fat diet,

administering live cultures of this bacterium reduces the adhesion of macrophages, crucial in atherosclerotic plaque formation to the endothelium by inhibiting the expression of tumor necrosis factor-alpha (TNF-alpha), MCP-1, and ICAM-1 (Li et al., 2016; Qu et al., 2021). Additionally, *A. muciniphila* significantly lowers soluble TNF receptor II (sTNFR II), reducing the severity of atherosclerosis. Importantly, the mechanism influencing atherosclerosis does not involve lowering lipid and sugar levels in circulating blood, nor does it affect the concentration of adiponectin, an anti-inflammatory substance (Li et al., 2016; Zhong et al., 2022). *A. muciniphila* plays a crucial role in weight control by reducing the absorption of lipids, achieved through maintaining the proper thickness of the intestinal mucosal layer, made possible by this bacterium's ability to adhere to the mucous membrane (Reunanen et al., 2015). These findings were observed exclusively in mice fed a high-fat diet, with studies on mice fed a normal diet showing no significant impact on these processes (Li et al., 2016).

Another significant cardioprotective action of *A. muciniphila* is countering arterial calcification, a component of atherosclerotic disease. This process involves the deposition of calcium salts in atherosclerotic plaques, leading to increased stiffness and, among other things, arterial hypertension. Short-chain fatty acids, propionate, and butyrate produced by human gut bacteria largely contribute to arterial calcification. Propionate reduces arterial calcification, while butyrate increases the intensity of this process (Zhong et al., 2022). Administering live *A. muciniphila* induces the production of, among other things, propionate, which has a protective effect on arterial calcification. No positive effects on the production of short-chain fatty acids were observed when pasteurized bacteria were administered (Yan et al., 2022).

Atrial fibrillation is the most common arrhythmic pathology in society, characterized by asynchronous atrial contractions often exceeding 150 beats per minute. This leads to blood stasis in these areas of the heart, which can result in clot formation and, ultimately, cause embolisms, with the most dangerous being those reaching the brain, often leading to a stroke. Atrial fibrillation is induced by factors such as cardiomyopathies, thyroid disorders, lung diseases, organ obesity, and less obvious factors, including a decrease in ambient temperature (Fustinoni et al., 2013). The latter also has a significant impact on the gut microbiota, including *A. muciniphila*, whose quantity is reduced at lower temperatures. It is *A. muciniphila* that exerts a significant influence on the frequency and duration of atrial fibrillation occurrences (Luo et al., 2022). Administering *A. muciniphila* cultures reduces the synthesis of trimethylamine (TMA), which is transformed into Trimethylamine N-oxide (TMAO). TMAO is responsible for recruiting M1 macrophages, which, by increasing inflammation associated with cytokine production, induce pyroptosis of cardiomyocytes in the heart atria (Luo et al., 2022). This relationship did not occur after administering pasteurized bacteria.

TABLE 1 Main studies dealing with the effects of *Akkermansia muciniphila* in cardiovascular diseases.

Study	Description	Design	Size	Patients	Length	Outcomes
Li et al. (2016)	Healthy	Animal study	—	Apoe$^{-/-}$ mice	8 weeks	*A. muciniphila* prevented inflammation induced by a Western diet both in the circulation and in local atherosclerotic plaques
Yan et al. (2022)	Healthy	Observational cohort study	92	Adults	—	*A. muciniphila* abundance negatively correlates with vascular calcification
Luo et al. (2022)	Healthy	Animal study	7	Rats	3 weeks	Oral supplementation of *A. muciniphila* mitigated pro-atrial fibrillation properties induced by cold exposure
Warmbrunn et al. (2024)	Healthy	Prospective cohort study	3,860	Adults	—	*A. Muciniphila* abundance is protective against ischemia heart disease

A. muciniphila demonstrates significant therapeutic value on a potentially large scale in the treatment of cardiovascular diseases. However, all existing studies clearly indicate that administering live bacteria is necessary to achieve a therapeutic effect. The impact on the aforementioned processes suggests the greatest potential application in Western diets, which largely rely on low-nutrient value products with high-saturated fat levels. The Western diet often leads to weight gain, resulting in overweight or even obesity and is the cause of systemic inflammation (Malesza et al., 2021; Warmbrunn et al., 2024). Both obesity and overweight contribute to the development of up to 50 different diseases, with a particular focus on the cardiovascular system. The application of live cultures of *A. muciniphila* reduces pyroptosis of cardiomyocytes, counteracting the development of atrial fibrillation, thereby reducing the risk of strokes (Christ et al., 2019). Moreover, *A. muciniphila* reduces the risk of ischemia heart disease in the African-Surinamese group playing a crucial role in cardiovascular diseases (Christ et al., 2019). Additionally, an increased abundance of this bacterium reduces endothelial inflammation, preventing the formation of atherosclerotic plaques and decreasing calcifications in already existing plaques. The reduction in both the quantity and hardness of atherosclerotic plaques contributes to a lower risk of unstable angina. Weight reduction, facilitated by *A. muciniphila*, also lowers average blood pressure, ultimately relieving the workload on the cardiac muscle counteracting the hypertrophy of the left ventricle and the development of aortic aneurysms. Further research involving a larger sample size is essential for the application of potential therapy. Main studies dealing with the effects of *A. muciniphila* in cardiovascular diseases are presented in Table 1.

Impact of *Akkermansia muciniphila* on the intestine

The main mechanism of action of *A. muciniphila* in the body is its involvement in the formation of the intestinal mucosal layer, where it resides. A healthy mucosal layer is responsible, among other things, for the efficient absorption of nutrients from food and the human immune response. A deficiency of *A. muciniphila* in the gut microbiota can lead to severe pathological conditions, such as inflammatory bowel diseases, a compromised host immune response, invasive microorganisms, or increased susceptibility to the detrimental effects of toxins on the body.

Inflammatory bowel disease is a term used to describe a group of chronic intestinal inflammations. The two main types are Crohn's disease (CD) and ulcerative colitis (UC). Despite many similarities, these diseases differ in several aspects. CD can affect any part of the digestive system, while UC primarily affects the large intestine. Another difference lies in the appearance of intestinal inflammation; CD creates skip lesions, whereas UC inflammation spreads continuously. It has been demonstrated that *A. muciniphila* supplementation significantly reduces symptoms of dextran sulfate-induced acute colitis and that its quantity is reduced in inflammatory bowel disease (Qu et al., 2021). It is crucial to minimize intestinal inflammation as much as possible, as inflammatory bowel diseases significantly increase the likelihood of developing colorectal cancer (Yao et al., 2019), (see Table 2).

The first mechanism through which chronic inflammatory bowel symptoms are alleviated (reducing the severity of intestinal inflammation, i.e., depth and extent at the histological level, as well as mitigating weight loss associated with reduced nutrient absorption) is the activation of NLRP3, which exhibits anti-inflammatory and immune actions (Qu et al., 2021; Guo et al., 2020). NLRP3 influences the production of IL-18, which plays a crucial role in creating the protective barrier of the intestine (Guo et al., 2020; Chiang et al., 2022). IL-18 regulates the gut microbiota, reducing the development of invasive colonies. Studies on mice showed significantly reduced mucin production from goblet cells in mice with decreased IL-18 levels compared to mice with normal levels (Chiang et al., 2022), demonstrating a positive correlation between IL-18 and mucin levels, whose breakdown fulfills the carbon and nitrogen needs of *A. muciniphila* (Derrien et al., 2010; Collado et al., 2007). Notably, there is an increase in the levels of Muc-2 and Muc-3 proteins.

TABLE 2 The impact of the *Akkermansia muciniphila* on intestines.

Study	Disease	Design	Size	Patients	Length	Outcomes
Qu et al. (2021)	Healthy	Animal study	10	Dextran Sulfate Sodium - fed mice	18 days	Oral administration of *A. muciniphila* significantly ameliorated the symptoms in dextran sulfate sodium (DSS)-induced acute colitis
Collado et al. (2007)	Healthy	Observatory study	249	Infants and Adults	—	*A. muciniphila* is correlated with normal mucosa development
Liu et al. (2022)	Healthy	Animal study	30	Dextran Sulfate Sodium - fed mice	2 weeks	*A. muciniphila*-based mechanisms play a fundamental role in driving the divergent induction of suppressive RORγt+ Treg cells in the gut-specific microenvironment

Another mechanism influenced by *A. muciniphila* is the activation of TLR4 receptors, whose levels are increased in patients with both Crohn's disease and ulcerative colitis (Liu et al., 2022; Hayashi and Nakase, 2022). The positive function of TLR4 in the body is the recognition of PAMPs and DAMPs, responsible for the human immune response in practice, while negatively influencing an increased likelihood of developing inflammatory bowel diseases (Liu et al., 2022; Moresco et al., 2011). The TLR-4-dependent anti-inflammatory response mainly depends on RORγt+ regulatory T lymphocytes, whose levels are reduced in the intestine during inflammatory bowel diseases (Liu et al., 2022). *A. muciniphila* can also activate TLR-2, but about a tenfold increase in the number of bacteria is required for this, and the activation of this receptor does not significantly impact the immune response stimulated by TLR receptors (Becken et al., 2021). TLR-2 and TLR-4 receptors are much more activated by phenotypic groups AmII and AmIV than by the AmI group, to which the MucT strain belongs.

An additional protective effect of *A. muciniphila* on the intestine is the inhibition of the expression of TNF-alpha, MCP-1, and ICAM-1, which, similar to the vascular endothelium, acts anti-inflammatory and inhibits the action of macrophages.

The association with obesity

Obesity and overweight are among the primary lifestyle diseases, affecting nearly one-third of the global population every day. Both disorders lead to various pathological conditions, predisposing individuals to diseases in almost every system, including the cardiovascular, musculoskeletal, respiratory, hormonal, and others. Cardiovascular diseases, responsible for approximately half of global deaths, prove to be particularly deadly. Although metabolic diseases result from various factors, such as genetic predispositions, gut microbiome, hormonal system, diet, upbringing during childhood, and the culture in which a person was raised, the most significant impact on these disorders still comes from a person's diet. The hope for treatment lies in many

therapies, both non-pharmacological and pharmacological, but the key to success is their simultaneous application (Cao et al., 2023).

Therapy typically begins with non-pharmacological treatment focusing on diet modification and increased physical activity. This is the healthiest way to reduce body weight but is often ineffective due to individuals' habits and accompanying health conditions that limit their ability to move.

When non-pharmacological treatment proves ineffective, the next steps involve introducing medications to assist in weight loss. These medications are usually chosen with attention to coexisting diseases. Examples include glucagon-like peptide-1 (GLP-1) analogs used in type II diabetes patients or thyroxine (T4) analogs in the case of hypothyroidism both proving to reduce weight while treating the underlying cause.

Let's focus on pharmacological treatment by influencing the gut microbiome. A promising and therapeutically valuable approach is the therapy using *A. muciniphila* bacteria. A widely available probiotic containing pasteurized *A. muciniphila* bacteria, specifically the MucT strain of the AmI group, has emerged worldwide. Oral therapy with *A. muciniphila* significantly reduces serum glucose and triglyceride levels, as well as tissue insulin resistance (Dao et al., 2016; Depommier et al., 2019). The reduction in serum glucose and triglyceride levels is likely associated with improved liver function, as indicated by decreases in aspartate aminotransferase (AST) and gamma-glutamyl transferase (GGT) levels, used as markers of liver dysfunction (Dao et al., 2016; Xu et al., 2023). An increase in *A. muciniphila* levels in patients is linked to a decrease in the average volume of adipocytes, making these individuals metabolically healthier (Dao et al., 2016). The adoption of a healthy diet by patients promotes and facilitates weight loss in individuals with higher levels of *A. muciniphila* (Dao et al., 2016; Cao et al., 2023). Results indicating no loss of muscle mass in patients who lost weight and had a higher quantity of *A. muciniphila* compared to those with a lower quantity of this bacterium prove to be very valuable. The studies also demonstrated the absence of the rebound effect in patients (Cao et al., 2023). The reduction in insulin resistance due to A. muciniphila lowers the risk of developing type 2 diabetes and

TABLE 3 Main studies dealing with the effects of *Akkermansia muciniphila* in bodyweight management.

Study	Disease	Design	Size	Patients	Length	Outcomes
Dao et al. (2019)	Obesity	Non-randomised prospective study	65	Adults	12 months	*A. muciniphila* abundance does not affect glucose tolerance and insulin sensitivity in patients after gastric bypass surgery
Shin NR (2014)	Healthy	Animal study	24	HFD-fed mice	6 weeks	*A. muciniphila* administration reduse adipose tissue inflammation
Depommier et al. (2019)	Overweight and obesity	Randomised double blind study	32	Adults	3 months	Increased *A. muciniphila* abundance negatively correlates with insulin resistance, inflammation markers and liver disfunction markers
Dao (2016)	Overweight and obesity	Randomised control study	49	Adults	3 months	Increased *A. muciniphila* abundance positively correlates with insulin sensitivity
Cao et al. (2023)	Obesity	Randomised double blind study	37	Adults	4 months	Increased *A. muciniphila* abundance positively correlates with weight loss

reduces drowsiness and fatigue. Additionally, it reduces hunger attacks leading to weight gain. It also decreases the activity of dipeptidyl peptidase-IV (DPP-IV) (Depommier et al., 2019), which is responsible for the breakdown of glucagon-like peptide 1 (GLP-1), responsible for inhibiting hunger and intensifying the feeling of fullness. Due to this many positive effects it leads to the assumption that therapies based on *A. Muciniphila* may become world spread. The studied focused on association between *A. muciniphila* and obesity are presented in Table 3.

Discussion and conclusion

The continuous rise in diseases related to overweight and obesity, including cardiovascular diseases, highlights the need for an effective and safe method to address this issue. Diseases associated with excess body weight are closely linked to a systemic inflammatory state triggered by adipocytes and by an imbalance in gut microbiota. It should be noted that while inflammatory bowel diseases (IBD) and metabolic diseases may seem etiologically distinct, treatment for IBD may increase the risk of metabolic conditions, including obesity. Furthermore, inflammation is a common factor in both, heightening the risk of further complications. *Akkermansia muciniphila* meets the criteria for potential treatment, as there is no evidence of human infection by this bacterium, and its use has shown promising results in promoting safe and sustainable weight loss, alongside a reduction in systemic inflammation. There are several reasons to believe that *A. muciniphila* therapy could have a positive impact on cardiovascular diseases, particularly atherosclerosis, which is linked to endothelial inflammation. Additionally, increasing the levels of *A. muciniphila* in the gut appears to alleviate the negative symptoms of chronic inflammatory bowel diseases, such as ulcerative colitis (UC) and Crohn's disease (CD).

Akkermansia muciniphila has demonstrated potential for comprehensive treatment of these diseases. Given the rising global prevalence of both inflammatory bowel diseases and metabolic disorders, this is a particularly important issue. Moreover, treatment with *Akkermansia muciniphila* is relatively affordable. However, the number of studies exploring the association between *A. muciniphila* and obesity, cardiovascular risk, and intestinal health is limited, and further research is needed to fully understand its effects on human health.

Future direction

The fundamental issue that needs to be addressed is the assessment of the safety of consuming live cultures of *Akkermansia muciniphila*. So far, research suggests a much broader potential for *A. muciniphila* in this form to achieve positive cardiovascular effects. It is essential to direct further research towards the circulatory system because, despite many indications of its positive impact, there is still a lack of large-scale studies involving a greater number of individuals to justify the implementation of such therapy.

[1]Clinical Laboratory, Ningbo Zhenhai People's Hospital (Ningbo No.7 Hospital), Ningbo, Zhejiang Province, China; [2]Department of Medical, Ningbo Zhenhai People's Hospital (Ningbo No.7 Hospital), Ningbo, Zhejiang Province, China

Objective: This study is an exploration of the relationship between chemical industrial environment and allergic skin diseases. **Methods:** In this retrospective analysis, 200 patients with allergic skin diseases who worked or lived in a chemical industrial zone and were admitted in our hospital between January 2018 and January 2020 were enrolled as Group A. Besides, 500 patients with allergic skin disease who lived in Zhenhai New District, five kilometers away from the chemical radiation zone, were selected as Group B. The specific immunoglobulin E (IgE) levels were determined by Western blotting. The allergen positivity, as well as allergen positivity between different age, sex and body mass index (BMI) were compared between the two groups. The positive food-specific allergen IgE antibody (sIgE) and positive inhalational sIgE were compared between the two groups. **Results:** The positive rate of total IgE and inhalational sIgE in Group A was higher than that in Group B (*P*<0.05), while there was no significant difference in positive rate in food sIgE between the two groups (*P*>0.05). In Group A, the differences in positive rates of total IgE, food-induced sIgE and inhalational sIgE were not significant between patients with different ages, sexes and BMI (*P*>0.05). There was no significant difference between the two groups in sIgE positive rates of wheat, mango, soybean/peanut/cashew nut combination, limb/beef combination, crab/shrimp/fish combination, milk and egg white (*P*>0.05). The positive rates of inhalational sIgE in tree combination and dust mites/household dust mites combination in Group A were higher than those in Group B (*P*<0.05), but had no significant difference between the two groups in the positive rates of inhalational sIgE in *Humulus japonicus*, mold combination 1, cockroach, cat/dog hair combination, and ragweed/artemisia combination (*P*>0.05). **Conclusion:** Chemical industrial environment is closely associated with allergic dermatosis, and the positive rate of total IgE and inhalational sIgE increases significantly in patients living there.

Keywords: Chemical industrial environment, sIgE, skin disease, allergic dermatosis, relevancy

INTRODUCTION

Allergic diseases are frequent diseases, which are mediated by the production of specific immunoglobulin E (IgE) antibody. They seriously impair health and have become a major public health issue (Tramper-Stranders *et al.*, 2021). Allergic diseases can occur at all ages and are primarily caused by the combined effects of environmental factors and genetic factors (Golebski *et al.*, 2020). In recent years, with the change of human dietary structure, the increase of antigenic substances, the aggravation of environmental pollution and the improvement of industrialization, the incidence of allergic diseases has continued to increase (Zhang *et al.*, 2021). With the continuous deterioration of environmental pollution, Zhenhai, as one of the chemical industrial zones, has particularly serious air pollution, and the occurrence of allergic diseases has also increased in this area (Lau *et al.*, 2021). It has been reported that air pollution in residential environment is significantly correlated with the high incidence of allergic diseases (Larson *et al.*, 2020).

At present, serum-specific allergen IgE assay (sIg) and skin prick test (SPT) are commonly used for detecting allergens (Du Toit *et al.*, 2018). However, there are rarely reports on chemical industrial environment and allergic skin diseases, and most of which analyzed the allergens in patients with allergic skin diseases (Eljaszewicz *et al.*, 2021). But the differences in allergic skin diseases between people in chemical and non-chemical areas have not been reported yet. This study explored the relationship between chemical industry environment and allergic skin diseases, aiming to provide reference for the prevention of allergic skin diseases.

MATERIALS AND METHODS

General Information

This is a retrospective analysis. A total of 200 patients with allergic skin diseases, who worked or lived in the chemical industry zone and were admitted to the hospital from January 2018 to January 2020, were selected as Group A. Besides, 500 patients with allergic skin diseases, who lived in Zhenhai New District, five kilometers away from the chemical radiation zone, were selected as Group B. This study was approved by the ethic committee of Ningbo Zhenhai People's Hospital.

Inclusion criteria (Eljaszewicz *et al.*, 2021): (1) Patients were diagnosed by examinations based on the criteria of Clinical Dermatology. Allergies occurred on the skin of the body, most of which were located on the head and face. The patient's skin lesions turned white and ap-

Table 1. Comparison of clinical data of two groups

Clinical data	Group A (n=200)	Group B (n=500)	t/χ_2	r

Autumn & winter	65	158	.	.
Disease type				
Urticaria	112	269		
Atopic dermatitis	88	231	.	.

peared as typical white spots, most of which were the size of nails and coins. The lesion shapes were round, oval or irregular, and expanded or merged into a large area with different shapes. Another typical leukoplakia was a strip or cord of discoloration along the nerve, with knife-cut edges. The histopathological features: the epidermis obviously lacked melanocytes and melanin granules, and the basal layer lacked dopa-positive melanocytes. (2) Patients had complete clinical data. (3) Patients received blood sampling after admission.

Exclusion criteria: (1) Patients accompanied by other allergic diseases that might affect the research. (2) Patients had recently taken medications such as glucocorticoids or immunosuppressants. (3) Patients were affected by serious abnormalities of heart, lung, liver or kidney.

Methods

Collection of serum specimens

Peripheral venous blood (5 mL) was collected from all patients, stood for 30 min and was centrifuged for 12 min (centrifugation radius 10.5 cm, 3000 r/min). The collected serum was stored at −70°C until testing.

Measurement of IgE

The reagent strips were put in an incubator box, added with diluted washing solution thickly and put on a mixer to fully wet for 5 min. After the reagent strips were dried, 1 ml of serum specimens were added and incubated in the mixer for 45 min. The above procedures were repeated 5 times. Thereafter, anti-human IgE antibody (Hangzhou Aibo Biotechnology Co., LTD.) was added, incubated for 45 min, and then rinsed repeatedly 5 times. The enzyme conjugate (Hangzhou Aibo Biotechnology Co., LTD.) was incubated in the mixer for 20 min, and then rinsed 5 times. The substrate was added and incubated in the mixer for 20 min. The strips were rinsed under running water, dried and scanned by an allergen scanner (Mediwiss Medical Diagnostics GMBH).

Detection of allergens

The detected allergens included total IgE and allergen-specific IgE antibodies (sIgE). The sIgE included food allergens and inhalational allergens. Food allergens contained wheat, mango, soy/peanut/cashew combination, limb/beef combination, crab/shrimp/fish combination, milk and egg white. Inhalational allergens included tree combination (Willosa/Ulmus/Quercus/Parasitae/Popu-

Table 2. Comparison of allergen positive cases between two groups (%)

lus deltoides), *Humulus scandens*, mold combination 1 (*Penicillium persicillium*/*Aspergillus fumigatus*/*Mycospora*/*alternaria*), cockroach, cat/dog hair combination, ragweed/Artemisia, and dust mite/house dust mite combination.

Observation of Indicators

(1) Allergen positive cases in the two groups were observed. (2) In Group A, allergen positive cases with different ages, different sexes and different body mass index (BMI) were observed. (3) The positive cases of food-induced sIgE and inhalational sIgE were observed in the two groups.

Statistical Processing

SPSS 26.0 software was applied for data processing. Measurement data were represented by (mean ± standard deviation), and the analysis method was independent samples t-test. Enumeration data were represented by n (rate), and the analysis method was χ_2 test. Two-tailed $P<0.05$ was considered as statistically significant.

RESULTS

Clinical data

There was no statistical significance between the two groups in sex, age, BMI, seasons of onset and disease types ($P>0.05$); see Table 1.

Comparison of allergen positive cases between two groups

The positive rates of total IgE and inhalational sIgE in Group A were higher than those in Group B ($P<0.05$).

While there was no significant difference in the positive rate of food sIgE between the two groups ($P>0.05$); see Table 2.

Comparison of allergen positive rates between patients at different ages in Group A

There was no significant difference in the positive rates of total IgE, food-induced sIgE and inhalational sIgE between patients of different ages in Group A ($P>0.05$); see Table 3.

Comparison of allergen positive rates between males and females in Group A

There were no significant differences in the positive rates of total IgE, food-induced sIgE and inhalational sIgE between males and females in Group A ($P>0.05$); see Table 4.

Comparison of allergen positive rates between patients with different BMI in Group A

There was no significant difference in the positive rates of total IgE, food-induced sIgE and inhalational sIgE between patients with different BMI in Group A ($P>0.05$); see Table 5.

Comparison of food-induced sIgE positive cases between the two groups

There was no significant difference between the two groups in sIgE positive rates of wheat, mango, soybean/peanut/cashew nut combination, limb/beef combination, crab/shrimp/fish combination, milk and egg white ($P>0.05$); see Table 6.

Table 5. Comparison of allergen positive rates between patients with BMI in Group A (%)

BMI	Number of cases	Total IgE	Food-induced	Inhalational immunoglobulin
			sIgE	E
>24 kg/m^2	81	67 (82.72)	19 (23.46)	47 (58.02)
≤24 kg/m^2	119	94 (78.99)	23 (19.32)	66 (55.46)
χ_2		0.426	0.495	0.129
P		0.514	0.482	0.720

BMI, body mass index.

Table 6. Comparison of food-induced sIgE positivity between the two groups (%)

Group	Number of cases	Wheat	Mango	Soybean/peanut/cashew nut	Sheep/beef	Crab/shrimp/fish	Milk	Egg white
Group A	200	4 (2.00)	5 (2.50)	12 (6.00)	8 (4.00)	7 (3.50)	2 (1.00)	4 (2.00)
Group B	500	9 (1.8)	12 (2.40)	23 (4.60)	19 (3.20)	12 (2.40)	6 (1.20)	6 (1.20)

χ_2		7.613	0.633	1.641	1.222	0.916	2.483	26.047
P		0.006	0.426	0.200	0.269	0.339	0.115	<0.001

Comparison of inhalational-sIgE positive cases between the two groups

The positive rates of inhalational-sIgE in tree combination and dust mites/household dust mites' combination in Group A were higher than those in Group B ($P<0.05$). There was no significant difference between the two groups in sIgE positive rates of Humulus japonicus, mold combination 1, cockroach, cat/dog hair combination, and ragweed/artemisia combination ($P>0.05$); see Table 7.

DISCUSSION

Allergic dermatosis is one of the most common and complex skin diseases with a large number of pathogenic causes and types. Allergens can enter the human body through multiple ways. The inhalational or ingested allergens can combine with antibodies to produce sensitization, form an immune complex to stimulate mast cells to degranulate and release transmitters such as leukotriene and histamine, thus inducing rapid allergic reactions (Venter *et al.*, 2022; Orengo *et al.*, 2018; Hereford *et al.*, 2021). Common allergic skin diseases include atopic dermatitis, eczema, urticaria and Henoch-Schönlein purpura. Atopic dermatitis refers to skin conditions such as peeling, wind, itching and redness caused by exposure to certain allergens. The most common causes of atopic dermatitis include fungal allergies, chemical fiber materials, rubber shoes, detergents, fertilizers, pesticides, air pollution, dust, pollen, insects, mites, animal fur, food, etc. Atopic dermatitis is usually caused by an allergy to a substance and can gradually disappear when the allergen is removed (Güngör *et al.*, 2019). Eczema is a common allergic skin disease that can occur in any part of the body. The specific cause of eczema has not been completely clarified. It is considered that allergic constitution may be the main cause of the disease (Holl *et al.*, 2020). Clinical surveys have shown that the increasing incidence of eczema may be related to continuous mental stress,

accelerated pace of life, poor management of wastes, environmental pollution and the abuse of chemical products (Yang *et al.*, 2020). Urticaria is a common skin disease with acute and chronic types. The causes of urticaria are various and complex, including parasites, bacteria, sunlight, drugs, nettle, mushrooms, pollen, animal feathers, crab, shrimp, fish, etc. (Fang *et al.*, 2021; Xiang *et al.*, 2021). Due to the extensive food intake and contact with objects in daily life, it is often difficult to identify the fundamental cause of allergies, which leads to recurrent urticaria (Hoof *et al.*, 2020). Henoch-Schönlein purpura is usually considered to be caused by antigenic substances entering the body, reacting with antibodies in the body of the patient, and depositing in the blood vessel wall and causing vascular damage. It is mainly a skin and mucosal lesion caused by allergic inflammation of blood vessels, with petechia or bruise as the main clinical manifestations (Ünal, 2020). The etiology of allergic purpura remains unspecified, and it is considered to be related to immune factors. At the same time, it can be induced by insect bites, drug pollen allergy, viral and bacterial infections, and exotic protein foods such as crab, shrimp and fish (Hanif *et al.*, 2019; Beaulieu *et al.*, 2022).

As a coastal chemical industrial area, Zhenhai provides local people with a lot of seafood. Therefore, total IgE, inhalational allergens and food-induced allergens were selected for detection in this study. We intended to understand the influence of the chemical industrial environment on allergic skin diseases through detecting allergenic factors. At present, the detection of allergens is usually by serum specific allergen IgE and skin prick. Skin prick test is to drop a small amount of highly purified allergen liquid on the forearm of the patient, and then to gently puncture the skin surface.

Allergic response is showing as red and swollen masses similar to mosquito bites and itching reaction at the spot within 15 minutes, and the skin color may also change. However, the skin prick test is an invasive test, which may cause severe systemic reactions, and accidents may occur in patients with severe allergies in acute phase. Serum specific allergen IgE detection, as an in-vitro test, is safe, painless and non-irritating. Serum specific allergen IgE detection can simultaneously conduct quantitative detection of more than a dozen specific IgE to identify allergens (Rauber *et al.*, 2020).

Chemical industrial pollution mainly exists in the chemical industrial zone, and the pollution sources include air pollution, water pollution, etc. Research reports in Zhenhai District have shown that the harmful substance in its chemical zone is ainly sulfur dioxide in the air. Such polluting substances, especially the inevitable large amount of dust, toxic gas and waste, may lead to the variation of the protein structure on the surface of pollens in the air, so that pollens that originally are not allergenic become highly allergenic (Guttman-Yassky *et al.*, 2019). In order to study the impact of the chemical industrial environment on allergic diseases, this article explored the connected factors of allergic skin diseases in patients who lived in Zhenhai chemical industrial district and Zhenhai New District, aiming to clarify that the identification of allergens is the primary method for prevention, clinical diagnosis and treatment of allergic diseases. The detection results of allergens, serum total IgE degree, and allergen-specific IgE may be different for people of different regions, races and ages. The detection of allergen-specific IgE can clarify the substances that cause allergic reactions in the region and help determine appropriate immunotherapy (Ryu *et al.*, 2020). Therefore, the application of serum allergen-specific IgE

can help find allergens and provides a valuable basis for the prevention and treatment of allergic diseases. With regard to the selection of research population, it was reported that air pollution was significantly reduced in areas 5 kilometers away from the chemical radiation zone (Sadreameli *et al.*, 2021). Therefore, patients with allergic skin diseases living in Zhenhai New District, which was 5 km away from the chemical industry zone, were selected as the control group in this study. This study showed that the positive rates of total IgE and inhalational sIgE of patients in Group A were higher than those in Group B, indicating that the positive rates of total IgE and inhalational sIgE in patients living or working in chemical industrial district were greatly increased. In terms of inhalational sIgE, allergies in tree combination and dust mites/household dust mites were significantly increased in patients living or working in chemical area. Our results are consistent with the previous results (Drislane *et al.*, 2020), which reported states that people living in chemical industrial areas showed more inhalational sIgE. We believe that it may be due to the presence of polluting substances in the air, which change the protein structure of pollen surface, thus triggering an increase in inhalation allergens.

In addition, in order to understand whether individual factors have an influence on allergic skin diseases, we analyzed sex, age and BMI (with 24.0 kg/m² as cut-off value) of patients in the chemical zone. It was found that patient's sex, age or BMI had no effect on the allergens detection results.

However, this is only a preliminary exploration in patients from different regions. We did not conduct in-depth investigations on the main pollutants and their concentrations in the chemical industrial area and did not analyze the mechanism of allergic reactions triggered by pollutants. Therefore, there are certain limitations in the current research. In follow-up studies, we will monitor pollutants and their concentrations in the chemical industrial area to determine whether the concentration of pollutants is related to the incidence of allergic skin diseases, and analyze the influence of chemical pollutants on the immune function of the body and the induction mechanism of allergic reactions *via* animal experiments.

In summary, the chemical industrial environment is significantly involved with allergic dermatosis, and patients who live there have significantly increased total positive IgE and positive aspirational sIgE.

Previously, the direct interactions of Bβ26-42 fibrin residues with prothrombin were demonstrated. It was also shown that forming prothrombin complexes with E- or DDE-fragments causes non-enzymatic prothrombin activation. The direct measuring of the prothrombin level in the blood plasma of patients with acute myocardial infarction (AMI) allowed us to find a situation where such an activation can occur *in vivo*. Blood coagulation parameters in the blood plasma of patients with AMI were measured at 2 hours, three days, and seven days after the thrombolysis by streptokinase accompanied with intravenous administration of anticoagulants: unfractionated high molecular weight heparin (HMWH) and low-molecular-weight heparin (LMWH). The prothrombin level in the blood plasma of patients with AMI was normal before thrombolytic therapy and substantially decreased after streptokinase administration. This effect was prominent in the case of concomitant anticoagulant therapy with LMWH and was not observed when HMWH was applied. It can be explained by the fact that LMWH preferentially inhibits factor Xa, while the HMWH is an effective inhibitor of both factor Xa and thrombin. This observation suggested that the prothrombin level decrease was caused by the thrombin-like activity and possible autolysis of prothrombin by thrombin. Also, thrombolytic therapy with streptokinase caused the accumulation of fibrin degradation products (FDPs), some of which were able to bind prothrombin. The dramatic decrease of prothrombin level in the blood plasma of patients with AMI during thrombolysis allowed us to conclude the non-enzymatic prothrombin activation with the following autolysis of prothrombin that contributes to the pathology.

Keywords: Prothrombin, non-enzymatic activation, acute myocardial infarction, thrombosis, soluble fibrin

INTRODUCTION

Thrombotic complications are the main reason for the development of cardiovascular diseases, particularly acute myocardial infarction (AMI), which causes acute or persistent ischemic anoxia of the coronary artery. Such anoxia and the occlusion of the coronary artery are caused by intravascular thrombus formation that terminates the proper blood flow in coronary vessels (Grover *et al.*,., 2018; Karbach *et al.*,., 2019; Hudeca *et al.*,., 2020; Wieczór *et al.*,., 2020).

Activation of the blood coagulation system leads to the appearance in the bloodstream of a considerable amount of thrombin due to the activation of prothrombin. Thrombin leads to the activation of platelets and conversion of fibrinogen to fibrin monomer, which, upon polymerization, forms a fibrin clot – the core of a thrombus (Pasupathy *et al.*, 2018; Toshiaki *et al.*, 2016; Wood *et al.*, 2011).

Thrombin and prothrombin (its inactive precursor) are crucial factors in physiological and pathophysiological coagulation. A general assessment of thrombin activity and prothrombin content is necessary for proper patient management (Korolova *et al.*, 2021). However, determining the prothrombin time, which characterizes the state of the coagulation factors of the external blood clotting pathway, does not allow for determining the contribution of prothrombin in the test result. Increases in thrombin generation are being detected by the determination of prothrombin fragment 1+2, thrombin-antithrombin complex, prethrombin-1, or soluble fibrin as products of thrombin-catalyzed reactions. The total level of prothrombin in the blood plasma of patients needs to be measured (Negrier *et al.*, 2019; Wexels *et al.*, 2016; Zhao *et al.*, 2023; Elged *et al.*, 2016).

The purpose of our work was to apply the direct measuring of the level of prothrombin in the blood plasma of patients with acute myocardial infarction (AMI). To achieve this goal, we studied blood coagulation parameters in the blood plasma of patients with AMI at 2 hours, three days and seven days after the thrombolysis by streptokinase accompanied with intravenous administration of anticoagulants: unfractionated heparin and low-molecular-weight heparin (LMWH).

MATERIALS AND METHODS

Materials

Chromogenic substrates S2238 (H-D-Phe-Pip-Arg-pNA), S2765 (Z-D-Arg-Gly-Arg-pNA), and S2236 (p-Glu-Pro-Arg-pNa) were purchased from BIOPHEN (Neuville-sur-Oise, France). Factor X activator from *Russel vipera* venom (RVV), thrombin from human blood plasma, sodium citrate, phosphate-buffered saline (PBS) tablets (pH 7.2, sodium chloride, 0.15 M) were purchased from Sigma-Aldrich (St. Louis, USA). APTT-reagent, control donors' blood plasma, and test systems for determining Protein C and antithrombin III levels were purchased from Siemens-Biomed (Marburg, Germany). The thrombin-like enzyme was purified from the venom of *Agkistrodon halys halys* according to the method described in (Solovjov et al., 1998). The activator of prothrombin (ecamulin) was purified from *Echis multisquamatis* venom according to the method of Solovjov and others (Solovjov et al., 1996). Monomeric fibrin desAB was purified according to the method described (Pozdnjakova et al., 1979).

Patients

The study included patients with large-focal and transmural AIM under 70 without signs of cardiogenic shock (n=57). The patients were treated at the State Institutional Scientific Center The M.D. Strazhesko Institute of Cardiology, Clinical and Regenerative Medicine of The National Academy of Medical Sciences of Ukraine, Kyiv.

On average, patients were taken to the division of reanimation and intensive therapy in the first 6 hours after the heart attack in 3.1±0.2 h. Patients were 57.4 years old on average. Some of them had arterial hypertension (45.5%), diabetes (7%), and 64% were smokers. The average BMI was 28.4 kg/m².

Inclusion criteria were clinical signs of acute coronary syndrome, registration of the elevation of the ST segment of the electrocardiogram by 2 mm or more in two measurements, age from 30 to 70 years.

Exclusion criteria were cardiogenic shock, severe forms of diabetes, bronchial asthma, kidney or liver failure, documented disorders in the blood coagulation system, bleedings during the last six months, level of hemoglobin below 100 g/l, violation of cerebral blood flow, and body weight above 110 kg or below 60 kg.

Systemic thrombolytic therapy was performed with streptokinase (SK) (Kabikinase from 'Pharmacia&Upjohn', USA) at 1500 000 IU and was carried out for 30–40 minutes. All patients received basic anti-platelet therapy, therapy by beta blockers, statins, ADP inhibitors, and nitrates.

Anticoagulant prophylaxis was performed with fraxiparin or heparin 4–6 hours after the start of thrombolytic therapy. Standard unfractionated heparin was administered by an intravenous infusion lasting 48 hours (activated partial thromboplastin time (APTT was controlled), in an average dose of 1000 IU per hour, then subcutaneously four times a day for 5–7 days.

Fraxiparine ('Sanofi-Synthelabo,' France) was administered by bolus administration (0.6 ml) and then three hours later under the skin at the same dose for 3 days. Administration of Fraxiparine was then continued at half the dose until the 6–7th day of myocardial infarction.

Platelet-poor blood plasma was prepared from citrated blood by centrifugation at 1200×*g* for 30 min. Sodium citrate (3.8%) added immediately after collection to the whole blood at a 1:9 ratio was used as an anticoagulant. All work was conducted under the Declaration of Helsinki. Studies were conducted per the Ethical Committee Approval N 3 form 04.04.2019 (Palladin Institute of Biochemistry of NAS of Ukraine).

Methods

Fibrinogen concentration

Fibrinogen concentration in the blood plasma was determined by the modified spectrophotometric method. Blood plasma (0.2 ml) and PBS (1.7 ml) were mixed in a glass tube. Coagulation was initiated by adding 0.1 ml of the thrombin-like enzyme from the venom of *Agkistrodon halys halys* (1 NIH/ml), which allowed to avoid fibrin cross-linking. The mixture was incubated for 30 min at 37°C. The fibrin clot was removed and re-solved in 5 ml of 1.5% acetic acid. The concentration of protein was measured using a spectrophotometer POP (Optizen, Korea) at 280 nm (ε=1.5) (Sokolovska et al., 2002).

Activated partial thromboplastin time

Activated partial thromboplastin time (APTT) was performed following the procedure: 0.1 ml of studied blood plasma was mixed with an equal volume of APTT-reagent and incubated for 3 minutes at 37°C. Then, the coagulation was initiated by adding 0.1 ml of 0.025 M solution of $CaCl_2$, and clotting time was monitored. The clotting time was evaluated using a coagulometer CT2410 (Solar, Belarus).

Prothrombin time

Prothrombin time (PT) was measured as follows: clotting was initiated by mixing 0.1 ml of blood plasma with 0.1 ml of 0.025 M $CaCl_2$ and 0.1 ml of thromboplastin reagent, time of clotting was monitored. Thromboplastin acts through the tissue factor pathway of coagulation and activates only carboxylated and uncleaved forms of prothrombin. The clotting time was evaluated using a coagulometer CT2410 (Solar, Belarus).

Prothrombin level

Total prothrombin level was measured using ecamulin (the prothrombin activator from *Echis multisqumatis* snake venom) and chromogenic thrombin-specific substrate S2238 (H-D-Phe-Pip-Arg-pNA). Ecamulin activates prothrombin and all of its inactive forms to determine total prothrombin level (Korolova et al., 2023).

In a well of a 96-well plate, 0.02 ml of studied blood plasma sample, 0.03 ml of S2238 solution (0.25 mM), and 0.03 ml of ecamulin solution (0.06 mg/ml) were admixed in the PBS with 0.001 M $CaCl_2$ at final volume of 0.25 ml. The generation of colorful p-nitroaniline (pNa) was monitored at 405 nm using a ThermoMultiscan multi-plate reader (ThermoFisher, USA). Results were presented as % from control values.

Soluble fibrin monomeric complexes (SFMCs)

For the SFMCs measurement in the glass tube, the 0.25 ml of studied blood plasma sample was mixed with an equal volume of 0.1 M KH_2PO_4 buffer pH 7.5. Then 0.4 ml of 1 M KH_2PO_4 buffer pH 7.5 was added to the whole volume after gentle mixing. Samples were incubated for 30 min at ambient temperature. After incubation, the accumulation of saturated SFMCs was estimated semi-quantitatively in the range of concentrations 7–140 µg/ml by following gradation: clear solution without turbidity – negative result;

Table 1. Hemostasis system parameters of the patients with AMI at the time of admission to the clinic. The median value, minimum, and maximum are given.

Parameter	Healthy donors (n=30)	Patients with AMI (n=57)
Fibrinogen level, g/l	2.5 (2.3–3.0)	3.2* (2.2–5.5)
APTT, sec	45 (41–49)	41.0* (23–71)
Prothrombin level, %	100 (85–105)	105* (64–127)
SFMCs, µg/ml	0.0 (0.0–3.0)	40.0* (17–140)
Protein C level, %	100 (90–115)	63* (40–110)
AT III level, %	100 (90–110)	100 (62–120)
Clotting factor X level, %	100 (90–100)	92 (60–120)

*$p<0.05$, compared to donors

several dots in the solution – up to 7 µg/ml; visible turbidity – up to 35 µg/ml; formation of flakes – up to 70 µg/ml; formation of fibers – up to 90 µg/ml; gel-like sedimentation – up to 140 µg/ml. For the calibration, we used blood plasma samples with monomeric fibrin desAB added at final concentrations from 7–140 µg/ml prepared according to the method (Pozdnjakova *et al.,* 1979).

Protein C level

Protein C (PC) level was determined using the activator of PC (Berichrom, Germany). The generation of activated PC was measured by chromogenic substrate assay using specific chromogenic substrate S2236 (p-Glu-Pro-Arg-pNa). The analysis was performed in 0.05 M Tris-HCl buffer pH 7.4, at 37°C. The chromogenic substrate concentration was 30 mM. The generation of para-nitroaniline was measured at 405 nm on a microtiter plate reader Multiscan EX (Thermo Fisher Scientific, Waltham, USA). Here and below for Multiscan EX: Linearity 0–2 Abs, ± 2.0% at 405 nm; accuracy ± 2.0% or ± 0.007 Abs at 405 nm. Results were presented as the ratio of PC level in the blood plasma of the studied sample to PC level in the blood plasma of the healthy donor.

Antithrombin level

Antithrombin III (ATIII) activity is determined based on its ability to neutralize thrombin in the presence of heparin. The overabundance of thrombin was inhibited by the ATIII-heparin complex proportionally to the ATIII in blood plasma.

The analysis was performed according to the recommendations of the manufacturer. The remaining activity of thrombin was measured using chromogenic thrombin-specific substrate S2238 (H-D-Phe-Pip-Arg-pNA). Colorful *p*-nitroaniline (pNa) generation was monitored at 405 nm using ThermoMultiscan (ThermoFisher, USA). The amount of ATIII was determined using the calibration curve.

Factor X level

The total factor X level was determined using RVV (Russell's viper venom reagent that specifically activates factor X) and factor Xa-specific chromogenic substrate S22765 (Z-D-Arg-Gly-Arg-pNA). In a well of 96-well plate, 0.02 ml of studied blood plasma sample, 0.03 ml of S2765 solution (0.25 mM), and 0.01 ml of RVV solution (Sigma, USA) were admixed in the PBS with 0.001 M $CaCl_2$ at a final volume of 0.25 ml. Colorful p-nitroaniline (pNa) generation was monitored at 405 nm using ThermoMultiscan (ThermoFisher, USA). Results were presented as % of control values (Budzynski *et al.,* 2001).

Statistics

Statistical data analysis was performed using the Wilcoxon-Mann-Whitney (WMW) test using an online calculator provided by Social Science Statistics (https://www.socscistatistics.com/). Statistical analysis was performed using Microsoft Excel (Microsoft Corporation, Redmond, WA, USA). Results are presented as the group's median, maximum, and minimum values. All assays were performed in a series of at least three replicates. Data were considered significant when $p<0.05$.

RESULTS

Blood coagulation system parameters

An analysis of the parameters of the haemostasis system was carried out in 57 patients with great magistral transmural host myocardial infarction (AMI) at admission to the clinic (Table 1).

A significant reduction in the blood plasma clotting time in the APTT test was revealed in 49% of patients, an increase in fibrinogen content in 31% of patients, and an accumulation of SFMC (17–140 µg/ml), which indicates the activation of the blood clotting system, was determined in all studied samples. Simultaneously with the activation of the components of the coagulation system, the potential of the anticoagulant link of the system (PC and ATIII) decreases, which, together with the increased content of fibrinogen, can contribute to the increase of further thrombotic complications and re-occlusions.

Figure 1. Level of prothrombin in the blood plasma of patients with acute myocardial infarction before thrombolysis (before) and after thrombolysis accompanied by concomitant anticoagulant therapy with low molecular weight heparin (LMWH after, n=28) or high molecular weight heparin (HMWH after, n=29). Samples were collected before, after 2 hours, and on the third day after thrombolysis. Donors – healthy donors' group (n=30). *$p≤0.05$ in comparison to donors.

Figure 2. Level of soluble fibrin monomeric complexes (SFMC) in the blood plasma of patients with acute myocardial infarction before thrombolysis (Before) and after thrombolysis accompanied by concomitant anticoagulant therapy with LMWH (LMWH after, n=28) or HMWH (HMWH after, n=29).
Samples were collected before, after 2 hours, and on the third day after thrombolysis. Donors – healthy donors' group (n=30). *$p \leq 0.05$ in comparison to donors.

Prothrombin level after thrombolysis

The prothrombin level in the blood plasma of patients with AMI was determined before thrombolytic therapy (at the time of admission to the clinic) and after thrombolytic therapy (on the first, third, and seventh days). The prothrombin total level in the blood plasma of patients with myocardium infarction was normal ($95 \pm 11\%$). During thrombolysis and concomitant therapy with LMWH, there was a decrease in the plasma levels of prothrombin (median 55%; min 40%, max 80%, $p<0.001$). Whereas less obvious change was observed in the case of HMWH (median 84%; min 56, max 110%, $p<0.001$) (Fig. 1). Statistic analysis in "Statistica 7" was used to calculate the correlations of total prothrombin level.

The low level of prothrombin in the case of concomitant therapy with LMWH was also found on the third day after thrombolysis. The normalization of prothrombin level was detected only on the seventh day after thrombolysis in this group of patients (median 87%; min 70, max 110%).

Correlation of prothrombin level and SFMC after thrombolysis

A decrease in the level of prothrombin in the blood plasma of patients who were injected with low molecular weight heparin (LMWH) is accompanied by a significant accumulation of SFMC (Fig. 2). In the group of patients who were injected with high molecular weight heparin (HMWH), the level of SMFC after thrombolysis was lower than in the case of LMWH injection. These data correlate to the decrease of prothrombin content at the same time points presented in Fig. 1.

DISCUSSION

A study of the blood coagulation system of patients with AIM revealed a violation of the balance between pro- and anticoagulants, which is a consequence of activating the coagulation link of the hemostasis system. The activation of the blood coagulation system is evidenced by the increased level of fibrinogen, the accumulation of SFMC, and the significant consumption of the main inhibitors – ATIII and protein C (Hudeca et al., 2020; Hoshino et al., 2018; Refaai et al., 2018).

Figure 3. Scheme of prothrombin activation by fibrin degradation products during thrombolysis.
1 – canonical prothrombin activation, 2 – thrombin cleaves fibrinogen with fibrin formation, 3 – streptokinase activates plasminogen with plasmin formation, 4 – plasmin cleaves fibrin with fibrin degradation products (FDP) formation, 5 – prothrombin and FDP form complexes, 6 – prothrombin in (prothrombin-FDP) complex forms thrombin-like active site.

The accumulation of SFMC is the result of the work of the central enzyme of the blood coagulation system – thrombin (Dizhou et al., 2023). The content of SFMC corresponds to the activity of thrombin and characterizes the degree of activation of the hemostasis system. There is no doubt that SFMC, as a marker of activation of the blood coagulation system, has a high prognostic value (Masahiro et al., 2009).

The prothrombin level in the blood plasma of patients with AMI was normal before thrombolytic therapy and substantially decreased after streptokinase administration. This effect was prominent in the case of concomitant anticoagulant therapy with LMWH and was not observed when HMWH was applied. It can be explained by the fact that LMWH preferentially inhibits factor Xa, while the HMWH is an effective inhibitor of both factor Xa and thrombin. This observation suggested that the prothrombin level decrease was caused by the thrombin activity and possible autolysis of prothrombin by thrombin (Croles et al., 2019; Makarem et al., 2023; Spencer et al., 2000).

Another important issue is fibrin degradation products (FDPs) accumulation due to thrombolytic therapy with streptokinase. Some of the FDPs (including DDE-complex and fibrin E-fragment) still have sites of interactions with thrombin and prothrombin (Capitanescu et al., 2016) (Fig. 3).

Previously, we demonstrated the direct interactions of high molecular weight E-fragment of fibrin (E_1-fragment) and DDE-complex with prothrombin. We confirmed that prothrombin can bind to Bβ26-42 fibrin residues, and the formation of such a complex causes a non-enzymatic prothrombin activation (Chernyshenko et al., 2015).

A similar complexation with the formation of a thrombin-like active site was shown for staphylocoagulase. Staphyloprothrombin, similar to prothrombin in a complex with E_1-fragment, is enzymatically active (Ashoka et al., 2020; Crosby et al., 2016).

As shown in vitro, non-enzymatic activation of prothrombin in a complex with E_1-fragment and DDE-complex was assumed as the additional mechanism of autolysis of prothrombin (Platonova et al., 2002; Savchuk et al., 2006). A study of the state of a hemostatic system at thrombolysis in AMI allowed us to find a pathology in which the proposed mechanism can occur in vivo. This suggestion was confirmed by the dramatic decrease of prothrombin level that occurs alongside the accumulation of FDPs and the inability to inhibit thrombin activity by low molecular weight heparin (LMWH).

CONCLUSIONS

The drop in total prothrombin level in the blood plasma of patients with acute myocardial infarction during thrombolysis was observed. It was strongly dependent on the type of anticoagulant therapy and was not obvious in the case of concomitant therapy with HMWH. It can be explained by the non-enzymatic activation of prothrombin by FDPs that contain Bβ26-42 residues (DDE, E_1 fragments). Such a novel type of non-enzymatic prothrombin activation was previously shown *in vitro*. Current findings allowed us to conclude the possibility of the activation *in vivo* when a huge amount of FDPs are forming. This newly discovered effect should be taken into consideration during patient management.

Review

Relationship of gut microbiota and immunological response in obesity-related non-alcoholic fatty liver disease in children

Pawel Czarnowski[1], Aldona Wierzbicka-Rucinska[1]✉ and Piotr Socha[2]

[1]Department of Biochemistry, Radioimmunology and Experimental Medicine, The Children's Memorial Health Institute, Warsaw, Poland; [2]Department of Gastroenterology, Hepatology and Nutrition Disorders, The Children's Memorial Health Institute, Warsaw, Poland

In the development of NAFLD plays an important role the intestinal microflora. Our aim was to characterize role microbiota in children. Distinctive gut microbiota composition was observed in children, characterized and short-chain fatty acid producing bacteria. For the treatment of NAFLD it is possible by therapeutic manipulations with prebiotics and probiotics to modulate the gut microbiota and maintain the integrity of the intestinal barrier are potential agents.

INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) is now recognized as one of the most common disorders in the proper functioning of the liver, both in the pediatric and adult population. It is estimated that it affects up to 10% of the entire pediatric population, including 26–41% children with obesity (Anderson *et al.,* 2015; Schwimmer *et al.,* 2006). In the adult population, this percentage ranges from 25 to 40% (Estes *et al.,* 2018). Younossi and others (Younossi *et al.,* 2016) in a systematic review estimated that the global prevalence of NAFLD reached 25%, which resulted in a significant increase in the interest of scientists, who are trying to find out the causes leading to its development. The global increase in NAFLD prevalence among children constitutes a poor prognosis for the future (Obesity Collaborators The GBD 2015). NAFLD by itself is defined as a metabolic dysfunction-associated liver disease caused by excessive accumulation of fat in hepatocytes, where it is possible to rule out secondary factors leading to accumulation of fat in liver cells, such as alcohol consumption, hereditary disorders, and drug intake (Chalasani *et al.,* 2012). Within this disease, we can distinguish a number of liver conditions that vary in severity degree, from steatosis to non-alcoholic steatohepatitis (NASH) with or without fibrosis, to cirrhosis (Buzzetti *et al.,* 2015). In the long term, NASH might progress to hepatocellular carcinoma

(HCC), a condition that increases liver-related morbidity and mortality. NAFLD is also related to metabolic syndrome (MS), including insulin resistance, dyslipidemia and visceral obesity (Boyraz *et al.,* 2013). The pathological mechanism leading to the onset and development of NAFLD is not fully known. According to the multiple-hit hypothesis we do know, that there are many factors leading to NAFLD. Among them, we can set apart genetic and epigenetic factors, lipotoxicity, insulin resistance, dietary determinants proinflammatory factors, and gut microbiome, which might be crucial due to the production of large amounts of molecular mediators that affect liver cells (Clemente *et al.,* 2012).

GUT MICROBIOME AND IMMUNOLOGICAL RESPONSE

The gut microbiota affects host physiology at least in part, through the release of metabolites and complex bacterial structural components such as lipopolysaccharides (LPS), peptidoglycans and flagellins. Metabolites derived from the gut microbiota include short-chain fatty acids (SCFAs) and branched-chain fatty acids (BCFAs), aromatic acid metabolites, vitamins, amino acids and other metabolites. Recent studies have shown that gut microbiome (GM) has a significant impact on the development of NAFLD. The gut microbiota includes microorganisms belonging to different kingdoms, such as bacteria, viruses, archaea and fungi. As a whole, they form a complex ecosystem that lives in symbiosis with its host. Human GM is dominated by four bacteria phyla: Actinobacteria, Bacteroidetes, Firmicutes and Proteobacteria, where Firmicutes and Bacteroidetes are most common (Tremaroli *et al.,* 2012). Bacteria are involved in many metabolic processes in the gut. They participate in energy harvest, regulation level of bile-acid, fermentation of polysaccharides, and lastly choline metabolism (Dumas *et al.,* 2006). Intestinal bacteria can also produce substantial amounts of endogenous ethanol, which is transported via the portal vein to the liver, where it might trigger inflammation. Disturbances in the composition of the intestinal microbiota are associated with chronic metabolic syndromes such as obesity, NAFLD and type 2 diabetes mellitus (T2DM) (Turnbaugh *et al.,* 2009; Loomba *et al.,* 2013; Donaldson *et al.,* 2016). Diet is one of the main factors that modulate the composition of gut microbiota – it has an influence on species richness. When the number of species decreases, then it comes to a condition known as dysbiosis, which has been associated with the pathogenesis of inflammatory diseases (Jennison *et al.,* 2021). Gut microbiota is responsible for maintaining of the intestinal epithelial barrier, thus preventing the entry of bacteria and their metabolites into the blood (Fig. 1). It is also known that bacterial metabolites play

Figure 1. Gut microbiota imbalance contributes to the development of NAFLD, may lead to the nutrition imbalance and change the gut microbiota composition and its metabolites, such as SCFAs, and bile acids.
Microbiota disorders promote the intestinal endocrine L cells to secrete GLP-1 to act on the vagus nerve to activate the gut–brain liver nerve pathway and regulate insulin sensitivity, glucose production, and fatty acid oxidation.

an important role in regulating immune system activity and metabolic functions of the human body, for example, they produce intestinal hormones such as glucagon-like peptide-1 (SvegliatiBaroni *et al.,* 2011). Symbiotic organisms are also responsible for the digestion of polysaccharides, the production of vitamins and the absorption of nutrients. Bäckhed and others (Bäckhed *et al.,* 2004) in his research found out that gut microbiota is involved in adipose tissue growth, due to modulation of energy absorption and stimulation of increased triglycerides synthesis in the liver. Bacteria overgrowth may cause intestinal permeability to increase the amount of endotoxins in the systematic circulation and that will allow for the development of endotoxemia with inflammation in the liver. Some other commensal metabolites may also influence the metabolism of the host and that impact can lead to the development and progression of NAFLD (Aron-Wisnewsky *et al.,* 2020).The human intestine contains at minimum 100 trillion microbes, which belong to at least 1000 different species with 150 times more genes than the human genome has (MetaHIT Consortium *et al.,* 2010; Chassaing *et al.,* 2014). The most common phyla in the human gut are Firmicutes and Bacteroidetes, which are followed by frequently identified Actinobacteria, Proteobacteria, Verrucomicrobia and Fusobacteria (Kamada *et al.,* 2014). There are many factors that influence the composition of GM such as gender, age, diet, hormonal changes, drug intake, travel and pregnancy (Rodríguez *et al.,* 2015; Uchiyama *et al.,* 2019). It is important to keep in mind internal factors that affect the composition of the intestinal microbiota, such as the state of the intestinal mucosa, which affects the permeability of the intestinal barrier and the state of the host immune system (Adams *et al.,* 2008). These factors can lead to unfavorable conditions for some bacteria, leading to lower microbial diversity – dysbiosis. Maintaining homeostasis of GM is crucial for keeping the human body (especially the liver) in good condition. It is linked with beneficial metabolites produced by commensal bacteria. Dysbiosis may occur due to an imbalance in the gut, which will manifest itself through excessive proliferation and overproduction of

harmful substances that affect the liver, due to the fact that the portal vein transports about 70% of the total amount of blood to the liver. This is the main reason why it is exposed to endotoxins or peptidoglycans first – they are transported with blood to the liver, where they will be neutralized. The continuous influx of microbial-derived products may cause disturbances in liver functioning and that might end up with inflammation in liver cells. That generates a response from receptors located on certain types of liver cells such as Kupffer cells, sinusoidal cells, biliary epithelial cells and hepatocytes (Chen *et al.,* 2019). Gut microbiota produce many metabolites and part of them have a negative impact on the liver causing inflammation. Among them, we can highlight bile acids, short-chain fatty acids (SCFAs), choline and ethanol (Chiang *et al.,* 2020). All of them are involved in the development of NAFLD. In this study, not all microbiome metabolites were included due to the character and purpose of this study.

SHORT-CHAIN FATTY ACIDS (SCFAs) ON NAFLD

Another important group of bacterial metabolites are short-chain fatty acids (SCFAs). SCFAs are mainly produced as a result of dietary fiber fermentation in the colon. Then they might be absorbed in the intestine (Liu *et al.,* 2021; Rau *et al.,* 2018). The most common SCFAs are acetate, propionate and butyrate, which are absorbed *via* the portal vein during lipid digestion. SCFAs are binding to G-protein coupled receptor (GPCR), which occurs in many organs, such as the liver, skeletal muscles, adipose tissue, and enteroendocrine L cells, exerting influence on their metabolic and immunological functions (Li *et al.,* 2022). The short-chain fatty acids, mostly acetate and propionate can stimulate gluconeogenesis and lipogenesis, leading to fat accumulation in liver cells (Bastos *et al.,* 2022). Butyrate is responsible for the suppression of insulin resistance and obesity while high fatty diet (HFD) intake in mice model (Gao *et al.,* 2009). Butyrate also has anti-inflammatory potential – it can reduce inflammation in the intestines and reduce inflammatory response due

to activation of regulatory T cells, which will inhibit T cells and Th17 cells (Arpaia *et al.,* 2013). Moreover, it reduces levels of proinflammatory cytokines, such as tumor necrosis factor-alpha (TNFα) or monocyte chemotactic protein-1, while increasing levels of prostaglandin E2, which has an anti-inflammatory effect (Smith *et al.,,* 2013; Usami *et al.,,* 2008; Mouzaki *et al.,* 2019). Butyrate is the most potent anti-inflammatory mediator and can reduce local inflammation in the gut and prevent the progression of inflammatory responses into the systemic circulation. Butyrate can also promote tight junction function and intestinal integrity. Another beneficial effect of butyrate is to provide colonocytes with an energy source to maintain intestinal health. Dysbiosis leads to a decrease in butyrate levels which may cause increased gut permeability, and translocation of bacteria or lipopolysaccharides (LPS) into the systemic circulation, which can lead to the development of NALFD (butyrate promotes the regeneration of enterocytes). T-cells are responsible for releasing Glucagon-like peptides, that stimulate fatty acids β-oxidation in hepatocytes. They also increase insulin sensitivity in liver cells, thus they are important to NAFLD development (SvegliatiBaroni *et al.,* 2011]. The gut microbiota regulates bile acid homeostasis through biotransformations such as deconjugation, dehydroxylation, oxidation and desulfation. In terms of deconjugation, Bacteroides, Lactobacillus, Bifidobacterium, Clostridium and Listeria produce bile salt hydrolases (BSH) that deconjugate the taurine and glycine groups in the primary bile acids produced in the liver (Ticho *et al.,* 2019). In experimental animals with dysbiosis or treated with antibiotics, taurine deconjugation by intestinal bacteria was blocked, shifting the balance toward almost exclusively taurine-conjugated bile acids, resulting in increased taurine-conjugated bile acids in the liver, heart and kidneys (Arab *et al.,* 2017). For dehydroxylation, Clostridium and Eubacterium of the Firmicutes tribe produce 7α-dehydroxylase of bile acid, which converts primary bile acids (cholic acid and chenodeoxycholic acid) into secondary bile acids (deoxycholic acid, lithocholic acid and ursodeoxycholic acid) (Lund *et al.,* 2018). 7α- dehydroxylation occurs after deconjugation and is the most physiologically relevant conversion of bile acids in humans. Regarding oxidation, bacteria from genera such as Bacteroides, Clostridium, Eubacterium, Escherichia, Eggerthella, Peptostreptococcus and Ruminococcus produce hydroxysteroid bile acid dehydrogenases (HSDH), which convert toxic bile acids into ursodeoxycholic acid, which is less toxic to human cells and more water-soluble (Ni *et al.,* 2022). Finally, several gut bacteria, such as Clostridium sp. Strain S2, produce sulfatases that are able to enhance the desulfation of bile acids (Jackson *et al.,* 2022). Desulfation of bile acids by intestinal bacteria facilitates the reabsorption of bile acids (Song *et al.,* 2019) and is essential for the homeostasis of the bile acid pool (Moszak *et al.,* 2021). In the liver are synthesized bile acids by the rate-limiting enzyme cytochrome P450 7A1 (CYP7A1) and secreted into the intestine. Intestinal epithelial cells (IECs) are reabsorbed bile acids by the distal ileum via apical sodium-dependent bile acid transporter (ASBT) where they activate farnesoid X receptor (FXR), inducing the expression and secretion of fibroblast growth factor 15/19 (FGF15/19) to inhibit hepatic bile acid synthesis. Luminal and basolateral bile acids activate Takega G protein-coupled receptor 5 (TGR5) in enteroendocrine L-cells, resulting in the release of the incretin glucagon-like peptide-1 (GLP-1), promoting glucose tolerance (Chiang *et al.,* 2020; Zhou *et al.,* 2014). Overproduction of bile acids can promote di-

arrhea by several distinct mechanisms. In the colon, bile acids disrupt barrier integrity allowing bile acids to reach the basolateral membrane of epithelial cells and induce chloride secretion, though the receptors underlying this phenomenon are unknown. Colonic FXR and TGR5 activation inhibits the secretion of chloride and other electrolytes, which may be a compensatory mechanism. Colonic bile acids activate TGR5 on enterochromaffin cells (ECs), promoting 5-hydroxytryptamine (5-HT) release and motility. Bile acids activate neuronal TGR5, which either stimulates or inhibits motility, depending on the type of neuron and region of the GI tract. Overproduction of bile acids induces colonic secretion and enhances motility, producing a diarrheal phenotype (Wang *et al.,* 2021; Krishnan *et al.,* 2018).

MICROBIAL SYNTHESIS OF ETHANOL

Some bacteria have the ability to produce ethanol in the intestine as a result of polysaccharide fermentation. Normally, the amount of produced ethanol is small, but if dysbiosis occurs its amount may be significantly bigger than that in healthy controls (de Medeiros *et al.,* 2015). The health effect of a high concentration of ethanol is an increase in the permeability of the intestinal barrier, which may result in the development of NAFLD and liver steatosis (Chen *et al.,* 2020). Recent studies have shown that increased ethanol levels in the human body are associated with a high abundance of genera Escherichia, Bacteroides, Bifidobacterium, Clostridium and *Klebsiella pneumoniae* (Engstler *et al.,* 2016; Mir *et al.,* 2016). Zhu *et al.,* in their study have observed that obese NASH patients have higher levels of endogenous ethanol than non-obese NASH patients or healthy controls. In turn, Yuan and others (Yuan J *et al.,* 2019) proved that the presence of Klebsiella pneumoniae K14 was common for patients with NAFLD – after transfer, isolates of bacteria cause NAFLD-like changes in mice. Also in children with NAFLD who were on the same diet as healthy children noticed that ethanol levels were significantly higher. Gut microbiota have enzymes which are involved in the metabolism of ethanol, e.g. aldehyde dehydrogenase. That enzyme converts ethanol into acetaldehyde and acetate. Acetaldehyde takes part in the translocation of microbiota metabolites due to the weakening tight junctions of the intestinal barrier (Schwimme *et al.,* 2020).

OBESITY AND NON-ALCOHOLIC FATTY LIVER DISEASE

Obesity is associated with impaired intestinal barrier function and dysbiosis, resulting in metabolites and other bacterial products such as LPS and other molecular patterns associated with the microbiota, gaining access to the lamina propria in higher concentrations. Diet-induced increases in blood LPS concentrations are known as metabolic endotoxemia. Changes in the intestinal microbiota suggest that changes in diet and intestinal barrier function underlie elevated blood LPS concentrations. Alteration of intestinal TJ proteins, mainly zonula occludens-1 (ZO-1) and occludin, is a major molecular mechanism contributing to increased intestinal permeability (Lin *et al.,* 2022). High-fat diets can lead to intestinal inflammation which in turn can result in TJ changes and increased intestinal permeability. Glucagon-like peptide 2 (GLP2), has been identified as a regulator of TJ protein expression and localization in obese mice. Although the expression pattern of metabolite receptors on

specific tissue-resident leukocytes, such as those in the lamina propria of the gastrointestinal tract, is still poorly understood, manipulation of immune cell metabolism by the gut microbiota may be a powerful approach. Gut-derived metabolites may be a powerful approach to direct the immune response. As is well known, obesity is a risk factor for the development of NAFLD, as well as metabolic syndrome (Rau *et al.,*, 2018). The prevalence of overweight and obesity has increased in children and adolescents worldwide over the past 30 years. Gut bacteria produce metabolites by modifying host metabolites, including secondary bile acids. In addition to the classic role of metabolites in bioenergetics and biosynthesis, metabolites can function as signaling molecules, much like hormones and neurotransmitters. Signaling metabolites generated from nutrients or by the intestinal microbiota primarily target the enteroendocrine, neuronal and immune cells in the lamina propria of the intestinal mucosa and liver, and through these tissues to the rest of the body. Metabolites from intermediary metabolism act as metabolic stressors in adipose tissue, liver and pancreas, being effective regulators of pro- and anti-inflammatory regulators of key immune cells, which function as important drivers of low-level inflammation associated with obesity. A large number of metabolite receptors are expressed on immune cells of both the innate and adaptive immune systems. and many different types of immune cells are found in the intestinal mucosa. In lean individuals, the immune cells of the lamina propria are dominated by anti-inflammatory subtypes of innate immune cells, including tolerogenic macrophages and dendritic cells, eosinophils, IL-22-producing innate lymphoid cells and resident regulatory T cells (Tregs) (Miura *et al.,* 2014). Lean but not obese fat is enriched with a unique population of regulatory T cells that influence metabolic parameters. Diet and a sedentary lifestyle are determinants of obesity in children, but obesity in infants is influenced by the gut microbiota profile. As indicated by recently published studies Bacteroides and Lacto Bacillus spp. are the most common microbes involved in overweight in infants. However, to date, there are no certain species or genera identified as causing childhood obesity *per se* (Clemente *et al.,* 2016). Early gut microbiota in infants can shape weight gain in childhood and controlling factors affecting early infant gut microbiota may prevent later overweight and obesity in children. Exposure to antibiotics changes the diversity of the gut microbiota. Infant exposure to antibiotics is strongly associated with childhood obesity. In children under <6 months of age, repeated antibiotic exposure puts boys at higher risk than girls of developing obesity.

CONCLUSION

In conclusion, bacterial metabolites mediate the communication between the commensal microbiota and the immune system, affecting the balance between pro- and anti-inflammatory mechanisms. Gut dysbiosis has been associated with NAFLD because the effects of an altered gut microbiota in abundance and diversity are mediated by many bacterial metabolites including bile acids, butyrate, choline, amino acids and ethanol. Modulation of the intestinal microbiota and supplementation of some bacterial metabolites may have a therapeutic benefit. The heterogeneous clinical features of NAFLD can be explained by consumption of various dietary factors, interpersonal gut microbiome variability and genetics. In summary, the interplay of dietary factors, gut microbiota

and intestinal barrier integrity plays an important role in the development of obesity and obesity-related NAFLD. Alteration of the gut microbiota is a result of diet, which can promote metabolic endotoxemia and inflammation contributing to the development of obesity and NAFLD. Understanding the role of the gut microbiome, and the mechanism of dietary factor influence gut microbiota, with the identification of components of the microbiome's metabolic activity which significantly affect host metabolism and possibly contribute to obesity and obesity-related NAFLD, might also be an important consideration for NAFLD treatment. Altogether, opportunities and challenges provided by microbiome research lead to future studies, which will hopefully elucidate the more specific role of gut microbiome in NAFLD and establish microbiota-targeted treatment approaches.

Highlights/Perceived strengths
• Intestinal microbiota plays an important role in the development of NAFLD.
• Impaired intestinal barrier integrity, metabolic endotoxemia and inflammation are closely associated with obesity and NAFLD.
• The gut microbiota and intestinal barrier function, promoting metabolic endotoxemia and inflammation can alter the absorption and metabolism of energy-reach foods and their ingredients (e.g., fat and fructose)
• Therapeutic manipulations with prebiotics and probiotics to modulate gut microbiota and maintain integrity of the intestinal barrier are potential efficient agents that should be further tested in NAFLD

Age-related effects of fenofibrate on the hepatic expression of sirtuin 1, sirtuin 3, and lipid metabolism-related genes

Adrian Zubrzycki*, Agata Wrońska*✉, Piotr M. Wierzbicki and Zbigniew Kmieć

Department of Histology, Faculty of Medicine, Medical University of Gdańsk, Gdańsk, Poland

Background: Sirtuin 1 (Sirt1) and sirtuin 3 (Sirt3) participate in the regulation of lipid metabolism. Our aim was to investigate the effects of the hypolipemic drug fenofibrate (FN) on hepatic Sirt1 and Sirt3 expression, in relation to the expression of lipid metabolism-related genes and in the context of aging. **Methods and Results:** Young and old male Wistar rats were fed standard chow or supplemented with 0.1% or 0.5% FN for 30 days (*n*=7–10 in each group). In young rats, 0.1% FN did not affect Sirt1 expression, however, 0.5% FN decreased Sirt1 and both doses reduced Sirt3 protein levels. In old rats, 0.5% FN decreased hepatic *Sirt1* mRNA and both doses reduced Sirt1 protein levels, but not Sirt3 expression. Although hepatic Pparα protein levels did not change, FN treatment of young rats induced *Cpt1b* expression, whereas *Lcad*, *Acox1*, *Pmp70*, and *Hmgcs2* expression increased only after 0.1% FN, and *Fas2* expression decreased after 0.5% FN. In the liver of old rats, both doses increased *Cpt1b* and *Lcad* expression. Only 0.1% FN increased *Pmp70* and *Hmgcs2* expression, and only 0.5% FN increased *Acox1* and *Fas2* mRNA levels. **Conclusions:** Treatment with fenofibrate at low or high doses may downregulate the expression of Sirt1 and Sirt3 proteins in the rat liver. The dosage of FN affects molecular changes, and aging alters the response to 0.5% FN.

Key words: aging; liver; fenofibrate; sirtuin; lipid metabolism

INTRODUCTION

Aging decreases the ability to respond to stress and leads to the accumulation of molecular damage (Pyo *et al.*, 2020). Aging-associated changes in energy metabolism and nutrient sensing pathways may lead to disorders in lipid homeostasis, which manifest as elevated concentrations of triglycerides, total cholesterol, and LDL cholesterol in blood plasma (Liu & Li, 2015). The hypolipemic drug fenofibrate (FN) is used to counteract disturbances in lipid metabolism. FN decreases serum triglyceride and VLDL- and LDL-cholesterol levels, while it increases serum HDL-cholesterol (Sahebkar *et al.*, 2017). In the liver, FN stimulates fatty acid oxidation in mitochondria and peroxisomes through the induction of peroxisome proliferator-activated receptor alpha (PPARα) (Gebel *et al.*, 1992). FN exerts additional beneficial effects through PPARα-dependent and independent mechanisms, e.g. in cardiac, renal, and vascular disorders (Balakumar *et al.*, 2019). FN may thus offer new treatment venues for conditions besides hyperlipidaemia. However, it has not been well investigated whether FN affects the expression of sirtuins in the liver.

Sirtuins (SIRT1-SIRT7) are a family of NAD^+-dependent deacetylases, which target histones and non-histone proteins (Zhao *et al.*, 2020). Sirtuins can protect cells against metabolic and oxidative stresses, and may therefore safeguard against some aging-associated alterations, as evidenced by genetic studies in mice (Rodgers & Puigserver, 2007; Pfluger *et al.*, 2008; Zhao *et al.*, 2020). The relationships between the activity of sirtuins and energy metabolism make them a potential therapeutic target for the treatment of metabolic diseases. Two members of the sirtuin family are particularly important for lipid metabolism. SIRT1, the best-studied member of the sirtuin family, decreases blood plasma cholesterol and triglyceride concentrations by inhibitory deacetylation of sterol regulatory element-binding proteins (SREBP) in the liver (Walker *et al.*, 2010). The SREBP belong to transcription factors that control lipid homeostasis by promoting the expression of lipogenic (e.g. fatty acid synthase, FAS) and cholesterogenic genes in the fed state (Walker *et al.*, 2010). Moreover, SIRT1 deacetylates peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1α) in the liver (Rodgers *et al.*, 2005; Rodgers & Puigserver, 2007), skeletal muscle and adipose tissue (Feige *et al.*, 2008). This post-translational regulation of PGC-1α leads to the induction of gluconeogenic genes and glucose output in the liver (Rodgers *et al.*, 2005) and enhances oxidative metabolism in muscles and brown adipose tissue (Feige *et al.*, 2008). SIRT1 also interacts with the transcription factor PPARα at the PPAR response element (PPRE) sequence of target genes (e.g. fibroblast growth factor type 21, FGF21). Upon this interaction with SIRT1, PPARα mediates the adaptive response to fasting and starvation by transcriptional activation of genes involved in fatty acid oxidation (Purushotham *et al.*, 2009).

The mitochondrial sirtuin SIRT3 regulates multiple mitochondrial enzymes both at the transcriptional level and through their reversible deacetylation in mitochondria. SIRT3 is induced during fasting, and

through deacetylation increases the activity of long-chain acyl-coenzyme A dehydrogenase (LCAD), a key enzyme of mitochondrial fatty acid β-oxidation (Hirschey *et al.*, 2010). Similarly, SIRT3 deacetylates and activates 3-hydroxy-3-methylglutaryl-CoA synthase 2 (HMGCS2) (Shimazu *et al.*, 2010), the rate-limiting enzyme in the ketone body β-hydroxybutyrate synthesis. In addition, SIRT3 activates enzymes of the tricarboxylic acid (TCA) cycle and the urea cycle, and regulates reactive oxygen species levels (reviewed by Zhao *et al.*, 2020). Thus, SIRT3 activity is involved in the regulation of multiple metabolic pathways in mitochondria.

Importantly, both SIRT1 and SIRT3 may mitigate metabolic dysfunctions which are often associated with aging. Transgenic models have shown that increased SIRT1 activity protects against insulin resistance, type 2 diabetes (T2D) and diabetic complications, high-fat diet-induced hepatic steatosis, and adipose tissue inflammation (Rodgers & Puigserver, 2007; Pfluger *et al.*, 2008; Guo *et al.*, 2015). Mice with whole-body SIRT3 knock-out showed peripheral insulin resistance due to increased fatty acid oxidation and reduced glucose uptake in skeletal muscle (Lantier *et al.*, 2015). When SIRT3 KO mice were fed a high-fat diet (HFD) they developed hyperlipidemia, impaired glucose tolerance, insulin resistance, and steatohepatitis (Hirschey *et al.*, 2011).

Despite the well-established roles of SIRT1 and SIRT3 in the control of fuel metabolism and suppression of some mechanisms of aging, there is limited data on the expression of these sirtuins in response to pharmacological challenge with fenofibrate, and in the context of ageing. It was reported that Sirt1 protein levels were upregulated by FN in TNFα-treated adipocytes (Wang *et al.*, 2013), the kidney (Kim *et al.*, 2016), endothelial cells (Wang *et al.*, 2014), and cardiac muscle (Liu *et al.*, 2016) in animal models, and Sirt3 protein abundance decreased in the mouse liver after bezafibrate (100 mg/kg/day for 4 weeks) (Barger *et al.*, 2017). However, it is not clear whether FN affects Sirt1 or Sirt3 levels in the liver. We, therefore, undertook to examine: (1) the effect of aging on hepatic expression of Sirt1 and Sirt3 in the rat; (2) whether FN affects the hepatic expression of Sirt1 and Sirt3 in non-obese, normolipemic rats; and (3) whether this effect of FN is modulated by physiological aging. In our previous work, we have demonstrated that FN had a significant hypolipemic effect in normally-bred old rats (Zubrzycki *et al.*, 2020). Therefore, in the present study, we decided to investigate the molecular changes brought about by FN treatment in rat liver in old as compared to young rats bred in standard, non-obesogenic conditions. We examined the gene expression of factors that play key roles in the regulation of lipid metabolism (Murray *et al.*, 2012): the transcriptional regulators *Ppara*, *Pgc1a*, and *Fgf21*; the mitochondrial enzymes carnitine palmitoyltransferase 1b (*Cpt1b*), long-chain fatty acid dehydrogenase (*Lcad*), as well as the rate-limiting ketogenic enzyme *Hmgcs2*. We also determined the expression of genes encoding the peroxisomal acyl-CoA oxidase (*Acox1*) and the organelle's marker, peroxisomal membrane protein 70 (*Pmp70*). Moreover, we investigated the expression of genes encoding the lipogenic enzymes ATP-citrate lyase (*Acl*) and fatty acid synthase 2 (*Fas2*). In this paper, we demonstrate that depending on the dose, fenofibrate differently affects the expression of genes involved in lipid metabolism and that aging affects the response to high-dose fenofibrate treatment.

MATERIALS AND METHODS

Animals, treatment, and material sampling

Young (4-month-old) and old (24-month-old) male Wistar-Han rats were bred in the Academic Animal Experimental Center in Gdańsk, Poland, and housed one *per* cage in standard breeding conditions (22±2°C, humidity 55±10%, 12 h/12 h light/dark cycle). For 30 days, the animals were given 0.5% FN (Glentham Life Sciences, Corsham, UK) mixed into standard rodent chow (high dose; *n*=10 young and 9 old animals). Control animals (*n*=10 young and 7 old) were fed the same chow without supplementation (Labofeed H, Wytwornia Pasz Morawski, Kcynia, Poland). The dose was expected to provide approximately 100 mg/day FF according to the measured baseline food intake (20.7±2.43 g, mean ± S.D., for the young and 23.4±4.97 g for the old rats). With respect to the mean body weight at the onset of the treatment (395 g for the young and 552 g for the old rats), the 0.5% FN dose was equivalent to 260 and 210 mg/kg body weight in young and old rats, respectively. Because the treatment with 0.5% FN had some negative effects on the histology of the liver in both young and old rats (Zubrzycki *et al.*, 2020), in a separate experiment we treated rats with 0.1% FN for 30 days (low dose; *n*=9–10 animals in each group) in the same breeding conditions as for 0.5% FN. At the end of the experiments, the animals were sacrificed under full isoflurane anesthesia through exsanguination from heart puncture. Liver samples were collected and immediately frozen in liquid nitrogen for molecular analyses. The experimental procedures were approved by the Local Ethics Committee in Bydgoszcz, Poland (protocols No. 41/2017, 58/2017, 40/2018, and 5/2019), and carried out accordingly.

Quantitative polymerase chain reaction (qPCR)

The mRNA levels of *Acox1*, *Acl*, *Cpt1b*, *Fas2*, *Fgf21*, *Hmgcs2*, *Lcad*, *Pgc1a*, *Pmp70*, *Ppara*, *Sirt1*, and *Sirt3* were assessed in liver samples by qPCR method (StepOne Plus apparatus, Life Technologies-Applied Biosystems, Grand Island, NY, USA). Total RNA Mini kit (A&A Biotechnology, Gdynia, Poland) was used for RNA extraction according to the manufacturer's protocol, and the obtained RNA was stored at –80°C. 1 µg RNA was reverse-transcribed (RT) with M-MuLV RT enzyme (Thermo Fisher Scientific, Fitchburg, WI, USA) and oligo(dT)$_{18}$ primers (Sigma-Aldrich, Munich, Germany). 5× diluted cDNA was used in qPCR reactions with SensiFastSybr™ No-Rox reagent (Bioline, London, UK) and primers at 200 nM final concentration. mRNA levels were quantified relative to the expression of the geometric mean of acidic ribosomal phosphoprotein P0 (*36B4*) and cyclophilin A (*CycloA*) levels, and analysed using the ΔΔCt method. The primers were designed using Primer3Plus software based on BLAST, Ensembl, and AceView databases (Table 1).

Western blotting (WB)

The semi-quantification of Sirt1, Sirt3, and Pparα proteins in liver samples (6 animals per group) was performed using the WB method. Whole-cell lysates were prepared with Mammalian Cell Extraction Kit (BioVision, Milpitas, CA, USA). Protein samples were separated by 10% SDS-PAGE, transferred to PVDF membranes (Bio-Rad, Warsaw, Poland), and blocked with

7% non-fat milk in TBS with 0.1% Tween20 (TBST) for 1 h. The membranes were incubated with the following primary antibodies at 4°C overnight: anti-Sirt1 (Bioss, bs-0921R; Woburn, MA, USA), anti-Sirt3 (Bioss, bs-6105R), or anti-Pparα (Bioss, bs-3614R) rabbit polyclonal antibodies, diluted 1:1 000 in 3% non-fat milk in TBST. After that, the membranes were washed and next incubated with HRP-conjugated anti-rabbit secondary antibodies (1:10 000 in 3% non-fat milk in TBS) (Merck Millipore, A9169; Darmstadt, Germany) for 2 h at room temperature. Bands were visualized using Clarity Western ECL Substrate (Bio-Rad, Hercules, CA, USA) and developed using ImageQuant LAS 500 Chemiluminescence CCD Camera (GE Healthcare Life Sciences, Pittsburgh, PA, USA). Sirt1, Sirt3, and Pparα protein levels were analyzed relative to glyceraldehyde 3-phosphate dehydrogenase (Gapdh) levels (1:50 000 in 3% non-fat milk in TBST, 1 h at room temperature) (Merck Millipore, AB2302) using QuantityOne Software (Bio-Rad).

Statistical analysis

Statistical analysis was performed using GraphPad Prism (v. 6.0; San Diego, CA, USA). Data were analyzed for outliers using the Grubbs' test. Because not all sets of data followed a normal distribution (Shapiro-Wilk test), statistical analysis was performed using the nonparametric Kruskal-Wallis ANOVA with Dunn's multiple comparisons test. Data are presented as mean ±S.D. and normalized to young control animals (expression level=1). Data obtained for control rats on normal diet in the two separately conducted experiments testing 0.1% and 0.5% FF were combined after checking that

there were no significant differences between the control groups. Statistical significance was set at $p<0.05$.

RESULTS

Sirt1 and Sirt3 expression at the mRNA and protein level

Young and old control rats did not differ with respect to the hepatic mRNA and protein expression levels of Sirt1 and Sirt3 (Fig. 1).

In young rats, FN treatment at either dose did not affect *Sirt1* and *Sirt3* mRNA levels in the liver (Fig. 1A). Even though *Sirt1* expression was notably upregulated in a subset of rats treated with 0.1% FN, no statistical significance was found. In old rats, 0.1% FN did not cause any changes in *Sirt1* expression, but 0.5% FN decreased *Sirt1* expression 6.25-fold ($p<0.01$; Fig. 1B). FN did not cause any changes in *Sirt3* expression in the liver of old rats (Fig. 1B).

In the liver of young rats, 0.1% FN did not affect Sirt1 protein expression; however, 0.5% FN treatment decreased hepatic Sirt1 protein level by 3.33-fold ($p<0.05$; Fig. 1C). Moreover, 0.1% and 0.5% FN decreased Sirt3 protein levels 3.86-fold and 3.33-fold, respectively ($p<0.05$ and $p<0.001$, respectively; Fig. 1C).

In old rats, 0.1% and 0.5% FN decreased hepatic Sirt1 protein level 3.03-fold and 2.86-fold, respectively ($p<0.05$ for both; Fig. 1D). However, neither dose of FN affected Sirt3 protein level in the liver of old rats (Fig. 1D).

Figure 1. Relative mRNA (A & B) and protein (C & D) expression of Sirt1 and Sirt3 in the liver of control and fenofibrate (FN)-treated young and old rats.

The mRNA and protein expression levels were determined by qPCR and Western blotting, respectively, with representative blots shown. Data are mean ± S.D., presented relative to the level in young control rats (set as 1), n=6–10 animals *per* group. For clarity, data from young and old rats are separated into two graphs, with the scale maintained. *p<0.05, **p<0.01, ***p<0.001 (Kruskal-Wallis ANOVA). Abbreviations: *YC* young (4-month-old) control rats; *YF1* young rats treated with 0.1% FN; *YF5* young rats treated with 0.5% FN; *OC* old (24-month-old) control rats; *OF1* old rats treated with 0.1% FN; *OF5* old rats treated with 0.5% FN

Ppara expression

In old as compared to young rats, hepatic *Ppara* gene expression was 4-fold higher (p<0.001), while Pparα protein levels were comparable in the two groups (Fig. 2).

In the liver of young rats, 0.1% FN increased *Ppara* expression by 3-fold (p<0.05), while 0.5% FN was without effect (Fig. 2A). In the liver of old rats, 0.1% FN did not affect *Ppara* expression, whereas 0.5% FN treatment decreased *Ppara* expression by 5-fold (p<0.01; Fig. 2A).

In both young and old rats, neither dose of FN changed the Pparα protein level in the liver (Fig. 2B).

The effects of fenofibrate on the expression of lipid metabolism-related genes in the liver of young and old rats

In our study, aging was not associated with any changes in the hepatic mRNA levels of *Cpt1b, Lcad, Pgc1a, Hmgcs2, Acox1, Pmp70, Acl, Fas2,* and *Fgf21* (Fig. 3).

In young rats, FN treatment increased the hepatic expression of genes encoding enzymes involved in mitochondrial β-oxidation of fatty acids. 0.1% and 0.5% FN increased *Cpt1b* expression levels by 100-fold and 90-fold, respectively (p<0.001 for both; Fig. 3A) and 0.1% FN increased *Lcad* expression by 1.5-fold (p<0.01).

However, neither dose of FN affected *Pgc1a* expression (Fig. 3A).

The expression of the key ketogenic gene, *Hmgcs2*, in the liver of young rats increased 3.5-fold (p<0.001; Fig. 3C) upon treatment with 0.1% FN; however, 0.5% FN was without effect. With regard to peroxisomal β-oxidation, the hepatic expression of *Acox1* increased 22-fold (p<0.01; Fig. 3C) in rats treated with 0.1% FN, with no effect of 0.5% FN. Similarly, only 0.1% FN highly increased *Pmp70* expression (p<0.05; Fig. 3C).

In young rats, the hepatic expression of the lipogenic gene *Acl* was not affected by FN treatment, while the expression of the key lipogenic gene *Fas2* decreased 4-fold (p<0.05) after treatment with 0.5% FN, with no effect of 0.1% FN (Fig. 3E).

In the liver of old rats, 0.1% and 0.5% FN increased *Cpt1b* expression 15-fold and 50-fold, respectively (p<0.01 for both) and increased *Lcad* expression 6-fold and 2.5-fold (p<0.001 and p<0.05, respectively; Fig. 3B). Similarly as in the liver of young rats, the mRNA levels of *Pgc1a* were not affected by FN treatment (Fig. 3B).

The expression of the ketogenic gene *Hmgcs2* in the liver of old rats increased 3.2-fold (p<0.01; Fig. 3D) upon treatment with 0.1% FN (but not 0.5% FN). In old rats, 0.1% FN did not affect *Acox1* mRNA level, while 0.5% FN increased its expression 17-fold (p<0.001;

Figure 2. Relative mRNA (A) and protein (B) expression of Pparα in the liver of control and fenofibrate-treated young and old rats.
The mRNA and protein expression levels were determined by qPCR and Western blotting, respectively. Representative blots are shown in (B). Data are mean ± S.D., presented relative to the level in young control rats (set as 1), n=6–10 animals *per* group. *p<0.05; **p<0.01; ***p<0.001 (Kruskal-Wallis ANOVA). Abbreviations as in the description of Fig. 1.

Figure 3. Relative mRNA expression of genes involved in lipid metabolism and Fgf21 in the liver of control and fenofibrate-treated young and old rats.
A & B: *Cptb1*, *Lcad*, and *Pgc1a*. **C & D**: *Hmgcs2*, *Acox1*, and *Pmp70*. **E & F**: *Acl* and *Fas2*. **G**: *Fgf21*. For clarity, data from young and old rats are separated into two graphs (except for G), with the scale maintained. The mRNA expression levels were determined by qPCR and presented as mean ± S.D. relative to young control rats (set as 1), n=7–10 animals per group. *p<0.05, **p<0.01, ***p<0.001 (Kruskal-Wallis ANOVA)

Fig. 3D). Only 0.1% FN highly increased *Pmp70* expression (*p*<0.05; Fig. 3D) in the liver of old rats.

The treatment of old rats with 0.5% FN did not alter hepatic *Acl* expression. However, in contrast to young animals, in old rats treated with 0.5% FN the hepatic expression of *Fas2* increased 6-fold (*p*<0.01; Fig. 3F).

The expression of *Fgf21* was not affected by FN treatment in either young or old rats (Fig. 3G).

DISCUSSION

We present a comprehensive analysis of Sirt1 and Sirt3 expression in the liver, the key organ of lipid metabolism, upon 30-day treatment of young and old rats with two doses of FN, i.e. 0.1% (low dose) and 0.5% (high dose). We demonstrate that these two doses of FN differently affected the expression of genes involved in lipid metabolism, with aging affecting the response to 0.5% FN.

Sirt1 and Sirt3 have both been associated with protection against age-related diseases, including metabolic derangements (reviewed by Zhao *et al.*, 2020). Therefore, we first examined whether aging affects the hepatic expression of these sirtuins. We found no age-related differences in either mRNA or protein levels of Sirt1 and Sirt3. Similarly, no effect of aging on Sirt1 protein level was observed in the liver of 19–26 month-old C57BL/6 mice compared to young, 2–4 month-old animals, even though there were reductions in other tissues (Xu *et al.*, 2020). In contrast, Jin and others (Jin *et al.*, 2011) reported that in the liver of old mice Sirt1 mRNA and protein expression decreased due to repression of the gene promoter by CCAAT/Enhancer Binding Protein/histone deacetylase 1 (C/EBPb-HDAC1) complex. Sirt3 protein level was downregulated in the liver of 20-month-old mice (Kwon *et al.*, 2017) and this reduction was attributed to the decreased level of Sirt1, which deacetylates and stabilizes Sirt3 (Kwon *et al.*, 2017). It is plausible that differences in chow composition and time of probing, together with different genetic backgrounds of rat and mouse strains may account for the discrepancies. Moreover, it is important to consider that aging-related changes differ between organs and tissues. For example, in the same rat strain bred under similar conditions, we have found that the old compared to young rats showed lower *Sirt3* expression in skeletal muscle, but maintained high expression in cardiac muscle (Ławniczak *et al.*, 2022).

Considering the involvement of Sirt1 and Sirt3 in the control of lipid homeostasis, we examined whether the hypolipemic drug FN affects their hepatic expression. Since dyslipidemia is increasingly common with advancing age (Liu & Li, 2015), we chose normal breeding conditions to determine the effect of FN during physiological aging. We found that depending on the dose and the rat's age FN decreased the protein abundance of Sirt1 and Sirt3 in the liver, with little effect on the mRNA levels. It is generally accepted that the protein levels rather than mRNA are more important for the activity of a particular bioactive molecule. Sirt1 activity can be regulated by several mechanisms, including activation through autocatalytic deacetylation (Fang *et al.*, 2017) or cAMP-dependent activating phosphorylation (Gerhart-Hines *et al.*, 2011). With regard to Sirt3, the decrease in protein levels observed in our study upon FN treatment of young rats may be related to the reduction in Sirt1 level, since Sirt1 was shown to deacetylate and stabilize Sirt3 (Kwon *et al.*, 2017).

To our best knowledge, this is the first study examining the expression of Sirt1 and Sirt3 in the liver of young and old FN-treated rats under normal breeding conditions. The FN-induced reduction of Sirt1 abundance is consistent with some other studies conducted in different experimental settings. In young Wistar rats with HFD-induced hyperlipidaemia, the highly elevated hepatic Sirt1 protein and mRNA expression was reduced after treatment with FN for 21 days, although to a level significantly higher than in control animals (Le *et al.*, 2014). In contrast, no effect on hepatic Sirt1 protein level was observed in young mice treated with approx. 400 mg/kg FN for 5 days (Li & Wu, 2018). Reports on hepatic Sirt3 expression upon FN treatment showed either no impact of the drug (approx. 400 mg/kg/day, 5 days) (Li & Wu, 2018) or prevention of iron overload-induced downregulation of Sirt3 (100 mg/kg, i.p., 6 weeks) (Mandala *et al.*, 2021).

We next analyzed the hepatic expression of genes encoding enzymes and transcriptional regulators involved in lipid metabolism, the activity of which is directly or indirectly regulated by SIRT1 and SIRT3. We have previously reported that in our cohort of rats FN exerted a hypolipemic effect, which was more prominent in old than in young animals (Zubrzycki *et al.*, 2020). The major molecular target activated by FN (Gebel *et al.*, 1992), the nuclear receptor PPARα, is regulated by ligand binding (Balanarasimha *et al.*, 2014) and post-translationally by phosphorylation (Nakamura *et al.*, 2019). Similarly to our results, various studies demonstrated FN action without altering PPARα level (e.g. Zhao *et al.*, 2015; Liu *et al.*, 2016). We analyzed several transcriptional targets of PPARα (Rakhshandehroo *et al.*, 2010): *Cpt1b*, an enzyme responsible for the transport of fatty acids across the mitochondrial outer membrane, *Lcad*, involved in mitochondrial β-oxidation of fatty acids, and *Acox1,* the rate-limiting enzyme of peroxisomal β-oxidation. Among the *Cpt1* isoforms, the *Cpt1b* gene is expressed in the liver at lower levels than the *Cpt1a* isoform, which is known to be upregulated by FN (e.g. de la Rosa Rodriguez *et al.,* 2018). The *Cpt1b* expression in our study was strongly upregulated by both doses of FN in either age group. *Lcad* expression was induced by 0.1% FN and to a smaller degree and only in old rats by 0.5% FN. Stimulation of mitochondrial fatty acid oxidation-related genes by FN confirms the results of most other studies (Karahashi *et al.*, 2013; Zhao *et al.*, 2017). While *Acox1* expression was induced by both FN doses in young rats, its induction by only the higher FN dose in old animals may reflect the general rule that in aging higher doses of activators are needed for the induction of many target genes (e.g. Kobilo *et al.*, 2014; Zubrzycki *et al.*, 2020). The expression of *Pmp70*, which has been described as a specific marker for PPARα activation and peroxisome proliferation (Colton *et al.*, 2004), was highly induced by 0.1% FN in both age groups.

SIRT1 has been reported to interact with PPARα at the PPAR response element sequence of target genes (Purushotham *et al.*, 2009). Sirt1 levels in young rats did not change upon 0.1% FN treatment but decreased after 0.5% FN. This may explain the induction of PPARα-regulated target genes for mitochondrial and peroxisomal enzymes primarily after 0.1% FN in young animals. However, old rats showed downregulation of Sirt1 protein levels after both doses, indicating Sirt1-independent modulation of genes for fatty acid oxidation. Indeed, Bonzo and others (Bonzo *et al.,* 2014) showed that hepatic SIRT1 is dispensable for FN-induced PPARα function *in vivo*. In young mice treated with 0.1% FN for

5 days following the HFD, hepatocyte-specific *Sirt1* knockout did not affect the induction of PPARα target genes (Bonzo *et al.*, 2014).

PPARα also controls the expression of *Fgf21*, a hepatokine that promotes lipid oxidation, lipolysis, and ketogenesis in the liver during ketotic states (Badman *et al.*, 2007) and upon treatment with sodium butyrate (Li *et al.*, 2012). We did not observe any significant changes in *Fgf21* mRNA expression upon treatment with FN, in contrast to the induction of both mRNA and protein levels of FGF21 reported in hepatocytes treated *in vitro* with 500 μmol/L FN (Li *et al.*, 2012). On the other hand, FGF21 has been recently demonstrated to be dispensable for FN action on lipogenesis- or autophagy-related proteins in the murine liver (Jo *et al.*, 2017). Furthermore, the ketogenesis-related gene *Hmgcs2*, whose transcription is regulated by both PPARα (Meertens *et al.*, 1998; Vilà-Brau *et al.*, 2011) and reciprocally by FGF21 (Meertens *et al.*, 1998; Badman *et al.*, 2007; Vilà-Brau *et al.*, 2011), was induced in our study after treatment with 0.1% FN in both young and old rats. In line with our results, a principal transcriptomics analysis of the livers of the FN-treated hepatocyte humanized mice revealed that among many established PPARα targets FN induced *Hmgcs2* (de la Rosa Rodriguez *et al.*, 2018). Likewise, dietary obese mice after a single injection of bezafibrate (100 mg/kg) showed elevated hepatic expression and serum concentration of FGF21, elevated expression of *Hmgcs2*, but no change in the serum concentration of the ketone body β-hydroxybutyrate (Li *et al.*, 2012). In our experimental setting, it is unlikely that the modestly increased *Hmgcs2* expression led to any significant change in ketone body production.

SIRT1 activates PGC1α by deacetylation (Rodgers *et al.*, 2005), whereas PGC1α stimulates the expression of SIRT3 (Kong *et al.*, 2010). PGC-1α and PPARα cooperate to control the transcription of genes encoding mitochondrial fatty acid oxidation enzymes (Vega *et al.*, 2000), whereas SIRT3 modulates the activity of these enzymes by deacetylation (e.g. Hirschey *et al.*, 2010; Shimazu *et al.*, 2010). Even though we noted no significant changes in *Pgc1a* mRNA expression, it should be stressed that this transcriptional coactivator is regulated primarily post-transcriptionally through phosphorylation, acetylation, monomethylation, and O-linked β-N-acetylglucosaminylation (Housley *et al.*, 2009). Similarly to *Pgc1a*, FN did not affect the mRNA expression of *Sirt3* in either age group. However, FN caused downregulation of the Sirt3 protein, which suggests decreased stability or increased degradation of Sirt3 upon treatment. Regrettably, in our study, it was not possible to assess Sirt3 function, e.g. by examining the acetylation status of Sirt3 target proteins. In contrast to our results, a study in *Ppara* knockout mice treated with 100 mg/kg FN for 6 weeks showed downregulation of hepatic Sirt3 expression, indicating the dependence of Sirt3 expression on PPARα in mouse liver (Mandala *et al.*, 2021). Moreover, the FN treatment prevented iron-induced downregulation of hepatic Sirt3 in wild-type iron-overloaded mice (Mandala *et al.*, 2021). Modulation of SIRT3 expression by FN appears to be variable under different experimental conditions.

We observed contrasting, dose-dependent effects of FN on the hepatic expression of the rate-limiting lipogenic *Fas2* gene in young and old rats, with *Acl* expression not significantly affected. In young rats, the decrease in *Fas2* expression upon 0.5% FN treatment (though not 0.1% FN) falls in line with similar results reported in adult rats fed a high-fructose diet and treated

subsequently with 100 mg/kg FN for 4 weeks (Abd El-Haleim *et al.*, 2016). Because FAS activity is mainly regulated at the transcriptional level by nutrients and hormones, this decreased expression could contribute to reduced accumulation of lipid droplets, which we observed under a transmission electron microscope in hepatocytes of young 0.1% FN-treated rats (Zubrzycki *et al.*, 2021). In contrast to young rats, in the old ones 0.5% FN increased *Fas2* expression. Similarly, a 2-week treatment with 0.2% FN strongly induced hepatic *de novo* lipogenesis and the expression of *Fas2* in mice (age not specified) (Oosterveer *et al.*, 2009). Likewise, an increase in FAS protein expression, concurrently with increased mSREB-P1c level was observed in the liver of 10–12-week-old mice fed 50 mg/kg/day FN for 3 weeks (Jo *et al.*, 2017). Further studies are needed to explain the reason for the apparent FN dose- and age-dependent differences with regard to the modulation of lipogenic genes' expression. Nevertheless, it should be noted that the impact on hepatic lipogenesis does not preclude the FN hypolipemic effect through mechanisms including the stimulation of fatty acid β-oxidation and increased lipoprotein lipase activity.

Available evidence suggests that PPARα acts not only as a regulator of fatty acid catabolism but plays a broader role in hepatic lipid metabolism. By using stable isotope techniques, Oosterveer *et al.* demonstrated that the treatment of mice for 2 weeks with 0.2% FN induced hepatic *de novo* lipogenesis and fatty acid elongation *in vivo* in parallel with an increased expression of lipogenic genes (Oosterveer *et al.*, 2009). This lipogenic induction was dependent on SREBP-1c which is a target for inhibitory deacetylation by SIRT1 (Walker *et al.*, 2010). Thus, in terms of our experiment, FN-associated reduction of Sirt1 expression in the liver of old rats may contribute to the increased *Fas2* expression. However, the striking contrast between young and old rats with respect to the effect of FN on lipogenic gene expression warrants further studies. One factor contributing to this outcome could be food intake. We previously reported that 0.5% FN was associated with markedly reduced food intake during the first few days, followed by increased consumption, more rapid in young than old rats (Zubrzycki *et al.*, 2020). A re-feeding effect could contribute to the elevation of lipogenesis in old rats.

Our study provides yet another piece of evidence that at least two concentrations of the studied compound should be applied under both *in vivo* and *in vitro* experimental conditions. We found clear discrepancies in the effects of low dose, i.e. 0.1% FN (equivalent to ca. 52 and 42 mg/kg/day in young and old rats, respectively) *versus* high dose, i.e. 0.5% FN (equivalent to ca. 260 and 210 mg/kg/day) in regard to the expression of Sirt1, *Ppara*, *Lcad*, *Hmgcs2*, *Acox1*, *Pmp70*, and *Fas2*. It should be noted that during long-term treatment in humans, FN is administered once daily typically at a dose of 50-150 mg (preceded by higher doses), whereas the dosage applied to studies in rodents varies widely, from 50 mg/kg/day (Jo *et al.*, 2017) to 400 mg/kg/day (Li & Wu, 2018). Comparison between FN dosage in humans and rodents is difficult because of species differences in the metabolism and elimination patterns of the drug (Caldwell, 1989).

Our study is not without limitations. Firstly, the results of a study examining PPARα agonist effects in rats cannot be directly transferred to human conditions. Upon administration of peroxisome proliferator chemicals, rodents respond with peroxisomes proliferation, hepatomegaly, and increased hepatocyte proliferation, whereas

such a response is typically absent in humans (Klaunig *et al.*, 2003; Peters *et al.*, 2005). Secondly, we measured the mRNA and protein levels of Sirt1 and Sirt3. Considering that activation of sirtuins may be achieved by increasing NAD^+ availability (Zhao *et al.*, 2020), analysis of the hepatic $NAD^+/NADH$ ratio would give more insight into Sirt1 and Sirt3 activity upon treatment with FN. Nevertheless, NAD^+-independent mechanisms of sirtuins' activation also exist, including phosphorylation of SIRT1 at Ser434 *via* the cAMP/PKA pathway (Gerhart-Hines *et al.*, 2011). Thirdly, we measured only the mRNA expression of some genes involved in fuel metabolism, selected as representative for particular metabolic processes and/or under PPARα transcriptional control. Certainly, activity assays, as well as analyses of protein levels and their acetylation status would be more informative with regard to the changes induced by FN. However, these methods were beyond the scope of this project. Lastly, additional studies are needed to examine the mechanisms responsible for the dose-dependent and age-dependent differences in fenofibrate's action in the liver.

CONCLUSIONS

Treatment with fenofibrate at low or high dose affects the hepatic expression of Sirt1 and Sirt3 proteins. The dosage of fenofibrate significantly affects the treatment-induced changes in the expression of lipid metabolism-related genes in the rat liver. Aging influences the response to high-dose fenofibrate. The results of our study emphasize the importance of considering the patient's age before adjusting the fenofibrate dose.

Declarations

Ethical approval: All animal experimental procedures had been authorized by the Local Ethics Committee in Bydgoszcz, Poland (protocols No. 41/2017, 58/2017, 40/2018, and 5/2019), and carried out in compliance with the EU Directive 2010/63/EU for animal experiments.

Conflict of interest: The authors have no relevant financial or non-financial interests to disclose.

Author contributions: Adrian Zubrzycki: Methodology; Investigation; Statistical analysis; Writing – original draft; Preparation of Figures. Agata Wrońska: Conceptualization; Methodology; Investigation; Statistical analysis; Resources; Writing – final draft, review & editing. Piotr M. Wierzbicki: Methodology; Statistical analysis; Writing – review. Zbigniew Kmieć: Conceptualization; Writing – review & editing; Supervision, Funding acquisition.

Objective: The aim of our study was to compare the total 25(OH)D fraction, the bioavailable vitamin fraction, and the free vitamin D fraction in spring and fall in a group of healthy individuals.

Methods: In our study, we collected blood samples from healthy participants at the end of both summer and winter, and measured serum levels of albumin, DBP, and 25(OH)D. Utilizing these data, we calculated the percentage of free and bioavailable vitamin D. Our cohort comprised 87 participants, with a male-to-female ratio of 14:73, aged 35.95 ± 12.55 years, ranging from 19 to 70 years. We employed the chemiluminescence method to determine the vitamin 25(OH)D levels, the ELISA method was utilized to determine DBP levels, the albumin BCP Assay was performed using the ADVIA biochemical analyzer (Siemens) and an online calculator was used to determine the free and bioavailable 25(OH)D levels.

Results: Our findings indicate significantly lower 25(OH)D levels in winter (44.13 ± 17.82 nmol/L) compared to summer (74.97 ± 22.75 nmol/L; $p < 0.001$). For vitamin D binding protein there was no significant difference from summer (236.2 ± 164.39 mg/L) to winter (239.86 ± 141.9 mg/L; $p = 0.77$), albumin levels were significantly higher in summer (49.37 ± 4.15 g/L vs. 47.97 ± 3.91 g/L, $p = 0.01$), but the magnitude of the change may not be large enough to be solely responsible for the stability of vitamin D levels throughout the year. In the winter season a significantly lower calculated bioavailable 25(OH)D vitamin (7.45 ± 5.66 nmol/L against 13.11 ± 8.27 nmol/L; $p < 0.001$) was observed, and the free fraction also showed a significant decrease (17.3 $\pm$

Abbreviations: BMI, body mass index; UV, ultraviolet; D3, cholecalciferol; D2, ergocalciferol; Total 25(OH)D, 25-hydroxycholecalciferol, calcifediol, calcidiol, 25-hydroxyvitamin D3; 1,25-(OH)D, 1,25-dihydroxyvitamin D; DBP, vitamin D binding protein; OR, Odds ratio.

12.9 pmol/L versus 29.7 $\pm$ 19.1 pmol/L; $p < 0.0001$). We observed a moderately positive correlation between 25(OH)D and bioavailable percentage in winter (r = 0.680; $p < 0.001$), in contrast with a lower positive association in summer (r = 0.343; $p < 0.001$).

Conclusion: Our data suggest a positive correlation between total and bioavailable 25(OH)D levels. In addition to the statistically significant variation in 25(OH)D between the two observation periods, there was an additional variation in the free vitamin D percentage. The summertime synthesis of vitamin D in the skin could contribute directly to the free fraction of vitamin D. Standardizing the measurement of free 25(OH)D and clinical studies is necessary to establish reference values before these methods can be implemented in clinical practice.

Introduction

Physiological functions

Vitamin D is a pro-hormone that plays a crucial role in phosphorus-calcium metabolism and is therefore essential for the maintenance of healthy bones and teeth (Holick, 2008a).

Vitamin D is also involved in several other important physiological functions, including: 1) maintaining immune function by stimulating white blood cell production, 2) regulating cell growth and differentiation, which is important for maintaining healthy tissues and organs, 3) reducing the risk of depression and improving cognitive function, and 4) regulating gene expression through vitamin D's involvement in the regulation of several genes important for maintaining health and preventing disease (Holick, 2008a; Haussler et al., 2008; Wacker and Holick, 2013; Bouillon and Carmeliet, 2018; Carlberg and Haq, 2018). In recent years, the status of vitamin D has received much attention in the context of COVID-19, which has also contributed to a significant increase in vitamin D supplementation compared to pre-pandemic levels (Žmitek et al., 2021; Vičič and Pandel Mikuš, 2023).

Vitamin D insufficiency and deficiency

Vitamin D deficiency is associated with bone diseases such as rickets and osteoporosis. Low vitamin D levels are also associated with an increased risk of other chronic diseases such as cardiovascular disease, cancer and autoimmune diseases (Calvo et al., 2004; Holick, 2008b; Heaney et al., 2017).

Based on the data that are now available and clinical considerations, various associations and organizations employ slightly different criteria for vitamin D insufficiency, deficiency, and sufficiency.

The Endocrine Society recommends that vitamin D status be assessed in patients who are at risk for vitamin D deficiency by measuring the circulating serum 25(OH)D level using an accurate test. A 25(OH)D level of less than 20 ng/mL (50 nmol/L) is considered to be vitamin D insufficiency, whereas a 25(OH)D of 21–29 ng/mL (52.5–72.5 nmol/L) is considered to be vitamin D sufficiency (Holick et al., 2011).

A multidisciplinary Polish panel developed concerns regarding the guidelines for treating and preventing vitamin D insufficiency in both the general population and in high-risk patient groups. The ranges of total blood 25-hydroxyvitamin D concentration indicating suboptimal status (>20 ng/mL, <50 nmol/L), ideal concentration (>30–50 ng/mL, <75 nmol/L), and vitamin D insufficiency (<20 ng/mL, <50 nmol/L) were confirmed on the basis of network discussions (Płudowski et al., 2023).

Vitamin D metabolism and fractions

Vitamin D sources, metabolism and bioavailability are schematically presented in Figure 1. Vitamin D is mainly obtained through diet and skin synthesis when exposed to UVB rays. Sun exposure is the primary source for most people, but without enough UVB exposure, dietary vitamin D becomes essential (Calvo et al., 2004; Spiro and Buttriss, 2014).

Vitamin D3 is produced from 7-dehydrocholesterol (7-DHC) in the skin through UVB radiation. It is converted to previtamin D3, which reaches peak concentration within hours (Holick, 2008a). This previtamin D3 is then transported to the liver via extracellular fluid and dermal capillaries, bound to vitamin D binding protein (DBP) (Holick et al., 2011).

FIGURE 1
Vitamin D sources, metabolism and bioavailability.

Dietary sources of vitamin D include vitamin D2 (ergocalciferol), D3 (cholecalciferol), and 25-hydroxycholecalciferol [25(OH)D] (Taylor et al., 2014). These forms are transported to the liver in chylomicrons via lymph and blood plasma.

In the blood, two main fractions of vitamin D are measured. Total 25-hydroxyvitamin D (25(OH)D) is the primary circulating form and is often used as a marker for vitamin D status. It binds to DBP and is taken up by the kidneys through receptor-mediated endocytosis involving megalin and cubilin (Nykjaer et al., 2001). The active form, 1,25-dihydroxyvitamin D [1,25(OH)2D], is produced in the kidneys from 25(OH)D under the influence of parathyroid hormone (Lips, 2006; Holick, 2008b). This active form binds to vitamin D receptors, influencing calcium and phosphorus metabolism (Holick, 2008a; Bikle, 2014).

Vitamin D status typically refers to serum 25(OH)D concentration, which does not include vitamin D stored in fat or other tissues (Prentice et al., 2008; Bolland et al., 2018). This status is influenced by factors like body fat, muscle mass, and genetic variation (Cashman and Kiely, 2011; Ross et al., 2011).

Free 25(OH)D is the fraction that is not bound to DBP and can enter cells directly (Powe et al., 2013a). Bioavailable 25(OH)D includes free and albumin-bound 25(OH)D, making it more readily available for tissue uptake (Bikle and Schwartz, 2019).

DBP transports and stores vitamin D, increasing its stability and protecting it from degradation (Bikle, 2014; Speeckaert et al., 2006). Higher DBP concentrations increase vitamin D binding capacity, forming a larger reservoir of bound vitamin D (Smith and Goodman, 1971).

Measuring free and bioavailable vitamin D is complex and costly, making these measurements uncommon in clinical practice (Chun and Nielson, 2018). These can be calculated using total 25(OH)D, DBP, and albumin levels, although accuracy varies (Vičič et al., 2022).

Vitamin D status fluctuates with the seasons, especially at latitudes above 40°N where UVB exposure is insufficient during

autumn and winter (Spiro and Buttriss, 2014; O'Neill et al., 2016).

Seasonal variation

Sunlight-induced vitamin D synthesis in lighter-skinned populations begins at the end of March, with serum total 25(OH)D levels peaking after the summer months and then declining from October onwards. Therefore, a significant proportion of the European population relies on vitamin D from food and endogenous stores to maintain an adequate vitamin D status, especially during the winter season. A rather high prevalence of vitamin D deficiency has been reported in several countries (Spiro and Buttriss, 2014; O'Neill et al., 2016; Zittermann et al., 2016), and was also found in our previous studies (Hribar et al., 2020; Hribar et al., 2023). In addition to geographic location and season, there are other important factors that influence vitamin D status, such as age, sex, body mass index, constitutional skin color and various lifestyle factors (Webb et al., 2018; 1988; Hribar et al., 2020; Žmitek et al., 2020; Hribar et al., 2023).

The amount of solar radiation reaching an area is affected by the amount of time spent in the sun and factors that affect the angle of the sun: season, latitude, altitude and time of the day. Before sun rays reach the skin they can be blocked by particles in the air ($PM_{2.5}$, PM_{10}) and later by sunscreen use, cosmetics with SPF, clothing and obstacles such as buildings (Neville et al., 2021). When sun rays reach the skin they are partially blocked by melanin, which is dependent on skin pigmentation (Webb et al., 2018; Neville et al., 2021). In our previous study we showed that constitutive skin color, as well as tanning, hours spent in the sun and protective behaviors against the sun affect individual vitamin D levels (Hribar et al., 2023). Older age is associated with decreased cholecalciferol synthesis in the skin (MacLaughlin and Holick, 1985).

In some cases, taking vitamin D supplements may be recommended to maintain adequate levels of this important nutrient, especially during the winter months or in people who are at higher risk of deficiency (Lips, 2001; Kimball et al., 2007).

Studies have shown that levels of both bioavailable vitamin D and free vitamin D vary seasonally, with higher levels generally observed in the summer months and lower levels observed in the winter months (Zerwekh, 2008; Lehmann et al., 2013).

Aims

The aim of the study was to determine and evaluate the relationship between the total 25(OH)D concentration, the amount of free and bioavailable vitamin D and the level of vitamin D binding protein (DBP) in Slovenian adults at the end of winter and at the end of summer.

Materials and methods

Study participants

Our study included 87 healthy volunteers aged 35.95 ± 12.55 years in the range (19–70 years), and the male-to-female ratio was 14:73. General information is presented in Table 1. The participants were part of the Nutri-D study: "Challenges in achieving adequate Vitamin D status in the adult population." For this study a sub-sample of the Nutri-D study participants recruited in 2020 (the second year of the study) was used. The study was conducted with two observation periods, one in winter (January–February 2020) and one after the end of summer (September 2020). The invitation to participate in the study was posted on social media and the website of the Nutrition Institute (Slovenia).

Caucasian race (Fitzpatrick skin types I–IV), age over 18 years, desire to abstain from artificial UVB sources, and willingness to adhere to all study protocols were the inclusion criteria. Pregnancy or breastfeeding, severe sun avoidance (e.g., sun allergy), use of sunbeds, use of supplements or medications containing vitamin D, fish oil, or omega-3 fatty acids in the three months prior to study enrolment, regular (daily) consumption of foods enriched with vitamin D (e.g., fortified margarine or plant-based milk alternatives), adherence to a diet prescribed by a dietitian or medical staff, adherence to special diets (e.g., vegetarianism, low-carbohydrate, high-fat, and calorie restriction); current diseases of the kidneys, thyroid, digestive tract, osteoporosis and other bone diseases, skin diseases and other conditions that interfere with the absorption and synthesis of vitamin D, were the exclusion criteria for the study.

The study protocol was carried out in compliance with institutional and local regulations and was approved by the Ethics Committee of the Faculty of Applied Sciences (VIST), SI-1000 Ljubljana, Slovenia (Approval No. 2018/4-ET-SK). It was also registered at ClinicalTrials.gov (ID: NCT03818594). To take part, each subject had to complete an informed consent form.

Methods of determination

In winter (January-February 2020) and after the end of summer (September 2020) a biochemical blood tube (4 mL) was collected. Albumin and total 25(OH)D were analyzed from fresh serum after blood collection, while the aliquot for DBP was stored at minus 80°C until analysis and all samples were analyzed simultaneously. Special care was taken to ensure that samples were taken from the same subject in the same batch on the same plate.

Measurements were performed at the Clinical Institute of Clinical Chemistry and Biochemistry (University Medical Centre, Ljubljana). Serum 25(OH)D, albumin and DBP, were

DBP, vitamin D binding protein. All values are presented as Mean ± SD or %. Values are presented as mean ± SD, $p < 0.05$ was considered statistically significant (p values of significant variables are in bold print).

measured in all participants using the following methods: vitamin 25(OH)D concentration was measured using a competitive luminescence immunoassay with a limit of quantification of 6 nmol/L (Architect analyzer, Abbott Diagnostics, Lake Forest, United States), Human Vitamin D Binding Protein was measured with ELISA (MyBioSource, Inc., San Diego, CA, United States); the limit of quantification was 31 mg/L. The concentration of albumin was measured with an automated Albumin Assay (ADVIA analyzer, Siemens, New York, United States). The assay is based on the reaction of albumin with bromcresol green followed by spectrophotometric detection; the limit of quantification was 10 g/L.

Specific formulas that use the amounts of total 25-hydroxyvitamin D [25(OH)D], vitamin D-binding protein (DBP), and albumin are used to calculate the bioavailable and free fractions of vitamin D. Predictive equations derived from equilibrium dialysis or ultrafiltration procedures may also be used to approximate these formulas.

Calculation of free vitamin D

Free vitamin D can be calculated using the following formula:

$$[\text{Free 25(OH)D}] = [\text{Total 25(OH)D}]/$$
$$\times \{1 + (K_{DBP} \times [DBP]) + (K_{Alb} \times [Alb])\}$$

Where:

- [Total [25(OH)D] is the total concentration of 25-hydroxyvitamin D.
- [DBP] is the concentration of vitamin D binding protein.
- [Alb] is the concentration of albumin.
- K_{DBP} is the affinity constant of 25(OH)D for DBP (approximately 5.98×10^8 M^{-1}).
- K_{Alb} is the affinity constant of 25(OH)D for albumin (approximately 6×10^5 M^{-1}).

Calculation of bioavailable vitamin D

Bioavailable vitamin D includes both the free and albumin-bound fractions. It can be calculated as follows:

$$[\text{Bioavailable 25(OH)D}] = [\text{Free 25(OH)D}] + \{[\text{Total 25(OH)D}]/$$
$$\times (1 + K_{DBP} \times [DBP]) + (K_{Alb} \times [Alb]) \times (K_{Alb} \times [Alb]))\}$$

Simplified, the bioavailable vitamin D formula can be written as:

$$[Bioavailable25(OH)D] = [Total25(OH)D] /$$
$$\times (1 + (K_{DBP} \times [DBP]) + (K_{Alb} \times [Alb]))$$
$$\times (1 + (K_{Alb} \times [Alb]))$$

Free and bioavailable 25(OH)D were calculated using an online calculator (Vičič et al., 2022) based on a modified Vermeulen equation (Vermeulen et al., 1999; Powe et al., 2013a; Bikle et al., 2017).

Statistical methods

The observed variables in the statistical analysis were total 25(OH)D, DBP, albumin, calculated bioavailable 25(OH)D and calculated free 25(OH)D. The explanatory variables were season (winter/summer), sex, and age.

The Endocrine Society cut-off values were used to assess total serum 25(OH)D levels target concentration for the optimal vitamin D effect: 75–125 nmol/L, insufficiency: 50–75 nmol/L and deficiency: <50 nmol/L (Holick et al., 2011; Holick et al., 2012; Vieth and Holick, 2018).

A paired sample t-test was performed to analyze differences between groups.

Values are expressed as mean ± SD or percentage (%) in the case of categorical variables. Statistical analysis was performed using SPSS, version 27 and MS Excel 2019.

A Pearson correlation coefficient was calculated to assess the linear relationship (Mukaka, 2012).

Odds ratios (OR) were calculated using binary logistic regression. For OR, 95% confidence intervals were calculated. The significance level was set at $p < 0.05$.

Results and discussion

Our results show that vitamin D levels are lower in the winter months than in the summer months, that serum albumin concentrations are stable, and that DBP remains almost unchanged. Free vitamin D and bioavailable vitamin D levels are higher in the summer compared to the winter.

Total vitamin D levels are significantly lower in winter 44.13 ± 17.82 nmol/L compared to summer 74.97 ± 22.75 nmol/L ($p < 0.001$) (This is likely due to reduced sun exposure and lower cutaneous vitamin D synthesis during the winter, as supported by previous studies (Hribar et al., 2020; Hribar et al., 2023).

Although there is a small but significant increase in serum albumin concentration from winter 47.97 ± 3.91 g/L to summer 49.37 ± 4.15 g/L ($p < 0.01$), this change is not large enough to explain the year-round stability of vitamin D levels.

There was no significant difference in DBP levels from winter 239.86 ± 141.9 mg/L to summer 236.2 ± 164.39 mg/L ($p = 0.77$).

This suggests that DBP is not a major factor in the seasonal variation of vitamin D levels.

There is a noticeable and significant increase in the free fraction of vitamin D from winter 17.3 ± 12.9 pmol/L to summer 29.7 ± 19.1 pmol/L ($p < 0.0001$), indicating higher availability of unbound vitamin D during the summer months.

The calculated bioavailable 25(OH)D is significantly lower in winter 7.45 ± 5.66 nmol/L compared to summer 13.11 ± 8.27 nmol/L ($p < 0.001$). This highlights the reduced availability of vitamin D for physiological use during the winter months.

The proportion of bioavailable 25(OH)D as a percentage of the total does not show a statistically significant difference between winter 16.9% ± 12.8% and summer 17.5% ± 11.0%. This suggests that while the absolute levels of bioavailable vitamin D vary seasonally, the relative proportion of bioavailable vitamin D to total vitamin D remains stable throughout the year.

These findings underscore the significant seasonal variation in vitamin D status, which is primarily driven by changes in sun exposure and subsequent synthesis of vitamin D. The stability of the proportion of bioavailable vitamin D relative to total vitamin D suggests that the body's mechanisms for maintaining vitamin D homeostasis are robust, even though absolute levels fluctuate with the seasons.

A box plot of the winter and summer total 25(OH)D data and the estimated values of the bioavailable percentage are displayed in Figure 2.

Correlation analysis

As part of our study, we also calculated the correlation between summer and winter total 25(OH)D and bioavailable vitamin results. The results are shown in Table 2.

Wintertime Correlation of Total and Bioavailable 25(OH)D ($p = 0.680$): The robust association suggests that the total 25(OH)D levels are a reliable indicator of the bioavailable 25(OH)D levels during the winter. This suggests that in the absence of considerable sunlight the body's regulatory systems may be at work to maintain a stable percentage of bioavailable vitamin D from the total amount available.

Winter total 25(OH)D and summer bioavailable 25(OH)D are correlated ($p = 0.370$): The fact that the association is smaller suggests that winter total 25(OH)D levels do not predict summer bioavailable 25(OH)D levels as well. Prediction based solely on winter levels is reduced because of seasonal variations and greater sun exposure in the summer, which probably result in additional factors influencing vitamin D bioavailability.

Summertime Correlation of Total and Bioavailable 25(OH)D ($p = 0.343$): Summertime correlations are similar to those observed in winter in that they are weak, meaning that although total 25(OH)D levels do affect bioavailable 25(OH)D

FIGURE 2
Box-plot comparison of winter and summer total and bioavailable 25(OH)D of healthy Slovenian adults aged 19–70 years. Study was carried out in winter (January-February 2020) and after the end of summer (September 2020).

TABLE 2 Pearson correlation coefficients (r) of blood biomarkers of healthy Slovenian adults aged 19–70 years. The study was conducted in winter (January–February 2020) and after the end of summer (September 2020).

		Bioavailable 25(OH)D		Total 25(OH)D	
		Winter	Summer	Winter	Summer
Total 25(OH)D	Winter	0.680*	0.370*	1	0.568*
	Summer	0.307*	0.343*	0.568*	1
Bioavailable 25(OH)D	Winter	1	0.509*	0.680*	0.307*
	Summer	0.509*	1	0.370*	0.343*

*Correlation is significant at the 0.01 level (2-tailed).

levels, the effect is not as great. This decreased correlation may be caused by both increased sun exposure and perhaps greater diversity in the sun exposure habits of each subject.

Summer total 25(OH)D and winter bioavailable 25(OH)D are correlated ($p = 0.307$): Summer total 25(OH)D levels appear to be a poor predictor of winter bioavailable 25(OH)D levels, based on this weak association. This is to be expected given the stark variations in sun exposure, which cause the amounts of total and bioavailable vitamin D to change dramatically.

In addition, we looked at how the concentrations of total 25(OH)D and bioavailable vitamin D varied with the seasons. The results are shown in Figure 3.

From winter to summer, there is a noticeable and constant increase in total and bioavailable 25(OH)D levels in all individuals. This seasonal change makes sense given the well-documented consequences of increased sun exposure in the summer. There is observable individual diversity in the absolute levels of total and bioavailable 25(OH)D as well as the degree of growth, despite the general trend. This diversity can be explained by variations in the amount of time that each person spends in the sun, skin type, food consumption, and even hereditary variables that affect the metabolism of vitamin D. Across all the individuals, the proportionate increase in bioavailable 25(OH)D relative to total 25(OH)

FIGURE 3
Spaghetti plot comparison of winter and summer total and bioavailable 25(OH)D of healthy Slovenian adults aged 19–70 years. Study was carried out in winter (January–February 2020) and after the end of summer (September 2020).

D appears to remain fairly constant. This implies that the mechanisms controlling the conversion and availability of bioavailable vitamin D are operating consistently in response to the elevated total vitamin D levels from summer sun exposure.

Seasonal variation of total 25(OH)D levels

According to our research, the concentration of vitamin 25(OH)D is considerably lower in the winter than it is in the summer (Hribar et al., 2023). This significant seasonal variation is in line with earlier studies showing that seasonal variations in sunlight exposure have an impact on vitamin D levels. Several studies (Hine and Roberts, 1994; Kull et al., 2009; Hribar et al., 2023) have shown comparable trends and linked lower winter levels to decreased ultraviolet B (UVB) radiation. UVB light is necessary for the production of vitamin D in the skin.

Serum albumin concentrations

Serum albumin concentrations varied significantly between the winter and summer ($p = 0.003$), but the magnitude of the variation was small. Higher summer levels of free and accessible vitamin D may be due in part to albumin, a key protein that binds to vitamin D. The small magnitude of variation, however, suggests that albumin alone has a limited effect on the seasonal variations in vitamin D levels.

Vitamin D binding protein (DBP) levels

According to our research, summertime vitamin D binding protein levels are slightly lower than wintertime levels, but the difference is not statistically significant ($p = 0.77$). This is consistent with other research, including the findings of Powe et al. (2013b) that DBP levels do not significantly fluctuate with the seasons. The stability of DBP levels indicates that variations in total 25(OH)D levels are more likely to be the cause of changes in free and bioavailable vitamin D than fluctuations in DBP.

Free fraction of vitamin D

There was a noticeable increase in the percentage of free vitamin D from winter to summer ($p < 0.0001$). There may be more unbound vitamin D available throughout the summer due to this significant seasonal increase in free vitamin D. This result is in line with recent studies showing that summertime increases in free vitamin D levels are caused by increased cutaneous production and decreased binding to albumin and DBP.

Bioavailable 25(OH)D levels

With a p-value <0.001, bioavailable 25(OH)D was considerably lower in the winter than in the summer. This notable seasonal variation highlights the influence of a lack of UVB exposure on vitamin D bioavailability. The decrease in bioavailable vitamin D during the winter months may have effects on the immune system and bone health. Bioavailable

vitamin D is essential for physiological processes and includes both free and albumin-bound fractions. These findings support research by several researchers (Bikle et al., 1986; Bouillon and Van Assche, 1995; O'Mahony et al., 2011; Charoenngam and Holick, 2020), highlighting the importance of bioavailable vitamin D in maintaining health.

Proportion of bioavailable 25(OH)D as a percentage of total

Research such as that of Chun et al. (2010), which addresses the homeostatic control of vitamin D bioavailability, supports the relatively stable proportion of bioavailable 25(OH)D as a percentage of total vitamin D (± standard deviation), with 16.9% ± 12.8% in winter and 17.5% ± 11.0% in summer, which is not a statistically significant difference. This stability suggests that while absolute levels of bioavailable vitamin D vary seasonally, the body's regulatory mechanisms maintain a consistent proportion of bioavailable to total vitamin D.

Correlation between total 25-hydroxyvitamin D and bioavailable 25-hydroxyvitamin D levels in winter and summer

Because there are fewer daylight hours and less direct sunlight during the winter, there is less exposure to UVB irradiation of sufficient intensity to induce endogenous vitamin D synthesis. As a result, in order to maintain their vitamin D levels, humans rely primarily on food sources and stored vitamin D (from summer sun exposure). Both newly synthesized and stored vitamin D from food sources are included in total 25(OH)D. Conversely, vitamin D that is attached to albumin and the free fraction of vitamin D are known as bioavailable vitamin D, and these are readily absorbed by cells. Consequently, it is expected that a higher level of bioavailable 25(OH)D would correlate with a higher level of total 25(OH)D. This may be because, in the absence of substantial vitamin D deficiency, part of the stored vitamin D becomes accessible.

Summertime is when humans in our latitudes can produce extra vitamin D in their skin due to increased sun exposure and a higher intensity of UVB irradiation. When more freshly generated vitamin D from sunlight is available in the summer, the weak correlation seen in the winter may become a slightly positive correlation. The amount of stored vitamin D that contributes to total 25(OH)D levels decreases as more vitamin D is produced in the skin during the summer. The association with bioavailable vitamin D may be reduced as a result.

The higher correlation in winter indicates that the body is more dependent on its stored vitamin D at times when vitamin D availability is reduced. On the other hand, the reduced summer correlation may be a result of higher synthesis rates and distinct binding dynamics during periods of increased vitamin D availability.

A study of healthy adults in Switzerland, for example, found that both total and free vitamin D levels were significantly lower in winter than in summer, while there were no seasonal differences in bioavailable vitamin D levels (Merlo et al., 2015). In contrast, a study of older adults in the United Kingdom found that while total vitamin D levels were lower in winter, there was no significant difference in free or bioavailable vitamin D between summer and winter months (Cashman et al., 2012; Hilger et al., 2014), Vitamin D supplementation may increase total vitamin D levels, including the bioavailable fraction. However, the extent to which supplementation affects the bioavailable fraction may depend on several factors, including the form and dose of vitamin D, individual differences in vitamin D metabolism and absorption, and the presence of underlying medical conditions.

A study conducted on postmenopausal women with low vitamin D levels found that supplementation with vitamin D_3 significantly increased both total and bioavailable vitamin D levels (Hassanein et al., 2023). Another study of overweight and obese adults with vitamin D deficiency showed that daily supplementation with high-dose vitamin D_3 for 16 weeks increased bioavailable vitamin D levels (Entezari et al., 2018).

However, some studies have also reported that vitamin D supplementation does not increase bioavailable levels equally in all individuals. For example, one study of healthy adults found that 12 weeks of vitamin D_3 supplementation did not significantly alter bioavailable vitamin D levels (Jorde and Grimnes, 2011; Chandler et al., 2015; Flueck et al., 2016).

Food fortification with vitamin D can be an effective strategy for increasing vitamin D intake in populations with low sun exposure or inadequate dietary intake.

Possibilities for food fortification with vitamin D are numerous Examples include but are not limited to: milk, fat spreads (Jääskeläinen et al., 2017), milk alternatives such as soy beverages (Vatanparast et al., 2020), orange juice (Tangpricha et al., 2003), flour and cereals (Allen et al., 2015), UV irradiated mushrooms (Cardwell et al., 2018), UV-irradiated yeast for the preparation of bread (EFSA Panel on Dietetic Products Nutrition and Allergies NDA, 2014), and biofortification of chicken eggs (Browning and Cowieson, 2014; Vičič et al., 2023). The media for fortification should be consumed regularly by the majority of the population and should minimally increase production costs and prices for consumers (Pilz et al., 2018).

Reliable total 25(OH)D, DBP, and albumin levels are necessary for calculation accuracy. Laboratory procedures and assays can differ, which can impact the outcomes.

Genetic variants and individual variations in DBP isoforms can affect binding affinities and concentrations, which in turn

can affect the estimated levels of free and bioavailable 25(OH)D (Fernando et al., 2020).

Although helpful, the formulas for determining the free and available fractions of vitamin D have some drawbacks. These include assumptions regarding individual biological differences, measurement variability in proteins, and binding constants.

Immunoassays made specifically to measure free 25-hydroxyvitamin D [25(OH)D], equilibrium dialysis, and ultrafiltration are direct methods for determining levels of free and bioavailable vitamin D. These techniques directly measure the unbound and albumin-bound fractions of vitamin D, with the goal of giving a more realistic picture of the physiologically active forms of the vitamin but their complexity and resource needs prevent frequent use, and are useful in research contexts and for detailed clinical assessments.

Study limitations and future research

The use of bioavailable 25(OH)D or free 25(OH)D may be useful in physiological and pathological conditions that affect DBP, such as pregnancy, genetic polymorphisms, liver disease, and kidney disease (Tsuprykov et al., 2018a), when comparing vitamin D status in premenopausal and postmenopausal women (Vičič et al., 2022) and in ethnically diverse populations (Aloia et al., 2015; Tsuprykov et al., 2018a; Abidin and Mitra, 2020). There is also a discrepancy between calculated free 25(OH)D and directly measured free 25(OH)D. This is more pronounced in African Americans and has been attributed to differences in DBP binding capacity between ethnic groups (Schwartz et al., 2014). Currently there are no generally accepted reference values for calculated or directly measured free and bioavailable 25(OH)D. Zeng et al. (2021) established reference values for free 25(OH)D through linear regression models but emphasized the need for clinical studies to validate their recommendations. Tsuprykov et al. (2018b) established different reference values in pregnant women for both calculated and measured free 25(OH)D. They concluded that both methods may be appropriate.

We did not evaluate bone health or markers of other significant diseases to determine whether bioavailable/free 25(OH)D is a better predictor of low bone mass density and other conditions. We are currently focusing on this assessment in patients with liver disease.

Conclusion

Calculating vitamin D fractions using formulas is a cost-effective and convenient alternative when direct measurement of individual fractions is not available or feasible. However, it is important to consider the assumptions, accuracy and variability associated with the formulas used and recognize that direct

measurement methods may provide more accurate and reliable results.

Our study provides important insights into seasonal variations in vitamin D status and bioavailability. We found that vitamin 25(OH)D concentrations are significantly lower in winter compared to summer, with a slight, non-significant difference in vitamin D binding protein from summer to winter, and significantly higher albumin concentrations in summer. Both bioavailable and free vitamin D levels are significantly lower in winter.

The primary cause of the winter decrease in total 25(OH)D levels is reduced sunlight exposure, which limits vitamin D synthesis. This also leads to reduced bioavailable and free vitamin D, indicating that not only is less vitamin D produced, but the amount available for use by the body is also reduced. The stable DBP levels suggest that DBP is not the main factor in the seasonal variation of free and bioavailable vitamin D. The seasonal increase in albumin concentration during summer may contribute to a greater amount of bioavailable vitamin D. Albumin's weaker binding affinity for vitamin D compared to DBP allows for easier dissociation of vitamin D, shifting the balance toward more free and albumin-bound vitamin D available for cellular uptake.

There is a moderately positive correlation between total and bioavailable 25(OH)D in winter and a lower positive correlation in summer. This stronger winter correlation suggests that during low vitamin D availability, the body relies more on existing stores, while the weaker summer correlation indicates that with higher vitamin D synthesis, bioavailability dynamics are less dependent on total vitamin D levels.

Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Ethics statement

The study protocol was approved by the Ethics Committee of the Faculty of Applied Sciences (Approval No. 2018/4-ET-SK). The studies were conducted in accordance with the local legislation and institutional requirements. All participants signed an informed consent form to participate. Study was registered at ClinicalTrials.gov (ID: NCT03818594).

Author contributions

Conceptualization, JO; formal analysis, JO, DS, KK, and MH; investigation, AJ, UČ, and TF; writing—original draft, JO and VV; writing—review and editing, JO, VV, EB, IP, and KŽ. All

authors contributed to the article and approved the submitted version.

Clinical study on the difference in intestinal microecology between patients with preeclampsia and pregnant women at different stages of pregnancy

Fan Xie†, Huan Zhang†, Min Peng* and TingTing Jiang*

Department of Obstetrics and Gynecology, Maternal and Child Health Hospital of Hubei Province, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China

Objective: To explore the difference in intestinal microecology between patients with preeclampsia and pregnant women at different stages of pregnancy.

Methods: From January 2020 to January 2022, clinical data, including blood routine, lipid profile, and renal function indicators, were gathered from a cohort consisting of 5 cases of preeclampsia and 34 cases of non-preeclampsia. The non-preeclampsia group was further categorized into 6 cases in the First trimester, 13 cases in the Second trimester, and 15 cases in the Third trimester. The data collection took place at the Obstetrics Department of the Maternal and Child Health Hospital of Hubei Province. Additionally, fecal samples were obtained from each subject for 16S rDNA gene sequencing and subsequent analysis. The clinical data and composition characteristics of the gut microbiota in each group were analyzed, and the correlation between gut microbiota and clinical data was analyzed by the Spearman correlation analysis method.

Results: In comparison to pregnant women without preeclampsia, preeclampsia patients exhibited a statistically significant elevation in blood routine parameters (WBC, N, L, and PLT count), a rise in lipid-related indicators (TC, TG, and LDL-C levels), a reduction in HDL-C levels, and an increase in renal function-related indicators (Cr, BUN, UA and Pro levels). Compared with non-preeclampsia pregnant women, preeclampsia women exhibited an augmented diversity of gut microbiota. Differences in gut microbiota composition between the two groups were observed at the gate and genus levels. Moreover, there are significant differences in the composition of gut microbiota between the preeclampsia group and the third-trimester group in terms of genus and species, and this difference is mainly caused by *Prevotella* and *s_ Bacteroides_ Uniformis* and *Ruminococcus_ bromii*. In addition, actinobacteria, bifidobacterium at the genus level, and *Ruminococcus_bromii* at the species level are positively correlated with clinically relevant indicators (excluding HDL-C).

Conclusion: There are significant differences in gut microbiota between preeclampsia pregnant women and late pregnancy pregnant without preeclampsia, including *Prevotella* and *Bacteroides_ Uniformis,* and *Ruminococcus_ bromii*. In addition, these differential bacteria are correlated with most clinical indicators. However, additional comprehensive analysis is required to ascertain the functional correlation between these bacteria and clinical indicators.

Introduction

Preeclampsia is a kind of hypertensive disorder complicating pregnancy (HDP) (Dimitriadis et al., 2023). The incidence of preeclampsia in pregnant women is 3%–5%, which is one of the main reasons for the increased mortality of pregnant women and perinatal infants (Arechvo et al., 2023; Hallum et al., 2023). Preeclampsia has adverse effects on the short-term and long-term health of pregnant women, including stroke, hypertension, and metabolic syndrome (Alanazi et al., 2022). Its offspring are prone to premature delivery, fetal distress, fetal growth restriction (FGR), neonatal hypoglycemia, and even death (Govender et al., 2023). The etiology of preeclampsia is multifactorial, including maternal factors such as family history of preeclampsia, multiple pregnancies, chronic kidney disease, and obesity, and placental factors such as uteroplacental insufficiency and increased placental volume/mass ratio (Syngelaki et al., 2022). However, the pathogenesis of preeclampsia has not been fully clarified. In addition to actively exploring effective treatment methods for preeclampsia and optimizing the prognosis, screening high-risk pregnant women with preeclampsia before pregnancy and taking targeted intervention measures may reduce the incidence of preeclampsia and fundamentally reduce the risk of pregnancy (Zheng et al., 2023).

In recent years, with the in-depth study of intestinal flora, it has been gradually found that changes in intestinal flora may be related to the onset of preeclampsia and affect the intestinal flora of offspring (Chen et al., 2020; Huang et al., 2022). The intestinal microbiota is a complex and huge microbial community living in the digestive tract, which can produce a variety of compounds that regulate the activities of remote organs and play an important role in host metabolism, immunity, and nutrition absorption (Ahmadian et al., 2020). Intestinal microorganisms promote the occurrence of insulin resistance by inducing the chronic inflammatory reaction of the host and causing the accumulation of fat by regulating the energy metabolism gene. Metabolic changes usually occur before clinical symptoms, so metabolic changes can be used as a marker to predict the occurrence and development of preeclampsia. Intestinal microorganisms and the human body form a "superorganism," and the change and management of intestinal microbial structure are of great significance.

This study focuses on investigating the role of intestinal microflora in preeclampsia by comparing pregnant women with preeclampsia as the research group and healthy pregnant women as the control group. The study utilizes macro genome sequencing of stool samples to analyze the structure, species, functional composition, and metabolic pathways of the intestinal microflora. Furthermore, the study examines the potential significance of key species and gene functions in the development of preeclampsia, aiming to gain insights into its pathogenesis. Additionally, the study aims to provide theoretical support for the application of prevention and control strategies by predicting the macrogenome of intestinal microflora in preeclampsia.

Materials and methods

General information

This study collected 39 pregnant women recruited by the Maternal and Child Health Hospital of Hubei Province from January 2020 to January 2022. Inclusion criteria: 1) Filing for prenatal examination at 12^{+6} weeks of pregnancy; 2) Intrauterine singleton; 3) Age: 20–45 years old; 4) Regular prenatal examination, complete clinical data, and acceptable follow-up. Exclusion criteria: 1) hypertension and/or renal dysfunction were diagnosed before or during pregnancy; 2) Large gastrointestinal surgery before pregnancy; 3) History of antibiotics in the first 3 months of pregnancy; 4) Combined with acute and chronic gastrointestinal diseases and severe autoimmune diseases; 5) Complications included gestational diabetes, gestational heart disease, intrahepatic cholestasis and other serious complications of pregnancy. According to the guidelines for the diagnosis and treatment of hypertensive disorders during pregnancy, pregnant women who were diagnosed with preeclampsia after 20 weeks of pregnancy were regarded as the preeclampsia group ($n = 5$). Pregnant women without preeclampsia were divided into First-trimester (1–12 weeks of pregnancy, $n = 6$), Second-trimester (13–25 weeks of pregnancy, $n = 13$), and Third-trimester (26–40 weeks of pregnancy, $n = 15$). Age, pre-pregnancy body mass, and height were recorded, and pre-pregnancy body mass

index (BMI) was calculated. The participants remained in a state of rest for 5 min, subsequently assuming a seated position, attentively relaxing their limbs, and selecting the cuff. The blood pressure of the right upper limb was measured, the cuff was at the same level as the heart, and the systolic blood pressure (SBP) and diastolic blood pressure (DBP) were recorded. The informed consent of all the subjects was signed by themselves or their families, and the ethics committee of the Maternal and Child Health Hospital of Hubei Province reviewed and approved the research (approval number: 20190911).

Clinical data collection

Determination of blood cell index

Peripheral blood (30 μL) was collected from the subjects' fingers and mixed with EDTA anticoagulant. The red blood cell (RBC) count, white blood cell (WBC) count, neutrophil count (N), lymphocyte count (L), platelet (PLT) count, and hematocrit (HCT) were measured by SYSMEX 5 classification automatic blood cell analyzer. The sample shall be tested after the quality control is qualified.

Collection and detection of serum samples

In the morning, 5 mL of elbow vein blood was collected from subjects on an empty stomach and centrifuged at 3,000 r/min for 10 min. The supernatant serum was collected, and total cholesterol (TC), triglyceride (TG), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), creatinine (Cr), urea nitrogen (BUN), and uric acid were measured by Beckman Coulter AU 5800 automatic biochemical analyzer.

Urine sample collection and detection

A sample of 24-h urine was collected, and the first urine was discarded at 6 a.m. All urine after 24 h was collected the day before, including urine at 6 a.m. the next day, and the 24-h total urine output was recorded. Using a Hitachi 7180 biochemical analyzer, the pyrogallol red method was used to measure the quantity of urine protein per milliliter of urine. 24 h urine protein quantity = urine protein quantity per milliliter of urine × 24 h urine volume.

Collection of stool samples and DNA extraction

Fresh fecal samples were collected from the subjects in sterile containers and immediately stored in liquid nitrogen. Following the standard protocol, 200 mg of each frozen fecal sample was obtained, and the genome was extracted using the QIAamp DNA Fecal Genomic DNA Extraction Kit (QIAGE, Germany). The concentration of the extracted DNA was determined using the NanoDrop 2000 spectrophotometer (Thermo Scientific, United States). The 16S rDNA V3 and V4 variable regions of all samples were amplified using the forward primer 338F (5′-ACCTAC GGGGCAG-3′) and the reverse primer (5′-GACTACHVGGGTWTCTAAT-3′).

16S ribosomal RNA (16S rRNA) amplicon pyrosequencing and microbial analysis

The products obtained from polymerase chain reaction (PCR) were quantified using a QuantiFluor ST fluorometer (Promega, United States). The mixture of PCR products was purified using a gel extraction kit provided by QIAGEN (Hilden, Germany). Illumina MiSeq instrument (Illumina, San Diego, California, United States) was utilized to establish a database, and data were assessed using fastqc (version 0.11.8) and multiqc (version 1.10). The metagenomic data underwent automatic low-quality data pruning and filtering using trim_galore (version 0.6.7). Bowtie (version 2.4.5) was used to compare RNA sequences with internal reference genes. Microbiome analysis was performed with Metapelan (version 3.0).

Usearch was used to cluster Tags with a similarity threshold of 97%. The α diversity (Shannon index) was determined using mother (version 1.39.1). Bray Curtis distance algorithm was used for principal component analysis (PCA). By dividing the number of sequences for phyla, genus, and species by the total number of sequences, the relative abundance was determined by applying normalization. The Linear Discriminant Analysis (LDA) method was used to evaluate the difference in species abundance among different samples. The threshold of LDA was 2. To facilitate a more comprehensive comparison of microbial communities, a phylogenetic tree was constructed using FastTree (ver2.1.9).

Statistical analysis

All statistical analyses were performed using SPSS 21.0 software (SPSS Inc., Chicago, Illinois, United States) and the results were presented as mean ± standard deviation. The statistical significance of differences between two or three groups (or more) was determined using unpaired two-tailed t-tests or one-way ANOVA. The correlation analysis was conducted using Spearman correlation and the results were expressed as Spearman coefficient. The p-value of the Spearman correlation was adjusted using the FDR method. $p < 0.05$ was considered statistically significant. GraphPad Prism 8.0 software (GraphPad Software, Inc., La Jolla, CA, United States) was utilized for data visualization.

Results

General data comparison

The age of pregnant women in the first trimester was (29.50 ± 3.62) years old, BMI before pregnancy was (19.69 ± 0.90) kg/m^2, SBP was (117.83 ± 6.65) mmHg, and DBP was (74.33 ± 5.20) mmHg. The age of pregnant women in the second trimester was (30.50 ± 3.15) years old, BMI before pregnancy was (20.35 ± 1.30) kg/m^2, SBP was (112.69 ± 5.62) mmHg, and DBP was (73.15 ± 4.54) mmHg. The age of pregnant women in the third trimester was (29.21 ± 2.58) years old, BMI before pregnancy was (20.66 ± 1.86) kg/m^2, SBP was (117.64 ± 6.80) mmHg, and DBP was (74.07 ± 4.23) mmHg. The age of preeclampsia pregnant women was (29.6 ± 2.65) years old, BMI before pregnancy was (20.2 ± 1.06) kg/m^2, SBP was (115.40 ± 5.46) mmHg, and DBP was (73.40 ± 4.31) mmHg. The results showed that age, BMI before pregnancy, and blood pressure of preeclampsia pregnant women were not significantly different from those of pregnant women at different stages of pregnancy ($p > 0.05$) (Figures 1A–D).

Comparison of blood cell parameters

RBC count of pregnant women in early pregnancy was (4.05 ± 0.22) × 10^{12}/L, WBC count was (8.86 ± 0.72) × 10^9/L, PLT count was (303.50 ± 25.99) × 10^9/L, N count was (6.98 ± 0.49) × 10^9/L, L count was (1.64 ± 0.15) × 10^9/L, and HCT was (36.24 ± 1.24)%. RBC count of pregnant women in the second trimester was (4.05 ± 0.25) × 10^{12}/L, WBC count was (8.92 ± 0.68) × 10^9/L, PLT count was (310.00 ± 23.32) × 10^9/L, N count was (7.07 ± 0.37) × 10^9/L, L count was (1.67 ± 0.13) × 10^9/L, and HCT was (36.04 ± 2.06)%. RBC count of pregnant women in the third trimester was (4.06 ± 0.19) × 10^{12}/L, WBC count was (8.90 ± 0.87) × 10^9/L, PLT count was (307.07 ± 23.47) × 10^9/L, N count was (7.10 ± 0.32) × 10^9/L, L count was (1.69 ± 0.12) × 10^9/L, and HCT was (36.06 ± 2.47)%. RBC count of preeclampsia pregnant women was (4.09 ± 0.14) × 10^{12}/L, WBC count was (10.93 ± 1.23) × 10^9/L, PLT count was (344.00 ± 23.90) × 10^9/L, N count was (8.17 ± 0.58) × 10^9/L, L count was (1.92 ± 0.09) × 10^9/L, and HCT was (36.10 ± 2.62)%. The results showed that the WBC count, N count, L count, and PLT count of preeclampsia pregnant women were significantly higher than those of

FIGURE 2
Comparison of blood cell parameters between preeclampsia and pregnant women at different stages of pregnancy. **(A)** Red blood cell count; **(B)** White blood cell count; **(C)** Neutrophil count; **(D)** Lymphocyte count; **(E)** Platelet count; **(F)** Hematocrit. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$, ****$p < 0.0001$.

pregnant women at different stages of pregnancy ($p < 0.01$, $p < 0.001$, $p < 0.0001$, $p < 0.05$) (Figures 2A–F).

Comparison of serum lipid indexes

TC, TG, LDL-C, and HDL-C were (4.32 ± 0.39) mmol/L, (1.24 ± 0.11) mmol/L, (2.32 ± 0.11) mmol/L, and (1.60 ± 0.15) mmol/L, respectively in early pregnancy. TC, TG, LDL-C, and HDL-C were (4.32 ± 0.32) mmol/L, (1.26 ± 0.13) mmol/L, (2.37 ± 0.14) mmol/L, and (1.53 ± 0.19) mmol/L, respectively in the second trimester of pregnancy. TC, TG, LDL-C, and HDL-C were (4.40 ± 0.22) mmol/L, (1.35 ± 0.11) mmol/L, (2.38 ± 0.14) mmol/L, and (1.52 ± 0.19) mmol/L, respectively in the third trimester of pregnancy. In preeclampsia pregnant women, TC was (4.98 ± 0.40) mmol/L, TG was (1.58 ± 0.11) mmol/L, LDL-C was (2.60 ± 0.10) mmol/L, and HDL-C was (1.27 ± 0.11) mmol/L. The results showed that the levels of TC, TG, and LDL-C in preeclampsia women were significantly higher than those in different stages of pregnancy ($p < 0.01$, $p < 0.001$, $p < 0.0001$, $p < 0.05$), while the levels of HDL-C were significantly lower ($p < 0.05$) (Figures 3A–D).

Comparison of renal function indicators

Cr of pregnant women in early pregnancy was (37.43 ± 1.74) μmol/L, BUN was (2.70 ± 0.13) mmol/L, UA was (296.13 ± 11.27) μmol/L, and Pro was (0.11 ± 0.02) g/24h. Cr of pregnant women in the second trimester was (37.05 ± 2.02) μmol/L, BUN was (2.73 ± 0.21) mmol/L, UA was (308.50 ± 13.82) μmol/L, and Pro was (0.11 ± 0.02) g/24h. Cr of pregnant women in the third trimester was (37.85 ± 2.46) μmol/L, BUN was (2.72 ± 0.15) mmol/L, UA was (308.86 ± 13.03) μmol/L, and Pro was (0.11 ± 0.03) g/24h. Cr of preeclampsia pregnant women was (57.10 ± 1.97) μmol/L, BUN was (3.34 ± 0.23) mmol/L, UA was (359.14 ± 22.64) μmol/L, and Pro was (0.20 ± 0.03) g/24h. The results showed that the levels of Cr, BUN, UA, and Pro in preeclampsia women were significantly higher than those in different stages of pregnancy ($p < 0.0001$) (Figures 4A–D).

Analysis of flora results

By observing the data quality of the original data, it was found that the sequencing data of 39 fecal samples were normal, and

FIGURE 3
Comparison of serum lipid indexes between preeclampsia and pregnant women at different stages of pregnancy. **(A)** Total cholesterol; **(B)** Triglyceride; **(C)** Low-density lipoprotein cholesterol; **(D)** High-density lipoprotein cholesterol. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$, ****$p < 0.0001$.

most of the sequencing readings were above q30, so there was no need to filter the samples. Shannon index can reflect the species diversity of the community. As shown in Figures 5A, B, the preeclampsia group and the First-trimester group had a higher diversity of intestinal flora. In addition, the gradual progression of the pregnancy cycle appears to be associated with a gradual decline in the diversity of the gut microbiota of pregnant women (Figures 5A, B).

At the gate level, the bar chart and the box chart were drawn with the relatively abundant phylum. The results showed that there were significant differences in the levels of *Bacteroides* and Actinobacteria between preeclampsia and other gestational periods, and the differences were more obvious between preeclampsia and other pregnancy periods (Figures 6A–C).

At the genus level, the bar chart and box chart were drawn with the relatively abundant bacteria. The results showed that the level of *Bacteroides* and *Bifidobacterium* in preeclampsia and other pregnancy periods was significantly different (Figures 7A, B). In addition, compared with other pregnancy periods,

Lachnospiracea increased in preeclampsia (Figures 7A, B). The PCA diagram at the generic level also showed that the difference between preeclampsia and late pregnancy was the most obvious in the overall difference comparison of each group, and the difference was mainly caused by *Prevotella* (Figure 7C). According to LDA, there were significant differences in abundance between different groups. At the genus level, the microbial community structure of the First-trimester group was mainly represented by *lachnospira* and *lachnochlostritium* under the phylum Firmicutes. The microbial community structure of the Second-trimester group was mainly represented by unclassified Proteobacteria under the phylum *Proteobacteria*; The microbial community structure of the preeclampsia group was mainly represented by *Actinobacteria* and *Bifidobacterium* under Phylum Actinobacteria (Figure 7D).

At the species level, the bar chart and box chart were also drawn with the top 10 species of relative abundance. The results showed that the abundance of *Bacteroides_uniforms* was relatively low in preeclampsia, while the abundance of

FIGURE 4

FIGURE 5
Alpha diversity analysis of microbial communities in different stages of pregnancy and preeclampsia. **(A)** Shannon index analysis of each sample; **(B)** Compare the Shannon index analysis of samples between groups. The Shannon index reflects the microbial composition. A higher Shannon index signifies a greater level of community diversity.

FIGURE 6
Analysis of bacterial flora level in different stages of pregnancy and preeclampsia. **(A)** Microbial distribution of each sample at the phylum level; **(B)** The distribution of the top 9 microorganisms at the phylum level in each group; **(C)** Differences in inter-group microbiota at the phylum level of principal component analysis (PCA).

Eubacterium Rectale was relatively high (Figures 8A, B). The PCA diagram at different levels also showed that in the comparison of the overall differences among the groups, the differences between preeclampsia and late pregnancy were obvious, and the main causes of the differences were *Bacteroides_uniforms* and *Ruminococcus_ bromii* (Figures 8C, D). Based on the LDA, at the species level, the microbial community structure in the First-trimester group was predominantly characterized by the presence of *Lachnospira_pentinoschiz*a, *Bacterodies_salyersiae* and *Bacterodies_ cellulosilyticus*. In the Second-trimester group, the bacterial genus structure was represented by *Proteobacteria_bacterium_CAG_139*, *Parasutterella_excrementihomins*, *Clostridium_citroniae,* and *Clostridium_asparagiforme*. Conversely, the species structure of the preeclampsia microbiota was predominantly represented by *Ruminococcus_gnavus*, *Blautia_sp_CAG_257*, and *Streptococcus_ infantis* (Figure 8E).

Correlation analysis

The correlation between different grades of bacteria and clinical data was analyzed. The results showed that *Bacteroides* at the gate level (except HDL-C) and *Bacteroides* at the genus level were negatively correlated with all clinically relevant indicators ($p < 0.05$, $p < 0.01$, $p < 0.001$), while *Bacteroides* at the gate level was positively correlated with HDL-C level ($p < 0.05$) (Figure 9). *Bacteroides_uniformis* at different levels were negatively correlated with WBC, TC, TG, Cr, UA, and Pro (Figure 9). In addition, Actinomycetes at the phylum level, *Bifidobacteria* at the genus level, and *Ruminococcus_bromii* at the species level were positively correlated with almost all clinically relevant indicators (except HDL-C) ($p < 0.05$, $p < 0.01$, $p < 0.001$), and negatively correlated with HDL-C level ($p < 0.01$) (Figure 9).

FIGURE 7
Analysis of bacterial flora level in different stages of pregnancy and preeclampsia. **(A)** Microbial distribution of each sample at the genus level; **(B)** The distribution of the top 10 microorganisms at the genus level in each group; **(C)** Differences in inter-group microbiota at the genus level of PCA; **(D)** Differential taxa between groups were identified using the LEfSe analysis at a threshold of 2.

Discussion

Preeclampsia is a metabolic syndrome related to pregnancy (Udenze, 2016; Hodgman et al., 2022). Hypertension and proteinuria occur after 20 weeks of pregnancy, which is the main cause of morbidity and mortality of pregnant women and perinatal infants. Its pathogenesis and its relationship with obstetric complications is a matter of concern today (Litwinska et al., 2021). At present, there is no reliable, effective, and economic screening method to predict preeclampsia (Khan et al., 2020). Studies have shown that some hematological changes occur during pregnancy, such as preeclampsia. The pathogenesis of preeclampsia is divided into two consecutive stages. Among them, the first stage occurs at the maternal-fetal junction. Due to the insufficient infiltration of trophoblast cells in the uterine wall and spiral artery, the blood flow of the uteroplacental artery is reduced, and the placental perfusion is insufficient, resulting in oxidative stress and placental dysfunction. This hypoxia state can induce

inflammation by releasing chemokines, promoting cytokines, anti-angiogenesis factors, and neutrophils. The second stage begins with the infiltration of activated neutrophils into the maternal vascular tissue and is related to maternal systemic vascular inflammation, which can lead to vasoconstriction, hypertension, endothelial dysfunction, and end-organ ischemia. The above conditions will lead to the increase of white blood cells and neutrophils in the peripheral blood of preeclampsia pregnant women (Gogoi et al., 2019; Lu and Hu, 2019). A blood routine is a simple and practical test item, in which RBC, WBC, PLT, N, and L are common peripheral blood parameters in blood routine. The results of this study showed that the WBC count, N count, L count, and PLT count of preeclampsia pregnant women were significantly higher than those of pregnant women at different stages of pregnancy. The main reason for the increase of WBC during pregnancy is the increase of granulocytes caused by bone marrow proliferation and the left shift of the nucleus, that is, more immature WBC appears in the blood circulation (Awor et al., 2023). Although the

FIGURE 8

number of WBCs increased, the chemotaxis and adhesion function of WBCs decreased from the second trimester of pregnancy. The inhibition of WBC function during pregnancy was related to the inhibition of humoral-cellular immune regulation function. Due to the poor ability of N denaturation, WBC is detained in the capillary in the low perfusion area of the thrombosis site, which releases lysosomes, histamines, leukotrienes, and other substances that are harmful to blood flow, resulting in microcirculation blood flow disorder (Moodley et al., 2020; Abdelzaher et al., 2022). The etiology theory of hypertensive disorder complicating pregnancy also believes that the abnormal immune regulation function and the toxic effect of oxidative stress reaction ultimately lead to N inflammatory infiltration.

The process of lipid metabolism *in vivo* is complex, and its parameters are risk factors for the occurrence and development of coronary heart disease, atherosclerosis like artery Congee, hypertension, and other diseases (Negre-Salvayre et al., 2022; Salma, 2022). Research shows that with the growth of pregnancy, the blood lipid level of normal pregnant women will increase (Vaught et al., 2023). The change in blood lipids in pregnant women is considered an adaptive change to support fetal development, but abnormal blood lipids will lead to adverse pregnancy outcomes including preeclampsia (Yang et al., 2022). The results of this study show that the serum lipid level of preeclampsia pregnant women were higher than that of other pregnancy periods, suggesting that the changes in serum lipid in early pregnancy have certain predictive value for preeclampsia. The lipid peroxidation of pregnant women is significantly enhanced, which can further promote the production and secretion of inflammatory factors, cause vascular endothelial damage, and promote the occurrence and development of preeclampsia (Phoswa and Khaliq, 2021).

Creatinine is mainly filtered by glomerulus and not reabsorbed by renal tubules (Tesfa et al., 2022; Wind et al.,

2022). It is a good indicator of glomerular filtration function. Serum uric acid is the product of purine metabolism in the body, and the physiological concentration of uric acid has a positive effect on the body (Atigan et al., 2022). For pregnant and lying-in women, uric acid concentration is affected by continuous physiological changes during the whole pregnancy. In early pregnancy, due to the increase in blood volume and glomerular filtration rate, serum uric acid decreases by about 25%–35%. In the second trimester of pregnancy, the serum uric acid concentration begins to rise and is close to or even higher than the uric acid value of non-pregnant women at term. Research shows that the sudden increase in serum uric acid concentration may be related to the development of potential hypertension, and the adverse outcome of preeclampsia patients is more related to high uric acid concentration (Yu et al., 2023). In addition, a large amount of proteinuria can lead to hypoproteinemia, which can promote the formation of pleural effusion and ascites in severe cases, and affect respiration function in pregnant women. At the same time, hypoproteinemia can also stimulate the mother to increase the synthesis of lipids and lipoproteins (Malz, 1946). Hyperlipidemia

can cause placental atherosclerosis. In addition, the spasm of placental arterioles can increase the blood flow resistance, and the placental blood flow perfusion is insufficient, putting the fetus in a chronic hypoxia state for a long time. It can also cause fetal intrauterine malnutrition, fetal growth restriction, fetal distress, and neonatal asphyxia. Therefore, the continuous occurrence of urinary protein will lead to further aggravation of preeclampsia, which can form a vicious circle. The results of this study showed that the levels of Cr, BUN, UA, and Pro in preeclampsia pregnant women were significantly higher than those in pregnant women at different stages of pregnancy, suggesting that abnormal renal function may be the influencing factor for the occurrence and development of preeclampsia.

In order to adapt to the physiological state during pregnancy and provide a good growth and development environment for the fetus, some metabolic changes will occur in the mother, and the abundance and diversity of intestinal flora will also change significantly during pregnancy, including preeclampsia. Intestinal flora can secrete inflammatory factors and anti-inflammatory factors, which are in a stable balance. Once the flora is out of balance, the balance will be destroyed, and inflammatory factors will increase, which will damage vascular endothelial cells, and then affect the stability of the blood system. *Bacteroides*, Bifidobacterium, and Lachnospiraceae have been proven to be related to the inflammatory-immune response mediated by intestinal flora (Miao et al., 2021; Huang et al., 2022; Lv et al., 2022). In addition, dyslipidemia and renal dysfunction are also important factors affecting the occurrence and development of preeclampsia. Bifidobacterium and Lachnospiraceae have been proven to be related to dyslipidemia and renal dysfunction (Sun et al., 2020). This is consistent with the results of this study. In our study, we observed a decrease in the abundance of *Bifidobacteria* and an increase in the abundance of *Lachnospiraceae* within the preeclampsia group. Furthermore, these patients exhibited abnormal blood lipid profiles and renal dysfunction.

To sum up, compared with pregnant women at different stages of pregnancy, the blood routine-related indicators (WBC count, N count, L count, and PLT count) of preeclampsia pregnant women were significantly increased, the blood lipid-related indicators (TC, TG, and LDL-C levels) were significantly increased, while the HDL-C level was significantly decreased, the renal function-related indicators (Cr, BUN, UA, and Pro levels) were significantly increased, the alpha diversity was relatively high, and the flora was relatively rich, which was the largest difference from late pregnancy. Among them, *Bacteroides* and actinomycetes have great differences at the phylum level, *Bacteroides* and *Bifidobacteria* have great differences at the genus level, *Bacteroides uniformis* and *Ruminococcus Bromii* have great differences at the species level, and the difference bacteria have a correlation with the relevant indicators of

pregnancy. However, a more extensive sample size is necessary to conduct further investigation into these findings, particularly in relation to the outcomes of gut microbiota.

Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/supplementary material.

Ethics statement

The studies involving humans were approved by the Ethics Committee of Maternal and Child Health Hospital of Hubei Province and written informed consent was provided by all patients prior to the study start. All procedures were performed in accordance with the ethical standards of the Institutional Review Board and The Declaration of Helsinki, and its later amendments or comparable ethical standards. The studies were conducted in accordance with the local legislation and institutional requirements. The participants provided their written informed consent to participate in this study. Written informed consent was obtained from the individual(s) for the publication of any potentially identifiable images or data included in this article.

Author contributions

FX and HZ designed the research study. MP and TJ performed the research. FX and HZ provided help and advice on the experiments. MP and TJ analyzed the data. FX and HZ wrote the manuscript. MP and TJ reviewed and edited the manuscript. All authors contributed to the article and approved the submitted version.

Funding

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
