Wound healing is a considerable problem for clinicians. Ever greater attention has been paid to the role of Chinese herbal monomers and compounds on wound healing. This study aims to elucidate the wound healing mechanism of Modified Hongyu Decoction (MHD) *in vivo* and *in vitro*. MHD wound healing activity *in vivo* was evaluated using an excision rat model. H and E staining, Masson's staining and immunofluorescence of wound tissue on days 7 and 14 were performed to evaluate the efficacy of MHD on wound healing. Subsequently, human umbilical vein endothelial cells (HUVECs) were used to evaluate wound healing characteristics *in vitro*. Cell Counting Kit-8 (CCK-8) and scratch assays were conducted to assess the effects of MHD on the proliferation and migration of HUVECs. The involvement of the VEGF/PI3K/Akt signaling pathway was assessed by western blotting. The rats in the MHD group displayed more neovascularization and collagen fibers. Western blotting of wound tissue showed that VEGF, PI3K, p-Akt and p-eNOS expression were significantly increased ($p<0.05$) in the MHD group. Cell Counting Kit-8 and scratch assays demonstrated that MHD promoted HUVECs proliferation and migration. MHD treatment significantly increased VEGF, PI3K, p-Akt and p-eNOS expression in HUVECs ($p<0.05$), which was inhibited by LY294002. Both *in vivo* and *in vitro* data indicated that MHD promotes wound healing by regulating the VEGF/PI3K/Akt signaling pathway.

Abbreviations: eNOS, endothelial Nitric Oxide Synthases; HPLC-Q-TOF/MS, high performance liquid chromatography coupled with quadrupole time-of-flight tandem mass spectrometry; HUVECs, human umbilical vein endothelial cells; MHD, Modified Hongyu Decoction; PI3K, PI3 kinase; rb-bFGF, recombinant bovine basic fibroblast growth factor; VEGF, vascular endothelial growth factor; VEGFR2, vascular endo-thelial growth factor receptor 2; α-SMA, alpha-smooth muscle actin

INTRODUCTION

Chronic and refractory wounds have become not only a major problem in the medical field, but also a challenge for doctors. Many factors, including chronic inflammation, diabetes mellitus and malignant tumors, can lead to delayed wound healing and even failure to heal. Indeed, millions globally suffer from chronic wounds. For example, a study from Germany in 2012 found that the prevalence of chronic nonhealing wounds was 1% to 2% in the general population (Heyer *et al.*, 2016). This not only affects their normal activities and reduces their quality of life, but also results in major social and economic problems. Care for such conditions has been reported to account for 2% to 3% of the healthcare budgets in developed countries (Frykberg & Banks, 2015; 2013; Richmond *et al.*, 2013). Many biological agents and dressings, containing a variety of growth factors, have been used to accelerate wound healing. However, there are also some complications, including the need for precise dosing to avoid the potential for excess scar formation and bioavailability (Zielins *et al.*, 2015). Additionally, these external treatments may cause adverse stimulation to the local wound, and changing wound dressings may cause unbearable pain for patients.

Wound healing is a dynamic and complex biological process, normally involving four phases: hemostasis, inflammation, proliferation and remodeling (Landen *et al.*, 2016). In the proliferative stage, neovascularization is an essential component of tissue repair, and also a key step of wound healing (Eming *et al.*, 2014; Shiojima & Walsh, 2002). Protein kinase B (Akt), a serine/threonine kinase, is a vital signal center for a wide range of cellular functions. PI3 kinase-dependent activation of Akt further affects the activity of several downstream pathways involved in cell proliferation, angiogenesis, senescence, apoptosis and cellular survival (Hoke *et al.*, 2016; Li & Wang, 2014). As upstream proteins of extracellular signaling, growth factors, including pro-angiogenic growth factors, activate many signaling pathways, including PI3K/Akt, which modulate several cellular activities involved in acute wound healing and maintenance of tissue homeostasis (Squarize *et al.*, 2010). Additionally, the bioactivities of pro-angiogenic growth factors are closely related to endothelial cell chemotaxis at the proliferative phase of angiogenesis and subsequently normal angiogenesis (Eming *et al.*, 2014; Zielins *et al.*, 2015). Among many pro-angiogenic growth factors, vascular endothelial growth factor (VEGF) is the most specific pro-angiogenic growth factor of the vascular endothelium (D'Alessio *et al.*, 2015). It activates the PI3K/Akt signaling pathway

after binding with VEGF receptor 2 (VEGFR2) on the cell membrane of endothelial cells, thereby participating in cell proliferation and angiogenesis (Olsson *et al.*, 2006).

Modified Hongyu Decoction (MHD) is composed of *Pulsatilla chinensis*, *Pseudostellariae radix*, *Sargentodoxa cuneate*, *Patrinia scabiosaefolia*, *Astragali radix* and *Cornus officinalis*. According to the theory of traditional Chinese medicine, it has the effect of clearing heat and toxic materials, benefiting qi for activating blood circulation. In clinical trials, MHD has been shown to have an outstanding effect on promoting wound healing. However, the underlying mechanisms have not been elucidated. Some active ingredients of MHD have been proved to protect wounds. Previous studies have reported that *A. radix* and its active ingredients, such as Astragaloside IV and Astragalus polysaccharide, promoted wound re-epithelization and angiogenesis and regulated extracellular matrix remodeling by enhancing VEGF expression and activating the PI3K/Akt signaling pathway (Zhang *et al.*, 2009; Chen *et al.*, 2012; Zhao *et al.*, 2017). Other active ingredients, for example, 5-hydroxymethylfurfural derived from processed *C. officinalis*, protected human umbilical vein endothelial cells (HUVECs) injured by high glucose and increased p-Akt protein expression (Cao *et al.*, 2013). Additionally, an aqueous extract of *Patrinia villosa* induced Akt phosphorylation and enhanced HUVECs proliferation and migration, consequently promoting angiogenesis (Jeon *et al.*, 2010). The above research indicated that the Akt signaling pathway may be the vital pathway for MHD to promote wound healing. Therefore, we investigated the therapeutic effect and the mechanism of MHD on wound healing *in vivo* and *in vitro* models.

MATERIALS AND METHODS

MHD preparation

The raw herbs for MHD were purchased from Beijing Tongrentang Co. Ltd (Beijing, China) (origin place of the raw herbs shown in Table S1 at https://ojs.ptbioch.edu.pl/index.php/abp/). *P. chinensis* 15 g (20180620), *P. radix* 15 g (200107), *S. cuneate* 30 g (20191204), *P. villosa* 30 g (200110), *A. radix* 30 g (20200214) and *C. officinalis* 15 g (20191218) were combined and submerged in distilled water (1000 mL) for 30 min. Subsequently, the mixture was extracted twice (1000 mL first followed by 500 mL) over 1 h. After two rounds of extraction, the resulting mixture was filtered. The filtrate was concentrated until the established drug content was 1.35 g/mL. To prepare the MHD extract used for cell experiments, 7.5 mL MHD (1.35 g/mL) was lyophilized using a LAB-1A-50E freeze dryer (Biocool, Beijing, China), yielding 2.02 g powder that was used in the *in vitro* study.

High-performance liquid chromatography of quadrupole time-of-flight mass spectrometry (HPLC-Q-TOF/MS) analysis of the main chemicals in MHD

For the qualitative analysis of the main ingredients in MHD, 0.2 mL MHD was extracted by adding 1 mL ethanol to a 1.5 mL tube. After 10 minutes of vortex, the mixture was centrifuged at $21\,000 \times g$ for 5 min. The supernatant was collected and injected into a HPLC-Q-TOF/MS system which contained a Shimadzu UFLC 20ADXR system (Kyoto, Japan) and TripleTOF 5600 mass spectrometer (AB SCIEX, USA).

For the column separation, a Waters ACQUITY™ BEH C18 column (1.7 μm, 2.1×50; 1.7 μm) was used, and the column temperature was set at 35°C. Separation was achieved using a mobile phase of 0.02% formic acid-water as solvent A and acetonitrile as solvent B. The flow rate was 0.3 mL/min and the gradient elution program was as follows: 0–2 min, 10% solvent B; 2–30 min, 10–90% solvent B; 30–32 min, 90% solvent B; 32–33 min, 90–10% solvent B; 33–35 min, 10% solvent B. An aliquot of 2 μL supernatant was injected into this system. For the MS analysis, the elution was by ionization using the ESI source both in the positive and negative modes, which could acquire more MS data. In this study, the m/z scan for MS1 was set at a range of 50–1200, and for information-dependent acquisition, the MS2 range was 50–1000. The other parameters used in this study were as follows: ion source gases 1 and 2 were both 50 psi, DP was set at 55 eV, EP was set at 15 ev and the collision energy was 15 eV.

Experimental animals

Twenty-four healthy male Sprague-Dawley (SD) rats (175–195 g) purchased from the Medical Center of Suzhou University (Suzhou, China) (certificate no. SCXK (Su) 2017-0001) were used in this study. Before the experiments, all rats were adaptively fed for one week in polyethylene boxes with free access to autoclaved water and diet under controlled temperature (25°C) and a 12-h light/12-h dark cycle. All experiments were performed in adherence to the guidelines of the Institutional Animal Care and Use Committee of China and were approved by the Ethical Committee of Zhangjiagang TCM Hospital Affiliated to Nanjing University of Chinese Medicine (2021-08-89).

Incisional wound rat model and treatment

The rats were randomly assigned to the following four groups (n=6 rats/group): control group, recombinant bovine basic fibroblast growth factor (rb-bFGF) group (as the positive group), low-dose MHD (L-MHD) group, high-dose MHD (H-MHD) group. All rats were weighed and subsequently anesthetized by intraperitoneal administration of 2% pentobarbital sodium (30 mg/kg). The dorsal hair was shaved, the shaved area was disinfected with 75% alcohol and 2 cm-diameter full-thickness skin wounds were produced on the dorsum in the midline of the backs. The skin wound lost the epidermis, most of the dermis, the fat, and the panniculus carnosus-exposing the fascia layer (Amin *et al.*, 2015).

After surgery, surgical dressing was applied to the rats and the animals were maintained in individual cages. The L-MHD group was given 6.975 g/kg MHD, while the H-MHD group received 13.95 g/kg MHD by intragastric administration once daily. In the rb-bFGF group, each skin wound was topically given rb-bFGF (150 AU/cm², Zhuhai Essex Bio-Pharmaceutical Co., Ltd, Guangdong, China) three times daily. On days 7 and 14, three rats in each group were euthanized by overdose anesthesia (Li *et al.*, 2015), and the wound granulation tissue, liver and kidney were excised from each rat. A portion of the harvested tissue was immediately stored in liquid nitrogen, and the remaining tissue, liver and kidney were maintained in 10% buffered formalin for the following tests.

Wound contraction assay

On days 0, 3, 7, 10 and 14 after injury, an image of each wound area was obtained and measured. The percentage of wound contraction was calculated by the following equation (Amin *et al.*, 2015): wound contraction = (initial wound area − present wound area)/(initial wound area) ×100%.

Histological analysis

The wound tissues, liver and kidney tissues collected at different time points, and livers and kidneys collected after rats sacrificed in each group were fixed with 10% formalin, dehydrated, embedded in paraffin and cut into 5 μm sections. Hematoxylin and Eosin (H&E) staining and Masson trichrome staining were performed using staining kits (Solarbio Technology Co., Ltd, Beijing, China) according to the manufacturer's instructions. Wound healing characteristics, including new epithelium, granulation tissue and collagen deposition, were observed under an inverted microscope (Olympus CX43). Organ sections were stained with H&E for toxicity evaluation.

Immunofluorescence staining

Paraffin sections of wound tissue from days 7 and 14 were dehydrated with xylene and gradient ethanol and subsequently repaired with sodium citrate. Following three washes with 0.3% Triton in PBS to rupture the cell membranes, sections were blocked with immunofluorescence blocking solution for 1 hour at room temperature and incubated with CD31 (ab28364, 1:50, Abcam), α-SMA (#19245, 1:50, CST), VEGFR2 (#9698, 1:800, CST), CD34 (ab81289, 1:100, Abcam) antibodies overnight at 4°C. Subsequently, the sections were incubated with secondary antibodies, including Alexa Fluor 488 donkey anti-rabbit IgG antibody (Invitrogen, Carlsbad, USA) and Alexa Fluor 555 donkey anti-mouse IgG antibody (Invitrogen, Carlsbad, USA), for 1 hour at room temperature at a dilution of 1:800. Finally, slides were counterstained with DAPI for 10 min and were observed with a laser confocal microscope (Olympus, CKX53), with images obtained using LAS X software (Qimaging, USA).

Cell culture and treatment

Human umbilical vein endothelial cells (HUVECs) were purchased from FUHENG Biotechnology Co., Ltd (Shanghai, China) and identified by the American Type Culture Collection (ATCC; Manassas, VA, USA). The cells were cultured in Endothelial Cell Medium (ECM; FUHENG Biotechnology Co., Ltd, Shanghai, China) supplemented with penicillin (100 U/mL), streptomycin (100 μg/mL) and 15% (v/v) fetal bovine serum (FBS; Beijing Biological Industries Co., Ltd, China) and maintained at 37°C under 5% CO_2. After 3 passages, the cells were used for the experiments.

HUVECs were incubated with different MHD concentrations for 24 h. For blocking assay, HUVECs were treated with different concentrations of general PI3K/Akt inhibitor LY294002 (Sigma).

Cell proliferation assay

Cell proliferation was determined using the cell counting kit-8 (CCK-8) kit (MedChemExpress LLC, NJ, USA) according to the manufacturer's instructions. HUVECs ($2×10^4$ cells, 100 μL per well) with ECM containing 15% FBS were seeded in 96-well plates and incubated

for 24 hours at 37°C under 5% CO_2. The culture medium was replaced by ECM with 15% FBS and different MHD concentrations. For the control group, cells were continued incubation with ECM containing 15% FBS. The MHD concentrations were as follows: 0.1 μg/mL, 1 μg/mL, 5 μg/mL, 10 μg/mL, 50 μg/mL, 75 μg/mL, 100 μg/mL, 200 μg/mL, and 500 μg/mL. Following incubation at 37°C under 5% CO_2. After incubation of 24 hours, the CCK-8 solution was added to each well and incubated at 37°C in humidified 95% air and 5% CO_2 for a further 1 hour. The absorbance was determined at 450 nm for each well using a Microplate Reader (Bio-Rad, Hercules, CA, USA).

Scratch assay

The effect of MHD on HUVECs migration was assessed by the scratch assay (Liang *et al.*, 2007). HUVECs in ECM with 15% FBS were seeded into six-well plates ($2×10^5$ cells/well) and incubated at 37°C under 5% CO_2. When the cells reached approximately 80% confluence, three vertical scratch lines were made in each well using a 200 μL pipette tip, and cell debris was immediately washed out with phosphate-buffered saline (PBS). Subsequently, serum-free ECM (control) and serum-free ECM with MHD (5 μg/mL, 10 μg/mL, 25 μg/mL or 50 μg/mL) were added to the corresponding wells for 24 h of incubation at 37°C and 5% CO_2. Images of the scratches from the same areas in each well were obtained at 0 and 24 hours, respectively, using an inverted microphotograph (Olympus CX43, Tokyo, Japan) at a magnification of 40×. The scratch area was measured using the Image-J software (NIH, USA).

Western blot

Wound tissues or HUVECs were lysed using lysis buffer with RIPA Lysis Buffer, Phenylmethanesulfonyl fluoride (PMSF), Ethylene Diamine Tetraacetic Acid (EDTA) and protease and phosphatase inhibitor. Total protein concentrations were then quantified using the BCA protein assay kit (Thermo Fisher Scientific, Waltham, USA). Subsequently, equal amounts of proteins were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene difluoride membranes (Millipore, Burlington, MA, USA) using a transfer system (Bio-Rad). After blocking in blocking solution for 1 hour at room temperature, the membranes were incubated overnight at 4°C with primary antibodies diluted in primary antibody dilution buffer, followed by incubation with the horseradish peroxidase-conjugated secondary antibodies for 1 hour at 37°C. The antibodies included anti-phosphorylate Akt (p-Akt, #4060, 1:1000, CST), anti-Akt (#4685, 1:1000, CST), PI3K (#4249, 1:1000, CST), VEGFR2 (#9698, 1:1000, CST), anti-phospho-eNOS (p-eNOS, ab215717, 1:1000, Abcam), anti-β-actin (ab8227, 1:5000, Abcam), horseradish peroxidase-conjugated anti-rabbit IgG (1:5000) and anti-mouse IgG (1:5000). Immunosignals were detected using a chemiluminescence detection kit (Millipore, Burlington, MA, USA) and a gel imaging system (Tanon Science&Technology Co., Ltd., Shanghai, China). β-actin was used as an internal reference. The signal intensity was quantified using Image-J software.

Statistical analysis

For statistical analysis, all data values were analyzed and calculated using GraphPad Prism 8.0 (GraphPad Software Inc., San Diego, CA, USA) and expressed as

Figure 1. Total ion chromatography of the standards and the Modified Hongyu Decoction (MHD) in negative/positive mode by HPLC-Q-TOF/MS.

mean ± standard error of the mean (SEM) of three determinations. The data analysis was performed by one-way analysis of variance (ANOVA) followed by Dunnett's test, and $p<0.05$ was considered statistically significant.

RESULTS

HPLC-Q-TOF/MS analysis of MHD

MHD consists of six herbs that are commonly used in China. For the qualitative analysis of the MHD, we constructed an in-house component library of the MHD, then we compared the MS1 and MS2 data with the literature or the standard solutions. Figure 1 shows the total ion chromatography of the standards and the MHD. The main chemical components in MHD detected by HPLC–Q-TOF/MS are shown in Table S2 at https://ojs.ptbioch.edu.pl/index.php/abp/.

Changes in body weight and hepatorenal toxicity in rats after MHD administration

During the entire experiment, the body weight of all the rats increased gradually. There was no significant difference in body weight among the four groups, which

Figure 2. Changes in body weight and hepatorenal toxicity in rats after Modified Hongyu Decoction (MHD) administration.
(**A**) The body weight of each group was increased with time. (**B**) Representative images of H&E staining in the liver and kidney of each group were observed on days 7 and 14 (40× magnification, scale bar=100 μm).

demonstrated that MHD did not affect body weight (Fig. 2A). H&E staining of rats' liver and kidneys showed that, compared with the control group, there were no significant pathological changes in the MHD treatment groups, which indicated that MHD has no hepatorenal toxicity (Fig. 2B).

MHD promoted wound healing *in vivo*

The wound areas of rats were observed, and images were obtained on days 0, 3, 7, 10 and 14. The representative images were combined and are presented in Fig. 3A. It was clear that the wound area in the four groups gradually decreased with time, indicating that the wounds were gradually healing. On day 7, the wound areas in the H-MHD and rb-bFGF groups were smaller than those in the control and L-MHD groups. On day 14, the wound areas in the H-MHD and rb-bFGF groups were almost healed, while the wound areas in the control and L-MHD groups were still apparent (Fig. 3A). Then, the wound areas were measured, and wound contraction of the designated days was plotted against post wounding days, as shown in Fig. 3B. From days 3 to 14, the percentages of wound contraction in the control group were respectively: 9.75%, 50.83%, 63.83% and 82.25%; and in the L-MHD group were respectively: 11.84%, 46.66%, 58.07% and 87.96%; H-MHD group were respectively: 11.84%, 77.94%, 93.18% and 99.52%; and the rb-bFGF group were respectively: 20.89%, 77.93%, 87.26% and 99.11%. On days 7, 10 and 14, the percentages of wound contraction in the H-MHD and rb-bFGF groups were significantly increased compared with the control and L-MHD groups. There was no significant difference in the percentages of wound contraction between the H-MHD and rb-bFGF groups (Fig. 3B). In general, MHD treatment promoted wound healing in rats.

MHD improved wound granulation tissue *in vivo*

H&E staining showed less inflammatory infiltration in the rb-bFGF and H-MHD groups compared with the control and L-MHD groups on day 7 (Fig. 4A). On day 14, epithelial layer regeneration in the H-MHD group

A

B

Figure 3. Modified Hongyu Decoction (MHD) promoted wound healing *in vivo*.
(**A**) Representative images of wound areas in each group on days 0, 3, 7, 10 and 14. (**B**) Percentage of wound contraction of the different groups on days 0, 3, 7, 10 and 14; n=3, *p<0.05, **p<0.01, compared with the control group.

was thicker and more complete than in the other groups (Fig. 4A). Masson's staining revealed more collagen fibers in the wounds treated with rb-bFGF or H-MHD than the control and L-MHD groups on both days 7 and 14 (Fig. 4B). These data indicated that H-MHD was almost comparable with rb-bFGF in promoting wound closure, particularly during the later wound healing stage. In conclusion, MHD significantly increased wound closure in rats in a dose-dependent manner.

MHD enhanced angiogenesis in the wound areas of rats

The quantification of new blood vessel density was defined as the ratio of the number of VEGFR2-, CD31-, CD34- and α-SMA-positive staining to DAPI per field. As shown in Fig. 5, both on days 7 and 14, the number of VEGFR2-, CD31-, CD34- and α-SMA-positive staining were rarely observed in the control and L-MHD groups, whereas significantly more positive staining was seen in the rb-bFGF and H-MHD groups (Fig. 5A–B). The quantification showed that both rb-bFGF and H-MHD augmented the production of VEGFR2, CD31, CD34 and α-SMA in the wound areas in rats, and there

was no significant difference between these two groups (Fig. 5C–D). The results demonstrated that MHD could enhance angiogenesis in the wound areas of rats.

MHD activated the VEGF/PI3K/Akt signaling pathway *in vivo*

To investigate molecular mechanisms underlying the therapeutic efficacy of MHD on dorsal full-thickness excisional wounds in rats, we evaluated the expression of proteins related to the VEGF/PI3K/Akt signaling pathway by western blotting. Both on days 7 and 14, the protein expression levels of VEGFR2, PI3K, p-Akt and p-eNOS in the H-MHD and rb-bFGF groups were significantly (p<0.05) higher than those in the control and L-MHD groups, whereas no significant differences were observed between the H-MHD and rb-bFGF groups (Fig. 6A–B). These results demonstrated that H-MHD activated the VEGF/PI3K/Akt signaling pathway *in vivo*.

MHD promoted HUVECs proliferation and migration

To determine the effect of MHD on the proliferation and migration of HUVECs, the CCK-8 assay, and

Figure 4. MHD improved wound granulation tissue *in vivo*.
(**A**) H&E staining was used to observe the wound tissues of each group on days 7 and 14 (upper: 40× magnification, scale bar=100 μm; lower: 200× magnification, scale bar=20 μm)n =3. (**B**) Masson's trichrome staining was used to analyze the changes in wound tissues of each groups on days 7 and 14 (upper: 40× magnification, scale bar=100 μm; lower: 200× magnification, scale bar=20 μm) n=3.

scratch assay were performed. The results showed that MHD promoted HUVECs proliferation in a concentration-dependent manner, and that the most potent stimulation was at 50 μg/mL (p<0.001) (Fig. 7A). As shown in Fig. 7B–C, the migration areas at 24 h at lower MHD concentrations (5 and 10 μg/mL) were respectively 18.30% and 20.03%, which was similar to that of the control group (11.42%) (Fig. 7B). Treatment with 25 μg/mL MHD clearly (p<0.05) reduced the wound width (31.62%), while treatment with 50 μg/mL MHD extensively (p<0.001) diminished the wound area (68.83%) at 24 h (Fig. 7B). 25 and 50 μg/mL MHD groups increased the migration rate of HUVECs compared with 5 and 10 μg/mL MHD groups (Fig. 7B). These data indicated that MHD accelerated the proliferation and migration of HUVECs in a concentration-dependent manner.

MHD activated the VEGF/PI3K/Akt signaling pathway in HUVECs

HUVECs were incubated with different MHD concentrations for 24 h, and the protein expressions related to the VEGF/PI3K/Akt signaling pathway were detected by western blot. MHD treatment increased the protein expression of VEGFR2, PI3K, p-Akt and p-eNOS of HUVECs in a concentration-dependent manner. The protein expressions of VEGFR2, PI3K, p-Akt and eNOS in the 50 μg/mL MHD treatment group were the highest among all concentrations of MHD groups (Fig. 8A).

Then, we observed the effects of different treatment times on the protein expression. The expression of VEGFR2, PI3K, p-Akt and p-eNOS protein at 5-30 min was increased in a time-dependent manner, while the expressions of protein were decreased at 60-120 min. The expressions of VEGFR2, PI3K, p-Akt and p-eNOS protein at 30 min of the treatment group were highest among all groups (Fig. 8B). Overall, these results indicated that MHD activated the VEGF/PI3K/Akt signaling pathway in HUVECs.

Figure 5. Modified Hongyu Decoction (MHD) enhanced angiogenesis in the wound areas of rats.
(**A–B**) CD31, VEGF, CD34 and α-SMA immunofluorescence staining of wound sections on days 7 and 14 (200× magnification, scale bar =100 μm) (**C–D**) Quantitative analysis of fluorescence intensity in CD31, VEGF, CD34 and α-SMA; n=3, $^*p<0.05$, $^{**}p<0.01$, $^{***}p<0.001$, $^{****}p<0.0001$, compared with the control group.

LY294002 reversed the effect of MHD on VEGF/PI3K/Akt signaling pathway in HUVECs

To further determine whether the angiogenic activity of MHD occurred through the Akt signaling pathway, LY294002 (a PI3K inhibitor) was used. After different concentrations of LY294002 treatment, the expression of PI3K, p-Akt, and p-eNOS were inhibited in a concentration-dependent manner, and the protein expression was significantly decreased after 20 μM and 50 μM

Figure 6. Modified Hongyu Decoction (MHD) activated the VEGF/PI3K/Akt signaling pathway *in vivo*.
(**A–B**) VEGFR2, PI3K and phosphorylation Akt (p-Akt) and eNOS *in vivo* on day 7 (**A**) and day 14 (**B**) were measured by western blot. Data shown in the graphs are representative of the mean ± SEM; n=3, $^*p<0.05$, $^{**}p<0.01$, $^{***}p<0.001$, compared with the control group.

Figure 7. MHD promoted HUVECs proliferation and migration.
(**A**) HUVECs were incubated with different Modified Hongyu Decoction (MHD) concentrations (0.1–500 µg/mL) for 24 h. The concentration-dependent effect of MHD on cell proliferation was determined by the CCK-8 assay; n=3, $^*p<0.05$, $^{**}p<0.01$, $^{***}p<0.001$, $^{****}p<0.0001$, compared with the control group. (**B–C**) The wounds of HUVECs were created and then treated with MHD at 5–50 µg/mL for 24 h. The images were obtained at the same positions at time 0 h and after 24 h treatment with MHD (40× magnification, Scale bar = 100 µm), and cell migration rate was assessed by measuring the distance between the wound edges; n=3, $^*p<0.05$, $^{****}p<0.0001$, compared with the control group.

LY294002 treatment compared with 0 µM LY294002 (Fig. 9A). Then, 20 µM LY294002 was added to MHD treated HUVECs. MHD treatment increased the PI3K, p-Akt and p-eNOS protein expression and the p-Akt/ Akt ratio in HUVECs. While LY294002 reversed the increasing of PI3K, p-Akt and p-eNOS protein expression and the p-Akt/Akt ratio induced by MHD (Fig. 9B). The results indicated that angiogenic activity of Modi-

Figure 9. LY294002 reversed the effect of MHD on the VEGF/PI3K/Akt signaling pathway in HUVECs.
(**A**) HUVECs were incubated with different concentrations of LY294002 (0.1–50 µM) for 24 hours, and the protein expression of PI3K, p-Akt, Akt and p-eNOS was detected by western blot assay. n=3, *$p<0.05$, **$p<0.01$, compared with the 0 µM group. (**B**) HUVECs were incubated with LY294002 (20 µM) before the exposure to MHD (50 µg/mL)After 24 hours of incubation, the protein expression of PI3K, p-Akt, Akt and p-eNOS was detected by western blot assay. n=3, *$p<0.05$, **$p<0.01$, compared with the untreated cells; ##$p<0.01$, ###$p<0.001$, ####$p<0.0001$, compared with MHD-treated cells.

fied Hongyu Decoction (MHD) was responsible for the VEGF/PI3K/Akt signaling pathway.

DISCUSSION

When a wound occurs, granulation tissue composed of new ECM, newly formed blood vessels and fibroblasts will fill the wound bed (Gurtner *et al.*, 2008). Neovascularization can provide oxygen and nutrition for the cells in the wound to maintain fibroblast proliferation, collagen synthesis and reepithelization (Zhang *et al.*, 2016a; Eming *et al.*, 2014), which is essential in wound healing. VEGF is a powerful stimulator of angiogenesis, which directly induces the proliferation and migration of endothelial cells (Simons *et al.*, 2016; Breen, 2007). It is considered to be the key signal molecule of angiogenesis during wound healing (Barrientos *et al.*, 2008). VEGF exerts biological effects by binding and activating VEG-FR2 on the cell membrane (Terman *et al.*, 1992; Eremina & Quaggin, 2004), after which several downstream signaling pathways, including the PI3K/Akt, IP3/Ca^{2+}/eNOS/NO, FAK, p38 mitogen-activated protein kinase and RAS/RAF-MEK/ERK pathways, can be activated (Olsson *et al.*, 2006). Therefore, the PI3K/Akt pathway is defined to be a VEGF-related signaling pathway (Xu *et al.*, 2014; Peng *et al.*, 2016b; Ewald *et al.*, 2014; Peng *et al.*, 2016a), and it is the central pathway to control the angiogenesis process of endothelial cells (Somanath *et al.*, 2006). Previous studies have shown that the PI3K/Akt signaling pathway is essential for the epithelial-mesenchymal transition and keratinocyte migration, and when dysfunctional, leads to compromised wound healing (Lee *et al.*, 2012). Our study confirmed that MHD promotes wound healing by activating the VEGF/PI3K/Akt pathway *in vitro* and *in vivo*.

In the *in vivo* experiments, we observed that a high MHD dose promoted wound contraction, and the effect was equivalent to the rb-bFGF group. Histological

analysis of wound tissues by H&E and Masson's staining confirmed that both the high MHD dose and rb-bFGF could decrease the number of inflammatory cells, facilitate granulation tissue formation and stimulate new blood vessels and collagen fiber formation. Moreover, H&E staining of the liver and kidney showed that MHD displayed no hepatorenal toxicity. We also labeled the markers of neovascular endothelial cells, such as VEGF, CD31, CD34 and α-SMA, using immunofluorescence. VEGF is an angiogenic factor which has high-efficiency and specific targeting characteristics for endothelial cells, and is closely associated with angiogenesis (Breen, 2007). It plays a key role in the initiation of angiogenesis and participates in the proliferation, migration, adhesion and permeability of vascular endothelial cells and other vascular wall components. VEGF promotes angiogenesis not only in physiological processes but also in inflammation, tumor, trauma and other conditions. CD31 is used to label endothelial cells and is expressed in normal blood vessels (Lertkiatmongkol *et al.*, 2016). CD34 is a type I transmembrane glycoprotein, which is also widely used to label vascular endothelial cells (Lanza *et al.*, 2001). α-SMA is mainly expressed in vascular smooth muscle cells and constitutes the contractile system of the vascular wall (Shinde *et al.*, 2017). The results showed that VEGF, CD31, CD34 and α-SMA in the high MHD dose and rb-bFGF were greater than in the control group. These results confirmed that MHD promotes wound healing by stimulating angiogenesis.

Previous studies suggested that traditional Chinese medicine and extracts, including *Panax ginseng*, *Angelica sinensis*, *A. radix*, *Cinnamomum cassia* and *Salvia miltiorrhiza* among others, could be used as therapeutic agents for wound repair by stimulating angiogenesis and collagen synthesis (Majewska & Gendaszewska-Darmach, 2011). These effects were achieved by activating the VEGF/PI3K/Akt signaling pathway. A number of their monomer components have been shown to be involved in

promoting wound healing by regulating the PI3K/Akt signaling pathway. For example, cinnamaldehyde was reported to promote angiogenesis and wound healing by upregulating the PI3K signaling pathway (Yuan *et al.*, 2018). One of the active ingredients of MHD, astragaloside IV, has also been reported to significantly stimulate angiogenesis through the PI3K/Akt signaling pathway (Zhang *et al.*, 2011). Using western blotting, we also found that a high MHD dose increased VEGF secretion, activated PI3K and induced the phosphorylation of Akt and its downstream target eNOS, thus promoting new blood vessel formation. There are also some reports in the literature about the effect of compounds on wound healing. For example, *Danggui Buxue* extract-loaded liposomes in thermosensitive gel enhanced *in vivo* dermal wound healing via activation of the VEGF/PI3K/Akt and TGF-β/Smads signaling pathways (Cui *et al.*, 2017). These studies were similar to our results and demonstrated that MHD has the potential to promote angiogenesis through the VEGF/PI3K/Akt signaling pathway and is beneficial for wound healing.

HUVECs are frequently used as an *in vitro* model of angiogenesis, as angiogenesis requires endothelial cell migration and morphogenesis (Li *et al.*, 2017). In this study, we also investigated the effect of MHD on HUVECs. In the CCK-8 and scratch assays, MHD promoted HUVECs proliferation and migration. Previous studies have also shown that some of the components of MHD, including *P. villosa* (Cao *et al.*, 2013), *C. officinalis* (Jeon *et al.*, 2010) and *Astragalus* (Lai *et al.*, 2014), stimulate HUVEC proliferation and migration and increase HUVECs viability, with which our results were consistent. By western blotting, we demonstrated that MHD promoted VEGF secretion and activated the PI3K/Akt signaling pathway in both a concentration-dependent and time-dependent manner. One of the active ingredients of MHD, *Astragalus polysaccharides*, has been reported to promote vascular endothelial cell proliferation and repair by activating the PI3K/Akt signaling pathway (Zhang *et al.*, 2016b). Additionally, astragaloside IV was also observed to display an angiogenic effect on endothelial cells, which was reversed by LY294002 (Zhang *et al.*, 2011). Similarly, we also used LY294002 to inhibit the PI3K/Akt signaling pathway and found that PI3K, p-Akt, and p-eNOS were significantly reduced in the MHD+LY294002 group compared with alone MHD group. This indicated that the MHD promotion of HUVECs proliferation depends on the activation of the PI3K/Akt signaling pathway.

While MHD is effective in clinical application, it is, however, a compound composed of a variety of natural medicinal plants. Therefore, the VEGF/PI3K/Akt signaling pathway may not be the only mechanism of its effect on promoting wound healing. Further potential molecular mechanisms need to be investigated. Besides, the limited number of rats used is also a shortage in our study. More animals should be considered in the following research.

CONCLUSIONS

This study showed that MHD significantly promotes wound healing by activating the VEGF/PI3K/Akt signaling pathway. Our study not only helps to explain the mechanism of MHD, but it also provides ideas for the development of new methods to improve wound healing.

Chrysophanol ameliorates oxidative stress and pyroptosis in mice with diabetic nephropathy through the Kelch-like ECH-associated protein 1/nuclear factor erythroid 2-related factor 2 signaling pathway

Xinzhu Yuan[1#], Wenwu Tang[1#], Changwei Lin[1], Hongni He[2] and Lingqin Li[3]✉

[1]Department of Nephrology, The Second Clinical Medical Institution of North Sichuan Medical College (Nanchong Central Hospital) and Nanchong Key Laboratory of Basic Science and Clinical Research on Chronic Kidney Disease, Nanchong, China; [2]Department of Gynaecology, The Second Clinical Medical Institution of North Sichuan Medical College (Nanchong Central Hospital), Nanchong, China; [3]Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China

Diabetic nephropathy (DN), a microvascular complication of diabetes, increases the risk of all-cause diabetes and cardiovascular mortalities. Moreover, oxidative stress and pyroptosis play important roles in the pathogenesis of DN. Rhubarb is widely used in traditional medicine, and chrysophanol (Chr), a free anthraquinone compound abundant in rhubarb, exhibits potent antioxidant properties and ameliorates renal fibrosis. Therefore, this study aimed to investigate the effects of Chr on renal injury, oxidative stress, and pyroptosis in mice with DN. A DN model was established by feeding the mice a high-sugar and fat diet and injecting them with 50 mg/kg streptozotocin as a positive control. The DN mice had significantly impaired renal function, thickened glomerular thylakoids and basement membranes, increased fibrous tissue, and inflammatory cell infiltration. Superoxide dismutase (SOD) levels were reduced, malondialdehyde (MDA) levels were increased, interleukin (IL)-1β and IL-18 increased, and cleaved caspase-1, caspase-1, and gasdermin D (GSDMD) involved in the process of pyroptosis were upregulated in DN. Kelch-like ECH-associated protein 1 (Keap1) expression was upregulated, and nuclear factor erythroid 2-related factor 2 (Nrf2) expression was downregulated. Compared to those in the DN group, the Chr-treated mice with DN had improved renal dysfunction, weakened glomerular thylakoid and basement membrane thickening, and reduced fibrous tissue proliferation and inflammatory cell infiltration. Additionally, Chr increased SOD levels, decreased MDA, IL-1β, and IL-18, down-regulated caspase-1, cleaved caspase-1, GSDMD, and Keap1 expression, and upregulated Nrf2 expression, which reversed the DN. Therefore, Chr reduced oxidative stress and pyroptosis in DNmice by activating the Keap1/Nrf2 pathway.

Keywords: Diabetic nephropathy, Chrysophanol, Keap1/Nrf2 pathway, Oxidative stress, Pyroptosis

INTRODUCTION

Diabetic nephropathy (DN) is the most common and serious microvascular complication of diabetes. More than 15–40% of patients with diabetes mellitus develop DN during their lifetime. Moreover, DN affects patients' quality of life and increases the risk of all-cause diabetes and cardiovascular mortality (Afkarian et al., 2013). Furthermore, DN is characterized by progressive renal impairment with the onset of glomerular basement membrane thickening and widening of the thylakoid matrix (Tervaert et al., 2010). This is followed by trace urine protein, hypertension, edema, renal insufficiency, and even renal failure, leading to end-stage renal disease (ESRD) (Hirawa et al., 2001; Sagoo & Gnudi, 2020).

The glomerular filtration barrier comprises podocytes, which are highly differentiated glomerular epithelial cells, and kidney diseases linked to diabetes may result from damage to podocytes (Lin et al., 2020). Cell death, including apoptosis, necrosis, autophagy, pyroptosis, and ferroptosis, has been observed in the process of DN (Sifuentes-Franco et al., 2018; Al Mamun et al., 2021; Chen et al., 2021). Pyroptosis is a newly discovered form of programmed cell death that has recently attracted increasing attention. In contrast to apoptosis, pyroptosis is a lysis and inflammatory death dependent on inflammatory vesicles and cystatinases and is characterized by plasma membrane rupture, cell swelling, and dissolution, which is mediated by the gasdermin D (GSDMD) protein family (Shi et al., 2017). Evidence suggests that oxidative stress and inflammation play key roles in the development of DN. Chronic hyperglycemia in patients with diabetes is thought to trigger a downstream cascade response. Excessive production of reactive oxygen species (ROS) in podocytes under high-glucose conditions can activate nucleotide-binding domain, leucine-rich–containing family, pyrin domain-containing-3 (NLRP3) to induce podocyte scorching, whereas mitochondrial autophagy can regulate cellular homeostasis and modulate ROS production (Lin et al., 2019; Qiu et al., 2019; Xiaodong & Xuejun, 2022). Podocytes have a huge energy requirement to maintain adequate mitochondrial numbers and normal function; thus, they are more vulnerable to mitochondrial damage (Gujarati et al., 2020; Su et al., 2020a).

Rhubarb is a common traditional Chinese medicine widely used in treating many diseases related to the circulatory, digestive, endocrine, respiratory, and skel-

etal systems, as well as infectious diseases (Rokaya *et al.*, 2012). Chrysophanol (Chr) is a natural anthraquinone component isolated from Rhubarb spp and is also known as chrysophanic acid and 1,8-dihydroxy-3-methylanthraquinone. Recent reports have demonstrated that Chr has many beneficial effects, such as anti-inflammatory, anticancer, antidepressant, and neuroprotective (Su *et al.*, 2020b). Renal fibrosis is effectively improved by Chr as the NKD2/NF-κB pathway is inhibited (Gu *et al.*, 2022). Additionally, Chr alleviates cisplatin-induced nephrotoxicity by simultaneously inhibiting oxidative stress, apoptosis, and inflammation (Ma *et al.*, 2021). Ovarian cancer cell death is induced by Chr which also inhibits cancer invasiveness via mitochondrial calcium overload (Lim *et al.*, 2018). Significant evidence suggests that Chr has strong antioxidant and ameliorating effects on renal fibrosis. However, the Chr function in DN progression remains unknown.

Nuclear factor erythroid 2- related factor 2 (Nrf2) and the endogenous inhibitor, Kelch-like ECH-associated protein 1 (Keap1), are ubiquitous and evolutionarily conserved intracellular defense mechanisms that regulate the redox imbalance caused by oxidative stress (Yang *et al.*, 2013; Bellezza *et al.*, 2018). However, Nrf2 can form an inactive complex with Keap1, which controls the subcellular localization and steady-state level under normal physiological conditions. Activation of the Nrf2 signaling pathway downregulates high glucose-induced ROS levels and podocyte apoptosis. When Nrf2 expression is downregulated, podocytes exposed to high glucose levels exhibit severe mitochondrial dysfunction (Zhang *et al.*, 2018).

Benazepril is considered an effective drug for treating DN because the medication reduces kidney volume and alleviates DN-associated pathological changes (Xue *et al.*, 2017). In the present study, we evaluated the renal pathology of mice with DN, and blood samples were tested for blood glucose, oxidative stress, and pyrogenic levels to assess the effect of Chr, which provides a further understanding of the protective mechanisms of Chr in DN.

MATERIALS AND METHODS

Animal protocols

C57BL/6 mice (6 weeks old, males) were obtained from the Chengdu Dossy Experimental Animals Company, China. The mice were randomized into six groups (seven mice per group): control, DN, DN + 2.5 mg Chr, DN + 5 mg Chr, DN + 10 mg Chr, and DN + benazepril. The control and DN groups were administered 0.9% saline, and the DN + 2.5 mg Chr, DN + 5 mg Chr, and DN + 10 mg Chr groups were administered with Chr at a dose of 2.5, 5, and 10 mg/kg/d, respectively. The benazepril group was administered benazepril at 1 mg/kg/d (Zhao *et al.*, 2016; Dou *et al.*, 2020; Ma *et al.*, 2021). All the mice were placed in an animal room without specific pathogens and under controlled temperature (24°C±1°C) and humidity (50–70%). The mice were adapted to a 12-h light and 12-h dark cycle. The control group was fed standard pellet feed, and the remaining mice were fed high-sugar and high-fat diets for six weeks. They were then injected with 50 mg/kg streptozotocin (STZ) to establish a DN model. Fasting blood glucose levels >7.0 mmol/L were considered to indicate an incidence of diabetes. When the model was successfully established, Chr gavage was ad-

ministered for eight weeks. Benazepril was used as the positive control. All experiments were performed by the guidelines for the care and use of laboratory animals. The kidneys of the mice were weighed, and kidney-to-body weight ratios (KBWR) were calculated based on the weight of the mice. All experimental procedures and protocols were approved by the Medical Ethical Committee of West China Hospital of Sichuan University (20230829001).

Renal function evaluation

After eight weeks of drug treatment, the mice were fasted overnight. All the mice were intraperitoneally injected with 1% sodium pentobarbital. Whole blood was centrifuged (12 000 rpm, 4°C, 15 min) to obtain serum. A fully automatic biochemical analyzer, Hitachi 7600-110, was used to measure serum creatinine (Scr), blood urea nitrogen (BUN), and 24-hour urine protein levels.

Hematoxylin and eosin (H&E) and MASSON trichrome staining

Masson trichrome and H&E staining were performed as described previously (Wang *et al.*, 2022). After execution of the mice, kidney samples were isolated and fixed in paraformaldehyde for 24 h, subsequently embedded in paraffin, and sectioned (4–5 μm). Tissue sections were stained with H&E and Masson trichrome stains.

Enzyme-linked immunosorbent assay (ELISA)

After eight weeks of drug treatment, the samples of kidney cortex from each group of mice were collected, homogenized in 0.05% phosphate-buffered saline (PBS), and centrifuged at 2500 rpm for 20 min. Anti-interleukin (IL)-1β and anti-IL-18 were purchased from R&D (Minneapolis, MN, USA). The supernatant was collected, and the levels of IL-1β and IL-18 were detected using corresponding ELISA kits according to the manufacturer's instructions.

Determination of superoxide dismutase (SOD) and malondialdehyde (MDA) activity

After treatment, the kidney cortex was collected from each group of mice, homogenized in 0.05% PBS, and centrifuged at 2500 rpm for 20 min. SOD and MDA kits (NJJCBIO) were used. Optical density was measured using a miniature multifunction panel reader (Biotek Instruments, Inc.). SOD and MDA activities in each group were calculated, according to the manufacturer's instructions.

Western blot (WB) analyses

The cortex tissue samples of the kidneys from each group were homogenized with protease inhibitors, lysis buffer, and a 1 mM mixture of phenylmethylsulfonyl fluoride. Total protein concentration was assayed using a bicinchoninic acid protein assay kit. Equal amounts of total protein extracts were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis at 20 μg per well and transferred to a polyvinylidene difluoride (PVDF) membrane. The PVDF membrane was immersed in tris-buffered saline Tween-20 with 3% bovine serum albumin for 1.5 h. The membrane was then incubated with the following specific primary antibodies (1:1000) overnight at 4°C: anti-Keap1, anti-Nrf2, anti-Pro-Caspase-1, anti-cleaved Caspase-1, and anti-GSDMD. The membranes were then incubated with

Figure 1. Effects of chrysophanol (Chr) on serum creatinine (Scr, A), blood urea nitrogen (BUN, B) and 24 h urine protein (C) in mice with diabetic nephropathy (DN) analyzed by sarcosine oxidase method, Uricase-GIDH method, and enzyme colorimetry, respectively.
Data are presented as mean ± S.D. Data were compared by one-way ANOVA and Tukey's multiple comparison test. $^*P<0.05$, $^{**}P<0.01$ as compared with control group; $^{\#}P<0.05$, $^{\#\#}P<0.01$ as compared with DN group. n=7.

peroxidase-coupled anti-rabbit or anti-mouse antibodies for 2 h at room temperature. Super-enhanced chemiluminescence reagent (Applygen Technologies Inc, Beijing, China) was added to the membrane to visualize the target band. The band intensity was calculated using ImageJ software, and the relative protein intensities were calculated. Anti-Keap1, Nrf2, and caspase-1 were purchased from Servicebio (Wuhan, China), cleaved caspase-1 antibody was purchased from Santa Cruz (1:200, Dallas, TX, USA), and GSDMD and actin antibodies were obtained from Abcam (Cambridge, MA, USA).

Statistical analyses

Data were analyzed using SPSS software (version 20.0; GraphPad Software, La Jolla, CA, USA), and GraphPad Prism 8.0 software was used for drawings. All data are expressed as mean ± standard deviation. Statistical anal-

yses were performed using a one-way analysis of variance and Tukey's multiple comparison tests for multiple group comparisons. Statistical significance was considered at $P<0.05$.

RESULTS

Chrysophanol improves Renal Dysfunction in C57BL/6 mice

As displayed in Fig. 1, after eight weeks of treatment, the levels of Scr, BUN, and 24-hour urine protein in the DN group were significantly higher than those in the control group. Moreover, Chr demonstrated varying levels of reduced renal dysfunction in the mice, indicating that Chr was effective in inhibiting a decrease in renal

Figure 2. Effects of chrysophanol (Chr) on kidney-to-body weight ratios (A) and pathological features (B and C) in mice with diabetic nephropathy (DN) analyzed by weighing, hematoxylin-eosin staining and Masson staining, respectively.

function in the DN mice. Additionally, 10 mg of Chr was more effective than benazepril.

Chrysophanol ameliorates morphological and pathological changes in C57BL/6 mice

The kidneys of each mouse group were evaluated. First, we evaluated the KBWR. The KBWR increased significantly in DN mice, but decreased significantly in Chr-treated mice (Fig. 2A). Figures 2B and 2C illustrate kidney slices stained with H&E and Masson's trichrome stains. Thicker glomerular thylakoid and basement membranes, capillary occlusion, epithelial cell swelling, small amounts of interstitial fibrous tissue hyperplasia, and lymphocytic infiltration were observed in the DN group. Compared to those in the DN group, the Chr-treated DN mice exhibited varying degrees of glomerular thylakoid and basement membrane thickening. Additionally, slight epithelial cell degeneration, fibrous tissue hyperplasia, and lymphocyte infiltration were observed in the 2.5 mg Chr group. In the 5 mg Chr group, swelling of epithelial cells with minimal fibrous tissue hyperplasia was observed. No significant fibrous tissue proliferation or inflammatory cell infiltration was observed in the 10 mg Chr group.

Chrysophanol reduces oxidative damage and pyroptosis of the renal cortex in C57BL/6 mice by regulating the Keap1/Nrf2 pathway

To evaluate kidney oxidative stress injury in the C57BL/6 mice, SOD, MDA, IL-1β, and IL-18 were measured and analyzed in the kidney cortex tissue. In the DN group, SOD significantly decreased, and MDA

significantly increased (Fig. 3A and Fig. 3B). However, Chr upregulated SOD and decreased MDA levels in the kidney cortex tissue. Additionally, Chr significantly decreased the levels of IL-1β and IL-18 (Fig. 3C and Fig. 3D), which indicated that Chr could alleviate oxidative stress inflammatory damage in the C57BL/6 mice.

The WB results (Fig. 4A–4G) revealed that the expression of cleaved caspase-1, caspase-1, GSDMD, and Keap1 was upregulated, whereas, the expression of Nrf2 was downregulated in the DN group. Additionally, Chr treatment downregulated the expression of cleaved caspase-1, caspase-1, and GSDMD, which are involved in pyroptosis, downregulated Keap1 protein, and upregulated the expression of Nrf2. These results suggest that Chr inhibits oxidative stress and pyroptosis by regulating the Keap1/Nrf2 signaling pathway.

DISCUSSION

DN is a chronic kidney disease that is a major cause of ESRD and is associated with significant healthcare costs. Although treatment options for DN have progressed, including the use of angiotensin II receptor blockers, angiotensin-converting enzyme inhibitors sodium-glucose co-transporter protein 2 inhibitors, and salt corticosteroid receptor antagonists, the outcomes remain very limited (Fried *et al.*, 2013; Barrera-Chimal *et al.*, 2019; Tesař, 2022). Thus, an urgent need to develop more valid DN regimens is present. Chr a unique anthraquinone, is a primary component of many plant extensions of traditional Chinese medicine. Moreover, Chr has a broad-spectrum curative potential and eco-relevance (Yusuf *et al.*, 2019), and the drug has been validated to

Figure 4. Effects of chrysophanol (Chr) on caspase-1 (A and B), cleaved caspase-1 (A and C), gasdermin D (GSDMD, A and D), kelch-like ECH-associated protein 1 (Keap1, E and F) and nuclear factor erythroid 2-related factor 2 (Nrf2, E and G) in kidneys of mice with diabetic nephropathy (DN) analyzed by western blots (WB).
Data are presented as mean ± S.D. Data were compared by one-way ANOVA and Tukey's multiple comparison test. $^{*}P<0.05$, $^{**}P<0.01$ as compared with control group; $^{#}P<0.05$, $^{##}P<0.01$ as compared with DN group. n=7.

be effective in the prevention and management of diabetes and its complications (Guo *et al.*, 2020). Benazepril is an angiotensin-converting enzyme inhibitor (ACEI) drug commonly used in treating hypertension and heart failure (Yan *et al.*, 2013). Numerous studies have demonstrated that benazepril improves DN and reduces proteinuria in rats (Jin *et al.*, 2014). In this study, we investigated the underlying effects and potential mechanisms of action of Chr on DN using benazepril as a positive control. Our results suggest that Chr can prevent DN by activating

the Keap1/Nrf2 pathway to attenuate oxidative stress and cellular scorching and reduce inflammation.

The molecular mechanisms underlying DN include inflammation, fibrosis, metabolism, and hemodynamics. Oxidative stress is considered a critical pathway in diabetic kidney injury in the presence of metabolic and hemodynamic abnormalities. Under normal conditions, ROS levels are too low to maintain cellular homeostasis. However, in high conditions, ROS generation in podocytes increases significantly (Bhatti & Usman, 2015). Exposure of podocytes to ROS leads to α-dystroglycan

deglycosylation, thereby decreasing the number of podocytes. Mitochondrial damage-induced podocyte apoptosis is considered to be the most devastating factor in DN progression (Feng *et al.*, 2019). In this study, we identified that Chr could repair high-fat, high-sugar, and STZ-induced mitochondrial damage, enhance antioxidative capacity, and inhibit the generation of oxidation products, thereby preventing apoptosis of podocytes and alleviating DN.

In addition to oxidative stress, inflammation is a key factor in DN development. Several studies have demonstrated that activating inflammatory signaling and infiltrating inflammatory cells are essential for DN progression (Rayego-Mateos *et al.*, 2020). The inflammasome is a multi-protein signaling platform that controls response to inflammation and coordinates antimicrobial host defense (Broz & Dixit, 2016). The NOD-like receptors (NLR), which contain the pyridine structural domain family 3, assemble an intracellular protein complex called the NLRP3 inflammasome when certain pathogen products or sterile danger signals are sensed (Wang *et al.*, 2021). Additionally, NLRP3 is present in natural immune and non-immune cells in the kidney, such as podocytes. NLRP3 recognizes a variety of pathogen- or injury-associated molecular patterns and is involved in intrinsic immune and inflammatory responses (Bai *et al.*, 2017). The NLRP3 inflammasomes mediate pyroptosis and play an important role (Wang *et al.*, 2017; Li *et al.*, 2021). When cells are stimulated externally, they activate the inflammatory complex and Caspase-1, which acts as a direct agonist to cleave IL-1β and IL-18 precursors, thereby recruiting other inflammatory cells and exacerbating inflammatory response by releasing them extracellularly. Simultaneously, they shear the GSDMD, release the active N-terminal (GSDMD-N) to bind to phospholipids in the inner layer of the plasma membrane, and accelerate nuclear pore formation, which releases mature forms of inflammatory factors to induce pyroptosis (Ystgaard *et al.*, 2015; Rathinam & Fitzgerald, 2016; Sborgi *et al.*, 2016; Sun & Scott, 2016). This inflammatory reaction further promotes the activation of NLRP3 inflammatory corpuscles, forming a vicious circle and aggravating the disease. In the present study, we demonstrated that Chr reduced caspase-1 levels and downregulated GSDMD expression in mice with DN to suppress inflammatory responses, thereby preventing pyroptosis and alleviating DN.

Proteinuria is an important indicator of DN progression (KDOQI Clinical Practice Guidelines and Clinical Practice Recommendations for Diabetes and Chronic Kidney Disease, 2007). However, assessing the severity or prognosis of DN solely based on the degree of proteinuria is accurate (Radcliffe *et al.*, 2017), and pathological changes are a beneficial addition to this assessment. In this study, renal tissue sections from mice in the DN group displayed severe morphological damage and fibrosis. Treatment with Chr restores renal histopathological damage to varying degrees and reduces renal fibrosis in C57BL/6 mice. This implies that Chr may have a protective effect on podocytes in DN. This protective mechanism might be related to the anti-inflammatory and antioxidant properties of Chr.

The present study confirmed that oxidative stress and inflammatory responses are closely associated with DN, and our results suggest that Chr is a potentially effective therapy for DN. Furthermore, because of the common upstream pathogenesis of many diseases, published evidence suggests that Chr may ameliorate various diseases associated with abnormal angiogenesis, including diabetes and cancer, by inhibiting oxidative stress and the Keap1/

Nrf2 pathway (Guo & Mo, 2020). We suggest that this profile could also be deduced from other products of natural origin with antioxidant and anti-inflammatory properties for treating diabetic complications. Furthermore, the findings provide conclusive evidence that the Keap1/Nrf2 signaling pathway is a potential target in DN.

Our study has some limitations. Although the current study suggests that Chr can treat DN by attenuating oxidative stress and inflammation, we did not directly elucidate the origin of oxidative stress-induced damage in the mouse models. The pathogenesis of DN is complex and involves various distinct cell types, such as podocytes, glomerular endothelial cells, thylakoid cells, and renal tubular epithelial cells. Numerous studies have established that oxidative stress and inflammation can affect the aforementioned cells, collectively leading to DN progression. Therefore, we hope that more extensive and targeted investigations will be conducted in the future.

CONCLUSION

In summary, our study provides evidence for the primary role and potential mechanisms of action of Chr in DN. The results display that Chr has a considerable impact on upstream events in the pathogenesis of DN rather than just focusing on late inflammatory infiltration and fiber formation. Chr can manage DN by mitigating both oxidative stress and inflammation and the primary mechanism is related to the inhibition of the Keap1/Nrf2 pathway.

Box 2455, Riyadh 11451, Saudi Arabia

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder that leads to the degeneration of motor neurons and the weakening of muscles. Despite extensive research efforts, there is currently no cure for ALS and existing treatments only address its symptoms. To address this unmet medical need, genome editing technologies, such as CRISPR-Cas9, have emerged as a promising solution for the development of new treatments for ALS. Studies have shown that CRISPR-Cas9-guided RNAs have the potential to provide accurate and effective silencing in the genetic disease of ALS. Results have demonstrated a 67% on-target score and a 98% off-target score with GC content within the range of 40–60%. This is further validated by the correlation between the gRNA's structural accuracy and the minimum free energy. The use of CRISPR-Cas9 provides a unique opportunity to target this disease at the molecular level, offering hope for the development of a more effective treatment. In silico and computational therapeutic approaches for ALS suggest that the CRISPR-Cas9 protein holds promise as a future treatment candidate. The CRISPR mechanism and the specificity of gRNA provide a novel therapeutic approach for this genetic disease, offering new hope to those affected by ALS. This study highlights the potential of CRISPR-Cas9 as a promising solution for the development of new treatments for ALS. Further research is required to validate these findings in preclinical and clinical trials and to establish the safety and efficacy of this approach in the treatment of ALS.

INTRODUCTION

Amyotrophic Lateral Sclerosis (ALS), commonly referred to as Lou Gehrig's disease, is a degenerative neurological condition that predominantly impacts the motor neurons that regulate voluntary muscle movement. The ailment was initially documented by the French neurologist Jean-Martin Charcot in 1869 and has subsequently been acknowledged as among the most catastrophic motor neuron disorders (Longinetti & Feng, 2019). ALS is a condition that impacts individuals of diverse ethnicities and age groups across the globe, with a marginal preponderance in males. The Etiology of ALS remains largely elusive, albeit a small proportion of cases, ranging from 5% to 10%, are deemed familial, stemming from heritable genetic mutations (Hardiman *et al.*, 2017). The vast majority of ALS cases are sporadic, lacking a discernible familial background. The prevalence of ALS exhibits heterogeneity among diverse populations, with an annual occurrence rate of 1 to 3 cases per 100 000 persons. ALS has an estimated prevalence of approximately 4-8 cases per 100 000 individuals, although certain regions have reported higher rates (Longinetti & Fang, 2019). Symptoms of ALS may first appear in the muscles that govern speech and swallowing, as well as in the hands, arms, legs, and feet. ALS has two types, depending upon the gene due to which it is caused. *SOD1* and *C9ORF72* are the genes that are responsible for this fatal disease. These genes play a crucial role in many processes including the control of motor neurons (Masrori & Vane Damme, 2020; Longinetti & Feng, 2019).

Regrettably, at present, there exists no remedy for ALS but the modern artificial intelligence-based technologies can be proved as enhanced treatment strategies with revolutionized drug design approaches (Naveed *et al.*, 2023a; Naveed *et al.*, 2023b). The mainstay of treatment approaches is centred on symptom management, provision of supportive care, and enhancement of the patient's quality of life. The implementation of a multidisciplinary approach entails the collaboration of a diverse group of healthcare professionals, such as neurologists, physical therapists, occupational therapists, speech-language pathologists, nutritionists, and palliative care specialists (Morimoto *et al.*, 2019). The primary objectives of therapy entail the deceleration of the disease advancement, effective symptom management, and the consideration of the emotional and psychological dimensions of the ailment. ALS is a disease that leads to paralysis and causes premature death of patients. A drug named Riluzole is a glutamate antagonist that increases the survival of patients by a few months. Another drug named Endaravone was recently approved by FDA in 2017 (Saitoh & Takahashi, 2020; Yoshino, 2019). However, the European Medicine Agency (EMA)

Calculation Thermodynamic ensemble prediction

The RNAcofold program was a reliable tool for estimating hybridization energy and analyzing the thermodynamic interaction between the target gene and the expected sgRNA. Additionally, the Vienna RNA program was also used for this purpose. Both programs showed how RNA sequences base-paired. The calculated communication energies and equilibrium duplex structure concentrations were determined using the RNAcofold program.

Secondary Structure Prediction

The Mfold Web server (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAfold.cgi), which included the UNAfold program, was used in the study and considered one of the most reliable and frequently referenced tools for predicting secondary structures. The UNAfold program was used to predict the secondary structure of the sgRNA strand by minimizing free energy, and it was able to predict sgRNA architectures containing pseudoknots.

RESULTS

Sequence Retrieval and Analysis

In this study, the *SOD1* (Superoxide dismutase 1) gene sequence was retrieved from the NCBI (National Center for Biotechnology Information) database (https://www.ncbi.nlm.nih.gov) using the accession number NM_000454.4. The selection of the sequence was based on a comprehensive literature review. The chosen sequence was the start codon of the *SOD1* receptor gene located on chromosome X at position 31659693-31668931.

Open reading frame (ORF) screening

The screening of the coding region of the *SOD1* gene was performed using the open reading frame finder (https://www.ncbi.nlm.nih.gov/orffinder). The ORF finder is a widely used tool for predicting and analysing open reading frames. In the case of the *SOD1* gene, 56 ORFs were identified and were calculated from the genomic coordinates 31659693-31668931. Figure 1 below represents the ORFs of *SOD1* gene.

Analysis of the designed guide RNA

The gRNA design was based on the objective of identifying or cutting the target gene. The CHOPCHOP tool, a web-based platform, was utilized to design the gRNA sequence. The *SOD1* gene was inserted into the software as the targeted gene, with the exon region represented by a blue box and the introns indicated by red lines. The structural representation of *SOD1* gene is given below in the Fig. 2 and the Table 1 below depicts the target sequences with their genomic locations inside the gene.

Table 1. Target sequences and genomic locations of the target sites in *SOD1* gene

The CHOPCHOP tool was utilized to generate multiple gRNA sequences for the target gene [3]. CHOPCHOP displayed the sequence with the minimum number of mismatches at the top, as it was crucial for the number of mismatches to be zero. If the number of mismatches were greater than one, both the targeted and non-targeted regions of the gene would have been cut. The top three target sequences were carefully selected from the CHOPCHOP results, taking into consideration both efficiency and 100% matching with the target. Figure 3 depicts the graphical representation of gRNA along with its primers and off-targets below. The specifications of the designed primers and their off-targets are given below in the Table 2.

The first rank was selected based on the target sequence CTAGCGAGTTATGGCGACGA and its genomic location on chromosome 21 at position 31659760. The target had a GC content of 55% and 2 instances of self-complementarity. The first pair of primers for the left coordinates on chromosome 21, located between positions 31659647 and 31659669, had a sequence of CGGAGGTCTGGCCTATAAAGTA with a melting temperature (TM) of 59.6°C. The right primer coordinates, located between positions 31659820 and 31659842, had a primer sequence of CTTCTGCTC-GAAATTGATGATG and had zero off-targets with a product size of 195. The location of the first gRNA was in the first exon, but in the case of general, mutations

near the C terminus of a protein are less likely to result in loss of function for that protein [4]. The graphical representation of the gRNA and primers for rank 2 are given below in the Fig. 4 and the primer specifications and off-targets are given below in the Table 3.

As represented in Fig. 4, the selection was made for rank 3 with a target sequence of CTTCGTCGC-CATAACTCGCT and a genomic location located at chr21:31659759, exhibiting a GC content of 59.6% and 2 instances of self-complementarity. The primer pair for the left primers was situated at chr21:31659647-31659669, with a primer sequence of CGGAGGTCTGGCCTATAAAGTA and a melting temperature (TM) of 59.6°C. The right primer was positioned at chr21:31659820-31659842, possessing a primer sequence of CTTCTGCTCGAAATTGAT-GATG, with zero off-target pairs and a product size of 195. It was generally observed that mutations close to the C-terminus of a protein had a reduced probability of causing a loss-of-function mutation in the protein [5]. The graphical representation of the gRNA and primers for rank 3 are given below in the Fig. 5 and the primer specifications and off-targets are given below in the Table 4.

Above figure represents the selection of rank 6, with a target sequence of GTCGCCCTTCAGCACG-CACA located on chr21:31659783 and a GC content of 65%, with zero self-complementarity. The first primer

Table 7. The approximate prediction of the secondary structure free energy model

Target No	Target RNA sequence	Free Energy of Thermodynamic	Frequency of the MFE	Ensemble Diversity
01	CTAGCGAGTTATGGCGACGAAGG	−1.87 kcal/mol	75.45 %	2.14

Figure 6. Designed plasmid for the expression of edited target in *SOD1*

Figure 7. (A) The minimum free energy (MFE) structure, a thermodynamic ensemble of RNA structures, and the centroid structure were represented. The optimal secondary structure, CTAGCGAGTTATGGCGACGAAGG was shown to have a minimum free energy of −1.87 kcal/mol and was depicted in the graph. **(B)** The MFE structure, the thermodynamic ensemble of RNA structures, and the centroid structure were represented. The graph depicted the optimal secondary structure CTTCGTCGC-CATAACTCGCTAGG with a frequency of minimum free energy −0.89 kcal/mol. **(C)** the MFE structure, thermodynamic ensemble of RNA structures, and the centroid structure were represented. The graph displayed the optimal secondary structure, GTCGCC-CTTCAGCACGCACACGG, with a minimum free energy of −1.73 kcal/mol. **(D)** The percentage GC Content.

pair had a left primer at coordinate's chr21:31659647-31659669, with a primer sequence of CGGAGGTCTG-GCCTATAAAGTA and a melting temperature of 59.6°C. The right primer was located at coordinate's chr21:31659828-31659848, with a primer sequence of CCTTGCCTTCTGCTCGAAAT, and its paired off-targets were zero, with a product size of 201. There were three miss-matches in this gRNA, which were caused by the off-target, and it was generally noted that mutations close to the C terminus of a protein are less likely to result in a loss of function mutation of that protein.

Three gRNAs were designed, sgRNA1, sgRNA2, and sgRNA3. SgRNA1 was positioned at chrX:31659760 in the *SOD1* gene, within the target sequence CTAGC-GAGTTATGGCGACGAAGG. SgRNA2 was positioned at chrX:31659759 in the *SOD1* gene sequence, within the target sequence CTTCGTCGCCA-TAACTCGCTAGG, and sgRNA3 was positioned at chrX:31659783 in the *SOD1* gene sequence, within the target sequence GTCGCCCTTCAGCACGCACACGG. The results are explained in Table 5.

Primer validation

For the validation of the primer CHOPCHOP tool was used and the results obtained from it are shown in Table 6.

Design of lentiCRISPR v2 for genome editing

The design of the detailed vector plasmid was obtained through the use of a benching tool, and the different regions were depicted in Fig. 6. The plasmid consisted of two expression cassettes, including the chimeric guide RNA and hSpCas9. The vector was digested using BsmBI, and a pair of annealed oligos were cloned into the single gRNA scaffold. The oligos were designed based on the target sequence site (20bp) and were flanked at the 3' end by a 3bpPAM sequence (AGG) upstream of the protospacer.

The use of LentiCRISPR v2 plasmids was studied for the delivery of CRISPR materials and targeted genome editing in the *SOD1* gene, work on high-efficiency multiplex genome editing of the *SOD1* gene using an engineered mechanism of CRISPR-Cas9. In this study, the LentiCRISPR v2 plasmid was designed by inserting a gRNA expression cassette, from which the Cas9 gRNA was co-expressed with a gRNA that recognized the target sequence or gene. As a result, it was hypothesized that the gRNA expression cas-

sette within the LentiCRISPR viral vector would be targeted and destroyed along with the target sequence of the gene, leading to sustained expression of Cas9. The LentiCRISPR v2 carried gRNAs targeting both the Cas9 and *SOD1* genes.

Thermodynamic ensemble prediction

The approximate prediction of the secondary structure free energy model was represented in Table 7. The frequency of the minimum free energy and ensemble diversity were analyzed against the target gRNA sequences. The RNAfold web server (http://rna.tbi.univie.ac.at/cgi-bin/RNAWebSuite/RNAfold.cgi) was used to predict the thermodynamic ensemble prediction, as shown in Figs 9, 10, and 11 (Graphical Representation of Thermodynamic Ensemble Energy).

Calculation of the GC Content

In the study, the "RNA /DNA GC Content Calculator" (http://www.endmemo.com/bio/gc.php) was used to predict the GC content. The gene to be knocked down needed to have a standard percentage of GC content as a requirement for use as a sgRNA CRISPR-Cas9. The Mfold server was used to predict the free energy of folding and secondary structure for the sgRNA. By using this server, it was found that the gRNA had 52%, 48%, and 43% GC content, respectively. The percentage GC content is given above in Fig. 8 (D).

Prediction of the secondary structure

The secondary structure of gRNA was predicted using an online tool from Mathew's lab (https://rna.urmc.rochester.edu/RNAstructure.html). The RNA sequence of interest was first input into the software, which then performed calculations including energy minimization and partition function analysis to predict the most likely secondary structure of the RNA molecule. The tool predicted the structure in a graphical format, such as a dot plot or a secondary structure diagram and outputted the structure in various formats for further analysis.

The Mathew Lab RNA Structure tool was widely used in the RNA research community, and it was capable of predicting the secondary structure of RNAs with high accuracy. However, it is important to note that these predictions were based on thermodynamics, which may not always reflect the true structure of an RNA molecule, particularly in the presence of specific proteins or other molecules that could impact its structure.

Designed gRNA evaluation

In this step, two sgRNAs (sgRNA1 and sgRNA2) were designed to target a specific sequence in the *SOD1* gene. The specificity of the complex was encoded in the first 20 nucleotides of the gRNA, which were represented in Fig. 11 (A) and (B) respectively, represented in green. The alteration of these 20 nucleotides resulted in changes to the DNA sequence.

The analysis of the gRNAs was performed. The Cas-9RNP was joined with the (-) sense strand of the gene and produced the double-strand break at the locations 31659693 and 31659843.

It was crucial to ensure that the gRNA was attached to the complementary sequence. The results confirmed the strong incorporation of the guided strand. The ability of the sgRNA to bind with the complementary sequence of the target region demonstrated its capability as a gRNA.

DISCUSSION

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease that affects nerve cells in the brain and spinal cord. It is also known as Lou Gehrig's disease, after the famous baseball player who was diagnosed with the disease in the 1930s. The disease causes the degeneration and death of motor neurons, which are the nerve cells that control muscle movement. As the motor neurons die, the muscles they control weaken and eventually stop working, leading to symptoms such as difficulty in speaking, swallowing, and breathing. The progression of the disease varies widely, with some people experiencing a rapid decline in their health, while others may live for many years with the disease (Krishnan *et al.*, 2020).

The current study demonstrates the proof-of-concept utilizing the cellular disorder model whereby genetic defect ALS could be corrected using CRISPR-Cas9 with results indicating that they are more similar to 99%. It demonstrates the on-target and off-target scores that hold GC content within 40-60%, observed by RNA / DNA GC Content Calculator (Meijboom et al., 2022). This prediction is considered significant for the implementation of sgRNAs action. The CRISPR-Cas9 mechanism on the mutant *SOD1* gene is shown in Figure 6. Three target sites of the *SOD1* gene were selected for designing target sgRNAs based on their location in the exonic region. Notably, the designed sgRNA1 and sgRNA2 targeted a sequence in the *SOD1* gene. The specificity of this complex is encoded in the first 20nt of the gRNA as shown in Figure 5 (A) and (B). The binding ability of sgRNA with the complementary sequence of the target region proves their aptitude for working as gRNA (Raikwar et al., 2019).

The target region in the mutant human *SOD1* gene is near the start codon. Scissors indicate the double-strand break location; black color highlights the CAG repeats in the *SOD1* gene, and orange or yellow indicates sgRNA cassettes. Further validations are the minimum free energy that is considered a benchmark of sgRNAs structural accuracy. It measures the stability of the guide strand. The Mfold web server was used to calculate the minimum free energy (Tyagi et al., 2020).. RNA structure webserver was used to predict the secondary structure of an oligonucleotide by folding minimum free energy. This server predicts the most stable structures of an oligonucleotide with max-expected accuracy as shown in the graphical representation in Graphs 1, 2, and 3. These graphs represent the MFE structure, the thermodynamic ensemble of RNA structures, and the centroid structure. The folded structures of oligonucleotides were predicted at a specific temperature of 39°C. These results indicate that CRISPR-Cas9 can provide one of the best therapeutic approaches to ALS.

Imbued by the CRISPR mechanism and suitability of gRNA, pharmaceuticals and researchers are working to utilize this strategy as a therapeutic approach for the next generation. By using CRISPR technology researchers can easily modify the gene function and alter the DNA sequence. The emergence of CRISPR technology opens a new avenue to correct genetic disorders (Duan et al., 2020; Tyagi et al., 2020). Recently, it has been used as an efficient tool for site-specific genome editing in single cells and entire organisms in a specific manner. This study presents a specific possible future candidate in the treatment of SBMA that holds a tremendous potential therapeutic approach for a genetic disorder (Muhammad *et al.*, 2023a; Muhammad *et al.*, 2023b, Muhammad *et al.*, 2023c; Naveed *et al.*, 2022)

Although these methodologies offer significant perspectives, they are unable to comprehensively depict the intricate biological mechanism within a living organism. Additional investigation utilizing animal models and clinical trials involving humans is imperative to authenticate the effectiveness and safety of CRISPR-Cas9 as a treatment for ALS (Kim *et al.*, 2020).

CONCLUSION

Using bioinformatics techniques, we predicted three sgRNAs against the *SOD1* gene on the X chromosome. The fast development of genome editing technologies and applications has been greatly aided by computational

and experimental work. Advanced alignment techniques are being used simultaneously to enhance gRNA design and forecast off-target regions, which might hasten the development of better and more precise editing tools. It is extremely advantageous to create multiple sgRNAs with the aid of CRISPR technology for the silencing of important genes in different biological systems. CRISPR technology may be an emerging key to a novel therapy against *SOD1*. Compared to other gene-editing methods including TALENs and ZFNs, the CRISPR-Cas9 method is being widely used for gene editing and gene correction treatment strategy for several genetic disorders. All this is because of its cost-effectiveness and ability to edit multiple genes at the same time. This research may open a milestone corridor in the therapy of ALS. Research revealed that CRISPR technology is an effective gene silencing method to cure genetic disorders in the future with much higher efficiency.

RECOMMENDATIONS

Since ALS is a disease caused by the production of toxin proteins, in this research we attempted to block the disease-causing expression of the gene by using CRISPR. The designed gRNA will bind to the target site allowing the enzyme to perform cleavage and this will result in the removal of those extra CAG repeats. This will cause the restoration of regular protein production similar to the use of CRISPR in other diseases, which are caused by abnormal numbers of CAG repeats in the gene, e.g., Huntington's disease. The bioinformatics-based approach has shown accurate results, which need to be backed by in vitro and in vivo results for the clinical manifestation of this method. We encourage further research on this particular and seemingly possible way of curing this disease as CRISPR-based gene editing has a tremendous potential for doing miracles in medical science.

Association of vitamin D with deoxyribonucleic acid (DNA) damage: A systematic review of animal and human studies

Mayang Indah Lestari[1,2], Krisna Murti[3]✉, Iche Andriyani Liberty[4], Zen Hafy[1], Violantina Linardi[5], Muhammad Khoirudin[5] and Tungki Pratama Umar[5]

[1]Doctoral Study Program in Biomedical Science, Faculty of Medicine, Sriwijaya University, Palembang, Indonesia; [2]Department of Anesthesiology and Intensive Therapy, Faculty of Medicine, Sriwijaya University-Dr. Mohammad Hoesin General Hospital – Siti Fatimah General Hospital, Palembang, Indonesia; [3]Department of Anatomical Pathology, Faculty of Medicine, Sriwijaya University-Dr. Mohammad Hoesin General Hospital, Palembang, Indonesia; [4]Department of Public Health, Faculty of Medicine, Sriwijaya University, Palembang, Indonesia; [5]Research Assistant, Department of Anesthesiology and Intensive Therapy, Faculty of Medicine, Sriwijaya University, Palembang, Indonesia

Vitamin D has anti-proliferative, anti-inflammatory, and apoptotic abilities. Vitamin D deficiency can induce deoxyribonucleic acid (DNA) damage. The aim of the study was to create a systematic review to analyze the relationship between vitamin D and DNA damage in various populations. PubMed, Scopus, EbscoHost, Google Scholar, and Epistemonikos were used to identify literature regarding the relationship between vitamin D and DNA damage. Assessment of study quality was carried out by three independent reviewers individually. A total of 25 studies were assessed as eligible and included in our study. Twelve studies were conducted in humans consisting of two studies with experimental design and ten studies with observational pattern. Meanwhile, thirteen studies were conducted in animals (*in vivo*). It is found that the majority of studies demonstrated that vitamin D prevents DNA damage and minimizes the impact of DNA damage that has occurred ($p<0.05$). However, two studies (8%) did not find such an association and one research only found a specific association in the cord blood, not in maternal blood. Vitamin D has a protective effect against DNA damage. A diet rich in vitamin D and vitamin D supplementation is recommended to prevent DNA damage.

Keywords: vitamin D, DNA damage, observational studies, *in vivo* studies, systematic review

INTRODUCTION

Vitamin D and its receptors play an essential role in cancer development due to its anti-proliferative, anti-inflammatory, and apoptotic properties (Nair-Shalliker *et al.*, 2012a; Deuster *et al.*, 2017; Elhusseini *et al.*, 2018). Endogenous synthesis of vitamin D begins with cholesterol oxidation, producing pro-vitamin D3. In the skin, Ultraviolet B (UVB) from sunlight converts pro-vitamin D3 to pre-vitamin D3. Then, isomerization of pre-vitamin D3 is done, with vitamin D3 (cholecalciferol) as its main end product (Osmancevic *et al.*, 2015). Two hydroxylations by the enzymes vitamin D 25-hydroxy-lase (CYP27A1) and renal mitochondrial 1-hydroxylase (CYP27B1) are required to convert vitamin D3 to active 1,25(OH)2D3 (calcitriol). Calcitriol binds to vitamin D receptors (VDRs) belonging to the nuclear receptor family and forms a complex with RXR to regulate gene expression (Deuster *et al.*, 2017). VDRs are nuclear receptor superfamily members expressed in tumours to regulate cell cycle-related proliferation and angiogenesis (Khrisnan *et al.*, 2012; Christakos *et al.*, 2015). In addition, vitamin D has been shown in several studies to be effective in stimulating Deoxyribonucleic acid (DNA) synthesis in mature alveolar cells, modulating epithelial cell proliferation, and repairing injury (Usman *et al.*, 2021).

Furthermore, adequate vitamin D levels help to maintain DNA integrity. Vitamin D's role can be divided into two categories: primary functions that prevent DNA damage and secondary processes that regulate cell growth rate (Nair-Shalliker *et al.*, 2012a; Wenclewska *et al.*, 2019). Vitamin D is really crucial since its deficiency is associated with an increased frequency of chromosomal aberrations, sister chromatid exchanges, micronuclei formations, and alteration of comet assays (related to oxidative stress, hypoxic, and apoptotic process), some important indicators of DNA damage (Peng *et al.*, 2010; Nair-Shalliker *et al.*, 2012a; O'Callaghan-Gordo *et al.*, 2017; Liu *et al.*, 2019). The potential of vitamin D in reducing oxidative DNA damage in humans refers to clinical trials in which vitamin D supplementation reduced levels of 8-hydroxy-2'-deoxyguanosine (8-OH-dG), an oxidative damage biomarker found in colorectal epithelial crypt cells (Nair-Shalliker *et al.*, 2012a). Vitamin D administration has also been shown to reduce oxidative stress-induced damage and chromosomal aberration, prevent telomere shortening, and inhibit telomerase activity in animal models and cell lines (Siebert *et al.*, 2018). Vitamin D's secondary functions in preventing DNA damage include regulating poly-adenosine diphosphate/ADP-ribose polymerase activity on the DNA damage response pathway during the DNA lesion detection process. Vitamin D can also inhibit the replication of damaged DNA and regulate apoptosis, which promotes cell death (Nair-Shalliker *et al.*, 2012a).

Although vitamin D has long been discussed as one of the essential DNA protectors, a systematic review of the relationship between vitamin D and DNA damage has yet to be found. As a result, the purpose of this study is to use a systematic review approach to examine the association between vitamin D and DNA damage in

different populations of human studies and animal models.

METHODS

The manuscript was arranged using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) 2020 guidelines (Page *et al.*, 2021). All members approved the review panel's study procedure before conducting the literature search. The protocol has been registered in the International prospective register of systematic reviews (PROSPERO) with the registration number: CRD42023393054.

Literature retrieval

A comprehensive literature search was conducted across five databases to identify manuscripts on the relationship between vitamin D levels and DNA damage in human and animal subjects. The articles were discovered using Scopus, PubMed, EBSCOHost, Google Scholar, and Epistemonikos. Hand-searching was also conducted based on the included study bibliography to identify relevant publications that were not indexed in the previously reported databases (Umar *et al.*, 2022). There will be no restrictions on geographical region or gender. However, we restricted our search to studies published between January 2012 and January 2023. The investigation was completed by January 19th, 2023. To ensure its validity, the study must be published in English. The search terms for this study are available as Supplementary Table 1 at https://ojs.ptbioch.edu.pl/index.php/abp/.

Study selection

We sought animal and human studies investigating the link between vitamin D levels and DNA damage. Studies must demonstrate the influence of a single vitamin D substance administration on DNA damage (rather than a formulation containing multiple compounds) to be considered. The study was deemed ineligible if its design consisted of a literature review (e.g., systematic review, narrative review, scoping review), opinion, book chapter, and editorial. Meanwhile, included studies must have ac-

cess to the full text. As a result, we excluded conference abstracts, posters, and unretrieved complete records. Duplicates were removed from the literature retrieval. Three independent reviewers (VL, MK, and ZH) assessed titles and abstracts (primary screening) using a semi-automated process aided by Rayyan QCRI software (Ouzzani *et al.*, 2016; Umar & Siburian, 2022). Following the completion of the first screening stage, the full text was assessed by two reviewers (IAL and TPU) to determine its eligibility for inclusion in the review. Any disagreements were discussed and resolved by a senior author (MIL) at any stage of manuscript evaluation.

Data extraction

The following information was extracted from the data: authorship, country of study, research participant data in the form of age, sex, and comorbidities (human), as well as experimental research data on animal type and age (animal studies), DNA damage parameters (comet tail length, tail DNA, and tail moment; phosphorylated Histone H2AX (γH2AX), 8-hydroxy-2'-deoxyguanosine (8-OHdG), chromosomal aberration, DNA damage score, micronuclei formation, telomere length, urinary cyclobutane thymine (T–T) dimer, and DNA repair indicator), and main findings. The information was recorded on the extraction sheet using Microsoft Office Excel 2019. Because of the vast diversity among included studies, the findings were presented as a qualitative synthesis rather than a meta-analysis.

Risk of bias analysis

The risk of bias (RoB) analysis was conducted for the animal studies using The Systematic Review Center for Laboratory Animal Experimentation's risk of bias (SYRCLE's RoB) tool. The RoB tool from SYRCLE contains ten items related to selection bias, performance bias, detection bias, reporting bias, and other biases (Hooijmans *et al.*, 2014). Meanwhile, we used three different scales for human studies: the Newcastle-Ottawa Scale (for observational studies), the Risk Of Bias In Non-randomized Studies – of Interventions (ROBINS-I), and Version 2 of the Cochrane risk-of-bias tool for randomized trials (ROB-2). The Newcastle Ottawa Scale is divided

Figure 1. Study selection flow

Figure 2. Risk of Bias for Animal Studies

Figure 3. Risk of Bias for Human Studies.
A, Newcastle-Ottawa Scale; **B**, Risk of Bias in Non-randomised Studies – of Interventions (ROBINS-I); **C**, Version 2 of the Cochrane risk-of-bias tool for randomized trials (ROB-2)

into three major domains (selection, comparability, and outcome) (Liana *et al.*, 2022). In contrast, the ROBINS-I (Sterne *et al.*, 2016) and ROB-2 (Sterne *et al.*, 2019) are divided into several parts within the pre-intervention, intervention, and post-intervention stages. The evaluation was carried out independently by two authors (IAL and TPU). In the event of a disagreement, the decision is made by a senior author (KM).

RESULTS

The search strategy identified a total of 942 studies. The search query found 551 studies on SCOPUS, 140 on Google Scholar, 211 on PubMed, 28 on EbscoHost, and 12 on Epistemonikos. Following duplicate detection, 243 studies were excluded. Then, 699 studies entered title and abstract screening, where 56 studies were deemed eligible for full-text screening, which resulted in 24 studies being included in the final analysis. Meanwhile, six studies were identified from the citation search, and only one was finally contained. This process resulted in 25 selected studies (13 animal studies/*in vivo* and 12 human studies (two experimental studies and ten observational research)) considered in the final process of manuscript evaluation (Fig. 1).

Study characteristics

All of the included studies evaluated the association of vitamin D with DNA damage. Animal studies (Table 1) were done on the vitamin D-deficient diet (Chen *et al.*, 2018; Elhusseini *et al.*, 2018; Merino *et al.*, 2018), hypertension (Machado *et al.*, 2016, 2019), oxidative stress (Haq *et al.*, 2019; Liu *et al.*, 2019), and neurological disorder (Alfawaz *et al.*, 2014; Mehri *et al.*, 2020). Meanwhile, all of the following parameters were assessed only in one study: diabetes mellitus (Meerza *et al.*, 2012), high-fat diet (Merino *et al.*, 2018), kidney disease (Mohammed *et al.*, 2019), aging (Qiao *et al.*, 2020), and ovariectomy (Siebert *et al.*, 2018) model. There are four main DNA damage detection methods, including immunohistochemistry

(Chen *et al.*, 2018; Elhusseini *et al.*, 2018; Mohammed *et al.*, 2019), comet assay (alkaline comet assay) (Alfawaz *et al.*, 2014; Liu *et al.*, 2019; Machado *et al.*, 2016, 2019; Siebert *et al.*, 2018), Enzyme-linked immunosorbent assay (ELISA) (Haq *et al.*, 2019; Mehri *et al.*, 2020), and micronuclei detection (Liu *et al.*, 2019; Machado *et al.*, 2016). Meanwhile, other detection methods are flow cytometry (Merino *et al.*, 2018), gel electrophoresis (Haq *et al.*, 2019), Western blot (Qiao *et al.*, 2020) and reverse transcription polymerase chain reaction (RT-PCR) (Siebert *et al.*, 2018). Rodents, both mice and rats, were used as

Figure 4. Risk of Bias Summary.
A, Animal studies; **B**, Human studies (limited to observational studies since experimental research only consisted of one study)

Table 1. Data extraction for animal studies

Author (year)	Country	Experimental animal	Disease model and inducer	Parameter	Method	Major findings
(Alfawaz et al., 2014)	Saudi Arabia	Western Albino rats (±21 days, n=28)	Neurotoxicity by PPA	Tail length, Tail DNA (%), Tail Moment (Unit)	Comet DNA assay	There is a potential impact of vitamin D in protecting and treating PPA neurotoxicity, while ameliorating the DNA-damaging effects of PPA. Prevention impact of vitamin D against PPA-induced DNA damage is more profound than its treatment effect
(Chen et al., 2018)	China	1α(OH)ase-/-and wild-type mice (120 pairs divided into four groups)	Vitamin D-deficient model	γH2AX, 8-OHdG	Immunohistochemistry	There is an increase of DNA damage in 1,25(OH)2D3-deficient mice as measured by γH2AX and 8-OHdG on tumor cells according to immunohistochemistry
(Elhusseini et al., 2018)	United States	Female C57BL/6 mice, (4–6 weeks old), control (n = 10), vitamin D-deficient diet group (n = 10)	Vitamin D-deficient model	γH2AX, DNA repair (RAD50 and RAD51)	Immunohistochemistry	Vitamin D-deficient mice showed increased γ-H2AX in myometrial tissue compared to healthy controls (P<0.05). Vitamin D deficiency caused a significant reduction in the expression of DNA repair genes such as RAD50 (P<0.005) and RAD51 (P<0.005) compared to healthy controls.
(Haq et al., 2019)	Saudi Arabia	Wistar Albino rats (1 week, n = 4)	Hydrogen peroxide (H2O2)	Chromosomal aberration (DNA fragmentation), 8-OHdG	Gel electrophoresis, ELISA	Vitamin D, which was given for 24 hours prior to the induced oxidative stress by H2O2 significantly (p<0.001) reversed the deleterious and damaging effect of H2O2 alone as presented by DNA fragmentation percentage. Significantly lower value of 8-OHdG following the administration of vitamin D+ H2O2 than H2O2 alone (p<0.05)
(Liu et al., 2019)	China	Male mice (7–8 weeks)	CP	DNA damage score, total DNA in the tail (%), tail length, tail moment, Micronuclei formation	Alkaline comet assay, Buccal Micronuclei Cytome assay	Vitamin D3 suppressed CP-induced micronucleus formation in mice Buccal cells, with an alleviation range of 36.73–44.46% (p<0.05). Vitamin D3 injection for a dose of 5,000 IU significantly reduced CP-induced DNA damage, with a 46.6% decrease in tail DNA percentage (p<0.05), a 24.2% decrease in tail length (p<0.05), and 37.3% decrease in olive tail moment (P<.05). However, it is not significant at the 1,000 or 10,000 IU dose
(Machado et al., 2016)	Brazil	Male Spontaneously hypertensive rats (SHR) and WKY (20 weeks) divided into six groups	Hypertension model	DNA damage score, total DNA in the tail (%), tail length, tail moment, Micronuclei formation	Alkaline comet assay, Micronucleus test	Vitamin D3 deficient diet was able to increase the percentage of DNA damage in both SHR (49%) and WKY rats (54%). SHR rats with a vitamin D3 deficient diet showed a significant increase in the incidence of micronuclei formation in the bone marrow and peripheral blood (p<0.05)
(Machado et al., 2019)	Brazil	Male Spontaneously hypertensive rats (SHR) and WKY (20 weeks) divided into six groups	Hypertension model	Total DNA in the tail (%)	Alkaline comet assay	There was no significant difference in the percentage of DNA in comet tails (p>0.05) in the vitamin D deficiency group when compared to the control group. Vitamin D3 supplementation or deficiency did not significantly affect cardiac genotoxicity.
(Meerza et al., 2012)	India	Female albino mice	Diabetes model by alloxan (200 mg/kgBW)	DNA tail length	Comet assay	Vitamin D-supplemented group showed a significant decrease in liver (21.80 ± 2.40 μm) and pancreatic (19.25 ± 1.90 μm) DNA tail length in diabetic mice
(Mehri et al., 2020)	Iran	Wistar rats (200–240g, n=48)	Alzheimer's Disease by 5 μl of Aβ-containing solution	8-OHdG	ELISA	The level of DNA damage in Vitamin D and Aβ + Vitamin D groups in hippocampus and Vitamin D group of serum samples was significantly lower than that of the Aβ group (p < 0.0001)
(Merino et al., 2018)	Chile	Male Sprague-Dawley rats (4 months, n=20 divided into four groups)	High-fat diet and vitamin-D deficient-diet	DNA Fragmentation	Flow cytometry	Vitamin D supplementation results in lower DNA fragmentation, either in the control or experimental group (p<0.05). The interaction between vitamin D deficiency and diet-induced obesity was significant in DNA fragmentation (p = 0.0359)

Reference	Country	Animal model	Condition	Method	Parameter	Result
(Mohammed et al., 2019)	Egypt	Male albino rats (8-10 weeks, n=24 divided into four groups)	Acute renal damage by gentamycin 100 mg/kgBW	Immunohistochemistry	8-OHdG	Vitamin D administration significantly reduces 8-OHdG immunohistochemical expression when compared to the control group (p< 0.01)
(Qiao et al., 2020)	China	Cyp27b1+/+ and wild-type mice (9 months)	Aging model	Western blot	γ-H2AX	1,25(OH)2D insufficiency increases γ-H2AX expression significantly (p<0.001) compared with the wild type mice
(Siebert et al., 2018)	Brazil	Wistar Albino rats (90 days or 180 days, divided into four groups)	OVX	Alkaline comet assay RT-PCR	DNA damage index Telomere length	OVX significantly increases DNA damage (p < 0.001) when compared to control. Vitamin D alone decreased the DNA damage index (p < 0.05 and p < 0.001), but when associated with OVX (OVX + VIT D), partially reversed DNA damage induced by OVX (p < 0.001). Vitamin D did not change telomere length (p > 0.05), and when associated with OVX (OVX + VIT D), Vitamin D supplementation was able to reverse the observed telomere shortening (p < 0.005).

Abbreviation: γ-H2AX, γ phosphorylated form of the histone H2AX, 1,25(OH)2D3, 1,25-dihydroxyvitamin D3, 1α(OH)ase, 1alpha-Hydroxylase, 8-OHdG, 8-Hydroxyguanosine, Aβ, Amyloid beta, C57BL/6, C57 black 6, CP, Cyclophosphamide, Cyp27b1, Cytochrome p450 27B1, DNA, Deoxyribonucleic acid, ELISA, Enzyme-linked immunosorbent assay, H₂O₂, Hydrogen peroxide, IU, International unit, mg/kgBW, milligrams/kilograms body weight, OVX, Ovariectomy, PPA, Propionic acid, RAD50, RAD51, DNA repair protein RAD50, RAD51, DNA repair protein RAD51, RT-PCR, Reverse transcription polymerase chain reaction, WKY, Wistar Kyoto rat

animal models in all studies. It was found that all DNA damage parameters are associated with vitamin D levels, except in one study which did not find significant difference in the percentage of DNA in comet tails in the vitamin D deficiency group when compared to the control group (Machado et al., 2019). Another study also showed that the preventive impact of vitamin D supplementation is better than its treatment effect to ameliorate DNA damage (Alfawaz et al., 2014).

Human research (Table 2) were conducted in experimental (randomized and non-randomized clinical trial) (Wenclewska et al., 2019; Gungor et al., 2022) and observational (cross-sectional and cohort) (Ladeira et al., 2015; Lan et al., 2014; Nair-Shalliker et al., 2012b; Najeeb et al., 2020; Ng et al., 2021; O'Callaghan-Gordo et al., 2017; Petersen et al., 2014; Usman et al., 2021; Wang et al., 2016; Fagundes et al., 2019) design. In human studies, the most commonly employed parameter is comet assay (comet tail length, DNA damage score, and percentage of DNA in comet tail) (Fagundes et al., 2019; Lan et al., 2014; Najeeb et al., 2020; Ng et al., 2021; Wang et al., 2016; Wenclewska et al., 2019) and micronuclei formation (buccal or lymphocyte) (Fagundes et al., 2019; Ladeira et al., 2015; Nair-Shalliker et al., 2012b; O'Callaghan-Gordo et al., 2017; Usman et al., 2021). Other parameters are aniline blue staining (sperm DNA damage) (Gungor et al., 2022), thymine dimer (Petersen et al., 2014), and ELISA (urinary 8-OHdG) (Usman et al., 2021). Several conditions were observed in the included studies, such as diabetes mellitus, cancer, obesity, vitamin D-deficient state, and infertility. A similar finding was also observed in animal studies when the majority of the investigations revealed a significant association between vitamin D and DNA damage status. However, a study on workers occupationally exposed to formaldehyde (Ladeira et al., 2015) and on the general population (Nair-Shalliker et al., 2012b) did not show a significant association between vitamin D level and micronuclei formation, while another study only found the association in cord blood but not in maternal blood (O'Callaghan-Gordo et al., 2017). Another research also did not present any association between vitamin D level and comet assay result as the DNA damage marker in the general population (Wang et al., 2016).

Risk of Bias

All of the animal studies included in the analysis followed a similar pattern (Figs 2 and 4), with a low risk of bias on baseline characteristics, random outcome assessment, selective outcome reporting, and other biases. However, it is noteworthy that allocation concealment, random housing, and intervention blinding were not met by all studies, resulting in a high risk of bias. Meanwhile, only four studies (Liu et al., 2019; Mehri et al., 2020; Mohammed et al., 2019; Siebert et al., 2018) have a low risk of bias for outcome assessor blinding, and only two studies (Mehri et al., 2020; Siebert et al., 2018) have a low risk of bias for incomplete outcome data analysis.

We assessed the risk of bias in human studies (Fig. 3) using three scales: NOS, ROBINS-I, and ROB-2. Most studies (10/12; 83.33%) have moderate/some concerns about bias. A non-randomized study, on the other hand, runs the risk of bias due to insufficient intervention classification. Meanwhile, there is only one study (O'Callaghan-Gordo et al., 2017) that has a low overall risk of bias. According to the summary graph (Fig. 4) on observational studies, 70% have a high risk of bias on comparability due to a lack of explanation on confound-

Table 2. Data extraction for human studies

Author (year)	Location	Design	Age	% Male	Population	Method	Outcome
(Fagundes et al., 2019)	Brazil	Prospective cohort	62.11 ± 9.64[a,d]	37	75 patients with type 2 diabetes mellitus who were given supplementation of vitamin D3 4000 IU/day for 8 weeks	Comet assay / Buccal micronucleus cytome assay	Decreased DNA damage index (comet assay) (p≤0.05) and micronuclei formation (p≤0.05) following supplementation with vitamin D3 and a wash-out period. There is a negative correlation between DNA damage index and vitamin D levels (r=0.2569; p<0.0001) but not in micronuclei.
(Gungor et al., 2022)	Turkey	Non-RCT	34.67±4.01[a,c]	100	58 men with unexplained infertility (+50 controls)	Aniline blue staining (sperm DNA damage)	There was a negative and significant correlation between vitamin D levels and sperm DNA damage (r = -0.605, p<0.001)
(Ladeira et al., 2015)	Portugal	Cross-sectional	39.64 ± 11.5[a,c]	65.45	55 workers occupationally exposed to Formaldehyde (+80 controls)	CBMN assay (buccal and lymphocyte)	Vitamin D has no association with the frequency of micronuclei (lymphocytes or buccal cells) in workers exposed to formaldehyde.
(Lan et al., 2014)	China	Cross-sectional	50 ± 10[a,c]	50	16 patients with severe asthma and vitamin D <30ng/ml (+16 controls and 16 patients with vitamin D >30ng/ml)	Comet assay (DNA damage score)	The total DNA damage score for a subject with Vitamin D deficiency was significantly increased compared to the scores in Vitamin D sufficiency (p = 0.002).
(Nair-Shalliker et al., 2012b)	Australia	Cross-sectional	46.0 (27.1-61.4)[b,d]	NA	207 participants	CBMN assay	There is no association between log serum 25(OH)D concentration and log-transformed frequency of any CBMN-cyt assay biomarker (p=0.3)
(Najeeb et al., 2020)	Iraq	Cross-sectional	61.87 ± 12.77[a,c]	48.89	45 cancer patients (+ 35 controls)	Comet assay	Correlation between Tail DNA% and plasma vitamin D is significant in cancer patients (r^2=0.3707; p<0.0001) and control (r^2=0.2824; p<0.001) with higher damage at lower vitamin D level
(Ng et al., 2021)	Malaysia	Cross-sectional	29.96 ± 0.63[a,c]	0	134 participants (47 obese, 87 non-obese)	Alkaline comet assay	Multivariate analysis revealed that individuals with serum 25(OH)D level of ≥ 31 nmol/L had a significantly lower tail moment (1.06 ± 0.22 nmol/L vs. 2.37 ± 0.60 nmol/L; p = 0.029) and tail olive moment (2.36 ± 0.24 nmol/L versus 3.41 ± 0.46 nmol/L; p = 0.031) compared to those with lower serum 25(OH)D level, in the obese group
(O'Callaghan-Gordo et al., 2017)	Spain	Cross-sectional	NA	NA	344 participants (173 mothers and 171 newborns)	CBMN assay	In cord blood, 25(OH)D insufficient values (<50 nmol/L) were associated with increased lymphocyte micronuclei frequency (adjusted IRR = 1.32 (1.00, 1.72)), but not in maternal blood
(Petersen et al., 2014)	Denmark	Cross-sectional	39.74 ± 7.22[d]	46.48	71 participants	Urinary cyclobutane thymine (T–T) dimers	The association between cyclobutane thymine dimers (T–T dimers) and vitamin D is significant (r^2 = 0.76; p<0.0001), strongly indicating that the harmful DNA effects of ultraviolet radiation are unavoidable
(Usman et al., 2021)	United Kingdom	Cross-sectional	14.60 ± 2.05[a,c]	45.28	132 adolescents (53 obese, control: 59 non-obese)	Buccal micronucleus cytome assay (buccal epithelial cells) ELISA (measures 8-OHdG from urine)	Vitamin D has significant correlation with 8-OHdG (r^2=-0.245; p<0.01) and buccal micronuclei (r^2=-0.305; p<0.01)
(Wang et al., 2016)	China	Cross-sectional	20.69 ± 1.50[a,d]	36.36	121 participants (44 males, 77 females)	Comet Assay IV Lite scoring system	No significant correlation was observed between 25(OH) D level and DNA damage (r = -0.0824; P > 0.05).
(Wenclewska et al., 2019)	Poland	RCT	63.43 ± 1.57[a,c]	29.17	92 people with vitamin D deficiency (intervention: 48 people, control: 44 people (14 with T2DM, 30 healthy)	Comet assay (peripheral lymphocyte)	The percentage of DNA in the tail decreased in the intervention group when compared to the control group, either with or without T2DM (p<0.05) DNA oxidative parameters (Fpg) decreased in the intervention group (113.63 ± 4.26 vs. 104.19 ± 3.06; p<0.05), especially in the T2DM group when compared to the control group (p<0.01).

Abbreviation: 25(OH)D, 25 hydroxy vitamin D, 8-OHdG, 8-Hydroxyguanosine, T–T dimers, cyclobutane thymine dimers, CBMN, cytokinesis-block micronuclei, Cyp27b1, Cytochrome p450 27B1, DNA, Deoxyribonucleic acid, ELISA, Enzyme-linked immunosorbent assay, H_2O_2, Hydrogen peroxide, IU, International unit, IRR, Incidence rate ratio, RCT, Randomized controlled trial, T2DM, Type 2 diabetes mellitus. Data was presented as: (a) mean ± SD or (B) median (min–max), (c) exposed mean, (d) overall mean

459

ing control. However, regarding selection, 70% of the studies have a low risk of bias, and 20% of the included research has a high risk of bias. Most studies have a moderate risk of bias in outcome assessment, primarily due to non-blinding outcome assessment.

DISCUSSION

DNA damage can be divided into two types, endogenous and exogenous. Endogenous DNA damage stems from chemically active DNA involved in hydrolytic and oxidative reactions with air and reactive oxygen species (ROS), which are naturally present in cells. On the contrary, exogenous DNA damage occurs due to the involvement of environmental, physical, and chemical substances such as UV and ionizing radiation, alkylating agents, and cross-linking agents (Chatterjee & Walker, 2018). Vitamin D is regarded as an essential factor in the status of DNA damage (Najeeb et al., 2020). Vitamin D deficiency (plasma 25(OH)D <50 nmol/l) and severe deficiency (<30 nmol/l) have been associated with elevated oxidative stress, DNA damage promotion, and overall mortality (Wang et al., 2016). The impact of vitamin D on DNA damage is prominent in several disorders, including hyperglycemia and cancer (Gabryanczyk et al., 2021).

Hyperglycemia increases the production of free radicals and also induces DNA damage (Giacco & Brownlee, 2010). Studies conducted in patients with type 2 diabetes mellitus (T2DM) showed that vitamin D significantly prevented DNA damage and oxidative stress in patients with T2DM ($p<0.05$). A vitamin D-responsive element has been identified in the promotion region of the insulin receptor gene in human (Gikas et al., 2009). Pancreatic cells express the nuclear receptor for 1,25-dihydroxyvitamin D3 (1,25(OH)2D3), which modulates insulin action (Bland et al., 2004). Furthermore, vitamin D minimizes insulin resistance by its effect on calcium and phosphorus metabolism along with the upregulation of the insulin receptor gene, as well as suppression of the synthesis of proinflammatory cytokines that contribute to insulin resistance, including interleukins and TNF-α due to its antioxidative properties (Wenclewska et al., 2019; Maestro et al., 2002; Talaei et al., 2013).

In malignancy, vitamin D had positive functions as anti-proliferative, proapoptotic, anti-inflammatory, anti-angiogenesis, anti-metastatic, and anti-invasion as well as estrogen signaling inhibitor (Vuolo et al., 2012; Deuster et al., 2017; Wacker & Holiack, 2013). Calcitriol (the active form of vitamin D) inhibits the proliferation of many malignant cells by inducing cell cycle arrest and cell accumulation in the G0/G1 phase of the cell cycle. In cells, calcitriol causes G1/G0 arrest in a p53-dependent manner by increasing the expression of the cyclin-dependent kinase inhibitors p21Waf/Cip1 and p27Kip1, decreasing the activity of cyclin-dependent kinase 2 (CDK2), and causing hypo-phosphorylation. Calcitriol also increases the expression of p73, a homolog of p53, which is associated with the induction of apoptosis in several human and murine tumor systems. Suppression of p73 abrogates calcitriol-induced apoptosis and reduces the ability of calcitriol to enhance the cytotoxic effect of agents such as gemcitabine and cisplatin in a squamous cell carcinoma (SCC) model (Krishnan & Feldman, 2010; Khrisnan et al., 2012). In the previous study, it was found that vitamin D deficiency is a risk factor for malignancy (cancer) and accelerates the invasion process (Najeeb et al., 2020; Migliaccio et al., 2022). The

population of the 25 studies in this systematic review is diverse. Twelve studies conducted in humans analyzed DNA damage in patients with comorbid diseases such as T2DM, obesity, infertility, cancer patients, and the general population. Meanwhile, thirteen in vivo studies analyzed DNA damage using animal models with hypertension, ovariectomy, nephrotoxicity, vitamin D deficiency, and oxidative stress.

Several studies on vitamin D indicated that the vitamin has a beneficial impact on all organ systems of the human body. Both 25(OH)D and its hormonally active form, 1,25(OH)2D are vital for physiological functions, especially to reduce inflammation and excessive cellular oxidative stress. The 1,25(OH)2D hormone or calcitriol modulates cell proliferation through direct and indirect pathways, such as by the inhibition of the transcription factor, Nuclear factor kappa-light-chain-enhancer of activated B cells (NF-ϰB) which is associated with an elevation of oxidative stress and cellular response to inflammation and injury (Tilstra et al., 2012). Due to suppression of NF-ϰB activation, calcitriol helps to reduce chronic inflammation (Myszka & Klinger, 2014). However, more research into the relationship between DNA damage, oxidative stress, and vitamin D is required.

Vitamin D receptor (VDR) is found in testicular tissue, prostate, and spermatozoa. In addition, the intense metabolism of vitamin D in the male reproductive system and increased expression of VDR in the neck of the sperm cause males to require vitamin D for functionally active sperm (Jensen et al., 2011). Incubation of semen samples with vitamin D for 30 minutes led to a significant increase in sperm velocity parameters. This progressive increase in motility is due to vitamin D-dependent calcium release and subsequent cyclic AMP/protein kinase A (cAMP/PKA) activation and Adenosine triphosphate (ATP) production (Gunter et al., 2004). There was a significant negative correlation ($p<0.05$) between vitamin D and sperm DNA damage in this systematic review. After binding to the VDR receptor, vitamin D initiates slow genomic effects by stimulating the release of ligand-activated transcription factors in the nucleus. In unexplained infertile patients with vitamin D deficiency, sperm DNA damage may occur due to delayed genomic effects (Jurutka et al., 2001).

Studies in various animal models showed that vitamin D exerts a protective effect on DNA. Vitamin D can reduce the DNA damage index (percentage of DNA in comet tails assessed from comet tests). In addition, in genomic instability animal models induced by cyclophosphamide, vitamin D can reduce the frequency of micronuclei formation (a marker of DNA damage). Besides the percentage of DNA in comet tails and the frequency of micronuclei, DNA damage can also be assessed by the levels of 8-OHdG, a marker of oxidative DNA damage (Smith et al., 2005). Elevated levels of 8-OHdG in rat animal models are also associated with a complete loss of VDR expression. Because the expression of VDR depends on the availability of 1,25(OH)2D, the loss of VDR suggests that there may be a role for 1,25(OH)2D in protecting cells against hyperproliferation and oxidative DNA damage (Kállay et al., 2002; Nair-Shalliker et al., 2012a). Decreased levels of 8-OHdG after vitamin D supplementation was proven in the animal model studies (Haq et al., 2019; Mohammed et al., 2019). The results of studies in animal models (in vivo) are in line with those of studies in cells (in vitro) (Chen et al., 2018; Liu et al., 2019). These outcomes can confirm that vitamin D has a protective effect on DNA.

Various parameters of oxidative stress are also presented in this systematic review. In human studies, vitamin D supplementation led to a significant decrease in NO and total thiols and an increase in the concentration of reduced glutathione (GSH) leading to a decrease in oxidative processes in cells (Fagundes *et al.*, 2019). In a study of animal models with hypertension, vitamin D was not significantly associated with DNA damage. However, vitamin D3 deficiency alters the level of Thiobarbituric Acid Reactive Substance (TBARS) in a mouse model of spontaneous hypertension, which is an indicator of Reactive Oxygen Species (ROS)-initiated peroxidation of unsaturated fatty acids in membrane lipids and alters the permeability, fluidity, and integrity of the plasma membrane (Potter *et al.*, 2011). Lipid peroxidation predisposes patients to conditions such as hypertension and thromboembolic (Yavuzer *et al.*, 2016). Vitamin D can reduce oxidative stress that occurs in cells thereby reducing DNA damage.

This systematic review proved that vitamin D protects against DNA damage. However, there are some limitations to this systematic review. First, the study populations are largely heterogeneous with different diseases and DNA damage parameters; thus, the results can be biased. In addition, human studies are still sparse (only one randomized controlled trial/RCT) and mainly with a moderate RoB. Consequently, the application of the results to humans still needs to be considered. Further studies with randomized controlled trial designs are expected in the future to increase the strength of evidence.

CONCLUSION

There is a significant association between vitamin D and DNA damage. However, although the majority of studies have found that vitamin D has a protective effect against DNA damage, other research found contradictory findings. Thus, the need of further investigations with stricter criteria must be commenced. Nevertheless, it is safe to conclude that a diet with sufficient vitamin D content and supplementation (more than 1000 IU/day, preferably about 2000–5000 IU/day) is recommended to prevent DNA damage and oxidative stress in cells.

LncRNA AC093850.2 predicts poor outcomes in patients with triple-negative breast cancer and motivates tumor progression by sponging miR-4299

Zhangbo Xu[1], Yongxue Gu[2], Ying Lei[2] and Lili Teng[3]✉

[1]Department of Breast and Thyroid Surgery, The Third People's Hospital of Chengdu, Chengdu, China; [2]Department of Breast Surgery, Weifang People's Hospital, Weifang, China; [3]Department of Infectious Diseases, Weifang People's Hospital, Weifang, China

Background: Accumulating evidence displays that non-coding RNAs (ncRNAs) are involved in the progression of triple-negative breast cancer (TNBC). This study aimed to investigate the role of lncRNA AC093850.2 in TNBC. **Methods:** The AC093850.2 levels were compared using RT-qPCR in TNBC tissues and corresponding normal tissues. The Kaplan-Meier curve method was conducted to assess the clinical significance of AC093850.2 in TNBC. Bioinformatic analysis was used to predict potential miRNA. Cell proliferation and invasion assays were carried out to explore the function of AC093850.2/miR-4299 in TNBC. **Results:** lncRNA AC093850.2 expression is raised in TNBC tissues and cell lines, which is related to the shorter overall survival of patients. AC093850.2 is directly bound to miR-4299 in TNBC cells. Downregulation of AC093850.2 reduces tumor cell proliferation, migration, and invasion abilities, while miR-4299 silence attenuated AC093850.2 silencing induced inhibition of cellular activities in TNBC cells. **Conclusion:** In general, the findings suggest that lncRNA AC093850.2 was closely related to the prognosis and progression of TNBC by sponging miR-4299, which might be a prognosis predictor and potential target for treating TNBC patients.

INTRODUCTION

The incidence and mortality of breast cancer have obvious regional variations around the world (Azamjah *et al.*, 2019). In recent years, the incidence of breast cancer in China has been increasing year by year, and women tend to be younger (Li *et al.*, 2016). The etiology of breast cancer is complex and closely related to a variety of genetic and non-genetic factors (Cappetta *et al.*, 2021). Studies have manifested that being unmarried, childless, on high-fat diet, obese, having multiple x-rays and obvious benign breast diseases are all risk factors for the occurrence of breast cancer (Rojas & Stuckey, 2016; Sun *et al.*, 2017). Currently, surgical resection and chemotherapy are the main treatments for breast cancer. However, breast cancer has the characteristics of being highly metastatic and spreads easily through lymphatic metastases (Kim, 2021). Breast cancer patients are prone to recurrence after surgical treatment, and the quality of life is also low, which seriously affects the clinical effect of breast cancer prevention and treatment. Among the subtypes of breast cancer, triple-negative breast cancer (TNBC) has a higher risk of recurrence and metastasis (Yin *et al.*, 2020). Due to the obvious heterogeneity of TNBC and the lack of expression of ER, PR, and HER-2, the clinical treatment is more difficult, so the survival rate of TNBC patients is not significantly improved (Yin *et al.*, 2020). Therefore, it is of great significance to explore effective methods and strategies for improving the prevention and treatment of breast cancer.

The functions of non-coding RNA (ncRNA) genes have attracted more attention in normal physiological functions and pathological processes (Panni *et al.*, 2020). ncRNAs are a general term for RNA that are not participating in protein-coding, such as long non-coding RNA (lncRNA) and microRNA (miRNA) (Yang *et al.*, 2020; Zhao *et al.*, 2020). With the continuous in-depth study of ncRNA, it was unexpectedly discovered that the mutation or differential expression of ncRNA is related to the occurrence and progression of many diseases (Anastasiadou *et al.*, 2017). Currently, the role of lncRNA in the process of cell proliferation, differentiation, and disease occurrence has received more and more attention (Mori *et al.*, 2018; Romano *et al.*, 2017). LncRNAs are relatively non-conservative in evolution and can regulate cellular activities at multiple levels, including chromatin modification, transcriptional level, and post-transcriptional level regulation (Barreca *et al.*, 2021). The abnormal lncRNA expression can not only affect tumor growth and metastasis but also serve as indicators for clinical detection and treatment (Schmitt & Chang, 2016; Wang *et al.*, 2017). Several lncRNAs are reported to be involved in the progression of breast cancer, such as NR2F1-AS1 (Zhang *et al.*, 2020), H19, and NEAT1 (Müller *et al.*, 2019). LncRNA AC093850.2 expression was increased in lung adenocarcinoma (Qiu *et al.*, 2015) and gastrointestinal esophageal cancer (Su *et al.*, 2022). A previous study reported that AC093850.2 has prognostic significance for breast cancer based on Gene Expression Profiling Interactive Analysis (GEPIA) (Zhang *et al.*, 2019), while its involvement in TNBC is elusive.

Herein, we investigated the role of AC093850.2 in the progression of TNBC. The expression of AC093850.2 was increased in TNBC tissues. miR-4299 functions as a suppressive miRNA in some types of cancer, such as lung cancer (Yang *et al.*, 2018). We observed that AC093850.2 functioned as the sponge of miR-4299 to regulate the progression of TNBC. Thus, the increased expression of

AC093850.2 may serve as a prognostic marker for TNBC patients and be a novel potential therapeutic target.

MATERIALS AND METHODS

Specimen source

A total of 135 cases of TNBC tissues and corresponding paracentral tissue specimens were collected from Weifang People's Hospital from January 2014 to December 2016 and stored in liquid nitrogen until use. All patients signed the informed consent. This study was approved by the Ethics Committee of Weifang People's Hospital. The inclusion criteria: 1) patients were first onset and initial operation; 2) patients were pathologically diagnosed as TNBC; 3) patients have a complete medical history and five-year follow-up information. The median age of patients was 50.5 years, ranging from 29 to 82 years.

Cell lines and transfection

TNBC cell lines (BT549, MDA-MB-231, and HCC1937), other subtypes of breast cancer cell lines (SKBR3, MCF7, BT474), and normal breast epithelial cell line MCF-10A were acquired from ATCC and were stored in our laboratory. Cells were cultured in a DMEM medium (Gibco) containing 10% FBS (Hyclone) in a 5% CO_2 incubator at 37°C, and the medium was changed every 48–72 h. The cells in good conditions were cultured in 6-well plates until the logarithmic growth period.

MDA-MB-231 and HCC1937 cells were used for cell transfection. The AC093850.2 siRNA (si-AC093850.2), siRNA NC, miR-4299 mimic, mimic negative control (mimic NC), miR-4299 inhibitor (inhi-miR-4299), inhibitor NC were obtained from GenePharma (Shanghai, China). These vectors were transfected or co-transfected into TNBC cells using Lipofectamine 2000 reagent.

RNA isolation and RT-qPCR

Total RNA was prepared from tissue specimens and cell lines using a pre-cooled Trizol isolation kit (Invitrogen) and cDNA synthesis was performed using a Transcriptor First Strand cDNA Synthesis Kit (Roche, Mannheim, Germany) for lncRNA and a miRVana miRNA isolation kit (Applied Biosystems) for miRNA. Then cDNA was amplicated by RT-qPCR using an SYBR Green PCR Kit (TaKaRa) for lncRNA or miRCURY LNA miRNA SYBR Green PCR kit (Qiagen) for miRNA. GAPDH and U6 were used as normalization controls. The relative levels of lncRNA and miRNAs were calculated by the comparative Ct method.

MTS assay for cell proliferation

Cell proliferation rate was evaluated using an MTS assay. The cells (3000 cells/well) were incubated in 96-well plates at 37°C. After 24, 48, and 72 h of incubation, the MTS reagent (Promega) was added to the well in a dark environment and incubated in the incubator for 2 h. After incubation, the absorbance value (OD value) of each well was detected at 490 nm by the microplate reader (BioRad).

Transwell assays

For migration and invasion assays, a 24-well Transwell chamber (8 μm core; Corning, NY) was adopted to carry out the experiments. The membrane in the upper chamber of the transwell was precoated with Matrigel (BD), which was used for the evaluation of the invasion abilities of tu-

mor cells. The migration assay does not need to be precoated with Matrigel. The serum-free medium was used to incubate the cells ($1×10^5$ cells) in the top chamber, and a 600 μl culture medium with 10% FBS was included in the lower chamber. The invading and migrating cells were fixed, stained, and counted with a microscope (Olympus).

Dual-luciferase reporter assay

The 3'UTR of AC093850.2 fragment with miR-4299 binding sites was inserted into the pmirGLO dual-luciferase vector (Promega) and named as AC093850.2 3'-UTR WT. The mutant 3'UTR of AC093850.2 was subcloned into pmirGLO and named as AC093850.2 3'UTR MUT. The WT or MUT fragment was co-transfected with miR-4299 mimic, or mimic NC into TNBC cells for 48 h. The luciferase activities were detected using a Dual-luciferase reporter assay kit (KeyGen, China).

Statistical analysis

Results were acquired from at least three independent experiments and were presented as mean ± S.D. The significance was assessed by the SPSS and GraphPad Prism software using the $χ^2$ test, Student's t-test, or one-way ANOVA. The survival rates and clinical prognostic value were evaluated by the Kaplan-Meier method and multivariate Cox regression analysis. The difference was considered statistically significant when $P<0.05$ for all statistical analyses.

RESULTS

High AC093850.2 expression was related to clinicopathological parameters and shorter overall survival

The expression of AC093850.2 was monitored using RT-qPCR in 135 pairs of tissue specimens. AC093850.2

Figure 1. Increased expression of AC093850.2 was related to the shorter overall survival of TNBC patients.
(**A**) The expression level of AC093850.2 in paired tumor tissues and normal tissues was analyzed by RT-qPCR. ***$P<0.001$. (**B**) The expression level of AC093850.2 in TNBC cell lines was measured by RT-qPCR. **$P<0.01$, ***$P<0.001$. (**C**) The Kaplan-Meier curve was conducted to assess the survival outcome of AC093850.2 in TNBC (log-rank test, $P=0.017$).

Table 1. Association of LncRNA AC093850.2 expression and clinicopathological parameters of TNBC patients

Variable	Cases (n=135)	AC093850.2 expression		P-value
		Low (n=67)	High (n=68)	
Age (years)				0.436
≤ 50	70	37	33	
> 50	65	30	35	
Tumor size (cm)				0.048
≤ 2	61	36	25	
> 2	74	31	43	
Pathological stage				0.098
I–II	75	42	33	
III	60	25	35	
Lymph node metastasis				0.007
Negative	75	45	30	
Positive	60	22	38	
TNM stage				0.001
I–II	77	48	29	
III	58	19	39	
Ki67				0.024
≤ 14%	86	49	37	
> 14%	49	18	31	

expression was upregulated in TNBC tissues ($P<0.001$, Fig. 1A). Further, the higher AC093850.2 expression was observed in TNBC cell lines (BT549, MDA-MB-231, and HCC1937) as shown in Fig. 1B ($P<0.01$). The expression of AC093850.2 in other subtypes of breast cancer cells was measured. The expression of AC093850.2 was also increased in other subtypes of breast cancer (SKBR3, MCF7, BT474) ($P<0.01$, Supplementary Fig. 1 at https://ojs.ptbioch.edu.pl/index.php/abp/), but not as high as that in TNBC cells except for SKBR3 cell.

The χ^2 test was used to evaluate whether the expression of AC093850.2 was associated with the clinical characteristics of TNBC patients. The results in Table 1 indicated that high expression of AC093850.2 was related to the aggressive characteristics of TNBC, including positive lymph node metastasis ($P=0.007$), advanced TNM stage ($P=0.001$), larger tumor size ($P=0.048$), and high Ki67 level ($P=0.024$). The data suggest that AC093850.2 was potentially associated with a higher risk of disease, which may be correlated with patients' survival. The clinical analysis verified high AC093850.2 expression in correlation with poor survival data of pa-

tients with TNBC (log-rank $P=0.017$, Fig. 1C). These results revealed that AC093850.2 upregulation may participate in the progression of TNBC and be potentially a valuable prognostic predictor for this disease. Moreover, multivariate Cox regression analysis included clinical characteristics and AC093850.2 expression in the evaluation of prognostic-related risk factors in TNBC. The results in Table 2 revealed that age and pathological stage were not independent risk factors for prognosis of patients, while AC093850.2 expression, tumor size, lymph node metastasis, TNM stage, and Ki67 were independent risk factors for the shorter prognosis of TNBC patients.

LncRNA AC093850.2 targeted miR-4299 and regulated its expression

Bioinformatics prediction (LncBase Predicted v.2) showed that AC093850.2 could potentially bind to several miRNAs, including miR-4299. Among these miR-NAs, miR-4299 expression was found to be increased in AC093850.2-knockdown TNBC cells, as shown in Fig. 2A ($P<0.001$). The targeting relationship between AC093850.2 and miR-4299 was displayed in Fig. 2B.

Table 2. Multivariate Cox analysis of factors for survival of TNBC patients

Variables	Multivariate Cox analysis		
	HR	95%CI	P value
AC093850.2 expression (low *vs* high)	0.226	0.060–0.846	0.027
Age (≤50 *vs* >50 years)	0.447	0.160–1.246	0.124
Tumor size (≤2 *vs* >2 cm)	0.202	0.044–0.920	0.039
Pathological stage (I–II *vs* III)	0.449	0.149–1.349	0.154
Lymph node metastasis (Negative *vs* Positive)	0.177	0.036–0.865	0.032
TNM stage (I–II *vs* III)	0.269	0.083–0.870	0.028
Ki67 (≤14% *vs* >14%)	0.305	0.099–0.939	0.039

Figure 2. AC093850.2 directly binds to miR-4299 in TNBC cells.
(**A**) miR-4299 was increased in AC093850.2 silenced cells. ***$P<0.001$. (**B**) Sequencing alignment showed putative binding sites between AC093850.2 and miR-4299. (**C**) The expression of miR-4299 was detected using RT-qPCR in TNBC tissues. ***$P<0.001$. (**D**) Overexpression of miR-4299 decreased relative luciferase activity of AC093850.2-WT but not AC093850.2-MUT in MDA-MB-231 cells. ***$P<0.001$. (**E**) Increased expression of miR-4299 reduced relative luciferase activity of AC093850.2-WT but not AC093850.2-MUT in HCC1937 cells. ***$P<0.001$.

Whereafter, the downregulation of miR-4299 expression in TNBC tissues was observed compared with that in normal tissues ($P<0.001$, Fig. 2C). The dual-luciferase reporter assay validated the binding relationship between AC093850.2 and miR-4299 and the results demonstrated that the luciferase activity of cells co-transfected with AC093850.2-WT and miR-4299 mimic was decreased ($P<0.001$), while no significant changes were observed in cells co-transfected with AC093850.2-MUT and miR-4299 mimic (Fig. 2D and 2E). The above results revealed that AC093850.2 targeted and regulated the expression of miR-4299.

Silence of AC093850.2 weakened cell proliferation possibly by regulating miR-4299

After transfection, downregulation of AC093850.2 by si-AC093850.2 reached more than 200% in cells of both TNBC cell lines ($P<0.001$, Fig. 3A). Silence of AC093850.2 led to the increased expression of miR-4299 in both cell lines, while downregulation of miR-4299 restrained the increased levels of miR-4299 by si-AC093850.2 ($P<0.001$, Fig. 3A).

Results of cell proliferation experiments indicated that silencing AC093850.2 inhibited proliferation abilities, while knockdown of miR-4299 reversed the inhibitory effect of si-AC093850.2 on the proliferation of cancer cells ($P<0.05$, Fig. 3B).

Influence of knockdown of AC093850.2 on cellular migration and invasion activities by regulating miR-4299

Following the above cellular experiments, Transwell assays were performed to evaluate the influence of si-AC093850.2 on cell migration and invasion capacities. Silencing of AC093850.2 expression effectively inhibited the migration of cells ($P<0.001$), whereas the im-

Figure 3. AC093850.2 acts as a ceRNA that regulate cell proliferation by sponging miR-4299.
(**A**) RT-qPCR analysis of AC093850.2 or miR-4299 expression in MDA-MB-231 and HCC1937 cells after transfection. ***$P<0.001$. (**B**) The proliferation abilities were inhibited by the knockdown of AC093850.2 while reversed by the silence of miR-4299. ***$P<0.001$.

Figure 4. Downregulation of miR-4299 reverses the inhibition of migration and invasion potential in TNBC cells induced AC093850.2 silencing.
(**A**) A Transwell migration assay was conducted to determine the effects of AC093850.2/miR-4299 knockdown on cell migration. ***$P<0.001$. (**B**) Transwell invasion assay was performed to measure the effects of AC093850.2/miR-4299 silencing on cell invasion capacities. ***$P<0.001$.

pact of knockdown of AC093850.2 was reversed by a miR-4299 inhibitor ($P<0.001$, Fig. 4A). Similar results were observed in invasion assays ($P<0.001$, Fig. 4B). These data suggest that AC093850.2 interference is a towardly strategy to prevent TNBC progression by targeting miR-4299.

DISCUSSION

TNBC is difficult to cure, easy to relapse, and has a high metastasis rate, which has become a major problem in the treatment of breast cancer. Hence, exploring novel prognostic and therapeutic targets is extremely important for improving clinical strategies and outcomes for TNBC patients. Growing studies suggest that lncRNAs involved in tumor prognosis and progression have been identified (Huang *et al.*, 2021; Volovat *et al.*, 2020). For instance, lncRNA HAGLR (Jin *et al.*, 2021), CARMN (Sheng *et al.*, 2021), and Uc003xsl.1 (Xu *et al.*, 2022) were involved in the tumor progression of TNBC and were associated with patients' prognosis. In this study, we clarified the expression levels of AC093850.2 that were remarkably increased in TNBC tissues compared with corresponding paracancerous normal tissues. Similarly, the expression pattern of AC093850.2 was observed in TNBC cell lines. These results speculated that AC093850.2 may be involved in the regulation of the malignant evolution of TNBC. Interestingly, a high expression of AC093850.2 was observed in an HER-positive breast cancer cell line (SKBR3 cell), which imply that AC093850.2 may not have an actual impact only on TNBC. In this study, we mainly investigated the role of AC093850.2 in TNBC.

To further investigate the association between AC093850.2 and the clinical properties of TNBC, the clinicopathological characteristics of patients were gathered and statistically analyzed. The expression of

AC093850.2 affected the tumor size, lymph node metastasis, TNM stage, and Ki67 of TNBC patients. However, TNBC is regulated by a variety of lncRNAs or other genes, and the expression levels of different lncRNAs in TNBC are not the same, and the relationship with the clinical characteristics of TNBC is not the same. For instance, serum lncRNA SUMO1P3 levels were related to positive lymphovascular invasion, lymph node metastasis, or high grade, but not related to tumor size (Na-Er *et al.*, 2021). Herein, further survival analysis revealed that TNBC patients with high AC093850.2 expression had a poor survival outcome. Multivariate Cox regression analysis revealed that AC093850.2 expression is a risk factor for the overall survival of TNBC patients. The clinical prognostic significance of AC093850.2 was reported in esophageal squamous cell carcinoma (Huang, *et al.*, 2018). A previous differently identifying RNA expression profiles study indicated that AC093850.2 has a prognostic value for breast cancer (Zhang *et al.*, 2019). Similarly, results in this study validated the prognostic value of AC093850.2 in TNBC using a bunch of TNBC patients. Therefore, AC093850.2 may be an independent prognostic factor for TNBC.

lncRNAs could act as a competitive endogenous RNA to regulate miRNA function. For instance, lncRNA XLOC-006390 as a ceRNA facilitates cervical cancer tumorigenesis by inhibiting miR-331-3p and miR-338-3p (Luan & Wang, 2018). The expression of lncRNA PCED1B-AS1 expression is increased in colorectal adenocarcinoma tissues and knockdown of PCED1B-AS1 suppresses tumor progression by sponging miR-633 (Liu *et al.*, 2022). In this study, we used an online database to identify miRNAs with AC093850.2 binding sites, which showed a binding relationship between miR-4299 and AC093850.2. The expression of miR-4299 was increased in AC093850.2-silenced tumor cells. We also observed that AC093850.2 functions as a sponge for miR-4299 in

TNBC. We also observed that miR-4299 expression was downregulated in TNBC tumor tissues. These data revealed that lncRNA AC093850.2 may act as a ceRNA to regulate tumor progression of TNBC by inhibiting miR-4299 expression.

The role of lncRNAs in tumorigenesis and progression has been widely investigated. Further cellular experiments were conducted to explore the influence of AC093850.2/miR-4299 on the cellular activities of TNBC cells. miR-4299 was downregulated in non-small cell lung cancer tissues and restrained tumor cell proliferation, migration, and invasion by modulating the activation of the PTEN/AKT/PI3K signaling pathway (Yang *et al.*, 2018). The expression of miR-4299 was also decreased in follicular thyroid carcinoma cells and could mediate the invasive properties by targeting ST6 (alpha-N-acetyl-neuraminyl-2,3-beta-galactosyl-1,3)-N-acetyl-galactosaminide alpha-2,6-sialyltransferase 4 (ST6GAL-NAC4) (Miao *et al.*, 2016). The current results revealed that knockdown of AC093850.2 restrained cell viability and migration of TNBC cells, whereas the impact of AC093850.2 knockdown was recovered by miR-4299 inhibitor, indicating that AC093850.2 interference is a towardly strategy to impede TNBC progression by targeting miR-4299.

There are some limitations of this study. This study mainly investigated the role of AC093850.2 in TNBC, but its impact on other subtypes of breast cancer remains to be explored. In future studies, other subtypes of breast cancer patients will be enrolled to explore the clinical role of AC093850.2 in other subtypes of breast cancer. On the other hand, the detailed mechanism of AC093850.2 in TNBC needs to be investigated in the future.

In general, lncRNA AC093850.2 was elevated in TNBC tissues and related to patients' prognosis. AC093850.2/miR-4299 suggests crosstalk between lncRNA and miRNA that might drive TNBC progression. This crosstalk between AC093850.2 and miR-4299 may reveal the mechanism of AC093850.2 in TNBC, which may be a potential target for TNBC treatment and prognosis prediction.

Anaplastic thyroid cancer (ATC) is a rare but lethal human malignant cancer with no known cure. Ellagic acid (EA), a natural plant extract, has shown antitumor activity against multiple cancers; however, its effects on the malignant phenotypes of ATC cells remain unknown. This study aimed to evaluate the effects of EA on proliferation, migration, and invasion of ATC cells and further explore the associated signaling mechanisms. The normal human thyroid cell line Nthy-ori3-1 and ATC cell line BHT-101 were used. Cytotoxicity assay was performed using the Cell Counting kit-8 (CCK-8) assay. Cell proliferation, migration, and invasion assays were performed using the CCK-8 and colony formation, wound healing, and Transwell invasion assays, respectively. Western blotting was used to detect the levels of related proteins. β-catenin nuclear protein levels were measured to evaluate the Wnt/β-catenin pathway. The phosphorylation level of the Akt protein was measured and calculated to evaluate the PI3K/Akt pathway. LiCl and IGF-1 were used as pathway agonists to determine the involvement of the corresponding pathway. The results showed that EA inhibited the proliferation, migration, and invasion of ATC cells. Furthermore, both the Wnt/β-catenin and PI3K/Akt pathways were suppressed by EA treatment, and activation of these two pathways reversed the EA-induced inhibition of the pathological phenotypes of ATC cells. These findings demonstrate that EA inhibits proliferation, migration, and invasion of ATC cells by suppressing the Wnt/β-catenin and PI3K/Akt pathways, suggesting that EA is a potential drug candidate for treating ATC and provides a theoretical basis for further *in vivo* experiments and clinical applications.

Key words: ellagic acid, anaplastic thyroid cancer, cell behaviors, Wnt/β-catenin pathway, PI3K/Akt pathway

Received: 10 April, 2022; revised: 15 October, 2022; accepted: 19 October, 2022; available on-line: 11 February, 2023

INTRODUCTION

Thyroid cancer is the most common malignant endocrine tumor with an increasing incidence worldwide every year (Hsu *et al.*, 2014; Haymart, 2021). Anaplastic thyroid cancer (ATC), also known as undifferentiated thyroid cancer, is a rare subtype of thyroid cancer. Although this subtype accounts for 1–2% of all thyroid cancers, it is the most lethal subtype (Molinaro *et al.*, 2017). Unfortunately, there is currently no effective treatment for ATC. Previous studies have shown that traditional cancer treatments, including surgery, chemotherapy and radiotherapy, do not significantly improve the prognosis of ATC patients (Tuttle *et al.*, 2017; Tiedje *et al.*, 2018). Therefore, it is important to explore novel ATC treatment strategies. Attenuation of proliferation, migration, and invasion of ATC cells is considered an effective strategy for suppressing the development of ATC.

Ellagic acid (EA) (molecular formula $C_{14}H_6O_8$; Fig. 1A) is a natural polyphenolic compound and dimeric gallic acid derivative that is widely distributed in various fruits and nuts. EA possesses a wide range of biological activities, including antioxidant, antiviral, and antitumor activities (Shakeri *et al.*, 2018). In the field of antitumor therapy, EA has been reported to exert inhibitory effects on various cancers, such as colorectal, breast, and prostate cancers (Ceci *et al.*, 2018). Additionally, in our previous study, we demonstrated that EA inhibited the proliferation and migration of hypertrophic scar fibroblasts (Liu *et al.*, 2021). However, the role of EA in ATC remains unclear.

The canonical Wnt/β-catenin and PI3K/Akt pathways play key roles in tumor development. Unphosphorylated β-catenin enters the nucleus and initiates the transcription of downstream target genes; the nuclear β-catenin level represents the activation level of the Wnt/β-catenin pathway (Rao & Kühl, 2010). Akt is a key molecule involved in the PI3K/Akt pathway, and its phosphorylation level represents the activation level of this pathway (Jiang *et al.*, 2020). Aberrant activation of the Wnt/β-catenin and PI3K/Akt pathways is associated with ATC progression (Saji & Ringel, 2010; Sastre-Perona & Santisteban, 2012; Jiang *et al.*, 2022; Zhang *et al.*, 2022).

In this study, we evaluated the effects of EA on proliferation, migration, and invasion of ATC cells. Furthermore, we investigated whether Wnt/β-catenin and PI3K/Akt signaling pathways are involved in EA-induced regulation.

MATERIALS AND METHODS

Cells culture

The normal human thyroid cell line Nthy-ori3-1 (cat. no. CTCC-003-0031) was obtained from Meisen Cell (Zhejiang, China), and ATC cell line BHT-101 (cat. no. BNCC359868) was obtained from the BeNa Culture Collection (Beijing, China). Both cell lines were cultured in Roswell Park Memorial Institute (RPMI) 1640 medium containing 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin at 37°C with 5% CO_2. All cell culture reagents were purchased from Gibco (Thermo Fisher Scientific, MA, USA).

Antibodies and drugs

The primary antibodies used for western blotting were as follows: anti-β-catenin (1:5000, cat. no. ab32572; Abcam, Cambridge, UK), anti-Histone H3 (1:2000, cat. no. ab1791; Abcam), anti-phospho-pan-Akt (1:500; cat. no. AF0016; Affinity, OH, USA), anti-pan-Akt (1:500; cat. no. AF6261; Affinity), and anti-β-actin (1:2000; 60008-1-Ig; Proteintech, IL, USA). The secondary antibodies (1:5000; goat anti-mouse cat. no. SA00001-1, goat anti-rabbit cat. no. SA00001-2; Proteintech) were used for western blotting analysis. EA (cat. no. B21073; Yuanye Biotech, Shanghai, China) was dissolved in 1 M NaOH. The final concentration of NaOH was ≤ 0.1% (v/v), which did not induce toxicity (Duan *et al.*, 2019). Lithium chloride (LiCl) (cat. no. L9650; Sigma-Aldrich, MO, USA), an agonist of the Wnt/β-catenin pathway, was dissolved in sterile double-distilled water and used at a concentration of 25 mM. Recombinant human insulin-like growth factor-1 (IGF-1) protein (cat. no. 291-G1; R&D Systems, MN, USA), an agonist of the PI3K/Akt pathway, was dissolved in RPMI 1640 and used at a concentration of 100 ng/mL.

Cytotoxicity assay

The Cell Counting kit (CCK-8) assay was used to perform the cytotoxicity assay. The assay was performed as previously described (Liu *et al.*, 2021). Briefly, cells were seeded at a density of $5×10^4$ cells per well in a 96-well plate (n=3). After cell attachment, the cells were treated with varied concentrations of EA (0–160 μM). After treatment for 24 hours, 10 μL of CCK-8 (cat. no. 40203ES60; Yeasen, Shanghai, China) reagent was added to each well. After incubation for 2 hours at 37°C, the absorbance was measured at 450 nm wavelength using a microplate reader (Thermo Fisher Scientific, MA, USA). The results were expressed as cell survival rates. Cell survival rate (%) = (OD value of treated group – OD value of blank)/(OD value of control group – OD value of blank) × 100.

Proliferation assay

A CCK-8 assay was used to assess cell proliferation. BHT-101 cells were seeded at $5×10^3$ cells per well in a 96-well plate (n=3), and the OD values were measured at 24, 48, and 72 h after treatment according to the experimental requirements. In addition, the OD value detection method was the same as that of the cytotoxicity assay. The results are expressed as OD values.

A plate colony formation assay was performed to assess cell proliferation. BHT-101 cells were seeded in 12-well plates (n=3) at a density of 200 cells/well. After incubation for 12 days at 37°C, colonies were fixed with 4% paraformaldehyde (cat. no. P1110; Solarbio, Beijing, China) for 20 min at room temperature and stained with 0.5% crystal violet stain solution (cat. no. 60506ES60; Yeasen) for 10 min at room temperature, and the number of colonies was counted using ImageJ software (version 1.51w).

Migration assay

A wound healing assay was used to assess cell migration. This assay was performed as previously described (Liu *et al.*, 2021). Briefly, BHT-101 cells were cultured in a 12-well plate (n=3) with RPMI 1640 containing 10% FBS until the cell confluence reached 100%. A scratch wound was made in the middle of each well using a 200-μL pipette tip. The culture medium was then replaced with serum-free RPMI 1640 medium. At 0 and 24 h after scratching, images were captured in five random fields of view using an inverted light microscope (magnification 100×; Olympus Corporation, Tokyo, Japan). The wound area was measured using ImageJ software. The results were expressed as migration rates. Migration rate (%) = (initial wound area – wound area at 24 h)/initial wound area ×100.

Transwell invasion assay

Transwell invasion assay was used to assess cell invasion. Transwell plates (24-well, 8 μm; Labgic, Beijing, China) were pre-coated with Matrigel (BD Biosciences, CA, USA) for 30 min at 37°C. BHT-101 cells were seeded in the upper chambers of Transwell plates (n=3) at a density of $5×10^4$ cells/well and incubated in serum-free RPMI 1640 medium. The lower chambers were supplied with a culture medium containing 10% FBS. After 48 h, non-invading cells on the upper face of the membrane were removed with a cotton swab, and the invaded cells were fixed with 4% paraformaldehyde for 20 min at room temperature and stained with 0.5% crystal violet stain solution for 10 min. Images were captured in five random fields of view using an inverted light microscope (magnification 200×). The number of cells was counted using ImageJ software.

Western blotting

Western blotting was used to assess protein expression levels. The harvested cells were processed using a nuclear and cytoplasmic protein extraction kit (cat. no. P0028; Beyotime, Shanghai, China) to extract nucleoproteins and RIPA lysis buffer (cat. no. 9806S; CST, MA, USA) to extract the total protein. Western blotting was performed to detect the levels of β-catenin and Histone H3 (loading control) in nucleoprotein, and total Akt (t-Akt), phosphorylated Akt (p-Akt), and β-actin (loading control) in total protein, as described previously (Liu *et al.*, 2021). Samples were separated using 10% SDS-PAGE gels, and subsequently electro-transferred to PVDF membranes (Millipore, MA, USA) for immunoblotting analysis. After incubation with primary antibodies, the membranes were incubated with the corresponding secondary antibodies. Protein chemiluminescence was detected using the Super ECL Detection Reagent (cat. no. 36208ES60; Yeasen) using a KETA GL Imaging System (Wealtec, NV, USA), and the gray values of the bands were quantified using ImageJ software.

Statistical analysis

The quantified data are presented as mean ± standard deviation (S.D.). The data were assessed for normality

using the Shapiro-Wilk test and were analyzed by one-way ANOVA followed by post hoc Dunnett's or Sidak test using the GraphPad Prism (version 7.03) statistical package. A P-value of <0.05 indicated a statistically significant difference.

RESULTS

Effect of EA on the proliferation of ATC cells

To determine the appropriate concentration of EA for use in ATC cells, we performed a cytotoxicity assay for EA on Nthy-ori3-1 cells, a normal human thyroid cell line, using the CCK-8 assay. The results showed that EA did not cause significant cytotoxicity in normal cells at a concentration ≤100 μM, which suggested the concentration range used in the following experiments (Fig. 1B). We also examined the cytotoxicity of EA in BHT-101 cells, an ATC cell line, and found that ATC cells were more tolerogenic (Fig. 1B). Next, we evaluated the ef-

fect of EA on ATC cell proliferation using CCK-8 and colony formation assays. As shown in Fig. 1C, ATC cell viability was significantly reduced in the EA-treated group (40 or 80 μM) at all time points. Notably, as the concentration of EA increased, cell viability significantly decreased. Additionally, the results of the colony formation assay showed that the colony number of ATC cells in the EA-treated group (40 or 80 μM) was significantly lower than that in the control group (0 μM), and a higher EA concentration resulted in lower colony number (Fig. 1D and 1E), which exhibited a similar trend to the CCK-8 assay. These data indicated that EA inhibited the proliferation of ATC cells in a dose-dependent manner.

Effect of EA on the migration of ATC cells

To evaluate the effect of EA on ATC cell migration, we performed a wound healing assay. As shown in Fig. 2A and 2B, the migration rate of ATC cells from the treated group (40 or 80 μM) was significantly lower than that of the control group (0 μM). As the concentra-

tion of EA increased, the migration rate of ATC cells decreased. These data indicated that EA inhibited the migration of ATC cells in a dose-dependent manner.

Effect of EA on the invasion of ATC cells

To evaluate the effect of EA on the invasion of ATC cells, we performed the Transwell invasion assay to assess cell invasion ability. As shown in Fig. 3A and 3B, the number of invaded ATC cells in the treated group (40 or 80 μM) was significantly lower than that in the control group (0 μM). With an increase in EA concentration, the invasion of ATC cells decreased. These data indicated that EA inhibited the invasion of ATC cells in a dose-dependent manner.

Role of Wnt/β-catenin pathway in EA-induced regulation of ATC cells

We further investigated the role of the Wnt/β-catenin pathway in EA-induced inhibition of ATC cells. First, we evaluated the effect of EA (80 μM) on this signaling pathway in ATC cells. The nucleoprotein level of β-catenin, a marker of the Wnt/β-catenin signaling pathway, was examined by western blotting. As shown in Fig. 4A, EA treatment significantly reduced the level of β-catenin, suggesting that EA inhibited the Wnt/β-catenin pathway in ATC cells. Next, we used LiCl (25 mM), an agonist of the Wnt/β-catenin pathway, to verify whether this signaling pathway was involved in EA-induced inhibition of ATC cells. The results of western blotting showed that LiCl significantly up-regulated the level of β-catenin (LiCl treated group vs. untreated group), and it significantly reversed EA-induced β-catenin down-regulation (EA+LiCl group vs. EA treated group), confirming the validity of LiCl and demonstrating that LiCl could reverse EA-induced inhibition of the Wnt/β-catenin pathway (Fig. 4A). We then measured the effects of activating the Wnt/β-catenin pathway on the EA-induced inhibition of proliferation, migration, and invasion of ATC cells. The results of the CCK-8 and colony formation assays showed that activation of the Wnt/β-catenin pathway significantly reversed the EA-induced inhibition of ATC cell (Fig. 4B and 4C). The results of the wound healing assay showed that activation of the Wnt/β-catenin pathway significantly reversed the EA-induced inhibition of ATC cell (Fig. 4D). The results of the Transwell invasion assay showed that activation of the Wnt/β-catenin pathway significantly reversed the inhibition of ATC cell invasion by EA (Fig. 4E). These data demonstrated that EA attenuated the proliferation, migration, and invasion of ATC cells by inhibiting the Wnt/β-catenin pathway.

Role of the PI3K/Akt pathway in EA-induced regulation of ATC cells

In addition to the Wnt/β-catenin pathway, we evaluated the role of the PI3K/Akt pathway, another ATC-associated signaling pathway, in the EA-induced antitumor effects. First, we assessed the effect of EA (80 μM) on the PI3K/Akt pathway by evaluating the phosphorylation level of the Akt protein, which was determined by the p-Akt/t-Akt ratio. As shown in Fig. 5A, EA treatment significantly decreased Akt phosphorylation levels, indicating that EA inhibited the PI3K/Akt pathway in ATC cells. Next, we used IGF-1 (100 ng/mL), an agonist of the PI3K/Akt pathway, to investigate whether this pathway was involved in the EA-induced regulation of ATC cells. The results of western blotting showed IGF-1 significantly increased Akt phosphorylation levels (IGF-1 treated group vs. untreated group), and it significantly reversed EA-induced inhibition of Akt phosphorylation level (EA+IGF-1 group vs. EA treated group), which proved the validity of IGF-1 as an agonist of the PI3K/Akt pathway (Fig. 5A). We then evaluated the effects of activating the PI3K/Akt pathway on the EA-induced suppression of cell proliferation, migration, and invasion of ATC cells. The results showed that activation of the PI3K/Akt pathway significantly reversed the EA-induced inhibition of cell proliferation (Fig. 5B and 5C), migration (Fig. 5D), and invasion (Fig. 5E). These data demonstrated that EA attenuated the proliferation, migration, and invasion of ATC cells by inhibiting the PI3K/Akt pathway.

DISCUSSION

In recent years, an increasing number of natural plant extracts have attracted the attention of researchers owing to their low toxicity and few side effects. Some natural extracts have been reported to possess anti-ATC activities. Yu and others found that chrysin (Yu et al., 2013b), a natural flavonoid, and resveratrol (Jaskula-Sztul et al., 2013a), a natural polyphenol phytoalexin, suppressed the growth and Notch1 signaling pathway in multiple ATC cell lines. Patel and others found that hesperetin, a natural flavonoid, exerted antitumor effects on ATC cells by inducing cell apoptosis and cellular differentiation (Patel et al., 2014). Lepore et al. found that cynaropicrin, a natural sesquiterpene lactone, inhibited the proliferation of ATC cells by reducing NF-κB expression and STAT3 phosphorylation (Lepore et al., 2019). Our study, for the first time, demonstrated that EA inhibited the tumor phenotypes of ATC cells and identified associated downstream signaling pathways, which expands our knowledge in the field.

Uncontrollable proliferation is an important characteristic of tumor cells. EA has been reported to inhibit the proliferation of multiple cancers. Malik and others reported that EA treatment inhibited the proliferation of prostate cancer cells (Malik et al., 2011). In ovarian carcinoma, EA was found to inhibit the growth of ES-2 and PA-1 cells (Chung et al., 2013). Wang and others suggested that EA exerts an inhibitory effect on the proliferation of glioblastoma cells (Wang et al., 2016). Similar to the above results, our study demonstrated that EA treatment effectively suppressed the proliferation of ATC cells (Fig. 1). Cell migration and invasion play key roles in the metastasis of malignant tumor. It has also been shown to inhibit cell migration and invasion in some cancers. Xu and others reported that EA inhibits the migration and invasion of osteosarcoma cells by down-regulating c-Jun expression (Xu et al., 2018). In melanoma, EA was found to be able to inhibit cell migration and invasion of WM115 and A375 cells via the epidermal growth factor receptor pathway (Wang et al., 2020). Our results were consistent with these studies, and we found that EA attenuated the migration and invasion of ATC cells (Fig. 2 and 3). In addition, the antiproliferative activity of EA was verified in these two

studies. These findings may reveal the broad suppressive effects of EA on cancer cell proliferation, migration, and invasion. However, this has yet to be experimentally confirmed in other cancers.

Previous studies on EA against cancers have revealed that regulation of signaling pathway is involved. Anitha and others found that EA treatment suppressed the Wnt/β-catenin pathway in an animal model of oral oncogenesis (Anitha et al., 2013). In another in vitro study, EA inhibited the Wnt/β-catenin pathway in colon cancer cells (Fang et al., 2015). Similar to these two studies, our work showed the inhibitory effect of EA on the Wnt/β-catenin pathway, and further demonstrated that this pathway was involved in EA-induced suppression of the pathological phenotypes of ATC cells (Fig. 4). As for the PI3K/Akt pathway, another ATC-associated signaling pathway, Liu et al. reported that EA exerted an inhibitory effect on this pathway in A549 lung cancer cells (Liu et al., 2018). Our study also showed that EA treatment inhibited the PI3K/Akt pathway, by which EA attenuated the proliferation, migration, and invasion of ATC cells (Fig. 5). These results enrich the mechanistic research on the antitumor activity of EA. Our study elaborated on specific signaling mechanisms for

the EA-induced inhibition of ATC cells (Fig. 6, created with BioRender.com). The mechanisms underlying the EA-induced regulation of ATC remain to be elucidated.

The present study has several limitations; the effects of EA on other phenotypes of ATC cells, such as drug resistance, remain to be investigated. Further *in vivo* animal

experiments are required to validate the antitumor effect of EA on ATC. These issues will be explored in future research.

In conclusion, this study demonstrated that EA inhibits the proliferation, migration, and invasion of ATC cells by inhibiting the Wnt/β-catenin and PI3K/Akt signaling pathways. These findings support EA as a candidate drug for ATC treatment and provide a theoretical basis for further *in vivo* experiments and clinical applications.

Surgical Department I (Urology Department), LONGHUA Hospital Shanghai University of Traditional Chinese Medicine, Xuhui District, Shanghai 200032, China

Background: Prostate cancer is one of the most common cancers in men worldwide. This study aims to elucidate the roles of c-Jun N-terminal kinase (JNK) in the progression of castration-resistant prostate cancer (CRPC). **Methods:** JNK overexpressing and knockdown cell lines were established on the PC-3 prostate cell line. qPCR and Western blotting were performed to determine the mRNA and protein levels of target genes in prostate tissues and cell lines. MTT and Matrigel invasion assays were conducted to evaluate the cell viability and invasive ability, respectively. The Kaplan-Meier estimator was performed to estimate the overall survival rate and second progression-free survival rate. Pearson's correlation coefficient was used to evaluate the relationship between JNK and prostate-specific antigen (PSA). **Results:** Relative JNK expression was correlated with Gleason score and PSA value in patients with CRPC. Kaplan-Meier analysis revealed that patients with low JNK expression exhibited high overall survival and second progression-free survival rate. *In vitro* assays demonstrated that JNK overexpression promoted cell viability and invasion as well as the protein expressions of extracellular signal-regulated kinase (ERK) and matrix metalloproteinase 1 (MMP1) in PC-3 cell lines. **Conclusions:** JNK overexpression promotes the development of CRPC via the regulation of ERK and MMP1.

INTRODUCTION

Prostate cancer is ranked as the second most common cancer among men and the fourth most common cancer among all types of cancers worldwide (Siegel *et al.*, 2021; Sung *et al.*, 2022). The incidence of prostate cancer is gradually increasing over the past decades (Schatten,

2018; Siegel *et al.*, 2022). For instance, the incidence rates of prostate cancer in the advanced stage have increased by 4%~6% annually from 2014 to 2018 (Schatten, 2018). In 2020, there are an estimated 1.4 million people who are diagnosed with prostate cancer in the world (Sung *et al.*, 2021). Depending on the stage of prostate cancer and its metastasis status, therapeutic options for prostate cancer include surgery, chemotherapy, radiation, androgen deprivation therapy (ADT), and combination therapy (Keyes *et al.*, 2013; Sowery *et al.*, 2007). Androgens are known as a key factor for stimulating prostate cancer cell growth, by lowering or stopping androgens are able to suppress proliferation and invasion of cancer cells (Harris *et al.*, 2009; Sharifi *et al.*, 2005). As one of the standard therapy options for prostate cancer, ADT is commonly used for patients with advanced prostate cancer and is shown to effectively control tumor growth. However, one of the major challenges is castration resistance, as supported by ADT therapy became less effective towards inhibit prostate cancer growth, and most of the patients who had ADT therapy developed castration-resistant prostate cancer (CRPC) (Chandrasekar *et al.*, 2015; Harris *et al.*, 2009; Sharifi *et al.*, 2005). Hence, developing new strategies that can overcome castration resistance is urgently required.

Several molecular pathways, such as the androgen receptor (AR) signaling pathway, c-Jun-N2-terminal kinase (JNK) signaling pathway, phosphoinositide 3-kinase (PI3K) signaling pathway, etc., are known to be involved in the prostate cancer (Mazaris & Tsiotras, 2013; Shtivelman *et al.*, 2014). The major underlying molecular mechanisms inducing CRPC are closely linked with the dysregulation of those signaling pathways (Dutt & Gao, 2009). For instance, the activation of PI3K leads to the phosphorylation of Akt and downstream cellular events, which is known as one of the major drivers of CRPC (Bitting & Armstrong, 2013). The aberrant modifications of AR increase the post-transcriptions of AR-related genes, leading to castration resistance (Yuan *et al.*, 2014). Interestingly, *in vitro* and *in vivo* data supported that targeting PI3K and AR signaling pathways by a combination of AR inhibitor (BEZ235) and mTOR inhibitor (EPI-002) effectively inhibited tumor growth as well as reduced prostate cancer resistance to ADT (Kato *et al.*, 2016). In addition, JNK is known to play a crucial role in the invasive prostate cancer (Xu & Hu, 2020). In 2020, Li and colleagues reported that a combination of JNK inhibitor (AS602801) and AR inhibitor (Enzalutamide) effectively suppressed proliferation and invasion of androgen-resistant prostate cancer cells *in vitro* and reduced tumor growth *in vivo* (Li *et al.*, 2020). These results suggest that targeting JNK might be an effective strategy for ameliorating prostate cancer resistance to ADT.

Figure 1. Schematic diagram of study profile.

MATERIAL AND METHODS

Enrollment of participants

As demonstrated in Fig. 1, a total of 280 patients were enrolled to assess eligibility. All patients have read and signed the informed consent. The patients that were aged less than 18 years old were excluded. Eastern Cooperative Oncology Group (ECOG) performance was assessed for all patients. Patients with ECOG performance status scored at 0 or/and 1 were included. In addition, only CRPC patients CRPC without any metastatic diseases were included. Finally, 161 patients who meet eligibility criteria participated in this study. The study was approved by the ethics committee of LONGHUA Hospital Shanghai University of Traditional Chinese Medicine, and the patients signed written consent.

Construction of cell lines

The PC3 cell line was obtained from ATCC (Manassas, VA) and cultured in the complete RMPI medium containing 10% fetal bovine serum and Penicillin-Streptomycin antibiotics. The construction of JNK overexpressing PC3 cell line (JNK OE) and JNK knockdown cell line (sh-JNK) were performed as previously reported. The cells were seeded into the 6-well microplates and incubated overnight to reach 70~80 % confluency. After that, the cells were transfected with plasmid containing JNK sequence or the plasmid containing JNK sequence plus shJNK by using Lipofectamine Transfection Reagent (ThermoFisher Scientific, Waltham, MA).

Cell viability and cell invasion assays

To evaluate the cell viability and cell invasion, 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and Matrigel invasion assay were determined, respectively. For the MTT assay, cells including PC3 cells, JNK overexpressing PC3 cells, and PC3 cells that were transfected with shJNK were seeded into the 96-well microplates at 1 000 cells per well. Abiraterone at concentrations of 5, 10, and 20 μM was added and incubated for another 3 days. Next, MTT working solution (5 mg/mL) was added to each well and incubated for 4 hours in the dark. Dimethyl sulfoxide solution was then added to dissolve the purple crystals. The plate

was read by using a microplate reader at wavelengths of 590 nm and 690 nm (reference wavelength).

For the Matrigel invasion assay, the invasion chambers were coated with Matrigel (0.5 mg/mL). Next, the cells were seeded into the upper chamber with serum-free medium and the lower chamber was filled with complete RPMI medium. Next, the cells were incubated for 48 hours and the non-invasive cells in the upper chamber were removed, and invasive cells were then fixed and stained with crystal violet staining solution. The cells were observed under a microscope and the number of invasive cells was counted.

qPCR

The prostate cancer tissue samples were collected from the participants. Total RNAs were isolated from the prostate cancer tissues by using the RNA extraction reagent (Invitrogen, Waltham, MA). The cDNA library was then constructed by using a reverse transcription kit (Invitrogen). The primers of JNK and internal control *GADPH* were synthesized by Descript. After that, the PCR reaction was performed and the mRNA levels of JNK were normalized to *GAPDH*. The Melt curves were applied to ensure the accuracy of the PCR reaction.

Western blotting

Protein was isolated from the prostate cancer tissues as previously reported (Yang *et al.*, 2017). In brief, a cold radio-immunoprecipitation assay reagent (Bio-Rad, Hercules, CA) was added to the shredded tumor tissues. A homogenizer was used to create the uniformed protein mixture buffer and centrifuge was used to remove the tissue debris. Next, the bicinchoninic acid assay reagent was used to qualify the protein concentration. Protein was loaded into the gel followed by the incubation with the primary antibody solution including anti-JNK (1:2000, Abcam, Cambridge, MA), anti-extracellular signal-regulated kinase (ERK, 1:2000, Abcam), anti-matrix metalloproteinase 1 (MMP1, 1:2500, Abcam), or GADPH (1:3000, Sigma, St. Louis). Next, the membrane was blocked with blocking buffer (5% bovine serum albumin) followed by the incubation of the secondary antibody solution. Chemiluminescence blot imaging was used to detect the proteins. The protein expression was normalized to GAPDH.

Statistical analysis

The Kaplan–Meier estimator was performed to estimate the overall survival percentage and second progression-free survival in patients with low JNK and high JNK. Pearson's correlation coefficient was used to analyze the correlation between JNK expression and PSA levels in patients with CRPC. Prism Software was used for data analysis. Data were expressed as the means ± standard deviation (S.D.). One-way ANOVA with Tukey's multiple-comparisons test was applied for multiple groups. Any p-values that were less than 0.05 were considered as statistical difference.

RESULTS

Trial patients and their clinical characteristics

As displayed in Fig. 1, initially 280 patients were assessed for eligibility, and we finally recruited 161 eligible patients for this study. After sampling and analysis,

Table 1. Patient Characteristics.

	Low JNK level (n=71)	High JNK level (n=71)	p-value
Age (years)	63.2 (7.0)	62.8 (6.7)	0.729
ECOG performance status			
0	58 (81.7)	55 (77.5)	0.678
1	13 (18.3)	16 (22.5)	
PSA (ng/ml)	7.2 (2.7)	8.8 (3.2)	0.002
Gleason score			
≤7	48 (67.6)	30 (42.3)	0.004
>7	23 (32.4)	41 (57.7)

Abiraterone	63 (88.7)	61 (85.9)	0.802
Docetaxel	52 (73.2)	55 (77.5)	0.697
Cabazitaxel	12 (16.9)	14 (19.7)	0.829

Data are n (%) or mean (S.D.). ECOG, Eastern Cooperative Oncology Group. PSA, prostate-specific antigen.

we conducted a 3-year follow-up study. After excluding the participants who were unwilling to continue, we analyzed the data from the 142 patients. Two cohorts including patients with low JNK levels and patients with high JNK levels were included (Table 1). We noticed that the levels of PSA in patients with low JNK levels were significantly decreased as compared to patients with high JNK levels (p=0.002). In addition, we observed less lymph node metastases in patients with low JNK levels as compared to patients with high JNK levels (24 vs 38). These results demonstrated that the levels of JNK were associated with the levels of PSA and lymph node metastases in patients with CRPC.

Relative JNK expression was correlated with Gleason score and PSA value in patients with CRPC

Next, we determined the relative JNK expression in CRPC patients with different Gleason scores. Interestingly, we found that the relative JNK expression in CRPC patients with low Gleason score (Gleason score ≤7) was significantly decreased as compared to the CRPC pa-

tients with high Gleason score (Gleason score>7), indicating the correlation between JNK and Gleason score (Fig. 2a). Besides, we also observed a positive correlation of JNK and PSA in patients with CRPC (Fig. 2b).

Patients with low JNK expression exhibited high overall survival and second progression-free survival rate

To explore the relationship between JNK expression and survival rate, we conducted a 3-year follow-up study. We found that patients with low JNK expression showed a higher overall survival rate as compared with those patients with high JNK expression (p=0.033, Fig. 3a). Consistently, we observed that patients with low JNK expression showed high second progression-free survival rate as compared with those patients with a high JNK expression (p=0.005, Fig. 3b). These results supported that patient with low JNK expression exhibited higher overall survival and second progression-free survival rate as compared to patients with high expression.

Figure 2. Relative JNK expression was correlated with Gleason score and PSA value in patients with castration-resistant prostate cancer (CRPC).
(**a**) The relative JNK expression in patients with different Gleason scores. (**b**) Pearson correlation showed the correlation of relative JNK expression with PSA levels in patients with CRPC. Data were expressed as the means ± S.D. **p<0.01.

Figure 3. Kaplan-Meier analysis estimated the overall survival percentage (a) and second progression-free survival (b) in patients with low JNK and high JNK.

JNK overexpressing promoted cell viability and invasion of PC3 cells

To confirm the roles of JNK expression in the CRPC, we tested cell viability and invasion in the abiraterone-treated prostate cancer cell line. We found that the cell survival rate of PC3 cells was significantly decreased in the treatment of abiraterone. However, cells with JNK overexpression displayed a higher survival rate as compared with those cells transfected with shJNK (Fig. 4a). Consistently, cell invasion assay also showed that JNK overexpressing cell lines have a higher number of invasive cells, whereas cells that were transfected with shJNK have a smaller number of invasive cells (Fig. 4b). Taken together, these results suggested that JNK overexpression promoted cell viability and invasion of prostate cancer cells.

JNK overexpression enhanced the protein levels of ERK and MMP1 in PC3 cells

Finally, we explored the changes of other cytoplasm proteins in the presence of JNK overexpression in PC3 cells. Cytoplasm proteins including ERK and MMP1 were determined by using Western blotting. The protein expressions of JNK were significantly increased in the JNK overexpressing cells, indicating that the JNK over-

expressing cells were successfully constructed (Fig. 5a and 5b). In addition to JNK, we found that protein expressions of ERK and MMP1 were also increased in the JNK overexpressing cells as compared to the PC3 cells and JNK overexpressing cells that were transfected with shJNK (Fig. 5a, 5c, and 5d). These results suggested that JNK overexpression enhanced the protein levels of ERK and MMP1 in PC3 cells.

DISCUSSION

In this study, we found that JNK expression was positively correlated to Gleason score and PSA value in patients with CRPC. Interestingly, high JNK expression in prostate tumor tissues is associated with low overall survival and second progression-free survival rate as compared with those patients with low JNK expression. In vitro data suggested that JNK overexpression promotes cell proliferation, invasion, and sensitivity to abiraterone treatment, whereas inhibiting JNK reversed these cellular events, suggesting the relationship between JNK and CRPC. Moreover, targeting JNK also resulted in the changes in ERK and MMP1, indicating the roles of JNK on prostate cancer associated with those cytoplasm proteins.

Figure 4. Effects of JNK on cell viability and invasion of PC3 cells. PC3 cells with JNK overexpressing or knockdown were constructed.
(**a**) JNK overexpressing enhanced abiraterone resistance, whereas the presence of sh-JNK decreased cell viability in PC3 cells. Besides, (**b**) Cell invasion of PC3 cells was evaluated by using the Transwell assay. Data were expressed as the means ± S.D. *$p<0.05$, **$p<0.01$ as compared with the control group. #$p<0.05$ as compared with the JNK OE group.

Figure 5. Effect of JNK on the protein levels of ERK and MMP1 in PC3 cells.
(**a**) Protein expressions of JNK (**b**), ERK (**c**), and MMP1 (**d**) were determined by using Western blotting. The relative expressions of those biomarkers were expressed as the fold of control. Data were expressed as the means ± S.D. *$p<0.05$, **$p<0.01$ as compared with the control group. #$p<0.05$, ##$p<0.01$ as compared with the JNK OE group.

ADT is commonly recommended for patients with advanced prostate cancer. However, CRPC is still one of the major challenges (Gunner *et al.*, 2016). Previous studies have demonstrated that JNK exerts a variety of functions in the regulation of cell differentiation, proliferation, invasion, and apoptosis in prostate cancer cells (Bode & Dong, 2007; Xu & Hu, 2020). Clinical studies revealed that JNK is highly expressed by the prostate cancer tissues (Bode & Dong, 2007). Interestingly, our study revealed less lymph node metastases in patients with low JNK levels as compared to those with high JNK levels. Consistently, JNK is also positively correlated to the levels of PSA and Gleason score, indicating that high JNK was more frequently observed in patients with advanced prostate cancer. In 2017, Zhang and colleagues reported the positive expression rate of the JNK in prostate patients with survival >5 years (60%) and survival ≤5 years (45%) in a cohort of forty samples (Zhang *et al.*, 2017). Interestingly, they found that the phosphorylation of JNK was higher in patients with survival >5 years than with survival ≤5 years (Zhang *et al.*, 2017). Our study revealed that patients with low JNK expression in their prostate cancer tissues showed a higher overall survival rate and second progression-free survival rate as compared with those patients with high JNK expression.

The link between JNK and AR signaling pathway has been well established by a series of studies (Li *et al.*, 2020; Xu & Hu, 2020). For instance, interactions between AR and JNK substrates regulate the therapeutic effects of the chemotherapy agent, taxane, against CRPC (Tinzl *et al.*, 2013). A reduction in the phosphorylation of JNK is associated with the repression of AR in prostate cancer cells (Shah & Bradbury, 2015). In this study, to confirm the roles of JNK in the CRPC, we established a series of cell lines including JNK overexpressing cells and JNK overexpressing cells that were transfected with shJNK. Interestingly, we observed that JNK overexpression promoted cell viability and invasion of PC3 cells that were treated with abiraterone. However, the presence of shJNK suppressed cell viability and invasion of PC3 cells. These results indicated that the levels of JNK are critical in the CRPC.

Targeting JNK exhibited broad effects in the treatment of prostate cancer (Xu & Hu, 2020). For instance, Kim and colleagues found that targeting ERK/JNK/AKT pathway with Oleanolic acid inhibits tumor growth in the DU145 animal model (Kim *et al.*, 2018). Another study initiated by Ma and colleagues reported that Corosolic acid regulates cell apoptosis in CRPC in part by the regulation of Inositol-requiring enzyme 1 and the JNK signaling pathway (Ma *et al.*, 2018). In our study, we found that targeting JNK regulated cell proliferation and invasion in the abiraterone-treated PC3 cells. However, when the JNK was overexpressed, the PC3 cells became less sensitive to the abiraterone treatment. These results confirmed that targeting JNK might be an effective strategy for regulating castration resistance of prostate cancer cells.

The Extracellular signal-regulated kinase (ERK) is another important kinase in CRPC, which is also known as a therapeutic target for prostate cancer (Gan *et al.*, 2010). The phosphorylation of ERK is a feature of CRPC and is associated with the incidence of prostate cancer recurrence (Nickols *et al.*, 2019). The activation of ERK leads to the overexpression of matrix metalloproteinase-1 (MMP-1) in the tumor tissues, which promotes tumor growth and metastasis (Nickols *et al.*, 2019; Quintero-Fabián *et al.*, 2019; Yang *et al.*, 2015). In this study, we fur-

ther explored the underlying mechanism of JNK on the regulation of CRPC. Interestingly, we observed a positive correlation of JNK with ERK and MMP1, as supported by the protein expressions of ERK and MMP1 were increased in the JNK overexpressing cells. However, the presence of shJNK inhibited the protein levels of ERK and MMP1 in PC3 cells. These results suggested that the effects of JNK on the regulation of cell viability and invasion in prostate cancer cells were associated with ERK and MMP1.

CONCLUSION

JNK expression is positively correlated with Gleason score and PSA value in patients with CRPC. Low JNK expression is also associated with high overall survival and second progression-free survival rate. Interestingly, JNK overexpression promotes cell viability and invasion, which is in part by the regulation of ERK and MMP1. These results suggest that JNK may be considered as an effective target for the CRPC therapy.

Background: We aimed to analyze the value of serum (sdLDLc*HCYc)/HDLc ratio in the stability of intracranial arterial plaques among patients with acute cerebral infarction. **Methods:** A retrospective analysis was conducted on 140 patients with acute cerebral infarction admitted to the neurology department and 101 healthy individuals for regular examinations in our hospital from 2013 to 2019, who were respectively allocated into the study group and the control group. Participants in both groups were measured for serum sdLDLc, HDLc, and HCYc using peroxidase method, enzyme-linked immunosorbent assay, and enzyme method, respectively. The laboratory indexes of the two groups were compared. The multivariate logistic regression analysis was done to analyze the influencing factors of the stability of intracranial artery plaque in patients with acute cerebral infarction. The value of high-density lipoprotein cholesterol (HDL-C), homocysteine, sdLDLc, (sdLDLc*HCYc)/HDLc in diagnosing the stability of intracranial artery plaque was also evaluated in patients with acute cerebral infarction. **Results:** There was no distinct difference in height, hypertension, diabetes, coronary heart disease, smoking history and drinking history between the two groups ($P>0.05$). The study group showed statistically significant differences in age, gender, weight, and BMI ($P<0.05$). The current study demonstrated no statistical difference in the levels of TG, low-density lipoprotein cholesterol (LDL-C), α-lipoprotein, and HCYc between the two groups ($P>0.05$). However, the levels of TC, HDL-C, sdLDLc, (sdLDLc*HCYc)/HDLc in the study group were significantly different when comparing with the control group ($P<0.05$). No statistically significant difference was found in the levels of TG, triglycerides, LDL-C, α-lipoprotein, and HCYc among patients with different degrees of stenosis in the study group ($P>0.05$). The level of HDL-C was significantly lower in cases of severe stenosis compared to no stenosis, mild stenosis and moderate stenosis, with severe stenosis showing the lowest levels; mild stenosis had lower levels than no stenosis, while moderate stenosis had lower levels than both no stenosis and mild stenosis ($P<0.05$). The levels of sdLDLc, (sdLDLc*HCYc)/HDLc exhibited a significant increase in cases of severe stenosis as compared tono stenosis, mild stenosis, and moderate stenosis. Furthermore, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were found to be higher in moderate stenosis as compared to no stenosis and mild stenosis. Similarly, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were observed to be higher in mild stenosis than no stenosis ($P<0.05$).The independent variables were set as the indicators with difference in single factor comparison, including age, gender, BMI, TC, LDL-C, HDL-C, HCYc, sdLDLc, (sdLDLc*HCYc)/HDLc. The dependent variable was the stability of intracranial artery plaque in patients with acute cerebral infarction. After variable selection, the results showed that the factors influencing the stability of intracranial artery plaque in patients with acute cerebral infarction were age, BMI, (sdLDLc*HCYc)/HDLc. The degree of plaque enhancement was used as a criterion to reflect the stability of plaque. ROC curve analysis showed that (sdLDLc*HCYc)/HDLc had a higher evaluation value for the stability of intracranial artery plaque than HDL-C, homocysteine, and sdLDLc in patients with acute cerebral infarction. **Conclusion:** The serum (sdLDLc*HCYc)/HDLc ratio was found to have potential in evaluating the stability of intracranial arterial plaques in patients with acute cerebral infarction.

Keywords: sdLDLc, HDLc, HCYc, acute cerebral infarction, stability of intracranial arterial plaques

INTRODUCTION

Currently, acute ischemic cerebral infarction stands as the most prevalent type of stroke, comprising over 75% of all stroke cases. This condition exhibits alarmingly high incidence and disability rates, and is prone to causing neurological function loss, thereby impinging not only upon daily quality of life of patients, but also their life safety (Edwards & Hughes, 2021; Shao *et al.*, 2022). A recent study has revealed that more than 25% of acute cerebral infarction cases arise from the rupture of unstable plaque caused by atherosclerosis, leading to thrombus formation (Kim *et al.*, 2013). The stability of intracranial atherosclerotic plaque is inextricably linked to factors such as plaque surface smoothness, ulcer formation, regularity, and presence of bleeding (Lu *et al.*, 2021; Tao *et al.*, 2021). Therefore, early detection of the nature and structure of intracranial atherosclerotic plaque

holds immense significance in predicting the occurrence of acute cerebral infarction.

The serum low density lipoprotein (LDL) level is acknowledged as the most important risk factor for atherosclerosis. But the determination of LDL level by conventional blood lipid detection methods fails to completely predict the risk of carotid atherosclerosis; some patients at a high risk of cardiovascular disease may have normal LDL level (Hartley et al., 2019). Based on previous research (QiaoZhen et al., 2019), LDL can be subdivided into several subtypes, from LDL1 to LDL7 using the Lipoprint lipoprotein classification detection system. The LDL1-2 lipoprotein is typically regarded as physiologically normal, as it fulfills the role of transporting cholesterol. Conversely, the LDL3-7 lipoproteins are deemed to be abnormal, as they manifest as small dense low-density lipoproteins (sdLDL) that exhibit heightened susceptibility to oxidative stress, possess diminished affinity for LDL receptors, demonstrate a protracted plasma half-life, and exhibit a greater inclination to penetrate the vascular wall, ultimately depositing plaque beneath the endothelium. The cumulative effect of these factors contributes to the development of cardiovascular and cerebrovascular diseases (QiaoZhen et al., 2019). Currently, copious studies are available to show that even if patients have normal LDL levels, an increase in the ratio of sdLDL in total LDL can still result in an increased risk of cardiovascular disease by more than three times (QiaoZhen et al., 2019). Therefore, sdLDL is considered an effective predictor of atherosclerosis. The clinical auxiliary diagnostic value of single biomarkers such as small dense low-density lipoprotein cholesterol (sdLDLc), homocysteine concentration (HCYc) and HDL-C concentration (HDLc) for cerebral infarction has been confirmed by many studies (Ishii et al., 2022; QiaoZhen et al., 2019; Santos et al., 2020), while the predictive value of (sdLDLc*HCYc)/HDLc in primary cerebral infarction is higher than that of a single biomarker, including sdLDLc, HCYc, and HDLc (Luo et al., 2022). Based on this, our study aimed to evaluate the value of serum (sdLDLc*HCYc)/HDLc ratio in the stability of intracranial arterial plaques in patients with acute cerebral infarction.

MATERIALS AND METHODS

Clinical data

A retrospective analysis was conducted on 140 patients with acute cerebral infarction admitted to the neurology department and 101 healthy individuals for regular examinations in our hospital from 2013 to 2019, who were allocated into the study group and the control group, respectively. In our hospital, about 100 cases of stroke patients are enrolled every year. Inclusion criteria: All patients met the diagnostic criteria for acute cerebral infarction established at the Fourth National Conference on Cerebrovascular Disease (Wang, 1996) in 1995, and were determined by intracranial high-definition magnetic resonance angiography; no oral or intravenous antibiotics, antiviral, non steroidal, or glucocorticoid drugs were administered within 14 days before the onset of the disease. Exclusion criteria were patients with serious infectious diseases; autoimmune diseases; malignant tumor diseases; diabetes; primary organ disorders, including heart, lung and other systemic diseases; new neurological deficits; other nervous system disease that may lead to neurological dysfunction, such as hereditary degenerative

diseases of the central nervous system, tumors, encephalitis, demyelinating diseases, brain trauma, epilepsy, etc.

The study protocol was approved by the Ethics Committee of Hebei General Hospital. Informed consent was obtained from all the study subjects before enrollment. All methods were designed in accordance with the Declaration of Helsinki.

METHODS

Clinical data

Clinical data of all participants, including age, gender, height, weight, BMI, hypertension, diabetes, coronary heart disease, smoking history, drinking history were collected.

Laboratory examination

After a 12-hour fast, 5 ml of venous blood of the study group was collected the following morning, and venous blood of the control group was also collected in the morning for physical examination. The serum was centrifuged for 10 min with a 3000 r/min high-speed centrifuge, and the supernatant was stored at –80°C for inspection. The experimental indicators were total cholesterol (TC), triglycerides(TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C) and other experimental indicators using AU680 automatic biochemical analysis system by Beckman Kurt. Serum sdLDLc was detected using enzyme-linked immunosorbent assay (ELISA) with a kit from Shanghai Enzyme-linked Biotechnology Co., Ltd. The reagent instructions for operation were strictly followed for quality control.

Intracranial high-definition magnetic resonance angiography

Using the HDX platform 3.0T MRI system (GE Healthcare, the US), multi-sequence MRI examinations were performed with application of an 8-channel standard coil. The HRMR scanning matrix was 320×256. The bright-blood technology was the first choice to perform three-dimensional time-of-flight magnetic resonance angiography, to clarify the location of the affected blood vessels after vascular reconstruction, and then use the black blood technology for multi-sequence scanning of intracranial diseased blood vessels. The scanning parameters were as follows: fast spin-echo T1-weighted imaging, fast spin-echo T2- weighted enhanced imaging, T1-weighted enhanced imaging, with repetition times of 567, 2883, and 567 ms, echo times of 15.8, 49, and 15.8 ms, and imaging field of view of 100 mm×100 mm, with a layer thickness of 2mm and a spacing of 2.5 mm. The T1-weighted variable flip angle 3D fast spin-echo sequence has a repetition time of 900 ms, an echo time of 5.6 ms, and a layer thickness of 0.5 mm. The enhanced examination was performed using MeglumineZapenate as the contrast agent. The participants were in travenously injected with contrast agent 5 minutes before scanning. The scanning parameters were the same as T1-weighted variable flip angle 3D fast spin-echo sequence. The completion time of the above sequence scanning was 30 to 40 minutes. IV contrast was used during MRI scanning

The assessment of intracranial responsible vessels included the degree of arterial stenosis and the characteristics of responsible plaques. Responsible blood vessels referred to the blood vessels that supplied responsible

Table 1. Comparison of clinical data

Indicator	Study group (n=139)	Control group (n=101)	χ^2/t	P
Age (year)	59.41±12.02	64 15±11.81	–3.044	0.003
Gender (male/female)	38/102	46/55	18.469	<0.001

Degree of vascular stenosis (n)			–	-
Grade 0: no stenosis	23 (16.43)			
Grade 1: mild stenosis	26 (18.57)			
Grade 2: moderate stenosis	29 (20.71)			
Grade 3: severe stenosis	62 (44.29)			

lesions. If there was only one lesion in the blood vessel, the plaque at that lesion was considered the responsible plaque; if there were multiple diseased blood vessels, the plaque with the most severe vascular stenosis was the responsible plaque. According to the warfarin-aspirin symptomatic intracranial disease (WASID) method, the degree of stenosis of the responsible vessel was measured on the maximum intensity projection image of MRA. The degree of stenosis is divided into 5 levels: no obvious stenosis (0%), mild stenosis (1–49%), moderate stenosis (50–69%), severe stenosis (70–99%), and occlusion (100%).

Observation indicators

The laboratory indexes of the two groups were compared. The multivariate logistic regression analysis was done to analyze the influencing factors of the stability of intracranial artery plaque in patients with acute cerebral infarction. The value of HDL-C, homocysteine, sdLDLc, (sdLDLc*HCYc)/HDLc in diagnosing the stability of intracranial artery plaque were also evaluated in patients with acute cerebral infarction.

Statistical analysis

We used SPSS 21.0 software to analyze the data and Excel to establish the database. The measurement data

conforming to the normal distribution was expressed in $\bar{x}\pm$ s. Using one-way ANOVA, the overall comparison of the data of each group was performed. And the pairwise comparison of the data between groups and within groups was conducted by LSD method. Moreover, the counting data was expressed in percentage (%) and compared using chi-square χ^2 test. Multiple logistic regression analysis was used to analyze the influencing factors, with $P<0.05$ as the significant difference.

RESULTS

Comparison of clinical data

There was no distinct difference in height, hypertension, diabetes, coronary heart disease, smoking history and drinking history between the two groups ($P>0.05$). The study group showed statistically significant differences in age, gender, weight, and BMI ($P<0.05$) (Table 1).

Comparison of laboratory indicators

The current study demonstrated no statistical difference in the levels of TG, LDL-C, α-lipoprotein, and HCYc between the two groups ($P>0.05$). However, the levels of TC, HDL-C, sdLDLc, (sdLDLc*HCYc)/HDLc

in the study group were significantly different when comparing with the control group ($P<0.05$) (Table 2).

Comparison of laboratory indicators for different degrees of stenosis in the study group

No statistically significant difference was found in the levels of TG, triglycerides, LDL-C, α-lipoprotein, and HCYc among patients with different degrees of stenosis in the study group ($P>0.05$). The level of HDL-C was significantly lower in cases of severe stenosis compared to no stenosis, mild stenosis and moderate stenosis, with severe stenosis showing the lowest levels; mild stenosis had lower levels than no stenosis, while moderate stenosis had lower levels than both no stenosis and mild stenosis ($P<0.05$). The levels of sdLDLc, (sdLDLc*HCYc)/HDLc exhibited a significant increase in cases of severe stenosis as compared to no stenosis, mild stenosis, and moderate stenosis. Furthermore, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were found to be higher in moderate stenosis as compared to no stenosis and mild stenosis. Similarly, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were observed to be higher in mild stenosis than no stenosis ($P<0.05$) (Table 3).

Multivariate logistic regression analysis of factors affecting the stability of intracranial arterial plaques in patients with acute cerebral infarction

The independent variables were set as the indicators with difference in single factor comparison, including age, gender, BMI, TC, LDL-C, HDL-C, HCYc, sdLDLc,

(sdLDLc*HCYc)/HDLc. The dependent variable was the stability of intracranial artery plaque in patients with acute cerebral infarction. After variable selection, the results showed that the factors influencing the stability of intracranial artery plaque in patients with acute cerebral infarction were age, BMI, and (sdLDLc*HCYc)/HDLc. (Table 4).

The value of HDL-C, homocysteine, sdLDLc, (sdLDLc*HCYc)/HDLc in diagnosing the stability of intracranial artery plaque in patients with acute cerebral infarction

The degree of plaque enhancement was used as a criterion to reflect the stability of plaque. ROC curve analysis showed that (sdLDLc*HCYc)/HDLc had a higher evaluation value for the stability of intracranial artery plaque than HDL-C, homocysteine, and sdLDLc in patients with acute cerebral infarction, as shown in Table 5 and Fig. 1.

DISCUSSION

Acute cerebral infarction is a life-threatening ischemic cerebrovascular disease that poses a significant threat to human health worldwide. The incidence of the condition has increased from 1.89% in 2012 to 2.19% in 2016, with a climbing disability rate with the passage of time. Acute cerebral infarction is deemed to be the leading cause of death and disability in adults in China (Zhang & Qin, 2022). Intracranial atherosclerosis accounts for

about 46.6% of cerebral infarction patients in China (Chu & Liu, 2021). The stability of intracranial artery plaque is highly associated with acute cerebral infarction. Earlier research indicated that high resolution magnetic resonance (HRMR) intracranial artery wall imaging was able to effectively assess the size, shape and stability of intracranial atherosclerotic plaque. The degree of plaque enhancement and intra plaque hemorrhage are greatly related to intra-plaque hemorrhage and plaque stability, but serum markers fail to effectively reflect the stability of intracranial atherosclerotic plaque (Xie et al., 2022).

The changes in the composition of LDL-Care are particularly pivotal in the progression of acute cerebral infarction. However, LDL-C is heterogeneous. The diameter of LDL-C main peak particles obtained by nondenaturing gradient gel scanning can be subdivided into LDL-C A with high cholesterol content, high density and large volume (diameter peak ≥25.8nm) and LDL-C B with low cholesterol content, high density and small volume (diameter peak <25.8nm), that is, small dense low-density lipoprotein cholesterol (sdLDLc) (Kanonidou, 2021). The latest research (Huang & Gu, 2021)asserted that, sdLDLc had a stronger atherogenic ability than LDL-C, and has been included in the newly discovered important risk factors for cardiovascular and cerebrovascular disease recommended by the adult treatment group of the National Cholesterol Education Program. sdLDLc is correlated with the number of atherosclerotic plaques and carotid stenosis caused by atherosclerotic plaques (Ikezaki et al., 2020). Ikezaki and others (Ikezaki et al., 2020) depicted that sdLDLc had a significant impact on

Figure 1. ROC curve of HDL-C, homocysteine, sdLDLc, (sdLDLc*HCYc)/HDLc in diagnosing the stability of intracranial artery plaque in patients with acute cerebral infarction.

the composition of carotid artery plaque cells. HCYc is an intermediate product of the methionine cycle. High levels of HCYc can promote the proliferation of smooth muscle cells, damage vascular endothelial cells, and affect the oxidation of LDL. It can activate platelets to increase platelet adhesion, promote thrombosis, cause arterial congee, and also reduce the bioavailability of nitric oxide, inhibit fibrin degradation, platelet aggregation, and promote atherosclerosis (Wang et al., 2021). Based on Yang and others (Yang et al., 2019) the severity of carotid atherosclerotic plaque in type 2 diabetes patients complicated with cerebral infarction was higher than that in simple diabetes patients, and the level of serum HCYc was positively correlated with the degree of carotid atherosclerosis, which may be involved in its occurrence and development. α-lipoprotein level is determined by genes and is an LDL-like protein composed of apolipoprotein (apo) A covalently continuous apoB-100. Lp(α) is believed to be involved in the occurrence of atherosclerosis, which is greatly related to thrombosis and fibrinolysis damage (Dai et al., 2019). However, limited clinical research exists on the value evaluation of serum (sdLDLc*HCYc)/HDLc ratio in the stability of intracranial arterial plaques in patients with acute cerebral infarction. Our study showed that the age, gender, weight, and BMI of the study group differed from the control group (P<0.05), indicating that patients diagnosed with acute cerebral infarction exhibited a higher prevalence among the female population, alongside elevated weight and BMI, while their age was comparatively younger. But the small sample size may contribute to the biased results. In our study, the levels of TC, HDL-C, sdLDLc, (sdLDLc*HCYc)/HDLc in the study group were significantly different as compared to the control group (P<0.05), suggesting that the levels of TC, HDL-C in patients with acute cerebral infarction decreased, and the levels of sdLDLc, (sdLDLc*HCYc)/HDLc increased. Gu and others (Gu et al., 2017)showed that HDL-C levels and TC/HDL-C ratios may effectively predict the severity of intracranial vascular stenosis. Similarly, another study (Zhang et al., 2020) depicted that sdLDLc could effectively evaluate the severity of acute cerebral infarction in elderly patients. According to our study, the level of HDL-C was significantly lower in cases of severe stenosis compared to no stenosis, mild stenosis and moderate stenosis, with severe stenosis showing the lowest levels; mild stenosis had lower levels than no stenosis, while moderate stenosis had lower levels than both no stenosis and mild stenosis (P<0.05). The levels of sdLDLc, (sdLDLc*HCYc)/HDLc exhibited a significant increase in cases of severe stenosis as compared to no stenosis, mild stenosis, and moderate stenosis. Furthermore, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were found to be higher in moderate stenosis as compared to no stenosis and mild stenosis. Similarly, the levels of sdLDLc, (sdLDLc*HCYc)/HDLc were observed to be higher in mild stenosis than no stenosis (P<0.05). It was suggested that the levels of HDL-C, sdLDLc, (sdLDLc*HCYc)/

HDLc varied in patients with acute cerebral infarction of different stenosis degrees. The more severe the stenosis degree, the lower the level of high-density lipoprotein cholesterol, and the higher the levels of sdLDLc, (sdLDLc*HCYc)/HDLc.

The stability of carotid atherosclerotic plaque in elderly patients with acute cerebral infarction was linked to factors such as age, HCYc (Bai & Wang, 2021). Another study suggested that elevated levels of LDL-C and HCY-C were risk factors that affected the stability of carotid plaques in patients with acute cerebral infarction (Hansha et al., 2022). Detecting and controlling the abovementioned indicators in clinical practice may help stabilize the carotid plaques in patients with acute cerebral infarction, thereby improving their prognosis. Our study showed that the influencing factors for the stability of intracranial arterial plaques in patients with acute cerebral infarction included age, BMI, (sdLDLc*HCYc)/HDLc, which was consistent with the above results. We further analyzed the value of HDL-C, homocysteine, sdLDLc, (sdLDLc*HCYc)/HDLc in diagnosing the stability of intracranial artery plaque in patients with acute cerebral infarction. The results revealed that (sdLDLc*HCYc)/HDLc exhibited a higher value in evaluating the stability of intracranial artery plaque in patients with acute cerebral infarction than HDL-C, homocysteine, and sdLDLc. (sdLDLc*HCYc)/HDLc consists of three components, encompassing their respective effects. The precise reasons are described as follows: (1) The formation of sdLDLc is related to the metabolism of VLDL rich in triacylglycerol. Cholesterol ester transporter protein (CETP) and hepatic lipase (HL) exert important roles in the formation of sdLDLc. When VLDL increases, especially when triglycerides in the core exchange with cholesterol esters in the LDL core, the proportion of cholesterol esters in the LDL decreases, and the proportion of triglycerides gradually increases. When triglycerides in the LDL reach a certain concentration and pass through the liver, they are hydrolyzed by hepatic lipase to remove triacylglycerol. The entire exchange process continuously reduces the diameter of LDL particles, increases density, forms sdLDLc, and the level of triacylglycerol increases. The active exchange process positively generates sdLDLc. During the development of atherosclerosis, sdLDLc is deposited in a certain part of the artery wall through the vascular endothelial gap, which is then taken up by monocyte macrophages, where lipids gradually accumulate and transform into foam cells. The above changes are mainly due to the presence of chondroitin sulfate proteoglycan (CSPG) in the extracellular matrix of tunica intima cells, which can combine with lipoproteins to form complexes, thus prolonging the residence time (Choi & Lee, 2022). In addition, some studies demonstrated that the structure of ApoB in sdLDLc may change, and sdLDLc was difficult to clear in the circulation, so there were more opportunities for sdLDLc to enter tunica intima (Zhou et al., 2020). The abovementioned results highlight the fact that sdLDLc is closely related to atherosclerosis. (2) HCYc is one of the initiating factors of atherosclerosis. Under the environment of high concentration of HCY, vascular oxidative stress reaction generates free radicals, which reduces the function of endothelial cells. Endothelial cells enter the death process ahead of time. The process can also inhibit the regeneration of endothelial cells, reduce the number of endothelial cells, with lipid deposition and fibrosis in the excess space. Moreover, HCYc has an impact on a variety of cytokines, cyclins and cellular active substances, thus damaging the vascular wall, causing the protection

and proliferation of vascular smooth muscle cells. Finally, the development of ischemia and hypoxia contributes to the vascular fibrosis, hardening and thickening the blood vessel. The impairment of the vascular wall leads to the aggregation of fibrin and platelets in the damaged vascular wall, ultimately contributing to the development of arterial atherosclerosis. HCYc can cause abnormalities in lipid metabolism, increase LDL-C levels, and produce oxidative reactions, resulting in cholesterol accumulation in the blood vessel wall. It also reduces the anti-atherosclerotic function of HDL-C in the blood vessels, where the role of endothelial cells in clearing cholesterol slows down, and then deposits under the vascular endothelium. The accumulated cholesterol gradually increases, ultimately forming arteriosclerosis (Lv et al., 2022). In addition, HCYc is able to cause abnormal platelet function and alter the activity of coagulation factors V and X, leading to platelet aggregation and abnormal coagulation function, and ultimately inducing cerebrovascular disease (Liu et al., 2019). (3) HDLc, as a receptor for cholesterol, mediates the flow of cholesterol from the intima of the arterial wall and transports it to the liver for metabolism through its interaction with the receptor, thereby reducing cholesterol levels in the plasma and preventing the occurrence of arteriosclerosis. HDLc has demonstrated the ability to prevent atherosclerosis via inhibiting the oxidation of LDL, which also participates in the reverse transport of oxidized LDL, reducing the damage caused by oxidized LDL. Additionally, HDLc inhibits monocyte cell adhesion and infiltration into the tunica intima and stimulates endothelial cell repair and proliferation. It can also inhibit the proliferation of vascular smooth muscle cells induced by growth factors and other mechanisms. Lastly, it exhibits property of anti-platelet aggregation, safeguarding against thrombosis (Woo et al., 2020; Yin et al., 2021).

CONCLUSION

The patients with acute cerebral infarction showed reduced levels of TC and HDL-C, and elevated levels of sdLDLc, (sdLDLc*HCYc)/HDLc. Age, BMI, (sdLDLc*HCYc)/HDLc were the influencing factors for the stability of intracranial arterial plaque in patients with acute cerebral infarction, of which (sdLDLc*HCYc)/HDLc exhibited superior value in diagnosing the stability of intracranial arterial plaque in such patients. However, there are a few shortcomings in this study. We noted that the participants in control group were not selected based on the age and gender of patients with acute cerebral infarction, resulting in a certain bias in the general data. Further multi-center studies are needed to determine the risk factors for intracranial arteriosclerosis in patients with acute cerebral infarction based on their age.

β-catenin promotes resistance to trastuzumab in breast cancer cells through enhancing interaction between HER2 and SRC

Xiaoyan Hao[1], Jialu Zheng[2], Xiaoqin Yu[3], Zhixin Li[1] and Guanghui Ren[4]✉

[1]Department of Thyroid, Breast Surgery, Shenzhen Traditional Chinese Medicine Hospital, Shenzhen, China; [2]Department of Thyroid, Breast Surgery, Longgang District Central Hospital, Shenzhen, China; [3]Department of Ultrasound, Longgang District Central Hospital, Shenzhen, China; [4]Department of General Surgery, Shenzhen Hospital, Southern Medical University, Baoan District, Shenzhen, Guangdong, China

More than 1 million women worldwide are diagnosed with breast cancer (BC) each year. This study aims to explore the molecular mechanisms of β-catenin affecting the trastuzumab tolerance in HER2-positive BC. β-catenin in BC and non-BC tissue samples were assessed by immunohistochemistry. β-catenin and HER2 were over-expressed and knockdown to evaluate their role in tumorigenicity and trastuzumab resistance in cell and animal models using soft-agar and xenograft assays. Confocal laser immunofluorescence assay and co-immunoprecipitation were used to assess protein-protein binding. Expression of genes was detected using Western blot analysis. β-catenin was highly expressed in primary and metastatic BC, overexpression of β-catenin increased the colony formation of MCF7 cells when it was co-expressed with HER2 and synergically increased the tumor size in immunodeficient mice. Overexpression of β-catenin also increased the phosphorylation of HER2 and HER3 and increased the size of tumor derived from HER2-elevated cells. Confocal laser immunofluorescence assay showed that β-catenin and HER2 were co-localized on the membrane of MDA-MB-231 cells, suggesting that β-catenin binds HER2 to activate the HER2 signaling pathway. Immunoprecipitation of β-catenin and HER2 also confirmed this binding. On the other hand, knockdown of β-catenin in MDA-MB-231 cell lines decreased the activity of SRC and decreased phosphorylation of HER2 at Y877 and Y1248. The interaction between HER2 and SRC was enhanced when β-catenin was overexpressed, and β-catenin increased the resistance of tumor derived from HER2 elevated BT474 cells to trastuzumab. Further analysis showed that trastuzumab inhibited the activation of HER3, but SRC was still highly expressed in cells overexpressing β-catenin. Our work demonstrates that β-catenin is highly expressed in BC and it synergically promotes formation and progress of BC with HER2. β-catenin binds with HER2 leading to enhanced interaction with SRC and resistance to trastuzumab.

Keywords: β-catenin; HER2-positive BC; trastuzumab; drug resistance

INTRODUCTION

Over one million women are diagnosed with breast cancer (BC) every year worldwide. Although the overall survival rate of BC has been greatly improved in the last decade, more than 450,000 people still die of BC each year (Anastasiadi *et al.*, 2017; Kolak *et al.*, 2017; Peairs *et al.*, 2017). Therefore, better understanding of the occurrence and development of BC is essential for clinical development for effective interventions (Fahad Ullah, 2019; Ganz & Goodwin, 2015). In the 1980s, the human epidermal growth factor receptor 2 (HER2) signaling pathway was found to be responsible for the abnormal proliferation of HER2 positive (HER2+) BC (Escriva-de-Romani *et al.*, 2018; Rajarajan *et al.*, 2020). HER2 is highly expressed in more than 20% of metastatic BCs and is associated with cancer metastasis and poor patient prognosis (Lewis Phillips *et al.*, 2008; Smith *et al.*, 2007).

HER2 is a member of the epidermal growth factor receptor family (ErbB family) and is activated by homo- or heterodimerization to promote phosphorylation of monomers and recruitment of receptor complexes, phosphoinositide 3-kinase (PI3K), SHC, and growth factor receptor-bound protein 2 (GBR2) (Dankort *et al.*, 2001; Ellis & Ma, 2019; Xie & Hung, 1996). Phosphorylated HER2 can activate the PI3K/AKT and MAPK/ERK signaling pathways to promote cell proliferation, survival and differentiation (Lee *et al.*, 2013; Ruiz-Saenz *et al.*, 2018). HER2+ BC is clinically very aggressive and a series of HER2-targeting drugs, such as trastuzumab, lapatinib, pertuzumab and T-DM1 have been developed for clinical treatment of BC with good clinical efficacy and significantly improved outcomes (Cameron *et al.*, 2017a; Derakhshani *et al.*, 2020; Hunter *et al.*, 2020; Rinnerthaler *et al.*, 2019; Saura *et al.*, 2020). However, metastatic HER2+ BC remains an incurable disease and new treatment options are required for better treatment (Bredin *et al.*, 2020; Harbeck *et al.*, 2019). Furthermore, drug resistance, especially trastuzumab resistance, in BC, particularly in HER2+ BC, has eventually emerged in the great majority of treated patients (Nahta *et al.*, 2006). A better understanding of mechanisms underlying the drug resistance in HER2+ BC is therefore critical to develop new treatment strategies and drugs.

Trastuzumab is a Food and Drug Administration (FDA)-approved humanized antibody targeting HER2. It is used in combination with chemotherapy drugs to treat HER2+ BC and has a good response in early-stage

BC (Cameron *et al.*, 2017b; Tolaney *et al.*, 2021). Paclitaxel, trastuzumab, and pertuzumab are recommended as first-line therapy for patients with HER2$^+$ BC who have not received trastuzumab or who have metastasized after 6 months of adjuvant trastuzumab therapy (Santa-Maria *et al.*, 2016). However, if metastases occur while receiving trastuzumab, T-DM1, may be the best option (Ramagopalan *et al.*, 2021; Uijen *et al.*, 2022). For example, in the CLEOPATRA clinical trial, patients received T-DM1 as a second-line therapy after receiving a first-line chemotherapy regimen (Larionov, 2018). In addition to T-DM1, lapatinib in combination with chemotherapy and trastuzumab is also a standard chemotherapy regimen, although the sequence of these agents has not been fully defined. Due to the development of drug tolerance in patients receiving trastuzumab, numerous studies and clinical trials have attempted to explore new ways to target the HER2 receptor where the Wnt/β-catenin signaling pathway plays an important role (Schade *et al.*, 2013). Therefore, identifying regulators targeting this pathway may provide new directions and strategies for BC treatment.

Wnt/ β-catenin signaling pathway is involved in the development of early embryos and the occurrence of diseases. It plays an important role in thermogenesis and can promote the abnormal proliferation of tumor cells (Wu *et al.*, 2012; Wu *et al.*, 2017). More than 20 target genes have been identified in the pathway and most of them are related to cell proliferation and occurrence of tumors, such as axin-2 (Doumpas *et al.*, 2019), c-myc, cyclin D1 and VEGF (Liu *et al.*, 2016; Zhang *et al.*, 2012). Studies have shown that Wnt/β-catenin signaling pathway is abnormally activated in human cancers, including BC (Brennan & Brown, 2004; Song *et al.*, 2016). Alternation of β-catenin expression may result from mutation and amplification, both of them lead to the occurrence and progression of BC (Sefidbakht *et al.*, 2021; Zhang *et al.*, 2021). Because β-catenin plays an important role in the formation and metastasis of tumor formation, small molecule inhibitors that target β-catenin are being developed to suppress tumor progression (Wang *et al.*, 2021). Studies have found that in BC cells with high expression of HER2 and trastuzumab resistance, the Wnt/ β-catenin signaling pathway is highly activated, suggesting that β-catenin plays an important role in HER2 signaling pathway (Hsieh *et al.*, 2016; Mir *et al.*, 2020; Shen *et al.*, 2020). However, how β-catenin promotes resistance to trastuzumab in BC is largely unclear.

This study aimed to explore the molecular mechanism of β-catenin affecting the trastuzumab tolerance in HER2-positive BC. The findings would provide new directions and potential targets for clinical treatment of HER2$^+$ BC.

MATERIALS AND METHODS

Patients and tissue samples

Tissue samples were collected from patients undergoing surgical treatments at our hospital between April 2013 and September 2017. Patients were female, aged between 32 and 55 years with primary BC that was histologically or cytologically proven. Patients were included if they were HER-2 positive based on assessments from certified laboratories, with ≤1 Eastern Cooperative Oncology Group Performance Status (ECOG PS) and ≥3 month predicted survival and at least one measurable lesion based on RECIST1.1. Patients were excluded if

they were male, had incomplete clinical and pathological data (including immunohistochemical), HER2 status was not verified with FISH, had recurrent BC, or died of non-tumor cause during follow-up.

This study was approved by the ethics committee of the Shenzhen Hospital Affiliated with Southern Medical University and carried out in accordance with the declaration of Helsinki (revised in Tokyo in 2004). Written informed consent was obtained from every patient.

Reagents and equipment

Herceptin (trastuzumab) was purchased from Roche, USA. 0.25% trypsin solution (cat no. 25200072), BCA protein assay kit (cat no. 23225), SDS-PAGE sample prep kit (cat no. 89888), RIPA buffer (cat no. J63306. AP), Lipofectamine™ 3000 Transfection Reagent (cat no. 13778150), ViraPower Lentiviral Packaging Mix (cat no. K497500), Protease Inhibitor Cocktail I (cat no. J64401.LQ), Pierce Direct Magnetic IP/Co-IP Kit (cat no. 88828), protein-G Dynabeads (cat no. 10003D), NP-40 lysis buffer (cat no. J60766.AP) were purchased from Thermal Scientific; OPTI-MEM reduced serum medium (cat no.31985-062) was from Gibco, USA;

Antibodies against β-catenin (cat no. ab223075, 1:1000 dilution), HER2 (cat no. ab134182, 1:1000 dilution), HER2 (phospho Y1248) (cat no. ab201013, 1:1200 dilution), HER3 (cat no. ab32121, 1:1000 dilution), HER3 (phospho Y1289) (cat no. ab76469, 1:1000 dilution), SRC (cat no. ab133283 1:1000 dilution), SRC (phospho Y416) (cat no. ab278693, 1:1000 dilution), horseradish peroxidase (HRP)-conjugated secondary antibody (cat no. ab6728, 1:1500), goat anti-mouse IgG H&L (Alexa Fluor® 488) (cat no. ab150113, 1:1500), goat anti-mouse IgG H&L (Alexa Fluor® 488) (cat no. ab150113, 1:1500), goat anti-mouse IgG H&L (Alexa Fluor® 555) (cat no. ab150114, 1:1500) ECL kit (cat no. ab133406) were purchased from Abcam, Waltham, MA, USA. FLAG antibody (cat no. F1804, 1:1500), type VII agarose (cat no. 39346-81-1) was purchased from Sigma-Aldrich. Colony counter (PhenoBooth+) was purchased from Singer Instruments, UK. Trans-Blot Turbo Transfer System was a product of Bio-Rad laboratories, USA.

Immunohistochemistry

The 5 μm transverse tissue sections were deparaffinized and rehydrated by going through an ethanol gradient. After washing in water, the slides were autoclaved for 4 min in sodium citrate buffer for antigen retrieval. Endogenous peroxidase activity was suppressed by treating with hydrogen peroxidase for 5 min at room temperature. The tissue sections were rinsed with tris buffered saline 1X (TBS), reacted to primary antibody against β-catenin for 1 h and subsequently washed with TBS for three times, and incubated with horse radish peroxidase-conjugated anti-goat IgG (H+L) for 30 min. Diaminobenzidine (DAB) and haematoxylin chromogen (Dako, Glostrup, Denmark) method was used to visualize the immunoreactivity. The slides were examined under a light microscope to score β-catenin-positive cells. For each sample, 10 randomly selected fields were evaluated.

Cell lines and culture conditions

Human cells MCF7 (cat no. HTB-22), BT474 (cat no. HTB-20), SKBr3 (cat no. HTB-30), and MDA-MB-231 (cat no. HTB-26) were purchased from American Type Collection Center, Manassas, VA, USA and were cultured in Eagle's minimum essential medium (EMEM)

(ATCC cat no. 20-2003) with 10% fetal bovine serum (FBS, (ATCC cat no. 30-2020), and 50 U/ml penicillin, and 50 μg/ml streptomycin sulfate (Fisher Scientific MT30001CI). All cell lines were cultured in 5% CO_2 at 37°C in a humidified incubator as instructed by the manufacturer. HEK293T cells were grown to produce virus for transfection experiment as previously described (Cipriano *et al.*, 2010) in DMEM medium (cat no. 12491, Thermo Scientific, Wilmington, Delaware, USA) supplemented with 5% FBS. Cultured cells were routinely tested for mycoplasma contamination using MycoSEQ Mycoplasma Detection Kit (cat no. 4460626, Thermo Scientific) to ensure they were mycoplasma-free.

Vectors and cell transfection

To generate the cell lines overexpressing β-catenin and HER2, Lentiviral vectors pLV-Puro-CMV containing β-catenin and HER2 were constructed (Cyagen Biosciences, USA). BT474 and SKBr3 cells were seeded into the wells of 12-well plates at a density of $1×10^5$ cells/well, grown to a confluency of 70–80%. The cells were transfected with vectors at multiplicity of infection (MOI) 50 based on the results of a pilot study. Mock transfection with LV-EGFP was employed as a negative control. Cell morphology was examined after transfection and the culture medium was refreshed 12 h after the transfection. Stably transfected clones were selected using puromycin at 1.5 μg/ml. The expression of genes was assessed using Western blot analysis.

Plasmids encoding shRNAs targeting SRC were designed using tools provided by the Genetic Perturbation Platform (https://portals.broadinstitute.org/gpp/public/) and inserted into pLKO.1. Lentiviral vectors were transfected into HEK293T cells using Lipofectamine 2000 together with ViraPower Lentiviral Packaging Mix according to the manufacturer's instructions. Supernatants containing viruses were collected and used to infect cells for 16 hours. Cells at 90% confluency were harvested, re-suspended in FBS-free DMEM medium, transfected with the shRNA vectors (5 μg/well) and 250 μl Opti-MEM and Lipofectamine 3000 according to the manufacturer's instructions. After incubation for 20 min, the transfection mixtures were added to the wells of 24-well plates to culture for 4 h.

Immunoblot and immunoprecipitation

Cells were harvested by centrifugation at $500×g$ at room temperature, lysed using RIPA buffer containing protease inhibitor cocktail. The protein content was determined using BCA protein assay kit according to the manufacturer's instructions. About 50 μg protein per lane was loaded for 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) or used for an immunoprecipitation reaction. For immunoprecipitation, 5 μg FLAG antibody was mixed with 50 μl PBS-washed protein-G Dynabeads in 500 μl RIPA lysis buffer containing protease and phosphatase inhibitors by rotating for 2 hours at 4°C. The complex beads were washed twice with PBS and added with protein lysates. The antibody-bead conjugates were rotated at 4°C for 2 hours, washed eight times with NP40 lysis buffer (150 mM NaCl, 1% NP-40, 50 mM Tris-Cl pH 8.0) and resuspended in 25 μl of 2X SDS BME loading dye for immunoblot analysis. After separation by SDS-PAGE, the proteins were transferred electrically to polyvinylidene difluoride (PVDF) membranes ((Millipore)) using Trans-Blot Turbo Transfer System. The membranes were blocked with 5% non-fat dry milk in 1X TBS buffer containing 0.1% Tween 20 for 6 h at 25°C and incubated with proper primary antibodies at 4°C overnight. After being rinsed three times with the same buffer, the blots were reacted with HRP-conjugated secondary antibodies at 25°C for 2 h and then visualized using the ECL kit as instructed by the supplier. Densitometric determination was conducted using Quantity One software (version v4.6.1; Bio-Rad Laboratories, Inc.) using β-actin as the internal control.

Xenograft assays

Eight-week-old specific-pathogen free (SPF) BALB/c-nu nude mice (female, weight 25–30 g) purchased from Saiye Biotech, Shanghai, were used. The mice were housed in hygienic and pathogen-free conditions at 25–26°C with good ventilation. They had free access to filtered water and diet under a 12/12 hours day/night cycle. Mice were randomly divided (n=36) and MCF7 cells expressing β-catenin and HER2 (100 μl, 5×106) were orthotopically injected into the mammary glands for BC development. Animals bearing tumors were then randomized into cohorts to receive administration of trastuzumab, which was administered intraperitoneally for two weeks (6 times) with a total dose of 10 mg/kg. (n=6 in each group). The control group received PBS only. Mouse sizes were recorded every five days till 35 days after injection. Gross necropsies were performed, and tissues were collected and snap frozen in liquid nitrogen for downstream analysis. At different times after the implanting, mice were sacrificed by euthanization with carbon dioxide applied at a flow rate of 20% of the cage volume per minute (5 L/min) and tumors were isolated for size measurement using Vernier caliper.

The animal experimental protocols were approved by Animal Research Ethics Committee of the Shenzhen Hospital Affiliated with Southern Medical University.

Soft agar assay

Soft agar assays were performed to assess the colony formation ability as previously described (Horibata *et al.*, 2015). Briefly, MCF7 cells $(1×10^5$ cells/ml) were suspended gently in 0.6% type VII agarose (maintained at 42°C) prepared in RPMI 1640 medium supplemented with 10% FBS and 1% penicillin/streptomycin. The cells were plated in triplicate onto a bottom layer of 1.2% agar in 60-mm dishes. After being solidified at room temperature for 30 min, the plates were covered and were placed into a 37°C humidified incubator to culture. Three weeks later, the cells were stained with 200 μl of 0.1% crystal violet per well overnight at 37°C. The stained colonies were analyzed using PhenoBooth+colony counter.

Confocal laser immunofluorescence assay

Human breast adenocarcinoma MDA-MB-231 cells were air dried on siliconized glass slides (Dako, Kyoto, Japan) at room temperature, fixed in pre-chilled methanol for 2 min and washed three times with PBS. The cells on the slides were incubated with 100 μl of each antibody against β-catenin and HER2 overnight at 4°C in a humid box. After being washed with PBS, the slides were incubated with 100 μl of goat anti-mouse IgG H&L (Alexa Fluor® 488) or goat anti-mouse IgG H&L (Alexa Fluor® 555) for 30 min. The slides were washed three times with PBS and countered stained with DAPI and mounted with buffered glycerol. The cells were visualized and photographed using a Leica confocal laser scan-

ning microscope equipped with an OG 515 filter (Leica AG, Heerbrugg, Switzerland).

Co-immunoprecipitation

Co-immunoprecipitation of β-catenin and HER2 was performed using Direct Magnetic IP/Co-IP Kit according to supplier's protocols. Briefly, confluent MDA-MB-231 cells expressing β-catenin and HER2 were added with ice-cold IP lysis buffer and the lysates were centrifuged at ~13 00×*g* for 10 minutes to pellet the cell debris. The supernatant was added to anti-HER2 antibody coupled beads and gently mixed and incubated on a rotating platform for 30–60 minutes at room temperature. After being washed with a washing buffer, the beads were collected with a magnetic stand and the proteins were eluted and analyzed using Western blot analysis.

Statistical analysis

Statistical analyses were performed with SPSS (version 19.0; SPSS, Inc., Chicago, IL, USA). Data are expressed as the means ± S.D. Differences between multiple sample means were analyzed using one-way ANOVA and the LSD-t method was used for comparison between the two groups. Statistical significance was defined as a two-tailed *P*<0.05.

RESULTS

β-catenin is highly expressed in primary and metastatic BC

The Wnt/β-catenin signaling pathway is well known to be involved in various human cancers. To demonstrate the role of β-catenin in human BC, we first analyzed the expression of β-catenin in normal tissues and BC tissues in the clinical samples using immunohistochemistry methods. It was found that β-catenin was expressed in 40.8% cells in the metastatic BC tissues, 20.1% cells in primary BC tissues and cells, and 2.2% in non-cancer tissues (Fig. 1A). Furthermore, among HER2+ BC cells, β-catenin was overexpressed in 12% of primary BC cells and 30% of metastatic BC cells (Fig. 1B).

β-catenin and HER2 synergically promote tumor development

To assess the synergy of β-catenin and HER2 in driving tumorigenesis, we established MCF7 cells that stably expressed β-catenin and HER2. Western blot analysis showed that non-transfected MCF7 cells (control) had very low background β-catenin and HER2 expression, and in the transformed cells β-catenin and HER2 expressions were significantly upregulated (*P*<0.01, Fig. 2A). Notably, only cells expressing both β-catenin and HER2 exhibited an unusual and invasive phenotype when cultured in monolayers, while single expression of either β-catenin or HER2 did not change cellular morphology dramatically (Fig. 2B). To assess the malignancy of transformed cells, soft-agar experiments were performed. Cells expressing β-catenin and HER2 alone formed more colonies than control and had similar number of colonies. However, the number of colonies formed by cells expressing both β-catenin and HER2 was more than doubled as compared with cells expressing single genes (*P*<0.01, Fig. 2C). To further confirm these findings, MCF7 cells expressing β-catenin and HER2 were used to inoculate immunodeficient mice for tumor development. The animal experiments demonstrated that overexpression of both HER2 and β-catenin significantly promoted tumor formation and progression, resulting in significantly large tumors, although β-catenin and HER2 alone induced tumor formation (*P*<0.01, Fig. 2D), suggesting that β-catenin might synergize with HER2 to promote the formation and development of tumor cells.

β-catenin promotes the phosphorylation of HER and tumorigenesis

To explore the effect of β-catenin on HER phosphorylation, we overexpressed β-catenin in two HER2-elevated BC cell lines BT474 and SKBr3. We used retrovirus containing GFP-β-catenin or GFP (control) to overexpress β-catenin in these two cell lines. The results showed that compared with the control, β-catenin was remarkably up-regulated. Meanwhile, phosphorylation of HER2 at Y1248 and HER3 at Y1289 was significantly increased (*P*<0.01, Fig. 3A). Notably, the phosphorylation levels of HER2 and HER3 were also significantly increased when cells were serum-starved (Fig. 3A).

To further examine the effect of β-catenin overexpression on the progression of HER2+ BC, we orthotopi-

cally injected BT474 cells expressing β-catenin into the mouse mammary glands in immunodeficient mice, and measured tumor growth. The results showed that compared with the control group, at 25 days post-injection, the tumors formed with β-catenin overexpressing cells were significantly greater than control (P<0.01, Fig. 3B).

β-catenin binds to HER2

Since β-catenin can promote the phosphorylation of HER2, we set to investigate if β-catenin and HER2 are physically in contact with each other. Using confocal immunofluorescence assay, we found that β-catenin and HER2 were co-localized on the cell membrane in MDA-MB-231 cell line (Fig. 4A), suggesting that they might be in direct contact with each other. We further performed co-immunoprecipitation of the proteins with extracts from SKBr3 and BT4742 cell lines. It was found that β-catenin and HER2 were co-precipitated in both cell lines (Fig. 4B).

β-catenin enhances HER2 interaction with SRC

Elevated SRC has been shown to stabilize HER2 to enhance cellular migration and survival (Mayer & Krop, 2010). Therefore, we investigated the impact of β-catenin on SRC and its phosphorylation. When β-catenin was knockdown in MDA-MB-361 cells, SRC and its phosphorylation, and HER2 phosphorylation at Y877and

Y1248 were significantly reduced (Fig. 4A). To explore whether the inactivation of SRC would affect the activation of HER by β-catenin, SRC was downregulated using two SRC shRNAs in SKBr3 cells expressing β-catenin.

Figure 5. Phosphorylation of SRC and HER2 after knockdown of β-catenin (A) and SRC (B) and interaction between SRC and HER2 after overexpressing β-catenin (C).
Left panel: representative Western blots, right panel: relative protein level. ** denote *P*<0.01 *vs* control.

As a result, we found that HER2 phosphorylation at Y877 and Y1248 were decreased in the SRC-knockdown cells (Fig. 5B). These results suggest that SRC might regulate β-catenin-mediated HER2 phosphorylation to impact tumor development. On the other hand, when β-catenin was overexpressed, the interaction between HER2 and SRC was enhanced (Fig. 5C).

To further elucidate the functional relevance among β-catenin, HER2, and SRC, we examined the effect of β-catenin overexpression on drug sensitivity of the tumor cells. Recent studies have shown that abnormal activation of SRC can lead to resistance of tumor cells to trastuzumab. We found that in HER2+ BC, overexpres-

*denotes *P*<0.01 *vs* control.

sion of β-catenin increased the resistance to trastuzumab (Fig. 6A). Further analysis found that trastuzumab inhibited the phosphorylation of HER2, but the SRC remained highly active in cells overexpressing β-catenin as compared to control cells (Fig. 6B).

DISCUSSION

A large number of *in vitro* and *in vivo* studies have shown that HER2 overexpression is related to the occurrence of BC (Loibl & Gianni, 2017). However, there is not enough evidence to confirm that HER2 can drive the transformation from benign to malignant and metastatic BC (Exman & Tolaney, 2021). It is also not clear whether other genomic variations can synergically promote BC with HER2. In this study, we found that β-catenin appears to be an important regulatory protein of HER2 that drives BC development and resistance to trastuzumab. β-catenin is highly expressed in BC, particularly in metastatic BC, and synergically promotes the development of BC in xenograft mouse models probably by increasing the phosphorylation of HER2. We also found that β-catenin binds with HER2 and enhances the interaction between HER2 and SRC, resulting in increased trastuzumab resistance. The findings from this study provide new insights and clues for the development of new therapeutic strategies and targets for BC.

Better understanding the molecular mechanisms underlying the metastatic dissemination of HER2+BC would be helpful to the development of effective clinical interventions. Wnt/β-catenin signaling pathway is well known to play important roles in human cancers (Zhang & Wang, 2020). Assessment of β-catenin expression in tumor tissues has shown that it is upregulated in BC, particularly in metastatic cancer. As a multifunctional protein with a central role in physiological homeostasis, β-catenin is often upregulated in various diseases, including cancer, as the result of mutations of canonical Wnt signaling pathway genes (Cui *et al.*, 2018; White *et al.*, 2012). In canonical Wnt pathway, Dsh, β-catenin, glycogen synthase kinase 3 beta (GSK3β), adenomatous polyposis coli (APC), AXIN, and T-cell factor (TCF)/ lymphoid enhancement factor (LEF) are the major signal transducers with β-catenin as core protein (Behrens *et al.*, 1996; Yost *et al.*, 1996). Our study further demonstrated that β-catenin is highly upregulated in HER2 BC, suggesting that there might be interactions between the two genes, particularly in metastatic BC. HER2 has been shown to interact with oncogenic/stemness signaling pathways including Wnt/β-catenin, and HER2 overexpression promotes EMT and the emergence of cancer stem cell properties in BC (Nami & Wang, 2017). Using MCF7 cells, we found that although β-catenin and HER2 alone increase the colony formation ability, co-expression of the two genes results in increased invasive transformation of the cells and higher tumorigenicity in immunodeficient mice as compared to single β-catenin or HER2 protein. These studies further demonstrate that β-catenin and HER2 have synergy in promoting BC. In gastric cancer cells, overexpression of HER2 was shown to increase the stemness and invasiveness, which is regulated by Wnt/β-catenin signaling (Jung *et al.*, 2019). Previously the aberrant expression of β-catenin was associated with more aggressive behaviors of BC although it was not statistically correlated to HER2 (Sefidbakht *et al.*, 2021). However, in epithelial ovarian cancer (EOC), high expression of β-catenin was found in HER2-positive EOC tissue samples and was correlated with a poor

patient prognosis. Therefore, Wnt3a/β-catenin/TCF7L2 signaling axis is considered to play an important role in EOC resistance to trastuzumab and HER2-targeted drugs may have the potential for EOC treatment (Shen *et al.*, 2020).

To elucidate the interaction between β-catenin and HER2, we investigated the effect of β-catenin on the HER activity by overexpressing β-catenin in BC cell lines BT474 and SKBr3 with elevated HER2 level. It was found that in these cells, there was increased phosphorylation of HER2 and HER3. Previously, HER2 phosphorylation was found to be due to the activation of other HER receptors, such as reactivation of HER3 and ADAM17-mediated ligand release (Gijsen *et al.*, 2010). In addition, the levels of phosphorylated HER2 increased significantly in cells treated with arenite and exogenous EGF, TGFα, NRG1, and HSP90 through the dimerization of HER2 with other members of HER family, such as HER3 (Jin *et al.*, 2018). Other proteins reported to phosphorylate HER2 include PTPN18 that regulates HER2-mediated cellular functions through defining both its phosphorylation and ubiquitination barcodes (Wang *et al.*, 2014). The activation (phosphorylation) of HER family gene by β-catenin is likely partially responsible for the enhanced tumorigenesis. Study with β-catenin knockdown may further define the relationship between β-catenin and HER2 activation.

To further investigate the model of action of β-catenin and HER2, we studied the co-location of these two proteins using confocal immunofluorescence assay. β-catenin and HER2 were found to be co-localized on the cell membrane, indicating that they might have direct physical contact with each other, and the results from immunoprecipitation in the two cell lines tested support this speculation. To further refine the interaction between β-catenin and HER2, protein variants might be used to better understand the structure-binding relationship.

SRC is one of the non-receptor tyrosine kinases that participates in cell proliferation, differentiation, survival, and invasion through the PI3K, MAPK, STAT3, FAK signaling pathways (Roskoski Jr., 2015). Studies have shown that increased SRC activation can stabilize HER2 to enhances cellular migration and survival and confers resistance of HER2+ BC cells to trastuzumab (Peiro *et al.*, 2014). Our analysis showed that the activation (phosphorylation) of both SRC and HER2 is reduced once β-catenin is knockdown, implying that β-catenin might be involved in regulating both SRC and HER2 signaling. On the other hand, knockdown of SRC in SKBr3 cells expressing β-catenin results in decreased HER2 phosphorylation, suggesting that SRC might regulate β-catenin-mediated HER2 phosphorylation to impact tumor development, and this SRC interaction with HER2 is enhanced by β-catenin. Since increased trastuzumab resistance and SRC activation were observed in tumors derived from cells expressing β-catenin, it is likely that SRC might also play a role in the drug resistance. Trastuzumab is a monoclonal antibody that binds HER2 extracellular subdomain IV to treat BC, although its mechanism of action is still not fully understood (Shawver *et al.*, 2002). It was demonstrated to reduce HER2 phosphorylation (Nami *et al.*, 2019). This is consistent with our results that following trastuzumab treatment, phosphorylation of HER2 is reduced. On the other hand, the activation-associated phosphorylation of SRC at tyrosine 416 remained significantly higher in tumors derived from cells expressing β-catenin than control, irrespective of trastuzumab treatment, suggesting that SRC activation is involved in trastuzumab re-

sistance. Previously, the SRC/STAT3 signaling pathway was found to be activated by chromosome condensin 1 complex subunit G (NCAPG), leading to trastuzumab resistance in HER2+BC and SRC phosphorylation may enhance nuclear localization and activation of STAT3 (Jiang *et al.*, 2020), leading to trastuzumab resistance (Zhang *et al.*, 2011). Since SRC phosphorylation occurs in tumors derived from cells overexpression β-catenin, further study is needed to explore β-catenin as a therapeutic target to overcome trastuzumab resistance.

CONCLUSION

β-catenin is highly expressed in BC tissues as compared to non-cancer tissue. It synergically promotes formation and development of BC with HER2. β-catenin interacts with HER2 leading to SRC activation and trastuzumab resistance. Due to these important roles, β-catenin may be further explored as a therapeutic target to overcome trastuzumab resistance in BC.

Impact of diet modification on body mass and kidney function in patients with diabetic nephropathy: a pilot study

Małgorzata Kaczkan[1], Sylwia Czaja-Stolc[1✉], Małgorzata Sikorska-Wiśniewska[2], Michał Chmielewski[2], Alicja Dębska-Ślizień[2] and Sylwia Małgorzewicz[1]

[1]Department of Clinical Nutrition, Medical University of Gdansk, Gdańsk, Poland; [2]Department of Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdańsk, Poland

Objectives: The increasing trend in chronic kidney disease (CKD) has occurred in parallel with the increased prevalence of obesity and diabetes type 2. The relationship between a reduction in body mass and protein intake in diabetic nephropathy (DN) has not been adequately understood. This study aimed to determine whether dietary intervention in an adult with DN is associated with decreasing proteinuria or changes in kidney function over six months. **Methods:** The study included 120 patients with DN, consecutively admitted to a dietitian from a Kidney Disease Clinic. Patients were classified into two groups: a reduction diet or a normal calorie diet, both with 0.8 g of protein/kg of ideal body weight/day. Anthropometric and laboratory assessments were done before and after observation. **Results:** After six months, in the study group of patients on a reducing diet, a decrease in body mass, body mass index (BMI) and stabilization of estimated glomerular filtration rate (eGFR) were observed. There was also a significant correlation between the time of diabetes diagnosis and eGFR and creatinine (R Spearman=–0.24 and 0.3, respectively; p=0.05). There were no other significant associations between body mass, BMI, albuminuria, eGFR, or creatinine. **Conclusions:** The study shows that obesity is a common comorbid disease in patients with DN and that dietary intervention is associated with a significant reduction in body mass and stabilization of eGFR in these patients.

Keywords: diet; obesity; diabetes; diabetic nephropathy; estimated glomerular filtration rate

INTRODUCTION

Diabetic nephropathy (DN), also known as diabetic kidney disease is one of the most common complications of diabetes and is the leading cause of end-stage kidney disease (ESKD) in the general population (Khan *et al.*, 2018). DN is characterized by the development of progressive albuminuria and the loss of the glomerular filtration rate (GFR) (Tutle *et al.*, 2014). Published studies have shown that among patients who started renal replacement therapy, the percentage of patients with diabetes (only DN) ranged from 24% to 51% (all causes were counted) and is still increasing (Buyadaa *et al.*, 2020).

According to the World Health Organization (WHO), the number of patients requiring renal replacement therapy is expected to double by 2030 (Luyckx *et al.*, 2018). Therefore, conservative treatment of chronic kidney disease (CKD) is becoming increasingly important from the point of view of preventing an epidemic of this disease. Experts point to the importance of proper dietary management and education in this area as one of the key points in the development of nephroprotective effects, which may have a measurable, positive impact on the quality of life of patients and inhibit the increase in the number of patients at the end-stage of the disease (Tutle *et al.*, 2014).

The main cause of excess body weight and its complications are lifestyle changes, limitation of physical activity, improper eating habits, and above all, the excessive consumption of high-energy products (Swinburn *et al.*, 2004). Changing incorrect eating habits is most effective in the early stages of diseases such as obesity, diabetes type 2, or CKD, but at every stage it is worth recommending that patients correct any eating mistakes. However, the relationship between overweight or obesity in patients with CKD and the mortality risk is not clear. Dietary intervention is particularly important in patients with CKD, as well as in other disease states and metabolic phenotypes such as obesity and diabetes, which affect the risk of developing and exacerbating the progression of CKD (Díaz-López *et al.*, 2021).

Treatment of DN includes intensive control of glycemia – glycated hemoglobin/hemoglobin A1c (HbA1c) <7%, proteinuria, hypertension through pharmacotherapy, as well as lifestyle modifications. The American Diabetes Association (ADA) recommendations for people with DKD do not promote a change in the amount of protein in the diet below 0.8 g/ kg/ day but rather suggest replacing the animal protein source with soybean to reduce cardiovascular risk (American Diabetes Association, 2014). Moreover, the latest recommendations of NKF KDOQI Clinical Practice Guideline On Nutrition In CKD: 2020 Update (Ikizler *et al.*, 2020) indicate the possibility of limiting protein consumption in the range of 0.6–0.8 g/kg/ day in the group of adults with diabetes and with estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m². The study aimed to determine whether dietary intervention in an adult with DN is associated with proteinuria or changes in kidney function during a six-month observation period.

MATERIAL AND METHODS

Study design

The current study was a 6-month interventional study to determine the effects of dietary intervention on renal function and proteinuria in adults with DKD. The nephrologist enrolled DKD patients in the study and referred them to a clinical dietitian. The dietitian then wrote down the rules of the diet and, based on the body mass index (BMI), divided patients into two groups. Dietitian visits were scheduled every 4–6 weeks, and nephrological control visits every 12 weeks.

DKD was diagnosed in patients with diabetes according to recommendations: if indicators of kidney damage persist ≥3 months:

– macroalbuminuria – urine albumin-to-creatinine ratio (UACR) >300 mg/g)

– microalbuminuria – 30–300 mg/g in the presence of diabetic retinopathy; in diabetes type 1 (additionally), when the duration of the disease is at least ten years (KDOQI, 2007).

Inclusion criteria for the study were: age >18 years old, DKD stages 2–5, good nutritional status, and signed consent to participate in the study.

All subjects gave informed consent to the inclusion before participating in the study. The study was approved by the Bioethical Committee.

Initially, 120 patients were enrolled in the study, but 50 (42%) were excluded because they did not follow the diet and did not attend follow-up visits. The scheme of the study is presented in Fig. 1.

Study population

Ultimately, the study population consisted of 70 clinically stable patients with DKD, at an average age of 65.1±11.8 years, admitted to the dietitian from the ambulatory Department of Nephrology, Transplantology and Internal Medicine at the University Clinical Center in Gdansk (Poland) in the years 2018–2020.

The results were collected over six months of follow-up, with visits every 1–3 months. At each visit, body weight, laboratory parameters and compliance with dietitian rules were assessed.

Dietary intervention

All patients who consented to participate in the study had a personal appointment with a dietitian with extensive experience in the management of CKD diet. Diet planning methodology included the determination of energy demand by measuring basal metabolic rate (BMR) based on bioimpedance mass indications. The patient's total daily energy expenditure (TDEE) was then calculated using the appropriate level of physical activity (PAL):

– 1.4 – for people with low physical activity,
– 1.6 – for people with medium physical activity,
– 2.0 – for people with high physical activity.

Protein intake was established at 0.8 g/kg of ideal body weight/day, phosphorus 800-1200 mg/day and potassium 2000–2500 mg/ day. The ideal body weight is calculated based on Broc's formula.

Patients with BMI ≥30 were qualified for the reduction diet – the amount of body weight loss per unit time was set at 0.5–1.0 kilograms per week – to unify the deficit of 500 kcal/day. Patients with BMI <30 were enrolled in a normal calorie diet.

The following nutrient requirements were determined in both groups: protein – 0.8 g/kg of ideal body weight/day, carbohydrates – 45-55% and fats – 30–35% of daily energy requirement. The mineral demand was determined based on the dietary standards of the Polish population. The patients' daily diet is defined as 4–5 meals. During the observation, patients met with a dietitian to obtain nutritional advice. At each control meeting, a 24-hour diet recall was conducted, and patients were asked to record their diet for three days before the visit. Patients were re-educated on the correct application of the diet. Each time during the meeting, patients were subjected to bioimpedance measurements, based on which BMR and TDEE were determined as the starting point for determining energy reduction in the diet, in accordance with the recommendations of the Polish Society of Dietetics and NKF KDOQI (KDOQI, 2007; Gajewska *et al.*, 2015). All patients were instructed to maintain a minimum level of 150 min. per week of physical activity throughout the study period.

BMI

Measurement of body mass with the scale (Tanita BC 420) was performed at each visit by a dietitian. The BMI was calculated using the following formula: BMI=body weight/height^2 (kg/m^2). The BMI classification was adopted: <18.5 – underweight; 18.5–24.9 – normal body weight; 25.0–29.9 – overweight; ≥30.0 – obesity. The ideal body weight was calculated according to Broc's formula (height in cm –100); height was measured in a stadiometer.

Laboratory Measurements

Albumin, triglycerides, total cholesterol, phosphorus, potassium, creatinine, fasting glucose, HbA1c, and blood counts were measured for all participants (baseline and at six months) using routine laboratory tests. UACR was calculated from urine albumin and creatinine. eGFR was calculated according to The Modification of Diet in Renal Disease (MDRD) equation and creatinine clearance (CC) was obtained from The Cockroft-Gault equation. After three months of observation, serum creatinine

Data are presented as mean ± S.D. and range Aberrations: M, men; F, female; BMI, body mass index; eGFR, estimated glomerular filtration rate; MDRD, Modification of Diet in Renal Disease; CC, creatinine clearance; HbA1c, glycated hemoglobin/hemoglobin A1c; CKD, chronic kidney disease

and UACR were measured. All patients performed self-monitoring of blood glucose and blood pressure during follow-up.

Statistical Analysis

Results are expressed as percentages (for categorical variables), mean, and standard deviation. The assumption of normality was verified by the Kolmogorov-Smirnov test. A p-value <0.05 was considered statistically significant. The Spearman correlation coefficient (R) was used to assess the correlation between the assessed variables. Comparisons between the two groups were assessed using the Student's t-test or the U-Mann–Whitney test, respectively. The change in value between the first visit and the last visit (value for the last visit minus the value for the first visit) was compared between the groups. The comparison was made using the Wilcoxon test. Statistical processing of the results was performed with the use of the statistical software STATISTICA PL v 13.0 (Statsoft, Kraków, Poland).

RESULTS

Characteristics of patients with DN

The results of 70 patients who completed the study were analyzed. The baseline patient characteristics are shown in Table 1. Diabetes type 1 was diagnosed among 11 patients (15%), and diabetes type 2 among 59 (85%). The mean duration of diabetes was 9.84 ± 4.8 years (range 4–18).

There were five obese patients in the G2 stage, G3 had 22 patients, G4 had four patients, and G5 had two patients. Most of the patients were treated with insulin, and 43% received oral antidiabetic drugs from various groups. Antihypertensive treatment with renin-angiotensin system blockers was received by 97% of patients.

Baseline results

A total of 33 patients (47.1%) were obese; 22 (31.4%) were overweight, and 15 (21.5%) presented normal BMI at baseline (Fig. 2).

The mean serum albumin level was 38.2±2.9 mg/L and indicated good nutritional status in patients. Serum levels of potassium and phosphorus were in reference ranges (4.6±0.6 mmol/L; 3.9±0.9 mg/dL, respectively). The mean fasting glucose level was 149.06±54.0 mg/dL and HbA1c – 6.6%. The mean eGFR was 41.3±20.5 mL/min/1.73 m² and the mean CC, according to the Cockroft-Gault formula, was 60.2±50.5 mL/min. The correlation between eGFR MDRD and CC was high (R=0.88; p<0.05). The UACR was in the range of 1120±152 mg/g.

In addition, a statistically significant correlation between the time of diabetes diagnosis and eGFR and creatinine (R Spearman=–0.24 and 0.3, respectively; p=0.05) was noted. There was no significant relationship between body mass, BMI, albuminuria, eGFR, CC and serum creatinine.

Follow-up results

As presented in Table 2, in the study group, after six months of dietary intervention, a decrease in body mass and BMI was noted in comparison to the baseline parameters. Serum creatinine, eGFR, UACR, albumin, phosphorus, and potassium were changed insignificantly. Changes in eGFR are presented in Fig. 3.

In the obese group, the mean body weight loss over six months was 7.0±2.2 kg, and in the non-obese group,

Glucose fasting (mg%)	148±48	132±54	156±68	143±59	145±87	156±50
UACR (mg/g creatinine)	1120±152	1525.5±120.8	2290±187	2131±213	1241±256	1820±252

Data are presented as mean ±S.D. Aberrations: BMI, body mass index; eGFR, estimated glomerular filtration rate; MDRD, Modification of Diet in Renal Disease; CC, creatinine clearance; HDL, high-density lipoprotein; HbA1c, glycated hemoglobin/hemoglobin A1c; UACR, urine albumin-to-creatinine ratio

it was 0.4±0.4 kg. The urinary protein excretion in both groups did not change significantly.

DISCUSSION

The occurrence of excess body mass in DN patients and the effectiveness of six months of dietitian intervention were observed in the study. The prevalence of obesity was 47%, and about 31% of the patients were overweight. After six months of the reduction diet, 63.6% of patients decreased their body mass and BMI. Excess weight is often associated with type 2 diabetes. Moreover, the accumulation of adipose tissue in the trunk area in patients with type 2 diabetes may be associated with potential consequences, for instance, albuminuria, proteinuria, and a decrease in GFR (Gnacińska *et al.,* 2009). Mild renal failure is associated with high cardiovascular risk in the general population: any decrease in eGFR below the norm of 5 mL/min increases cardiovascular risk by 26% (Schram *et al.,* 2004; Ronald *et al.,* 2002). Serum creatine concentrations >1.6 mg/dL are associated with a 20% increased risk of mortality for all causes, cardiovascular and ischemic cardiovascular conditions (Wannamethee *et al., 1997).*

The presented results confirm that obesity is a major public health problem among diabetic patients, including those with DN. The prevalence of excess body mass reached 80%, which indicates that a significant number of patients in nephrology outpatients required appropriate nutritional treatment (Bijelic *et al.,* 2020). It is also worth emphasizing that a significant number of patients (50/120, 42%) did not agree with the proposed diet, which is a significant problem in clinical practice. However, in the obese group, about 36% of patients did not lose significant body weight, possibly due to non-compliance with the diet. The resignation from dietitian intervention was more frequent in the beginning – perhaps

more accurate education is needed among patients with diabetes. Despite recommendations for lifestyle modification at every stage of diabetes, patients were not cooperative.

In the current study, a diet of 0.8 g protein/kg ideal body weight/day was followed as recommended. Additionally, in obese patients, a caloric deficit of 500 kcal/day was established. The primary goal of the diet was adequate glycemic control, as measured by self-measured fasting glucose and HbA1c. In the current study, the average level of HbA1c was 6.8% and did not change throughout the observation. The second goal was to reduce body weight in obese patients and to establish an association between weight loss and eGFR, CC, and proteinuria. It is well known that a properly balanced diet allows for a sustained reduction in body weight by an average of 0.5-1 kg per week (Bray *et al.,* 2003; Sacks *et al.,* 2009; Hruby *et al.,* 2015).

In the current study, the mean weight loss in obese patients (BMI>30) was approximately 7 kg/6 months. Despite a weight loss of about 1 kg per month, no statistically significant changes were found in eGFR, CC or albuminuria. The average decrease in eGFR in the study was 0.37 mL/min/1.73 m², and satisfactory and stable results were obtained. The observed decrease in CC from 80.2–60.2 mL/min in the obese group is favorable because it indicates a decrease in hyperfiltration and also indicates that eGFR, according to MDRD, is a less accurate parameter, especially in obese people. Navanethan S.D. and others showed in a meta-analysis that weight loss as a result of dietary or bariatric intervention is associated with a reduction in proteinuria, blood pressure and, in the case of severe obesity, with normalization of eGFR (Navaneethan *et al.,* 2009). Moreover, Diaz-Lopez et al., in the PREDIMED-Plus trial, concluded that the lifestyle intervention approach may preserve renal function and delay CKD progression in adults with excess body mass (Diaz-Lopez *et al.,* 2021). The RIGOR-TMU

study also indicated that weight loss after bariatric surgery was associated with eGFR preservation in patients with CKD (Becerra-Tomás *et al.,* 2019).

The ADA published a nutrition care model that provided evidence-based, standardized, high-quality care for non-dialyzed patients with CKD. The document reported that: "nutrition care provided by a registered dietitian up to twice monthly over one year can have a valuable role in the medical care of patients with CKD by providing nutrition assessment and interventions to delay kidney disease progression in addition to co-morbid conditions, such as diabetes, cardiovascular disease (CVD), dyslipidemia, gout, and nephrolithiasis" (American Diabetes Association. Choose Your Foods, 2014). In the current study, follow-up visits were established every 4-6 weeks, while in everyday practice, meetings with dietitians are less frequent. The effectiveness of diet modification might be better if the ADA recommendations were applied in both research and practice.

The primary goal of diabetes treatment is to maintain optimal glycemic control and to prevent complications, including renal and cardiovascular complications. The NKF KDOQI recommendations from 2020 focus on dietary protein intake as a factor in the progression of kidney damage and suggest 0.6–0.8 g of protein/kg/day in adult patients with diabetes and CKD stages 3–5. The NKF KDOQI recommendations are based on expert opinion and must be used with caution, i.e., only in patients in good clinical condition, in good nutritional status, and cooperating well, otherwise, there is a risk of malnutrition (Ikizler *et al.,* 2020). In the current study, despite 0.8 g of protein/kg of ideal body weight/per day, there was a tendency to lower the level of albumin.

The Kidney Disease: Improving Global Outcomes (KDIGO) guidelines suggest a more liberal diet when protein intake is 0.8 g/kg body weight per day and does not exceed >1.3 g of protein/kg body weight (Avesani *et al.,* 2005). KDIGO guidelines underline that reducing protein intake is associated with slowing the progression of CKD, improving urea and phosphate levels, and reducing acidosis (Cupisti *et al.;* 2020). However, some studies have shown that low-protein diets reduce hyperfiltration (Kontessis *et al.,* 1990; De Nicola *et al.,* 2020).

In the second studied group (on a normal calorie diet with 0.8 g of protein/kg/day), changes were not noted in any body mass, eGFR, or UACR during the observation period, and the dietitian's assessment indicated good adherence to the recommendations in this group. In the study, a diet based on animal and plant products was used, but there are reports that plant protein is more beneficial in CKD. Some authors (McGraw *et al.,* 2016; Moorthi *et al.,* 2017) have suggested that plant-based diets are more beneficial for DKD patients, especially those with high cardiovascular risk.

In everyday practice, it is very important to correct a patient's diet. It should be noted that not only the supply of protein is important, but also the content of calories, fat, and carbohydrates as well as vitamins and minerals (Skrypnik *et al.,* 2019). The ADA recommends lifestyle modifications based on increased physical activity and the assumptions of the Mediterranean or DASH diet, reducing the consumption of saturated fatty acids and trans isomers and increasing fiber and unsaturated fatty acids (American Diabetes Association. Choose Your Foods, 2014).

The authors would like to emphasize the need to educate patients and medical staff in the field of primary and secondary prevention. Proper modification of the diet is recommended by nephrological societies in delayed kidney dysfunction and is also recommended as prophylaxis of cardiovascular events (Skrypnik *et al.,* 2019; Skrypnik *et al.,* 2020). The current results suggest the advantages of including simultaneous pharmacological and dietary intervention in the overall prevention of ESKD and cardiovascular risk in patients with excess body weight and diabetic nephropathy. To draw more precise conclusions, more research is needed on the effects of weight loss and modification of protein intake on the progression of CKD in obese patients with DN.

LIMITATIONS OF THE STUDY

The current study has several limitations. The first limitation is the small group of patients. Other limitations include the lack of detailed diet analysis and strict control of diet compliance, e.g., by the excretion of urea nitrogen in the urine. The observation time was short, and long-term studies are needed to analyze the renal outcomes, such as the development of renal dysfunction.

The strengths of the study include the demonstration of the role of a dietitian in the treatment of patients with diabetes and kidney diseases and the need to educate patients on non-pharmacological methods of treatment.

CONCLUSION

The study shows that obesity is a common symptom in patients with DN, and dietary intervention is associated with a significant reduction in body weight and stabilization of eGFR in these patients. As the majority of DN patients are at risk of obesity-related mortality, the advice of a dietitian should become part of both routine clinical evaluation and intervention.

PRACTICAL APPLICATION

The study shows the effect of dietary interventions on the progression of DN. The study also emphasizes that it is necessary to educate patients on the impact of diet on the progression of the underlying disease and the risk of complications, especially cardiovascular-related ones.

Metformin promotes the normalization of abnormal blood vessels after radiofrequency ablation deficiency in hepatocellular carcinoma by microRNA-302b-3p targeting thioredoxin-interacting protein

HaiGang Niu[1,2], ShuYing Dong[1], GuoMing Li[3], ShiLun Wu[1] and WenBing Sun[1]✉

Metformin has shown great promise in the treatment of HCC. Radiofrequency ablation (RFA) deficiency results in recurrence and metastasis of remaining HCC tumors. Here, we aimed to investigate the role and mechanism of metformin in HCC after RFA deficiency. HCC cell line Hep-G2 was selected to simulate RFA deficiency and named HepG2-H cells. After treating cells with different concentrations of metformin (2.5, 5, 10 µM) or transfecting related plasmids, cell proliferation, migration, invasion, apoptosis and angiogenesis were detected, *in vitro* permeability test was performed, and an angiogenesis-related protein VEGFA was analyzed. The residual HCC model after RFA deficiency was established in mice. Metformin was administered by gavage to detect changes in tumor volume and weight, and CD31 staining was used to observe microvessels. The targeting relationship between miR-302b-3p and *TXNIP* was demonstrated by the bioinformatics website, dual-luciferase reporter assay, and RNA pull-down assay. The results found that metformin inhibited RFA deficiency-induced growth and angiogenesis of HCC cells *in vitro*. miR-302b-3p counteracted the therapeutic effect of metformin on RFA deficiency. miR-302b-3p targeted regulation of *TXNIP*. The up-regulation of *TXNIP* reversed the effects of overexpression of miR-302b-3p on RFA-deficient HCC cells. Metformin inhibited RFA-deficiency-induced HCC growth and tumor vascular abnormalities *in vivo*. Overall, metformin promotes the normalization of abnormal blood vessels after RFA deficiency in HCC by miR-302b-3p targeting *TXNIP*, which can be used to prevent the progression of HCC after RFA.

INTRODUCTION

Hepatocellular carcinoma (HCC) is an extremely familiar primary liver malignancy and the main reason for cancer-linked deaths worldwide (Harati *et al*., 2021). Over the past 10 years, the incidence of HCC has been increasing, causing a huge socioeconomic burden (Schulte *et al*., 2019). Because the early symptoms of HCC are ambiguous, most patients are already at an advanced stage when being diagnosed, and are accompanied by distant tumor metastasis, leading to an extremely unpleasing overall survival rate and prognosis (El Shorbagy *et al*., 2021). Currently, the clinical approaches for HCC mainly cover surgical resection, chemotherapy, drug therapy, and surgical resection. However, not all patients can undergo surgical resection, and there are few effective options for patients at an advanced stage. Radiofrequency ablation (RFA) has been successfully applied to treat diversified primary tumors, covering HCC (Lassandro *et al*., 2020). However, the malignant progression of residual HCC cells after RFA limits the treatment outcome of patients (Jia *et al*., 2020).

Metformin is anti-tumor (Shankaraiah *et al*., 2019) and it can restrain the malignant progression of HCC through multiple signaling pathways. For example, metformin refrains liver cancer cell proliferation by reducing the glycolytic flux of the hypoxia inducible factor (HIF)-1α/6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase 3/phosphofructokinase-1 pathway (Hu *et al*., 2019). Metformin represses HCC progression by activating the Hippo pathway (Zhao *et al*., 2021). Meanwhile, metformin synergizes with other drugs to refrain the progression and the drug resistance of HCC. For example, metformin combined with curcumin refrains HCC growth, metastasis, and angiogenesis *in vitro* and *in vivo* (Zhang *et al*., 2018). Metformin can enhance the sensitivity of orthotopic HCC mice to sorafenib, thereby decreasing postoperative recurrence and metastasis of HCC (You *et al*., 2016). However, the role of metformin in HCC after RFA is uncertain.

MicroRNAs (miRNAs) are a class of short endogenous single-stranded non-coding RNAs that reduce mRNA stability and translation by combining with the 3′-untranslated region (UTR) of target mRNAs (Alberti *et al*., 2018). Plentiful studies have manifested that abnormal expression of miRNAs is linked with the occurrence of cancers covering HCC (Yerukala *et al*., 2020). For example, miR-15a-3p represses HCC metastasis by interacting with heme oxygenase 1 (Jiang *et al*., 2020) and miR-448 depresses cell growth by targeting B cell lymphoma 2 in HCC (Liao *et al*., 2019). MiR-302b-3p is a pluripotency-linked miRNA, which has been discovered to participate in the physiological and pathological processes of cancers, such as pancreatic cancer (Xu *et al*., 2021), gastric cancer (Wang *et al*., 2021), and colorectal cancer (Hu *et al*., 2021). However, no study has indicated its expression and function in HCC.

This study aimed to investigate the function and latent mechanisms of metformin in HCC after RFA deficiency. *In vivo and in vitro* experiments were conducted to determine the function of metformin in the growth and angiogenesis of residual HCC cells after RFA deficiency, and further analyze the interaction between metformin and miR-302b-3p. It is hypothesized that metformin promotes the normalization of abnormal blood vessels after HCC by miR-302b-3p targeting the thioredoxin-interacting protein, offering new insights into HCC treatment.

MATERIALS AND METHODS

Tissue sample

Human HCC tissue and para-tumor samples were collected from 45 HCC patients who underwent surgical resection, while 18 of them were residual tumors from RFA-undertreated HCC patients. All tissue samples were kept in liquid nitrogen at −80°C, and informed consent was obtained and approved by the Ethics Committee of our hospital.

Cell culture

HCC cell line Hep-G2 (Type Culture Bank of the Chinese Academy of Sciences, Shanghai, China) and normal human liver cell line L02 (Shanghai Academy of Sciences, Shanghai) were cultured with 10% fetal bovine serum, 100 U/mL penicillin, and 100 mg/mL streptomycin in Roswell Park Memorial Institute-1640 medium (Gibco) (Ni *et al.*, 2021). All the media were provided by Gibco.

In vitro RFA deficiency

RFA deficiency was modeled *in vitro* as previously described (Zhang *et al.*, 2017). Briefly, Hep-G2 cells were seeded in 6-well plates ($5×10^4$ cells/well) and immersed in water at 47°C after 24 h. Afterward, cells were allowed to recover, and when the surviving cells reached 80% confluence, cells were propagated into 6-well plates and treated for 10 min as described above. This process was repeated ten times for 15, 20, and 25 min in sequence. Cells that survived were named HepG2-H cells.

Cell transfection

The pcDNA3.1 (+) vector for *TXNIP* overexpression and its corresponding control, miR-302b-3p mimic, miR-302b-3p inhibitor, and their negative controls were all synthesized by GenePharma (Shanghai, China). Cells were seeded in 6-well plates at a density of $5×10^5$ cells/well and transfected after 24 h of incubation. *In vitro* transfection was performed using Lipofectamine™ 3000 reagent (Thermo Fisher Scientific).

Cell viability

A total of $5×10^3$ cells were seeded and incubated in 96-well plates. Then, 10 µl CCK-8 solution (CCK-8, Dojindo, Tokyo, Japan) was added to each well. Finally, the absorbance was read at 450 nm (Zhang *et al.*, 2021).

Colony formation assay

Cells were plated in 6-well plates at 500 cells/well. The colonies formed on the plate were fixed with 4% paraformaldehyde (Solabio), stained with 0.5% crystal violet, and counted (Zhu *et al.*, 2019).

2Transwell assay

Cells were made into cell suspension at $1×10^6$/mL. In the invasion assay, 50 mg/L Matrigel was diluted at a ratio of 1: 8 and spread on the bottom of the chamber. Matrigel was not applied in the migration assay. Then, 600 µL complete medium was added to the lower chamber and 200 µL cell suspension was placed in the bottom chamber. After 24 h, the chamber was washed with phosphate-buffered saline (PBS), and the cells were fixed with paraformaldehyde (40 g/L) and stained with crystal violet (1 g/L). Finally, cells were counted under an inverted microscope in 6 fields of view (Xu *et al.*, 2021).

Apoptosis detection

Apoptosis assays were performed with Alexa Fluor 488-Annexin V/propidium iodide (PI) (Invitrogen, CA, USA). A BD LSR II flow cytometer (BD Biosciences, San Jose, CA, USA) was utilized to acquire the data and FlowJo analysis software (Tree Star, Inc., Ashland, OR, USA) was used to evaluate the results. Annexin V positive cells were regarded as apoptotic cells.

Tube formation experiment

A conditioned medium of tumor cells was collected. Afterward, $2×10^4$ human umbilical vein endothelial cells (HUVECs) were incubated with 100 µL conditioned medium and observed with an inverted microscope (CKX40, Olympus). The branch point numbers were counted in 5 random fields.

In vitro permeability assay

HUVECs were plated on transwell membranes (0.4 µm in diameter; Corning-Costar, New York, USA). Subsequently, rhodamine-dextran (average MW ~ 70,000; 20 mg/ml) was added to the upper chamber. The absorption of 40 µl the lower cavity medium was measured at 544 nm excitation wavelength and 590 nm emission wavelength.

Quantitative real-time polymerase chain reaction (PCR)

Extraction of total RNA was done using Trizol (15596-018, Invitrogen). cDNA was synthesized from 1 µg RNA by cDNA Synthesis Kit (K1631, Thermo Fisher Scientific). In a PCR detection system (CFX96, Bio-Rad, Hercules, CA, USA), PCR reactions were performed with the One-step PrimeScript RT-PCR kit (RR064B, Takara, Shiga, Japan). The thermal protocol was set as pre-denaturation at 95°C for 5 min, denaturation at 95°C for 15 s, annealing at 58°C for 30 s, extension at 72°C for 30 s, for a total of 40 cycles, and extension at 72°C for 10 min. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and U6 were internal controls. The primer sequences were manifested in Table 1. Relative expression was analyzed by the $2^{-\Delta\Delta CT}$ method (Teng *et al.*, 2020).

Western blot

Cells were lysed by a mixture of protease inhibitor and radio-immunoprecipitation assay lysis buffer. Protein samples were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and then electro-blotted onto polyvinylidene fluoride (PVDF) membranes (Bio-Rad). After blocking with 5% skim milk powder, the PVDF membranes were incubated with anti-human *TXNIP* (ab188865, 1: 1000, Abcam), vascular endothelial growth factor A (ab46154, VEGFA; 1: 1000, Abcam),

and GAPDH (2118, 1: 1000, Cell Signaling Technology). Proteins were developed by a chemiluminescence detection system (Millipore, MA, USA) and imaged by a FluroChem E imager (Protein Simple, Santa Clara, CA, USA) (Sun *et al.*, 2021). Densitometry and quantification were performed using Image Lab™ software (version 3.0) (Bio-Rad Laboratories).

The luciferase activity assay

The target genes of miR-302b-3p were predicted by Starbase 3.0. The wild-type (Wt) or mutant (Mut) sequence of *TXNIP* was cloned into the dual-luciferase reporter vector pGL3. The reporter was then co-transfected with miR-302b-3p mimic or NC into HepG2-H cells using Lipofectamine 2000 (Invitrogen). The relative luciferase activity was determined in the light of the instructions of the dual luciferase reporter kit (Promega) (Yuan *et al.*, 2020).

RNA pull-down analysis

HepG2-H cells were transfected with biotinylated miR-302b-3p (Bio-miR-302b-3p) and biotinylated NC (Bio-NC) (RiboBio). Then, cells were lysed and incubated with streptavidin beads (Thermo Fisher Scientific). Afterwards, the bound RNA was eluted and purified using the RNeasy Mini Kit (Qiagen) and analyzed by PCR to measure *TXNIP* expression.

Tumors in nude mice

Twelve male BALB/c nude mice (nu/nu) (6 weeks old; body weight of 16–20 g) were purchased from the Model Animal Research Center of Nanjing University. The mice were raised in cages (n=6/cage) and placed in a sterile room with 12-h light/dark cycle with free access to food and water. All animal studies complied with the regulations of the Institutional Animal Care and Use Committee and were approved by the Medical Ethics Committee of Beijing ChaoYang Hospital, Capital Medical University. HepG2-H cells (5×10^6) were suspended in 200 µl serum-free Dulbecco's Modified Eagle Medium and Matrigel (1:1) and injected subcutaneously in the upper right flank. After 1 week, mice were orally administered metformin (200 mg/kg/d) or PBS as a control for 24 d. The size of the xenograft tumor was measured with a vernier caliper every 6 d, and the tumor volume was calculated according to the formula of

0.5×length×width². After 24 d, the mice were euthanized by cervical dislocation, and tumor tissues were collected for pathological and molecular expression analysis.

CD31 immunohistochemistry

Tumor tissue was fixed and embedded in paraffin. The tumor sections (5 μm) were incubated with a rabbit monoclonal antibody CD31 (550274, eBioscience, Inc., San Diego, CA, USA) or the universal NC antibody control. After incubation with the appropriate biotinylated secondary antibody, the sections were incubated with horseradish peroxidase-conjugated streptavidin (KeyGen Biotech.), followed by the addition of 3,3'-diaminobenzidine working solution (Sigma) and counterstaining with hematoxylin. Quantification of intratumoral microvessel density (IMVD) was performed by counting CD31-positive (brown) cells in the nine most vascularized areas.

Statistical analysis

Data were analyzed with SPSS (IBM, Armonk, NY, USA) and manifested as mean ± standard deviation (S.D.). Differences were analyzed by Student's *t*-test or one-way analysis of variance (ANOVA) and Tukey's post-hoc test. Correlation analysis was done with Pearson analysis. $P<0.05$ emphasized statistical meaning.

RESULTS

This study explored the potential role and mechanism of metformin in RFA deficiency of HCC. *In vivo* and *in vitro* experiments were performed to determine the function of metformin in the cell growth and angiogenesis of HCC after RFA deficiency, and the interaction between

metformin and miR-302b-3p was further analyzed. It is concluded that metformin promotes the normalization of abnormal blood vessels after RFA deficiency in HCC by miR-302b-3p targeting *TXNIP*, which can be used to prevent the progression of HCC after RFA.

RFA promotes the growth of HCC cells and accelerates tumor angiogenesis

To study the impact of metformin on RFA-deficient HCC cells, RFA deficiency *in vitro* was simulated to construct a cell model named HepG2-H. As measured, the proliferation, invasion, and migration were promoted and apoptosis was reduced in HepG2-H cells after RFA (Fig. 1A–E). Angiogenesis, the process by which original blood vessels grow out of new blood vessels, has been implicated in the growth and progression of solid tumors (Ramjiawan *et al.*, 2017). This study found that the relative lumen number of cells was increased after RFA (Fig. 1F). Vascular permeability experiments found severe vascular leakage of HUVECs after HepG2-H incubation (Fig. 1G). In addition, the angiogenesis-related protein VEGFA was also detected and the finding indicated that VEGFA expression was elevated in HepG2-H cells after RFA (Fig. 1H). The above experiments manifested that RFA accelerated the growth of HCC cells and tumor angiogenesis.

Metformin restrains the growth and angiogenesis of HCC cells induced by RFA deficiency *in vitro*

To figure out whether metformin could mediate RFA deficiency-induced impacts on HCC cells, HCC cells were treated with metformin. Our data found that metformin inhibited the viability of HepG2 and HepG2-H cells and reduced colony numbers in a dose-dependent

Figure 2. Metformin refrains the growth and angiogenesis of HCC cells induced by RFA deficiency _in vitro_

manner (Fig. 2A, B). RFA-induced quantitative increases in cell migration and invasion were also inhibited by metformin (Fig. 2C, D). Meanwhile, metformin also increased the apoptosis rate of HepG2 and HepG2-H cells in a dose-dependent manner (Fig. 2E) and inhibited tumor angiogenesis and permeability _in vitro_ (Fig. 2F–H). All in all, metformin could refrain the growth and angiogenesis of HCC cells induced by RFA deficiency _in vitro_. The treatment effect of 10 μM metformin was most pronounced and was therefore selected for further experiments.

MiR-302b-3p counteracts the therapeutic effect of metformin on RFA deficiency

Notably, miR-302b-3p levels were elevated in RFA-induced HepG2-H cells (Fig. 3A) which was dose-dependently counteracted by metformin (Fig. 3B). In addition, a decrease in miR-302b-3p expression was also detected in metformin-treated HepG2 cells (Fig. 3B). To further figure out miR-302b-3p's impacts on RFA deficiency, miR-302b-3p mimic and inhibitor were transfected in metformin-treated HepG2-H and HepG2 cells, and the

transfection efficiency was verified (Fig. 3C). Subsequent experiments manifested that miR-302b-3p mimic counteracted the therapeutic effects of metformin on HepG2-H and HepG2 cells, leading to promoted cell growth, angiogenesis, and vascular leakage, whereas miR-302b-3p inhibitor had the opposite effects (Fig. 3E–K).

MiR-302b-3p targets _TXNIP_

It was also found that _TXNIP_ expression was reduced in RFA-induced HepG2-H cells (Fig. 4A, B), while metformin dose-dependently elevated _TXNIP_ expression (Fig. 4CD). TargetScan 7.2 predicted the binding site sequences of _TXNIP_ and miR-302b-3p (Fig. 4E). The interaction between the two was further confirmed, clarifying that after co-transfection of the miR-302b-3p mimic with the psiCHECK-2 _TXNIP_ 3'UTR Wt plasmid, the luciferase activity was reduced by 50% (Fig. 4F). It was further confirmed that miR-302b-3p could combine with _TXNIP_ in RNA pull-down assay (Fig. 4G). In addition, the expression of miR-302b-3p and _TXNIP_ in normal human liver cell line L02 and HepG2 cells was detected by PCR, and it was found that compared with L02, the

Figure 3. MiR-302b-3p counteracts the therapeutic effect of metformin on RFA deficiency
(**A–C**) PCR detection of miR-302b-3p; (**D**) CCK-8 detection of cell viability; (**E**) Plate clone detection of cell proliferation; (**F/G**) Transwell detection of cell migration and invasion; (**H**) Flow cytometry detection of cell apoptosis; (**I**) Detection of angiogenesis after metformin treatment; (**J**) Permeability assay *in vitro*. expression of miR-302b-3p was increased, and the expression of *TXNIP* was decreased in HepG2 cells (Supplementary Fig. 1A,B). Next, *TXNIP* expression was measured in cells transfected with miR-302b-3p mimic or inhibitor, showing that miR-302b-3p mimic reduced *TXNIP,* while miR-302b-3p inhibitor elevated *TXNIP* expression (Supplementary Fig. 1C, Fig. 4HI at https://ojs.ptbioch.edu.pl/i). Taken together, miR-302b-3p could directly target *TXNIP.*

TXNIP turns around the effect of elevated miR-302b-3p on RFA-deficient HCC cells

To further figure out the mechanism between *TXNIP* and miR-302b-3p, HepG2-H+Met cells or HepG2+Met

cells transfected with miR-302b-3p mimics were transfected with *TXNIP* overexpression vector (Fig. 5A). It was found that *TXNIP* reversed the effect of overexpression of miR-302b-3p on RFA-deficient HCC cells, reduced cell proliferation, migration, and invasion levels, increased apoptosis, and inhibited angiogenesis and permeability *in vitro* (Fig. 5B–I). In short, *TXNIP* turned around the effect of elevated miR-302b-3p on RFA-deficient HCC cells.

Metformin refrains RFA deficiency-induced HCC tumor growth and tumor vascular abnormalities *in vivo*

To figure out the application potential of metformin in the treatment of RFA deficiency *in vivo*, a residual can-

cer model of HCC after incomplete RFA was established in mice, and metformin was administered by gavage. It was discovered that tumor weight and volume were reduced in the HepG2-H+Met group (Fig. 6A–C). MiR-302b-3p and *TXNIP* expression in mouse tumor tissue was detected, manifesting that miR-302b-3p expression was reduced, but *TXNIP* expression was elevated in the HepG2-H+Met group (Fig. 6D, E). Moreover, microvessels were observed by CD31 staining and it was found that metformin reduced IMVD (Fig. 6F). Taken together, metformin repressed RFA-deficiency-induced HCC cell growth and tumor vascular abnormalities *in vivo*.

Up-regulation of miR-302b-3p enhances the malignancy of residual HCC cells after RFA

Finally, the correlation of miR-302b-3p with HCC development was analyzed. As shown in Fig. 7A, miR-302b-3p was elevated in HCC tissues compared with para-tumor tissues. More interestingly, miR-302b-3p was further enhanced in residual HCC tissues collected from RFA-deficient patients (Fig. 7B). These results suggest that miR-302b-3p may play an accelerating role in the development of residual HCC after RFA.

DISCUSSION

Angiogenesis has been reported to take on a critical role in the development, progression, and metastasis of HCC (Lin *et al.*, 2018). Many studies have testified that RFA is a safe and efficient approach for liver metastases, while residual tumors can grow aggressively after RFA, driven in part by the upregulation of VEGF (Agarwal *et al.*, 2014). Meanwhile, RFA deficiency promotes angiogenesis of residual HCC cells through HIF-1α/VEGFA

axis (Kong *et al.*, 2012). These studies suggest that angiogenesis after RFA is a momentous physiological process in residual HCC. In the present study, it was found that RFA treatment accelerated HCC cell growth *in vitro*, increased cell relative lumen number, vascular permeability, and VEGFA expression. Metformin treatment could repress the facilitating effect of RFA on HCC. The *in vivo* results also confirmed that metformin could repress the growth and angiogenesis of HCC cells after RFA treatment.

It is well known that metformin is an anti-diabetic biguanide drug with safety and pleiotropic effects. In recent years, it has been proved to have anti-tumor effects in diversified cancers, such as cervical (Xia *et al.*, 2020), breast (Teufelsbauer *et al.*, 2020), and gastric cancers (Cunha Júnior *et al.*, 2021). Although some of the functions of metformin in HCC have been elucidated, many of its specific underlying mechanisms in HCC have not been identified, especially in HCC treated with RFA. In the study, RFA deficiency was simulated *in vitro* to construct a cell model, and it was found that RFA treatment facilitated HCC cell growth and angiogenesis, while metformin treatment restrained HCC cell growth, tumor angiogenesis, permeability, and VEGFA expression. Next, an RFA-deficient HCC *in vivo* model was established and administered metformin by gavage. It was discovered that metformin refrained RFA-deficiency-induced HCC cell growth and tumor vascular abnormalities *in vivo*, suggesting that metformin partially counteracts RFA deficiency-induced vascular abnormalities in HCC tumors. Some former studies have manifested that metformin represses tumorigenesis by modulating miRNAs. For example, metformin induces G1 cell cycle arrest by upregulating tumor suppressors miR-let-7a, miR-let-7b, and miR-let-7e, thereby restraining HCC cell proliferation (Miyoshi *et al.*, 2014). Metformin stimulates pyroptosis

Figure 5. *TXNIP* **turns around the effect of elevated miR-302b-3p on RFA-deficient HCC cells**
(**A**) PCR detection of *TXNIP* in cells; (**B**) CCK-8 detection of cell viability; (**C**) Plate clone detection of cell proliferation; (**D/E**) Transwell detection of cell migration and invasion; (**F**) Flow cytometry detection of cell apoptosis; (**G**) Detection of angiogenesis after metformin treatment; (**H**) Permeability assay *in vitro*. in human esophageal cancer cells by regulating miR-497 (Wang *et al.*, 2019). Here, it was discovered that metformin treatment downregulated miR-302b-3p in HCC.

Former studies have manifested that miR-302b-3p is abnormally expressed in diversified cancers (Liang *et al.*, 2019) and that it is also associated with nerve cell inflammation (He *et al.*, 2020) and neuronal damage (Li

et al., 2021). In this study, it was originally found that miR-302b-3p was elevated in RFA-induced HCC cells, and up-regulation of miR-302b-3p counteracted the therapeutic effect of metformin on HCC cells, while down-regulation of miR-302b-3p further enhanced the therapeutic effect of metformin on HCC. This result suggests miR-302b-3p was a downstream target of metformin in

Figure 6. Metformin depresses RFA deficiency-induced HCC cell growth and tumor vascular abnormalities *in vivo*
(**A–C**) Detection of the changes of tumor weight and volume in 30 d; (**D/E**) qPCR and Western Blot detection of miR-302b-3p and *TXNIP* in mouse tumor tissue; (**F**) CD31 staining to observe micro-vessels. n=8. The measurement data were presented as mean ± S.D. *vs. the HepG2-H+PBS, P<0.05.

al., 2012), while the effect of RFA deficiency on ROS production and whether ROS in turn affects HCC cell growth and angiogenesis remains to be further verified. It is hoped that these issues can be further addressed.

CONCLUSION

Overall, the study manifests that RFA deficiency can accelerate cell growth and angiogenesis in HCC, while metformin can alleviate the negative impact of RFA deficiency on HCC. The results suggest that metformin represses HCC cell growth and angiogenesis *in vitro* and *in vivo* by miR-302b-3p to upregulate *TXNIP*. The results offer brand-new insights into overcoming RFA deficiency to promote the malignant progression of residual HCC cells.

Declaration of Conflicting Interests. Authors declared no conflict of interest.

HCC. Many studies have manifested that miRNAs function in various diseases by targeting mRNAs. For example, miR-302b-3p targeting insulin-like growth factor 1 receptor represses gastric cancer cell proliferation (Guo et al., 2017). Next, it was found that miR-302b-3p targeted *TXNIP* in RFA-induced HCC cells. TargetScan 7.2 forecasted the existence of binding sites for miR-302b-3p and *TXNIP*.

TXNIP is an α-arrest family protein that modulates intracellular reactive oxygen species (ROS) (Sheth et al., 2006). *TXNIP* takes on an irreplaceable role in the development of HCC, and *TXNIP* deficiency is sufficient to induce HCC and *TXNIP* is a new tumor suppressor gene for HCC (Sheth et al., 2006). In the present study, it was found that *TXNIP* was down-regulated in RFA-induced HCC cells, and elevation of *TXNIP* turned around the effect of elevated miR-302b-3p on RFA-deficient HCC and refrained HCC cell growth, angiogenesis, and permeability *in vitro*. These results suggested that metformin repressed HCC cell growth and angiogenesis *in vitro* and *in vivo* by targeting the miR-302b-3p/*TXNIP* axis.

However, the research still has some limitations. First, the sample size was insufficient due to limited laboratory conditions. Meanwhile, it has been documented that ROS production is elevated after RFA (Richter et

An mRNA-based reverse-vaccinology strategy to stimulate the immune response against *Nipah virus* in humans using fusion glycoproteins

Muhammad Naveed[1]✉, Sarmad Mahmood[1], Tariq Aziz[2]✉, Muhammad Hammad Arif[1], Urooj Ali[1,3], Faisal Nouroz[4], Christos Zacharis[2], Metab Alharbi[5], Abdulrahman Alshammari[5] and Abdullah F. Alasmari[5]

[1]Department of Biotechnology, Faculty of Science and Technology, University of Central Punjab, Lahore, 54590 Pakistan; [2]Department of Agriculture, University of Ioaninna Arta, 47132 Greece; [3]Department of Biotechnology, Quaid-I-Azam University Islamabad, 45320 Pakistan; [4]Department of Bioinformatics, Hazara University Mansehra, 21300 Pakistan; [5]Department of Pharmacology and Toxicology, College of Pharmacy, King Saud University,11451 Riyadh, Saudi Arabia

The zoonotic pathogen, Nipah virus, is considered a potential healthcare threat due to its high mortality rates and detrimental symptoms like encephalitis. Ribavirin, an antiviral drug helps in overcoming the number of casualties and reducing the mortality rate, but no long-lasting solution has been proposed yet putting global health security in jeopardy. Given the cognizance of mRNA-based vaccines as safe and efficacious preventative strategies against pathogens, the current study has utilized the reverse-vaccinology approach coupled with immunoinformatics to propose an mRNA-based vaccine candidate against the Nipah virus. To ensure the effectiveness of the vaccine candidate against all strains of Nipah and associated viruses, three fusion glycoproteins from Nipah and Hendra viruses were selected. A total of 30 potential epitopes, 10 B-cell-, 10 MHC-I-, and 10 MHC-II-specific, were screened for the construct. The finalized epitopes were highly antigenic with scores ranging from 0.75 to 1.7615 at a threshold of 0.4 for viruses and non-homologous to *Homo sapiens* eradicating any chance of immune tolerance. The construct, with a World population coverage of 97.2%, was structurally stable, thermostable, and hydrophilic with indices of 32.91, 93.62, and –0.002, respectively. The vaccine candidate's tertiary structure was predicted with a TM score of 0.131 and the refined model displayed superlative RAMA improvement (98.2) and MolProbity score (0.975). A quality factor of 93.5421% further validated the structural quality and stability. A prompt and stable immune response was also simulated, and the vaccine candidate was shown to eliminate from the body within the first five days of injection. Immune complexes count of 7000 mg/mL was predicted against the antigen with a small but non-significant danger signal, countered by the cytokines. Lastly, strong molecular interactions of the vaccine candidate with TLR-3 (331.09 kcal/mol) and TLR-4 (-333.31 kcal/mol) and molecular dynamics simulation analysis authenticated the immunogenic potential of the vaccine candidate. This vaccine candidate can serve as a foundation for future *in-vitro* and *in-vivo* trials to minimize or eradicate the diseases associated with the Nipah virus or the Henipaviral family.

INTRODUCTION

Nipah Viral Disease is a zoonotic disease that has a high mortality rate of 91% (Pillai *et al.*, 2020). The disease first emerged in 1998 in Malaysia and spread to neighboring countries including South-East Asia, like Bangladesh, Singapore, and India (Aditi & Shariff, 2019). It was isolated and identified at the University of Malaysia, Faculty of Medicine in 1999. As this virus was first spread in the Malaysian village Sungai Nipah, in pig farms and people associated with them, so scientists named this virus as Nipah virus (Pillai *et al.*, 2020). This virus belongs to the Paramyxoviridae family and genus Henipa viruses. This virus is classified into two strains, the first one was isolated from Malaysia and Cambodia, and the other one was isolated from India and Bangladesh (Mourya *et al.*, 2018). This virus leads to the development of rapid progressive illness in the human respiratory tract and causes encephalitis in the brain. Initially, because of the encephalitis-related symptoms, scientists thought of this disease as Japanese encephalitis, but it was confirmed later that the Nipah virus causes a different disease (Singh *et al.*, 2019). The main host reservoirs for Henipa viruses are fruit bat *Pteropus*. These bats manipulate different fruits like date palms by secreting saliva and urine that is further consumed by animals. The most recent outbreak ruptured in Kerala, India with a loss of 17 human lives (Weingartl *et al.*, 2009). The Nipah virus causes severe breathing issues, destroying the human lung structures and the membrane of the cerebrum. In this condition, the brain enlarges, causing memory loss and severe pain (Rockx *et al.*, 2010). Its symptoms include brain encephalitis, headache, muscular pain, and respiratory disorders. Nausea, giddiness, and fever are also clinically significant (Reddy, 2018). According to the Centers for Disease Control (CDC), the Nipah virus has the potential to create a global emergency and, hence, deserves the immediate attention of the scientific community (Fischer *et al.*, 2018). Ribavirin, an antiviral drug helps in overcoming the number of casualties and reducing the mortality rate,

but no long-lasting solution has been proposed yet (Deb *et al.*, 2019). Vaccines are an efficacious solution to fight this deadly viral agent. mRNA-based vaccines are among the most effective candidates utilized to develop protective immunity against the pathogen. The vaccine shots activate the immune system, and the B-cells and T-cells develop immunologic memory for when a real pathogen attacks the host the immune system recognizes and destroys it. The mRNA vaccines are further appreciated for being cost-effective and timesaving (Kumar *et al.*, 2015). With computational approaches, the labor intensity and process complexity are minimized (Naveed *et al.*, 2022; Naveed *et al.*, 2023a; Naveed *et al.*, 2023b), making mRNA vaccines worthy solutions against viruses like the Nipah virus.

The current work is based on the proposition of an mRNA vaccine utilizing *in-silico* and immunoinformatics tools. The computational approach is considered to safely predict the immune response against the proposed vaccines. Three transmembrane proteins of the Nipah virus were selected for their significant role in the early interactions with the hosts. The selection of the transmembrane proteins was based on their antigenicity, allergenicity, non-toxicity, and non-resemblance with human proteins. Potential epitopes following the criteria of Naveed and others (Naveed *et al.*, 2022a; Naveed *et al.*, 2022b) are shortlisted and the construct is evaluated based on its population coverage, immune response simulations, molecular docking with respective toll-like receptor(s), and physicochemical properties.

MATERIALS AND METHODS

Selection of Target Proteins

The Nipah and Hendra Henipavirus genomes were retrieved from the NCBI database and downloaded in FastA format. CELLO2GO, an online server available at (http://cello.life.nctu.edu.tw/cello2go/), was utilized to study the gene ontology and localization of all the proteins present in the genomes. The conservation and homology evaluation was performed using blastp available at (https://blast.ncbi.nlm.nih.gov/Blast.cgi?PAGE=Proteins). It ensured that the selected proteins based on protein localization are non-homologous to the human host and are conserved across Henipaviruses. Lastly, the online servers Vaxijen2.0, available at (http://www.ddg-pharmfac.net/vaxijen/VaxiJen/VaxiJen.html), and AllerTop, 2.0 accessed at (https://www.ddg-pharmfac.net/AllerTOP/method.html), were utilized to predict the antigenicity and allergenicity of the shortlisted proteins, respectively.

Protein Selection & Sequence Retrieval

The online server UniProt (www.uniprot.org) was used to retrieve the Nipah virus virulent protein sequences. Based on different factors like higher antigenic capacity, non-allergenicity, non-toxicity, and non-resemblance with *Homo sapiens*, three trans-membrane fusion glycoproteins (one belonging to Hendra virus and two belonging to the identified strains of Nipah virus) were selected for a potential vaccine candidate.

Prediction of B-cell Epitopes

ABCpred webserver (https://webs.iiitd.edu.in/raghava/abcpred/ABC_submission.html) was used for the prediction of B cell epitopes from each protein. We only selected the epitopes having non-allergenic, highly antigenic, and non-toxic analyses. We used the online server (https://www.ddg-pharmfac.net/AllerTOP/), Vaxijen 2.0 (http://www.ddg-pharmfac.net/vaxijen), and ToxinPred (http://crdd.osdd.net/raghava/toxinpred/), respectively. Moreover, we screened the predicted epitopes to see if they have homologs among humans and excluded the epitopes which might induce autoimmunity.

Prediction of the MHC-1 Epitopes

MHC-1 binding prediction tool of IEDB (http://tools.iedb.org/mhci/) was used to predict the conserved epitopes with the NetMHCpan BA 4.0 version (Reynisson *et al.*, 2020). MHC source specie was selected as human and epitopes were screened based on higher antigenicity value, non-allergenicity, and a specified range of IC_{50} values lower than 100.

Prediction of MHC-II Epitopes

MHC-II binding prediction tool (http://tools.iedb.org/mhcii/) was used to predict the conserved epitopes. NetMHCIIpan 4.0 BA version (Reynisson *et al.*, 2020) was utilized to predict the conserved epitopes. Epitopes were screened based on higher antigenicity value, non-allergenicity, and a specified range of IC_{50} values lower than 100.

Population Coverage

The evaluation of population coverage of the selected MHC-I and MHC-II epitopes was carried out with the IEDB population coverage tool (http://tools.iedb.org/population/). All the selected epitopes with their corresponding alleles were included in the input file. On the input page, the number of epitopes was changed accordingly. A combined MHC-I and MHC-II epitopes input file was provided, and the World was selected as the target population.

Vaccine Construct

The finalized epitopes of B- and T-cells were reverse-translated and fused together with the help of linkers, adjuvants, a MITD sequence, polyA-tail, 5' and 3' UTRs, and methyl-guanosine cap at the start of the construct to enable it for in-host expression.

Analysis of Physiochemical Properties

The physicochemical properties of the vaccine construct were predicted by the ProtParam tool of the ExPasy web server (https://web.expasy.org/protparam/). Toxicity prediction was done using Toxinpred. The Vaxijen tool was run to predict the antigenicity of the vaccine construct and to check the vaccine construct's allergenicity.

Prediction of Secondary Structure of the Proposed mRNA Vaccine

PSIPRED (http://bioinf.cs.ucl.ac.uk/psipred/) was used for the prediction of the secondary structure. The mRNA vaccine candidate sequence was first translated to its primary protein sequence using EXPASY translate, and this primary sequence was used as an input sequence on PSIPRED. Out of a variety of analyses available on the server, the cartoon structure along with the basic prediction was interpreted.

Prediction and Refinement of the Tertiary Structure

The tertiary structure of the mRNA was predicted using the online server trRosetta https://yanglab.nankai.edu.cn/trRosetta/. This online server for protein docking has been continuously extended and refactored. Its advantages include interoperability between modeling capabilities and performance (Leman *et al.*, 2020). Refinement of the tertiary structure of our proposed mRNA vaccine was done by Galaxy WEB's Galaxy REFINE https://galaxy.seoklab.org/.

Validation of Tertiary Structure of the Proposed mRNA Vaccine

After refinement of the tertiary structure, we validated our proposed mRNA tertiary structure by Ramachandran plot analysis using the PROCHECK server (https://saves.mbi.ucla.edu/), whereas the structure quality was validated using ERRAT quality score on the PROCHECK server.

Immune Simulations

To validate whether the mRNA-based vaccine construct has the potential to elicit a stable immune response, C-IMMSIM analyses were performed through the webserver available at https://kraken.iac.rm.cnr.it/C-IMMSIM/index.php?page=1. An immunogenic response of single-dose injection was calculated.

Molecular Docking and Simulation Analysis

Molecular docking predicted the immune response stimulation capacity and molecular interaction between the proposed mRNA vaccine protein and toll-like receptors. HDOCK webserver (https://www.nature.com/articles/s41596-020-0312-x) was used. For this purpose, TLR-3 (PDB ID: 3ULV) and TLR-4 (PDB ID:4R7N) were retrieved from RCSB PDB (https://www.rcsb.org/). For simulation analysis of the docked complexes, iMODS (https://imods.iqfr.csic.es/) was utilized.

Figure 1. Process overview of the mRNA-based vaccine construct

Cloning of the Construct

The mRNA-based construct was converted into the DNA sequence after codon optimization using JCAT (http://www.jcat.de/Result.jsp). The optimized construct was cloned in the pBluescribe vector at the BsoB1 site with the removal of overhangs using Snapgene https://www.snapgene.com/. The methodology is schematically represented in Fig. 1.

RESULTS

Target Proteins' Selection

Analyzing 2335 proteins present in the genomes of Nipah and Hendra Henipavirus on the CELLO2GO tool, we selected several pathogenic transmembrane proteins. Out of 108 transmembrane proteins, 3 transmembrane proteins were selected for vaccine design.

Selection and Sequence Retrieval of Transmembrane Proteins

Based on different factors like higher antigenic capacity, non-allergenicity, non-toxicity and non-resemblance with a human protein, three transmembrane fusion glycoproteins

Table 1. List of selected transmembrane proteins for vaccine design against the Nipah virus

Accession ID	Protein name	Antigenicity	Allergenicity	Toxicity
Q9IH63 (Nipah virus)	Fusion glycoprotein F0	0.5012	Non-Allergen	Non-toxic
O89342 (Hendra virus)	Fusion glycoprotein F0	0.5534	Non-Allergen	Non-toxic
A0A1L7B8D7 (Nipah)	Fusion glycoprotein F0	0.5056	Non-Allergen	Non-toxic

	SLCIGLITFI	1.0498	HLA-A*02:03, HLA-A*02:01, HLA-A*02:06, HLA-A*68:02, HLA-A*32:01, HLA-B*15:01

were selected for vaccine design. UniProt protein database was used for the sequence retrieval of fusion glycoproteins under specific allocated UniProt IDs given in Table 1.

Prediction of B cells Epitopes

After protein selection and their sequence retrieval, we screened the predicted B-epitopes according to their higher antigenic capacity, non-allergenicity, non-homology, and non-toxicity. Ten B-cells epitopes, shown in Table 2, extracted from three selected fusion glycoproteins were included in the vaccine construct. All the short-listed epitopes were non-allergenic and antigenic with a score between 0.7 and 1.21, having a threshold of 0.4.

Prediction of MHC-1 Epitopes

For the prediction of MHC-I-restricted epitopes, all alleles of the HLA dataset were selected, and the peptide length was taken as 9 and 10. The epitopes were sorted based on predicted IC50 values. All other parameters were kept as default. The shortlisted epitopes were screened based on higher antigenicity value, allergenicity

and an IC50 value <100 giving a total of 10 epitopes, provided in Table 3.

Prediction of MHC-II epitopes

The length of the predicted MCH-2 cell epitopes was set at 15 and all other parameters were kept as default. The predicted epitopes were saved as an XHTML output table and peptides are sorted according to their adjusted rank. Further screening relied upon antigenicity values and non-allergenicity. The finalized epitopes, shown in Table 4, having a higher antigenicity value, non-allergenicity and IC50 values <100 were selected for the vaccine construct. The restricting alleles for both the MHC-I-restricted and MHC-II-restricted epitopes were recorded for population coverage analysis.

Vaccine Construct

The screened epitopes with a cumulative World population coverage of 97.2%, shown in Fig. 6A, were converted to the mRNA sequence, and fused together using universal linkers (EAAAK, GPGPG, KK, AAY). The 5'

and 3' components along with the RpfE adjuvant and the Kozak sequence were added to the construct, shown in Fig. 1A, for stability, improved immunogenicity, and ease of entry into the host cells.

Physiochemical Properties Prediction

The physicochemical properties computed for the vaccine candidate by translating the construct into its peptide sequence indicated that it was antigenic (0.8746), non-allergenic, stable (32.91), thermostable (93.62), hydrophilic (-0.002), non-toxic, and had 683 amino acids. Table 5 discusses the analysis and indication of the physicochemical properties of peptides.

Prediction of Secondary Structure

The secondary structure predicted by PSIPRED, shown in Fig. 2B, depicts the alpha-helices, beta-turns, and coils of the vaccine candidate. Most of the amino acid residues were predicted as coils indicating the vaccine candidate's transmembrane localization.

Prediction and Refinement of Tertiary Structure

trRosetta predicted the tertiary model of the vaccine candidate with a TM-score of 0.131. Since, this was below the ideal TM score, the model was refined and GalaxyREFINE predicted 5 models, out of which the first one was selected (depicted in Fig. 2C) based on the most improved RAMA scores (98.2) indicating the torsion angle distribution of the vaccine candidate. Other metrics like MolProbity (0.975) that evaluates the model quality at both protein and nucleic-acid levels and least RMSD (0.356) calculating the difference in protein backbone conformation in the initial and final structures were also considered for model selection.

Validation of Tertiary Structure

ERRAT calculated the overall quality factor score of 93.5421 and the Ramachandran plot (Fig. 2D) indicated that most of the residues lie in the most favored region. 541 residues constituted 96.8% of the total protein, residues in the additional allowed region were 2.3%, in the generally allowed region were 0.4% and in the disallowed region were 0.5%.

Immune Simulation Response

C-IMMSIM predicted a potent and stable immune response against the injected antigen. The graph in Fig. 2E illustrates that the server predicted the antigen to be eliminated from the host system within the first 5 days

Table 5. The Physiochemical Properties of the proposed mRNA vaccine

Property	Measurement	Indication
Antigenicity	0.8746	Antigenic
Allergenicity	Non-Allergen	Non-Allergen
No. of Amino Acids	683	Appropriate
Formula	$C_{3337}H_{5316}N_{880}O_{933}S_{11}$	Appropriate
Total number of -ve charged residues (Asp + Glu)	52	–
Total number of +ve charged residues (Arg + Lys)	90	–
Theoretical pI	9.74	Basic
Estimated Half Life (mammalian reticulocytes)	1 hour	Easily eliminated
Instability Index	32.91	Stable
Aliphatic Index	93.62	Thermostable
Grand average of hydropathicity (GRAVY)	–0.002	Hydrophilic
Toxicity of Vaccine Construct	Non-toxic	Non-toxic

after escalating to 700 000 antigen count per mL on the first day. The immune complexes (IgG+IgM) were generated when the antigen count was almost 0 and escalated up to 7000 for the first 15 days of injection. The complex count decreased afterward but became steady at 3600 after a month indicating stability and longevity of the immune response. The graph in Fig. 2F illustrates the cytokine production and danger-signal produced by the body in response to the antigen. A small danger signal was produced lasting for up to 25 days but was not significant. The interleukin-2 count escalated up to 250 000 mg/mL on the 5th day and steadily decreased afterward. It was clear from the graph that the increase in IL-2 count was a direct response to the signal validating the potent response. IFN-gamma was also readily produced by the immune system.

Molecular Docking Analysis

HDOCK webserver predicted 10 models of the docking poses of mRNA vaccine construct with TLR-3 (PDB ID: 3ULV) and 10 models with TLR-4 (PDB ID:4R7N). With TLR-3 docking, the first model was selected having a docking score of –331.09 kcal/mol and a confidence score of 0.9740, shown in Fig. 3A. With TLR-4 docking, the first model (Fig. 3B) was selected for having a docking score of –333.31 kcal/mol and a confidence score of 0.975.

Molecular Dynamics Simulations

With an eigenvalue of 2.95646e-06 and 4.0524e-06, illustrated in Figs. 4d and 5d respectively, the docked complex (Figs. 4a, 5a) was predicted to be stiff with little dynamic residues. The B-factor (shown in Figs. 4b and 5b) also showed minimal flexibility, except for the last few residues. The deformability plot shown in Figs. 4c and 5c was found consistent with the eigenvalue and the B-factor plot indicating that only a few residues towards the end of the docked complex were flexible/deformable. The variance and co-variance map (Figs. 4e, 5e and Figs. 4f and 5f, respectively) show stable amino acid-pair interactions validating strong molecular interactions. Lastly, the elastic network map showed that the atoms in the docked complex are closely linked to each other, demonstrated in Figs. 4g and 5g, reflecting on the covariance findings.

Expression Analysis

The CAI score of 0.95518 and GC content of 67.057% reflected the maximum codon optimization of the construct sequence, illustrated in Fig. 6B. pBluescribe plasmid was utilized for the *in-silico* cloning experiment. The plasmid was cut by the AHD-I enzyme producing sticky ends, enabling unidirectional cloning of the construct into the vector. Figure 6C shows the cloning process, whereas Fig. 6D represents the cloned vector.

DISCUSSION

Nipah virus first emerged in the late nineties, with fruit bat as its mediatory host. First, it was observed in the pig but was soon observed in the human population (Aditi & Shariff, 2019). Due to a high fatality rate in developing countries, this virus is thought to evoke a potential zoonotic pandemic like coronavirus (Kulkarni *et al.*, 2013). Ribavirin, a drug initially used against hepatitis and liver-virus infection, has been utilized to minimize viral load in Nipah viral disease patients (Deb *et al.*, 2019). However, the mortality rates are still high (Naveed *et al.*, 2021). Owing to the absence of preventative strate-

gies being present, this study proposed a mRNA-based vaccine design to develop protective immunity against the pathogen. This effort was in line with the previous studies proposing protective immunity against diseases (Al Tbeishat *et al.*, 2022) like mucormycosis (Maruggi *et al.*, 2017) and HPIV-1 (Naveed *et al.*, 2022). Recently, COVID-19 RNA-based vaccines like Pfizer-BioNtech's 'Comirnaty' have worked wonders by developing prior immunity in the human body against the SARS-Cov-2 attack (Rotshild *et al.*, 2021). It has been observed that vaccines have some epigenetic impact on immune system genes, which train the immune system (Kumar *et al.*, 2015). Likewise, the focus of this study was to develop a long-lasting memory in the form of activated B cells and T cells. The HTL induces IL-10, IL-4, and IFN-γ, antigen-presenting cells express epitopes of HTL, and the lymphocyte can secrete chemokines, all play crucial roles

against the virus (Al Tbeishat *et al.*, 2022). We observed the production of all these immune system components in response to the antigen. Except for the memory cells, all the immune cells died and were eliminated with the destroyed antigen. B cells with membrane-bound immunoglobulin receptors identified the antigen epitopes and internalized them to become presenting cells for memory-making units of the immune system. Furthermore, we noticed a hike in plasma-secreted antibodies (up to 40 000 counts) that are utilized to neutralize the antigen (vaccine candidate injection) and produce memory cells. Our results were consistent with previous mRNA-based vaccine findings (Naveed *et al.*, 2022; Maruggi *et al.*, 2017), predicting an efficacious vaccine construct with the ability to elicit long-lasting protective immunity.

The tools utilized in this study have revolutionized biotechnological research. The reverse-vaccinology ap-

Figure 6. (A) Population coverage of the T-cell-specific epitopes; (B) Codon optimization chart of the proposed mRNA vaccine construct; (C) The history map of cloning, the black vector shows pBluescribe plasmid, 2040 bps long, the red line shows vaccine construct and the final construct after insertion in which red color shows gene of interest (4791 bps long); (D) The cloned Bluescribe vector with the gene of interest shown in red color

proach has saved time, preliminary clinical trials, and labor costs (Kumar *et al.*, 2015). We followed this approach because of its proclaimed merits in prediction ((Naveed *et al.*, 2022a; Naveed *et al.*, 2022b) as well as clinical studies (Hall *et al.*, 2021; Pormohammad *et al.*, 2021). The *in-silico* prediction of antigenicity, allergenicity, and toxicity significantly helped us in characterizing the potential epitopes. These tools have the potential to save lives at pre-clinical trials (Xinhui *et al.*, 2021) as researchers may have already predicted the immunogenic, allergenic, or toxic outcome of a proposed vaccine before it is administered to the public (Naveed *et al.*, 2023a; Naveed *et al.*, 2023b). Lastly, the wide population coverage of the proposed candidate validates that it can be efficacious worldwide irrespective of race, ethnicity, or area.

Declarations

Ethics approval and consent to participate: Not applicable.

Competing interests: The authors declare no conflict of interest.

Funding: No external funding was received.

Authors' contributions: Conceptualization, M.N. and S.M.; methodology, M.H.A; software, U.A.; validation, F.N., and T.A.; formal analysis, M.N; investigation, U.A and S.M.; resources, M.N.; data curation, M.S and M.E.A.; writing – original draft preparation, M.A and C.Z; writing – review and editing, T.A.; visualization, M.A. A.F.A, and A.A.S; supervision, T.A.; project administration, M.N.; funding acquisition, T.A.

Availability of data and material: All the data used in this research work has been included in this manuscript.

Box 2455, Riyadh 11451, Saudi Arabia

The natural Fisetin and its derivatives have been shown to have effective bioactivity and strong pharmacological profile, which is continuously drawing the interest of therapeutic applications to the development of new biomolecules against Breast cancer and Monkeypox, and Marburg viral infection, while computational approaches and the study of their structure-activity relationship (SAR) are the most eloquent and reliable platform for performing their hypothetical profile renovation. So, the main perspective of this investigation is to evaluate dual function of Fisetin and its derivatives against both virus and cancerous target. First and foremost, the prediction of activity spectra for materials (PASS) valuation has provided preliminary data on the antiviral, antibacterial, antiparasitic, and anticancer possibilities of the mentioned compounds. According to the evidence, PASS predicted scores were shown to perform better in antineoplastic and antiviral than antibacterial, and antiparasitic efficiency; as evidenced by their higher PASS scores in antineoplastic and antiviral drug tests. Breast cancer, Monkeypox, and Marburg virus have been selected as targeted pathogens, and different *in silico* studies were conducted to determine the dual function of mention derivatives. The "Lipinski five rules," on the other hand, has been subjected to extensive testing for drug-like characteristics. Molecular docking against Breast cancer, Monkeypox, and Marburg virus have been accomplished after confirmation of their bioactivity. The molecular docking evaluation against targeted disease displayed re-markable binding affinity and non-bonding engagement, with most of the results indicating that derivatives are more effective than the FDA approved standard antiviral, and antineoplastic drugs. Finally, the ADMET characteristics have been computed, and they indicate that the substance is suitable to use and did not have any chance to produce adverse effects on aquatic or non-aquatic environment, as well as having a highly soluble capacity in water medium, high G.I absorption rate, with outstanding bioavailability index. Therefore, these mentioned Fisetin derivatives could be suggested as potential medication against Breast cancer and newly reported Monkeypox, and Marburg virus, and may further proceed for laboratory experiment, synthesis, and clinical trials to evaluate their practical value.

INTRODUCTION

Breast cancer is the most frequent cancer in women globally, where it is accompanied with a devastating impact on life among females (Bhattacharyya *et al.*, 2020). Every year, many patients have been identified by Breast cancer globally. Among them, many patients cannot survive due to limitation of proper treatment. Currently, finding on literature review, chemotherapeutics drugs, radiation therapy, surgery, hormone therapy, targeted therapy, and immune therapy seem to be the treatment options for Breast cancer that applies, which is very expensive with numerous side effects like killing healthy cells (Eniu *et al.*, 2008; Pilla *et al.*, 2018; Schirrmaker, 2003). Recently, it has been seen that several cancer-fighting medications (chemotherapeutic agent) are becoming increasingly ineffective or cancerous cells gain resistance against them. As a result, alternative options for Breast cancer treatment should be found for the future generation (Naveed *et al.*, 2022a; Naveed *et al.*, 2023b; Afshari *et al.*, 2022; Farkona *et al.*, 2016; Poojan *et al.*, 2020).

One the other side, human Monkeypox seems to be a *zoonotic orthopoxvirus* and composed of double stranded DNA, transmitted by Monkey to human, which is particularly reported in tropical Western and Central African areas. It was first reported in 1958 when during the out-breaks of a pox-like infection (Naveed *et al.*, 2023c; Mileto *et al.*, 2022; Pal *et al.*, 2017). Previously, tropical Western and Central African areas were a major region of Monkeypox virus (MPXV), but recently the MPXV resurfacing and expanding throughout the world is causing a major threat to human life and it especially affected most of the European countries, as well as North and South America (Hatmal *et al.*, 2022; Majie *et al.*, 2023). About 4900 infected of human Monkeypox were reported in more than 50 countries at the end of June 2022, and one infected person has died (Mucker *et al.*, 2022). So, it is a reminder that another pandemic might happen around the globe, which make concern to the global policymaker, and healthcare system. For more

09	0.392	0.039	0.327	0.050	0.301	0.056	0.754	0.018

than couple of decades, scientists have worked to enhance Smallpox vaccinations and find medicines to assure immunity against Smallpox or Smallpox-like illnesses. But investigation reported that there is no authorized medication against MPXV till now (Gong *et al.*, 2022). Besides, following corona virus epidemic, another pandemic is knocking at the door, which might be caused by Marburg virus (MARV). The Marburg virus (MARV) has been considered as the deadly hemorrhagic infection that may produce a fatal condition. MARV is suspected to be a zoonotic infection spread by animals (Albaqami *et al.*, 2023; Reuben & Abunike, 2023). The virus may spread from bats to people by extended exposure to bat colonies' tunnels and caves, and by interaction with bat saliva, excrement, and infected fruits (Asad *et al.*, 2020; Mortlock, 2013). Recently, it was in the headlines in mid-July 2022 due to an epidemic in Ghana, an African country, where two affected people have died. MARV is an enclosed single-stranded RNA virus of the *Filovirus* genus, which composed to the *Filoviridae* family, like the Ebola virus. Although, the MARV is happening consciously and infects the patients, Scientists did not find any suitable treatment for the inhibition of MARV (Chakraborty *et al.*, 2022; Sah *et al.*, 2022). The natural bioactive compounds of Fisetin should be an alternative approach for the treatment of Breast cancer, and Monkeypox, and Marburg virus. So, in this research, the natural compounds of Fisetin have been counted as

primary compounds and we modified its structure by different functional groups to develop a potential medication, which might have better efficacy, lower toxicity, and capability to inhibit Breast cancer, Monkeypox, and Marburg virus.

In these circumstances, computational drug design tool is used, which is the most efficient approach of finding potential therapeutic candidates and implementing them into the therapy regimen in short period of time (Aziz *et al.*, 2023; Moingeon *et al.*, 2022; Patel *et al.*, 2022; Aziz *et al.*, 2022). In comparison to traditional drug discovery procedures, computational drug design offers many benefits, including substantially lower costs, faster drug development durations, and possibility to eliminate phase 1 clinical trial. Thus, this approach of computer-aided drug design (CADD) could be a helpful method.

RESULTS AND DISCUSSION

PASS prediction analysis

It seems that a substantial proportion of investigations should not go to the end of the process due to significant harmful side effects and toxicity that are unclear. These undesirable effects are discovered or manifest much too late in the development. In today's high-tech, possibility to fail or reject any compounds has been min-

imized since the probability to be active and probability to be inactive for any molecules could be identified at early stages (Filimonov et al., 2014). In Table 1 below, probability to be active (Pa) and probability to be inactive (Pi) has been listed and it has been shown that the mentioned bioactive molecules are most potent against antineoplastic and antiviral effects compared to antibacterial and antiparasitic effects. In antiviral, the range of Pa is reported from 0.392–0.471 while the Pa score against antineoplastic is found between 0.508–0.849. So, based on the score, the Breast cancer and Monkeypox, and Marburg virus has been chosen and completed the investigation.

Lipinski rule, and pharmacokinetics

Lipinski rule is a potential assessment of any pharmacological or bioactive molecules which makes them to be a potential oral medication based on different parameters. So, in view of Lipinski rule, number of hydrogen bond acceptor 06-10, hydrogen bond donor 02–06, topological polar surface area 89.13 Å² to 163.73 Å², which has shown that all the medications are fully accepted and followed Lipinski rule by all Fisetin derivatives (Santos et al., 2016; Walters, 2012). For any oral medication, bioavailability is the most essential parameter, and it is noticed that almost all the drugs are highly effective and

have a similar score and that only Ligand 09 has poor bioavailability. On the other portion, six ligands out of nine molecules have higher G.I absorption rate, which is another important parameter to make them as oral medication. Finally, it is said that these mentioned molecules could be effective against the Breast cancer, Monkeypox, and Marburg virus. Data of Lipinski rule, and pharmacokinetics are displayed in Table 2.

Molecular docking against Breast cancer

Molecular docking is an established and effective method for explaining how two molecules interact and make the optimal ligand arrangement to produce a complex. Any molecules could be active and produce biological response if their minimum binding energy is –6.0 kcal/mol and considered as a potential drug (Nath et al., 2021). In view of these studies, all the bioactive Fisetin derivatives have been documented that they have much better binding affinity than the standard and FDA approved Epirubicin hydrochloride. The maximum docking energy has been obtained in ligand 07 (–11.00 kcal/mol) against PDB: 3HB5, in protein PDB: 7KCD, the maximal score is found to be –9.6 kcal/mol, and the last one PDB: 6NLV has obtained –9.1 kcal/mol maximum in the same ligand (Table 3). In the overall analysis, it is clear that all the ligands have crossed the binding affini-

ties and compared much better to standard drugs, which turn into them as oral medication against breast cancer protein.

Binding affinities against pathogenic Monkeypox and Marburg virus

According to the result of pass prediction value, it was shown that these mentioned ligands could be effective against viral pathogens, followed by antibacterial and antiparasitic, since the antiviral score is higher than the antibacterial and antiparasitic. So, the Monkeypox and Marburg virus are also included in this investigation, and it is found that the reported ligand may also act as a potential inhibitor against Monkeypox and Marburg virus. In given Table 4, it is notable that the maximum affinities for Monkeypox virus (PDB ID 4QWO) is –9.0 kcal/mol, –9.4 kcal/mol, where –10.1 kcal/mol has been obtained against Marburg virus (PDB 4OR8), and it has also significantly better binding affinities. As, there is no documented or authorized medication against Monkeypox and Marburg virus, a common antiviral medication (acyclovir) is also compared with our development drug, where the standard acyclovir has provided –6.3 kcal/mol and –5.8 kcal/mol, which is much lower than the reported ligands. So, it is understood that all these may be possible therapeutic approaches as inhibitors against Monkeypox and Marburg virus.

Ligand-protein interaction and molecular docking poses

The interactions between the inhibitor and the targeted protein active side, docking pocket drug-protein are graphically represented in Figs 1a, 1b and 1c. In the 2D

configuration, the active side of amino acid residue with bond angle has been seen and in most cases the number of hydrophobic bond residue is higher than the other bonds, such as hydrogen, electrostatic, Van der Waals interactions and Halogen bond. This result has been obtained by importing protein ligand complex file into the Discovery Studio Visualizer (Balasubramaniam & Reis, 2020; Wang et al., 2015). This figure has been configured based on maximum binding energy. The first illustration (Fig. 1a) determined drug-protein pocket, or how a drug attached to protein during the formation of the complex. It has been designed after molecular docking, by using Pymol application. Then, (Fig. 1b) represented hydrogen bonding donor or acceptor region, where the sky blue indicates donor region, and red hue indicates acceptor region. Finally; (c). 2D picture of ligand and protein interaction, where X: TYR-218, X: LEU-149, X: MET-147: X: TYR-155, X: PHE-226, X: PHE-226, X:PRO-187, X: LEU-149, X:PRO-187, X: VAL-225, X: MET-193, X: CYS-185.X: VAL1-88, against breast cancer, A: GLU-18, A: GLU-18, A: PHE-17, A: SER-12, A: SER-12, A: ILE-8, A: ILE-35, A: LYS-13, against Monkeypox virus, and A: ASN-171, A: THR-72, A: VAL-193, A: MET-195, A: TRP-69, A: LEU-75. A:VA-L170, A: LEU-198, against Marburg virus are seen in most of the cases.

Absorption, Distribution, Metabolism and Excretion. (ADME) studies

It was possible to forecast the ADMET features of drugs or chemical compounds by utilizing the free PkC-SM online web tool, which was developed by machine

Table 5. ADME Properties summary

learning (Pires *et al.*, 2015). ADME is the key factor of any drug molecules to establish them as safe and usable medication. In listed data, it is observed that the drugs are moderately soluble in water and the Caco-2 perme-ability range is –0.621 to 1.076. VDss (human) level is –0.041 to –1.364 and no drugs can penetrate the BBB (Table 5). All the drugs can inhibit the CYP450 1A2 in-hibitor except 05 and 07 and only ligands 05, 06, and 07 can inhibit the CYP450 2C9 inhibitor. Finally, al-most all the ligands have better Total clearance rate, and no drugs can substrate through Renal OCT2 substrate. Above all discussion, the Table 5 data for ADME pa-rameters might suggest them as a suitable medication.

Aquatic and non-aquatic toxicity

Aquatic and non-aquatic toxicity studies are per-formed to analyze the drug safety of animals and the en-vironment, because during the production of drugs they might be mixed with environment, which may have an impact on surrounding animals (Kar & Roy, 2012). Our findings on the aquatic and non-aquatic toxicity of the examined substances have shown that all of the medica-tions investigated are non-cancerogenic and non-AMES poisonous and only 06 and 07 may be responsible for hepatotoxicity. So, patients with liver disease may use these two medications with caution. Secondly, the max. tolerated daily dose could be between 0.329 mg/kg/day

to 1.211 mg/kg/day. The Oral Rat Acute Toxicity and Oral rat chronic toxicity level is also lower compared to standard drugs and no drugs can produce skin sensitiza-tion. These findings give insight into these new modified Fisetin derivatives that are safer to use (Table 6).

Experimental methodology

Preparation of Ligand and Structural Activity relationship (SAR) studies

Firstly, we have collected the chemical structure of Fi-setin from the PubChem database. After that, we have observed how it is antineoplastic and antiviral properties change if the side chain is substituted by adding differ-ent functional group. So, all the derivatives of Fisetin have been generated using ChemBioDraw 12.0 and in each case, two -OH functional groups have been substituted by four functional groups such as Benzene ring, NH-CH2-OH, OCH_3 and -COOH(Milne, 2010). Finally, ge-ometry optimization has been conducted by using density functional theory (DFT) in material studio at the DFT/B3LYP/6-31G and after optimization has been done, all the atoms of molecule have been reached at the most sta-ble state with the optimum ground state energy and saved as PBD format for molecular docking, ADMET, and oth-er computational experiment (Eno *et al.*, 2022; Oyeneyin *et al.*, 2022). The optimization technique is utilized in the

context of protein-ligand docking investigation to determine the optimal binding posture of a ligand against a bioreceptor. Optimization is the fundamental and important parameter for an accurate design of the ligands (Kobir *et al.*, 2022). The modified structures, and the optimized figures are given in Fig. 2 and Fig. 3.

Pass prediction

The pass prediction is an important feature for computer-based drug design, which is described by Pa and Pi ratio, where Pa means probability to be active and Pi means probability to be inactive. It is possible to separate most active molecules by screening pass prediction values which reduce the time and cost for developing new drugs (Pa>Pi value) (Filimonov *et al.*, 2014; Poroikov & Filimonov, 2005). The pass prediction data has been collected from the PASS online website "http://way2drug.com/PassOnline/predict.php". First enter the PASS online then the Pa>Pi value has been collected for the selected molecule and all the values are shown in Table 1.

Determination of ADMET, Lipinski rule and pharmacokinetics

With the help of pkCSM (http://biosig.unimelb.edu.au/pkcsm/prediction), and SwissADME, (http://www.swissadme.ch/index.php) we investigated the overall pharmacokinetic parameter of Fisetin and its derivatives. This section mostly investigated human intestinal absorption, distribution, metabolism, excretion, water solubility, bioavailability, toxicity, carcinogenicity, and drug likeliness (Azzam, 2023). The Lipinski Rule and drug likeness are important features for oral medication development (Tian *et al.*, 2015). Once the drugs have satisfied the Lipinski Rule, they should be considered as oral drug candidates.

Protein preparation and Molecular docking study and visualization

The crystal structure of Monkeypox virus (PDB ID 4QWO), Marburg virus (PDB ID 4OR8), and Breast Cancer (PDB: 3HB5, PDB: 5KCD and 6NLV) (Figs. 4

and 5) have been collected from the databank of RCSB protein (http://www.rcsb.org). Inadequate bonds, omitted hydrogens and side chain defects, access water have then been investigated and rectified, as necessary. Once all these issues have been resolved, they were saved as pdbqt file format. Then, the structure file has been loaded into PyRx AutoDock Tools, followed by usual processes to obtain binding affinities (Dallakyan & Olson, 2015). Finally, BIOVIA Discovery Studio Visualizer was used to investigate the interaction between the ligands and the protein (Zothantluanga, 2021).

CONCLUSIONS

This investigation has been designed to identify the dual mode of function of the ligands against virus and cancerous proteins. Our computational investigation has found that all the evaluated natural Fisetin derivatives demonstrated adequate reactivity with excellent binding affinity to be a viable therapeutic target for Breast cancer, Monkeypox, and Marburg virus. The biological characteristics of reported compounds such as toxicity, carcinogenicity, and Lipinski rule are good enough for human usage of the selected drug. We ran their various parameters *in silico* to verify their durability as a highly potential drug candidate, and these results assessed their acceptability as a potential new drug candidate. Following the investigation of protein-ligand (drug) interactions, several outstanding binding affinities were discovered, which will effectively assist in the discovery of the ideal natural medication or a novel drug. The highest value of docking energy has been found in Ligand 07 (–11.00 kcal/mol) against PDB: 3HB5 for breast cancer and the highest docking energy for Monkeypox virus (PDB ID 4QWO) is –9.0 kcal/mol, –9.4 kcal/mol, where -10.1 kcal/mol has been obtained against Marburg virus (PDB 4OR8). Besides, the results of pharmacokinetics, drug likeness and aquatic toxicity meet the requirements of the newly developed molecules. All the parameters are recorded as significant and better than standard. Concluding, the reported drug can be a candidate for further use.

Long noncoding RNA TPTEP1 suppresses diabetic retinopathy by reducing oxidative stress and targeting the miR-489-3p/NRF2 axis

Xinfa Wang[1], Xianbo Zhou[1], Fang Wang[2], Nan Zhang[1], Yan Zhang[3], Zhen Ao[4]✉ and Fang He[4]✉

[1]Department of Ophthalmology, The First People's Hospital of Lin'an District, Hangzhou City, Zhejiang Province 311300, China; [2]Department of Nephrology, General Hospital of Central Theater Command of PLA, Wuhan City, Hubei Province 430010, China; [3]Department of Ophthalmology, The Seventh Medical Center of the PLA General Hospital, Haidian District, Beijing 100700, China; [4]Department of Ophthalmology, The Eighth Medical Center of the PLA General Hospital, Haidian District, Beijing 100091, China

Background: Diabetic retinopathy (DR) is a diabetic complication with complex etiology and severe visual impairment. Dysregulated long noncoding RNAs (lncRNAs) are closely associated with DR. This article focused on the impact of lncRNA transmembrane phosphatase with tensin homology pseudogene 1 (TPTEP1) in DR. **Methods:** First, sera were collected from DR patients and healthy control. Human retinal vascular endothelial cells (HRVECs) were exposed to high glucose (HG) to construct a DR model *in vitro*. A real-time quantitative polymerase chain reaction (RT-qPCR) was carried out to detect TPTEP1. Targeting relationships were predicted using StarBase and TargetScan, and confirmed by the Dual-Luciferase Reporter Assay. Cell Counting Kit 8 (CCK-8) and EdU staining were applied to measure cell viability and proliferation, respectively. Protein expression was determined by a western blotting assay. **Results:** lncRNA TPTEP1 expression was significantly decreased in the serum of DR patients and HG-stimulated HRVECs. Overexpression of TPTEP1 reduced cell viability and proliferation induced by HG and oxidative stress. In addition, overexpression of miR-489-3p impaired the effects of TPTEP1. Nrf2, which was targeted by miR-489-3p, was down-regulated in HG-treatment HRVECs. Knockdown of Nrf2 enhanced the influence of miR-489-3p and antagonized the effects of TPTEP1. **Conclusion:** This study demonstrated that a TPTEP1/miR-489-3p/NRF2 axis affects the development of DR by regulating oxidative stress.

Keywords: diabetic retinopathy, TPTEP1, oxidative stress, NRF2

INTRODUCTION

DR is a common ocular complication in diabetic patients. Recent years have witnessed an increased annual incidence of DR (Yumnamcha *et al.*, 2020). Moreover, DR patients are inducive to blindness (Crawford *et al.*, 2009). Recent studies evidence that abnormal angiogenesis, metabolic abnormalities, inflammation and oxidative stress caused by hyperglycemia are important factors for DR. Nowadays, the prevailing strategy for DR is anti-vas-cular endothelial growth factor (VEGF) therapy, which is only effective for patients with advanced DR (Singer *et al.*, 2016). Therefore, it is urgent to develop a new therapy for the prevention and treatment of DR.

Oxidative stress (OS) is caused by the imbalance of the oxidation system and antioxidant system, which frequently induces tissue damage. Hyperglycemia is an important reason for inducing OS response, the accumulation of which contributes to multiple complications in patients with diabetes (Brownlee, 2005). Studies have shown that OS in the retina can lead to DR by regulating the pathways involved in polyol metabolism, hexosamine metabolism (Eshaq *et al.*, 2014). NRF2 can up-regulate the expression of antioxidant proteins (Yu & Kensler, 2005). However, the roles of Nrf2 in DR are still unclear.

Long non-coding RNAs (lncRNAs) are a number of RNA with a length greater than 200 nt but without the function of protein-coding properties. As an important regulator of gene expression, lncRNAs play an important role in chromatin remodeling, transcription, post-transcriptional regulation and protein metabolism (Shi *et al.*, 2013). lncRNAs regulate gene expression in the form of competitive endogenous RNA (ceRNA) through the miRNA response element (MRE) (Thomson & Dinger, 2016; Yan *et al.*, 2014). Recently, the roles of lncRNAs in DR attract increasing attention. The abnormal expression of lncRNAs in DR patients regulates the chemokine signaling pathway, mitogen-activated protein kinase (MAPK) signaling pathway, and pyruvate metabolism (Yan *et al.*, 2014). Therefore, lncRNAs may be a potential regulatory factor of the pathogenic mechanism of DR. Aberrant expressed lncRNA TPTE pseudogene 1 (TPTEP1) is closely associated with the pathogenesis of DR (Sun *et al.*, 2021). However, the roles of TPTEP1 in DR have not been fully elucidated.

In our research, the roles of TPTEP1 in DR were investigated. A luciferase assay was performed to verify the binding sites between miR-489-3p and TPTEP1 or NRF2. Cellular functions were detected using CCK-8 and EdU assays. TPTEP1/miR-489-3p/NRF2 axis may be a potential target for DR.

MATERIALS AND METHODS

Patient samples

Clinical blood samples were gathered from DR patients (n=50) and healthy volunteers (n=50) at The

Table 1. Clinical and pathological parameters in all subjects

Variables	Control (n=50)	DR (n= 0)
Male/Female	21/29	32/18
Age (years)	52.8±5.5	53.5±4.3
Diabetes duration (years)	/	12.2±2.9
BMI (kg/m2)	23.4±1.8	33.5± 3.3[a]
FPG (mmol/L)	4.55± 0.96	8.21± 0.16[a]

Note: a Mean values within a row with unlike superscript letters were significantly different ($P<0.05$). Control: healthy volunteers; DR, diabetic retinopathy patients; BMI, body mass index; FPG, fasting plasma glucose.

Eighth Medical Center of the PLA General Hospital. The study was approved by The Eighth Medical Center of the PLA General Hospital. Signed informed consents were obtained from each individual. The blood samples of the patients were collected with the fasting abdomen in the morning and stored at −80°C for further experiments. The clinical and pathological parameters in all subjects was shown in Table 1.

The inclusion criteria: patients who met the 1999 WHO diabetes diagnosis (fasting blood glucose≥7.0mmol/l or postprandial blood glucose≥11.10mmol/l); Fundus examination conforms to DR diagnostic criteria. The exclusion criteria: suffering from heart, liver, kidney and other organic diseases; with multiple eye diseases; combined with malignant tumor; suffering from infectious diseases; combined with other types of diabetes mellitus; abnormal endocrine function; mental illness and consciousness disorder.

Cell culture and cell transfection

HRVECs were purchased from the Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China). DMEM with 10% foetal bovine serum, 100 mg/mL of penicillin and 100 U/mL of streptomycin (all from Gibco, Waltham, MA, USA) was applied to culture cells. Cells were grown in the condition with 5% CO_2 at 37°C. HRVECs were planted in 6-well cell culture plates at a density of $1.5×10^6$ cells/well in the HG treatment experiments, and then incubated in 5.5 mM for 24 h. Then HG (33 mmol/L) or mannitol isotonic control (33 mmol/L) were used to treat cells for 24 h.

TPTEP1 overexpression plasmids, miR-489-3p mimic/inhibitor, NRF2 small interference RNA (si-NRF2) and their negative controls (Abiocenter Biotech Co., Ltd.), were transfected into the cells with Lipofectamine® 2000 reagent (Invitrogen) at 37°C according to manufacturer's protocols. After 48 h transfection, cells were used in the following experiments.

Real-time quantitative polymerase chain reaction (RT-qPCR)

Total RNA was extracted using the TRIzol® reagent (Invitrogen; Thermo Fisher Scientific, Inc.). The cocentration and purity of the total RNA were assessed from OD 260/280 readings (ratio>1.8) using a spectrophotometer (NanoDrop Technologies, Wilmington, DE, USA). Reverse transcription and qPCR were carried out by BlazeTaq One-Step SYBR Green RT-qPCR Kit (with ROX) (QP071; GeneCopoeia Inc.) on SEDI Thermo Cycler controlled by the Control Bus Net software package (Wealtec Bioscience Co., Ltd). All primers were de-

signed and synthesized by Nanjing Genscript Biotech Co., Ltd., the GAPDH and U6 were used as an internal reference. Fold changes of the indicated genes were calculated with the 2-ΔΔCt method. The sequences of the primers used were as followed:

TPTEP1:
F: 5'-CTGGGAGAAGTGCCCTTGC-3',
R: 5'-CACCTCATCAGTCATTTGCTCA-3';
miR-489-3p:
F: 5'-GCGCGGTGACATCACATATAC -3',
R: 5'-AGTGCAGGGTCCGAGGTATT -3';
NRF2:
F: 5'-GAGACAGGTGAATTTCTCCCAAT-3',
R: 5'-TTTGGGAATGTGGGCAAC-3';
GAPDH:
F: 5'-ACTCTTCCACCTTCGATGC-3',
R: 5'-CCGTATTCATTGTCATACCAGG-3';
U6:
F: 5'-CGACAAGACGATCCGGGTAAA-3',
R: 5'-GGTTGAGGAGTGGGTCGAAG-3'.

The PCR products were detected by agarose gel electrophoresis. And the thermal profiles and of TPTEP1, miR-489-3p and NRF2 were shown in Supplementary materials.

Cell viability assay

After resuspended to $1×10^5$ cells/ml, 100 µl HRVECs were seeded in 96-well plates. Each well was added with 10 µl CCK8 reagent (AMJ-KT0001; AmyJet Technology Co., Ltd.) and cultured for 4 h at 37°C. The absorbance values were evaluated with a microplate reader (HBS-1096C; Nanjing DeTie Experimental Equipment Co., Ltd.) at the wavelength of 450 nm.

5-Ethynyl-2′-deoxyuridine assay

HRVECs were fixed with 4% paraformaldehyde and treated with EdU. Then 1X Apollo reaction cocktail was used to stain cells for 0.5 hours before incubating with Hoechst 33342. Afterwards, cells were captured with a fluorescence microscope (Leica, Germany).

Assessment of reactive oxygen species (ROS), malondialdehyde (MDA), and Glutathione (GSH) activity

The level of ROS was detected with a fluorescence probe dichloro-dihydro-fluorescein diacetate (Jiancheng Biotech, Nanjing, China). MDA Assay Kit and GSH Assay Kit (Beyotime, Jiangsu, China) to examine MDA and GSH, respectively.

Western blot analysis

After rinsing cells with pre-chilled PBS solution, pre-chilled RIPA lysis buffer was applied for the extraction of total protein for 30 min. The protein concentration was quantified by a BCA Protein Assay Kit (Beyotime, Jiangsu, China). Next, running electrophoresis was performed to separate the protein with 10% SDS-PAGE at 120v until the bromophenol blue reach the separation adhesive base. Then the separated protein was transferred onto the PVDF membranes (Millipore) in an ice box at 100v for 1.5 h. The membranes were blocked with a blocking buffer at 4°C for 1 h. After being washed with TBST solution, primary antibodies including anti-NRF2, anti-HO-1, anti-NQO1 (1:1,000; Abcam) and anti-GAPDH (1:3000, Leading Biology) were used to incubate the membranes on a

Figure 1. TPTEP1 is downregulated in DR.
(**A**) The expression level of TPTEP1 in DR patients. **$P<0.01$ versus normal. (**B**) The expression level of TPTEP1 HG stimulated cells. ***$P<0.001$ *versus* control. DR, diabetic retinopathy; HG, high glucose.

shaking table at 4°C overnight and with anti-IgG antibody (1:2 000, MultiSciences, Shanghai, China) for 2 h at room temperature. At last, the protein bands were captured by the ECL system (Thermo Fisher Scientific, Inc.).

Dual luciferase reporter assay

The wild (WT) and mutant (MUT) type 3'-UTR region of TPTEP1 and NRF2 luciferase reporter vectors were designed and synthesized by Guangzhou RiboBio Co., Ltd. After 24 h, cells were co-transfected with luciferase reporter vectors as well as miR-489-3p mimic/control for 48 h. Luciferase activities were detected by a Luciferase Reporter Assay Kit (K801-200; BioVision Tech Co., Ltd.). The luciferase activity normalized the luciferase activity to Renilla luciferase activity.

Statistical Analysis

Each experiment was performed at least three times. GraphPad Prism (version 7, GraphPad Software Inc.) was used to analyze all data. Data were presented as mean ± S.D. The Student's *t*-test was used to compare the differences between two groups, and the compari-

son among multiple groups used the analysis of variance (ANOVA) followed by Duncan's post-hoc test. $P<0.05$ suggested a significant difference.

RESULTS

TPTEP1 was downregulated in DR.

The expression level of TPTEP1 in serum of patients with DR was significantly reduced compared with normal controls (Fig. 1A). Besides, the expression of TPTEP1 in HRVECs stimulated with HG was also significantly decreased compared with a control group (Fig. 1B).

TPTEP1 promoted cell proliferation and ameliorated oxidative stress stimulated by HG.

Figure 2A showed that the expression of TPTEP1 was significantly increased, indicating that cell transfection was successful. Overexpression of TPTEP1 significantly suppressed the increase in cell viability induced by HG (Fig. 2B). Moreover, TPTEP1 overexpression remarkably inhibited the proliferation of HRVECs (Fig. 2C). Additionally, overexpression of TPTEP1 alleviated the increase of ROS and MDA and the decrease of GSH induced by HG (Fig. 2D-2F). For further exploration of the effect of TPTEP1 on oxidative stress, NRF2, NQO1 and HO-1 proteins' expressions were also measured. The results showed that overexpression of TPTEP1 could increase the expression of antioxidant-related proteins (Fig. 2G).

TPTEP1 directly bound to miR-489-3p.

TPTEP1 might function as ceRNA and regulate biological processes via sponging miRNAs. So, we used the online database Starbase 3.0 (http://starbase.sysu.edu.cn/) to predict the potential target miRNAs of TPTEP1. Figure 3A showed the binding region of miR-489-3p and TPTEP1, which was further verified via dual luciferase reporter assay

(Fig. 3B). Furthermore, miR-489-3p expression was significantly declined by TPTEP1 (Fig. 3C). However, miR-489-3p expression was significantly increased by HG (Fig. 3D).

Overexpression of miR-489-3p reversed the effects of TPTEP1 on cell proliferation and oxidative stress

As shown in Fig. 4A, the expression of miR-489-3p in the mimic group was significantly increased compared with the empty vector group, but the expression was significantly declined in the inhibitor group, indicating that the transfection was successful. Overexpressed miR-489-3p significantly weakened the inhibitory effect of TPTEP1 on cell viability (Fig. 4B), and promoted cell proliferation of HRVECs (Fig. 4C). In addition, overexpressed miR-489-3p alleviated the

effects of TPTEP1 on the release of ROS, MDA and GSH (Fig. 4D- 4F). Moreover, overexpressing the miR-489-3p inhibited the protein expression of anti-oxidant genes, such as NRF2, NQO1 and HO-1 (Fig. 4G).

3.5 miR-489-3p targeted NRF2

In order to find specific regulatory pathways containing TPTEP1 and miR-489-3p, TargetScan (http://www.targetscan.org/mamm_31/) was applied to predict the target gene of miR-489-3p. We found dramatically that the OS-related NRF2 mentioned above was its target gene (Fig. 5A). Dual luciferase reporter assay further confirmed the targeting relationship between NRF2 and miR-489-3p (Fig. 5B). In addition, the expression of NRF2 in miR-

489-3p inhibitor group was significantly increased (Fig. 5C). Additionally, the expression of NRF2 was significantly declined in cells exposed to HG (Fig. 5D).

Knockdown of NRF2 reversed the regulation of miR-489-3p on cell proliferation and oxidative stress

As shown in Fig. 6A, NRF2's expression was significantly declined in both si-NRF2 groups, indicating successful transfection. si-NRF2 2# was more potent, which, therefore, was used in all subsequent experiments. Fig. 6B and Fig. 6C showed that NRF2 knockdown alleviated the regulation of miR-489-3p inhibitor and promoted the proliferation of HRVECs. In addition, knockdown of NRF2

increased the release of ROS, MDA and decreased GSH as well as suppressed the expression of NRF2, NQO1 and HO-1 (Fig. 6D–G).

DISCUSSION

Diabetic retinopathy is a common eye complication in diabetic patients and an important cause of blindness (Bourne *et al.*, 2013). Oxidative stress response in eye tissue and cells induced by a long-term high glucose environment is considered to be positively correlated with the severity of DR (Arden & Sivaprasad, 2011). The activation of the anti-oxidant NRF2 signaling pathway inhibits

the occurrence and development of DR (Tan *et al.,* 2014). Dysregulated lncRNA TPTEP1 is associated with a variety of diseases, including DR (Yan *et al.,* 2014). Dysregulated TPTEP1 interacts with STAT3 and induces the progression of DR (Sun *et al.,* 2021). Therefore, our study explored the regulatory role of TPTEP1 in DR and the potential molecular mechanism. In this study, TPTEP1 was significantly reduced in DR patients and HRVECs stimulated by HG. Overexpression of TPTEP1 sponged miR-489-3p to activate the NRF2 signaling pathway, which suppressed oxidative stress and proliferation of HRVECs.

LncRNAs are usually used as a competitive RNA binding miRNA to regulate the target genes' expression. At present, the lncRNA-miRNA axis has been proved to be related to the pathogenesis of DR (Zhang *et al.,* 2017; Kovacs *et al.,* 2011). For example, lncRNA BANCR inhibits the proliferation and migration of HRVECs in DR (Zhang *et al.,* 2019). HOTAIR prevents oxidative stress response in DR (Biswas *et al.,* 2021). In this study, the expression of TPTEP1 was decreased in DR, which was consistent with a previous study (Sun *et al.,* 2021). Overexpression of TPTEP1 inhibited the viability and proliferation of HRVECs, and suppressed oxidative stress, suggesting that TPTEP1 could be a potential target for DR. Additionally, further study showed that TPTEP1 could directly target miR-489-3p. MiR-489-3p is related to the regulation of gastric cancer (Mao *et al.,* 2021) and inflammatory response (Wang *et al.,* 2021; Ye *et al.,* 2021). However, miR-489-3p is rarely studied in the development of DR/The reports on the roles of miR-489-3p in DR are limited. In this study, the expression level of miR-489-3p in DR patients was overexpressed. However, overexpressed miR-489-3p relieved the effects of TPTEP1 on the proliferation of HRVECs and oxidative stress.

NRF2 belongs to the Cap-n-Collar (CNC) regulatory protein family, which is a transcription factor with a highly conserved basic leucine zipper (bZip) structure. NRF2 signaling possesses antioxidant properties in various diseases, including diabetic complications. NRF2 effectively combats OS and inhibits the occurrence and development of DR (Liu *et al.,* 2014). Moreover, NRF2 reduces the toxicity of hydrogen peroxide and protects retinal vascular endothelial cells by regulating heme oxygenase-1 (HO-1) (Castilho *et al.,* 2012). In this study, NRF2 was the target gene of miR-489-3p. NRF2 knockdown promoted oxidative stress and proliferation of HRVECs, suggesting its beneficial roles in DR.

In summary, the expression of TPTEP1 was reduced in DR. Overexpression of TPTEP1 resisted oxidative stress and proliferation of HRVECs through miR-489-3p/NRF2 axis, thereby inhibiting the development of DR. These findings may provide a therapeutic target for DR.

Overexpression of miR-483-5p predicts venous thromboembolism onset in patients with lung cancer especially in high BMI cases

Miao Zhang[1], Juanjuan Li[2], Guigang Tai[3], Chao Li[4] and Hongcai Wu[5]✉

[1]Department of Respiratory Medicine, Qingdao Jiaozhou Central Hospital, Jiaozhou 266300, Shandong, China; [2]Endocrinology and Blood Department, Qingdao Jiaozhou Central Hospital, Jiaozhou 266300, Shandong, China; [3]Emergency Department, Qingdao Jiaozhou Central Hospital, Jiaozhou 266300, Shandong, China; [4]Internal Medicine Department, Jiaozhou Jiaodong Sub-district Office Central Health Center, Jiaozhou 266317, Shandong, China; [5]Cardiothoracic Surgery Department, Jiaozhou Hospital, East Hospital Affiliated to Tongji University, Jiaozhou 266300, Shandong, China

Background: Venous thromboembolism (VTE) is a common complication in patients with lung cancer. The important roles of microRNAs (miRNAs) in VTE have emerged, however, studies about the roles of miRNAs in VTE remain scarce. This study aimed to measure the expression of miR-483-5p in lung cancer patients with VTE, evaluate whether miR-483-5p could predict VTE onset in patients, and further evaluate its predictive value in patients with different BMI values. **Methods:** A total of 170 patients with lung cancer were recruited in this study, including 70 patients with VTE, and 110 patients with non-VTE. The expression of miR-483-5p was detected by quantitative real time PCR. Receiver operating characteristic analysis was used to screen VTE patients from non-VTE patients. Whether miR-483-5p was independently associated with VTE onset in lung cancer patients was evaluated by univariate and multivariate logistic regression analyses. **Results:** miR-483-5p was higher in VTE patients than that in non-VTE patients. miR-483-5p was correlated with body mass index (BMI), hypertension, C-reactive protein (CRP), and platelet count in VTE patients. In addition, miR-483-5p had high diagnostic value to differentiate between VTE patients and non-VTE patients and served as an independent biomarker in predicting the VTE onset in lung cancer patients. Moreover, miR-483-5p had the highest diagnostic accuracy to screen VTE patients from non-VTE patients in patients with high BMI values. **Conclusion:** miR-483-5p, increased in VTE patients, can independently predict VTE onset in lung cancer patients especially in patients with high BMI values.

Keywords: miR-483-5p; Predict; Venous thromboembolism; Lung cancer; BMI

INTRODUCTION

Venous thromboembolism (VTE) is a common vascular disease in which blood clots occur within a vessel.

The pathogenesis of VTE formation is endothelial injury, hypercoagulability or vessel walls injury, and blood stasis, known as Virchow's triad (Kruger *et al.*, 2019). It is known that cancer was one of the most common risk factors for VTE (Falanga & Zacharski, 2005), and the risk of VTE occurrence among cancer patients was estimated to be 4 to 7 times that of the general population (Heit *et al.*, 2000; Walker *et al.*, 2013; Blom *et al.*, 2005). In cancer patients, VTE is not only associated with a worse prognosis, but also with increased medical costs and worse quality of life (Lopez-Nunez *et al.*, 2018). The prevalence of VTE in patients with lung cancer is one of the highest among all cancer patients (Corrales-Rodriguez & Blais, 2012). The risk factors for VTE in lung cancer patients are diverse, such as obesity and high body mass index (BMI), trauma, leukocyte, complications and platelet elevation (Du & Chen, 2018). Notably, obesity has been found to function as an independent and moderate risk factor for VTE (Hotoleanu, 2020). A previous study has found that the survival rate in lung cancer patients with VTE is lower than that in lung cancer patients without VTE (Chen *et al.*, 2015). Thus, early and accurate assessment to identify the patients who at high risk for VTE is clinically necessary for the right treatment option. However, to date, reliable VTE risk assessment tools for lung cancer patients treated with anticancer therapies remain an unmet medical need. Therefore, exploring the key molecules involved in the VTE development may provide targets for treating VTE in lung cancer patients.

The microRNAs (miRNAs) are a group of endogenous, small (about 22 nucleotides) non-coding RNAs that can regulate gene expression by binding to the 3'-untranslated region (3'-UTR) of their target mRNAs (Li *et al.*, 2016). Many studies have demonstrated that miRNAs are associated with VTE development and can be used as markers for the prediction of VTE. For example, miR-134 may be a novel biomarker for predicting VTE (Xiang *et al.*, 2019). miR-374b-5p promotes the formation of VTE and may be used as a promising diagnostic marker for VTE (Zhang, Miao, *et al.*, 2020). However, there are only a few studies on the relationship between miRNAs and VTE disease. miR-483-5p has been found to be significantly associated with obesity and BMI (Gallo *et al.*, 2018), and serves as an angiogenesis-regulating factor (Qiao *et al.*, 2011). In addition, a study has shown that miR-483-5p can regulate the function of pulmonary microvascular endothelial cells (Leng *et al.*,

2020). Thus, we speculated that miR-483-5p may be associated with VTE development.

Therefore, the purpose of this study was to measure the expression of miR-483-5p in VTE and non-VTE patients, and to explore its clinical value for predicting VTE occurrence in patients and in patient groups with different BMI values. This study will provide new biomarker and insight for early predicting VTE occurrence in lung cancer patients.

MATERIALS AND METHODS

Patient recruitment

This study was approved by the Ethics Committee of Qingdao Jiaozhou Central Hospital and all patients had signed the informed consent before this study. A total of 170 patients with lung cancer who received therapy in Qingdao Jiaozhou Central Hospital from 2017 to 2020 were enrolled in the case-control study. Sixty of the lung cancer patients developed VTE after surgery (VTE group), and 110 patients with lung cancer did not develop VTE after surgery (non-VTE group). The inclusion criteria were as follows: (a) age ≥ 18 years, (b) patients received surgical therapy, (c) patients were diagnosed with lung cancer pathologically, and (d) VTE was diagnosed by CT pulmonary angiography (CTPA) and/or vascular color Doppler ultrasound imaging (CDFI). Patients were excluded if they: (a) had other malignant tumors, (b) had other hematologic diseases, (c) had combined VTE before surgery or had previous history of VTE, (d) got anticoagulant therapy preoperatively and postoperatively because of other diseases, (e) were in TNM stage IV, and (f) were in gestation and lactation.

Collection of serum samples

Venous blood samples were collected from all the lung cancer patients on admission. Then, serum was obtained by centrifuging blood samples at $1500 \times g$ for 10 min at $4°C$ and stored at $-80°C$ for further use.

RNA isolation

Total RNA was isolated from the serum using TRIzol Reagent (Invitrogen; Thermo Fisher Scientific, Inc.). To prevent contamination of genomic DNA, samples were treated with RNase free DNase I (Fermentas, Thermo Fisher Scientific). Then, the optical density (OD) at 260 nm and 280 nm (OD 260/OD 280) was measured using a NanoDrop 2000 (Thermo Fisher Scientific, Waltham, MA, USA) to evaluate the purity of total RNA, and the concentration of total RNA was evaluated by the OD at 260 nm. All the protocols were performed following the instructions of manufacturers.

Quantitative real time PCR (qRT-PCR)

At first, a reverse transcription step was performed to synthesize the cDNA of miRNA with the Prime-Script RT reagent kit (Takara Bio Inc.). The SYBR Green PCR Master Mix kit (Invitrogen; Thermo Fisher Scientific, Inc.) was used for the qRT-PCR analysis of miR-483-5p expression in a 7300 Real-Time PCR System (Applied Biosystems; Thermo Fisher Scientific, Inc.). All procedures were performed according to the manufacturer's instructions. The thermocycling conditions were as follows: an initial denaturation step at 95°C for 10 min, followed by 40 cycles at 95°C for 30 s, 60°C for 30 s and 72°C for 10 s. Primer sequences were as follows (5'-3'): miR-483-5p, forward: GCCGAGAAGACGGGAGGAAA and reverse: CTCAACTGGTGTCGTGGA; U6, forward: CTCGCTTCGGCAGCACA and reverse: AACGCTTCACGAATTTGCGT. The data of the relative miR-483-5p expression levels were calculated using the $2^{-\Delta\Delta Ct}$ method (Livak & Schmittgen, 2001). U6 was used as an internal control for miR-483-5p expression.

Statistical analysis

SPSS 21.0 software (SPSS, Inc., Chicago, USA) and GraphPad Prism 7.0 software (GraphPad Software, Inc.) were used to perform all statistical analyses in this study. All data were shown as mean ± standard deviation (S.D.). Differences between two groups of continuous variables and categorical variables were compared using Student's t-test and Chi-square test, respectively. Pearson correlation analysis was used to analyze the correlation of miR-483-5p with continuous variables, and Chi-square test was used to analyze the association between miR-483-5p and categorical variables. The ability of miR-483-5p to differentiate between VTE patients and non-VTE patients in all the patients and in patient groups with different BMI values was evaluated by receiver operating characteristic (ROC) analysis. Univariate and multivariate logistic regression analyses were used to evaluate the ability of miR-483-5p to predict VTE onset in lung cancer patients. $P<0.05$ was considered as statistically significant.

RESULTS

Baseline characteristics of lung cancer patients

The baseline characteristics of all patients with lung cancer were presented in Table 1. There were no significant differences in age, gender, histological type, TNM stage, diabetes, coronary heart disease, and hemoglobin between VTE patients and non-VTE patients (all $P>0.05$). Additionally, compared to non-VTE patients, VTE patients had significantly higher BMI ($P=0.001$), C-reactive protein (CRP, $P=0.022$), platelet count ($P=0.023$), leukocyte count ($P=0.041$), and a higher proportion of population with hypertension ($P=0.037$).

High miR-483-5p expression in VTE patients

The expression level of miR-483-5p was presented in Fig. 1. miR-483-5p expression was significantly upregulated in VTE patients compared with that in non-VTE patients ($P < 0.001$).

Correlation between miR-483-5p expression and VTE patients' clinicopathological characteristics

As shown in Table 2, miR-483-5p expression was found to be correlated with BMI (r=0.416, $P=0.001$), hy-

pertension (P=0.012), CRP (r=0.301, P=0.020), platelet count (r=0.291, P=0.024), and leukocyte count (r=0.276, P=0.024) in VTE patients. In addition, no correlation was found between miR-483-5p expression and age, male, histological type, TNM stage, diabetes, coronary heart disease and hemoglobin (all P>0.05).

The significance of miR-483-5p for predicting VTE onset in lung cancer patients

The clinical characteristics that might predict the onset of VTE in lung cancer patients were included in the logistic regression analysis, and the analysis results were shown in Table 3. The results after multivariate correction demonstrated that BMI [odds ratio (OR)=3.731; 95% confidence interval (CI)=1.414-9.848; P=0.008] and miR-483-5p (OR=8.441; 95% CI=3.732–19.094; P<0.001) were independently associated with VTE onset in lung cancer patients. In addition, by ROC analysis (Fig. 2), miR-483-5p was demonstrated to have high ability to screen VTE patients from non-VTE patients with an area under the ROC curve (AUC) of 0.907. At the cutoff value of 1.32, the sensitivity and specificity were 71.67% and 92.73%, respectively.

Comparison of the predictive value of miR-483-5p in patients with different BMI values

As shown in Fig. 3, the percentage referred to the ratio of the number of VTE patients in different BMI groups to the total VTE patients, and the ratio of the number of non-VTE patients in different BMI groups to the total non-VTE patients. Patients with BMI<18.5, 18.5≤BMI<24, and BMI≥24 were defined as underweight, normal BMI, and overweight groups, respectively. The percentage of VTE patients and non-VTE patients was the highest in the normal BMI group. The percentage of VTE patients was higher and the percentage of non-VTE patients was lower in the overweight group than that in the underweight group. In addition, in the underweight group, the percentage of non-VTE patients was higher than the percentage of VTE patients. In the overweight group, the percentage of VTE patients was higher than the percentage of non-VTE patients. miR-485-3p had a

certain role in differentiating between VTE patients (n=6) and non-VTE patients (n=22) in the underweight group (AUC=0780, Fig. 4A). Figure 4B revealed that miR-485-3p had the ability to discriminate between VTE patients (n=36) and non-VTE patients (n=74) in the normal BMI group with an AUC of 0.906 (sensitivity of 80.56%, specificity of 85.14% and cutoff value of 1.21). Figure 4C showed the high ability of miR-485-3p in screening VTE

The ability of miR-483-5p in differentiating between VTE patients and non-VTE patients in BMI<18.5 group (Fig. 4A, AUC=0.780), in normal BMI group (Fig. 4B, AUC=0.906), and in BMI≥24 group (Fig. 4C, AUC=0.968). AUC, area under the ROC curve; ROC, receiver operating characteristic. VTE, venous thromboembolism.

patients (n=18) from non-VTE patients (n=14) in the overweight group (AUC=0.968, sensitivity=88.89%, specificity=100% and cutoff value=1.705).

DISCUSSION

Increasing evidence has indicated the correlation of miRNAs with VTE. For example, Wang and others have shown the role of miR-195-5p and miR-205-5p as potential biomarkers in cervical cancer patients treated for VTE (Wang et al., 2020). Zhang and others have reported that miR-338-5p is downregulated in VTE and that it suppresses VTE (Zhang et al., 2020). In addition, miR-483-5p has been found to play an inhibitory effect on angiogenesis (Qiao et al., 2011). A study has shown that miR-483-5p can regulate the function of pulmonary microvascular endothelial cells (Leng et al., 2020). Therefore, we concluded that miR-483-5p may also be correlated with the progression of VTE. This study revealed a higher miR-483-5p expression in VTE patients than that in non-VTE patients. In addition, the correlation of miR-483-5p with BMI, hypertension, CRP, and platelet count in VTE patients was found. Thus, miR-483-5p may be correlated with VTE progression in lung cancer patients.

miRNAs may be ideal biomarkers with the advantages of low detection limits and strong stability. Many studies have shown the prognostic value of miRNAs for various diseases. For instance, miR-892a may act as a prognostic marker for patients with gastric cancer (Lv et al., 2020). Serum miR-22 may be used as a new prognostic biomarker for acute myeloid leukemia (Qu et al., 2020). miR-211-5p can serve as an independent prognostic factor for the poor prognosis of atherosclerosis (Zhang et al., 2021). In addition, many studies have found the potential of miRNAs in predicting the VTE occurrence, such as miR-296-5p (Pan et al., 2021), miR-195-5p (Jin et al., 2019), and miR-374b-5p (Zhang et al., 2020). In this study, Cox analysis results indicated that BMI and miR-483-5p were independently correlated with the occurrence of VTE in lung cancer patients. Additionally, ROC analysis results indicated that miR-483-5p has a high ability to differentiate between VTE patients and non-VTE patients. Thus, our study results demonstrated that miR-483-5p can be used as an independent predictor of VTE in lung cancer patients. Notably, aberrant miR-483-5p has been reported to be a biomarker for other diseases, such as adrenocortical cancer (Oreglia et al., 2020), coronary plaque rupture (Li et al., 2017), and esophageal squamous cell carcinoma (Xue et al., 2017).

Thus, serum miR-483-5p may function as an independent biomarker to predict the occurrence of VTE in lung cancer patients.

Considering that miR-483-5p and BMI were two independent risk factors for VTE occurrence and that they were significantly correlated, we analyzed the predictive value of miR-483-5p for VTE occurrence in three groups of patients with different BMI values. Notably, it has been found that BMI is an independent risk factor for VTE (Hotoleanu, 2020), and a study has demonstrated that miR-483-5p is significantly correlated with obesity and BMI (Gallo et al., 2018). The results of this study indicated that miR-483-5p had the highest ability in differentiating between VTE patients and non-VTE patients in the overweight group. Thus, in the group with high BMI values, referencing miR-483-5p levels would enable a more accurate screening of patients at high risk of VTE. Therefore, it can be speculated that miR-483-5p may be related to obesity and BMI, thereby participating in the occurrence and development of BMI-related diseases. In clinical practice, patients with higher BMI should pay more attention to their miR-483-5p levels, because patients with significantly increased miR-483-5p levels have a higher risk of developing VTE.

Further validation analyses are important, so we estimate the statistical power of the study due to the time limitation. A total of 170 lung cancer patients treated at our hospital were enrolled in this study, including 60 VTE patients and 110 non-VTE patients. Where an included sample has been identified, the statistical power has a high probability value of meeting the statistical data variation of VTE patients being different from non-VTE patients, suggesting that the included VTE patients indeed differ from non-VTE patients in a statistical sense and that the findings were reliable. However, there were some limitations. First, of the 170 lung cancer patients recruited who met the inclusion criteria, there were only 32 (18.82%) overweight lung cancer patients, including 18 (30.00%) overweight lung cancer patients who developed VTE after surgery, and 14 (12.73%) overweight lung cancer patients did not develop VTE after surgery. Whether it concerns the overall included lung cancer patients or the overweight lung cancer patients, the sample size of this study is small and further research is needed on a larger scale. Second, this study has not elucidated how miR-483-5p functions in VTE, and the mechanism is urgently needed to be explored by further experimental analysis. Previous studies have shown that miR-483-5p targeted RNA binding motif protein 5 (RBM5) (Wang et al., 2018) and proprotein convertase subtilisin/kexin type 9 (PCSK9) (Dong et al., 2020) and was involved in the disease progression. The results

of the present study revealed that miR-483-5p was increased in VTE patients and could independently predict VTE onset in lung cancer patients, eliciting a potential indirect link of VTE to RBM5 and PCSK9 via miR-483-5p. Therefore, we speculated that the mechanism might be that miR-483-5p was associated with VTE by targeting RBM5 or PCSK9. However, this speculation needs to be verified by further experimental analysis, which is also our next research direction.

In conclusion, the findings of this study indicate that miR-483-5p is higher in VTE patients than that in non-VTE patients, is associated with BMI in VTE patients, and can serve as an independent predictor of VTE in lung cancer patients. Additionally, miR-483-5p had the highest value in differentiating patients with and without VTE in patients with high BMI. Thus, miR-483-5p overexpression can independently predict VTE onset in patients with lung cancer, especially in patients with high BMI. This study may provide new targets and ideas for screening patients with high VTE risk among lung cancer patients.

ACTA ABP BIOCHIMICA POLONICA

A novel ferroptosis-related gene signature associated with cuproptosis for predicting overall survival in breast cancer patients

Xiaoyu Zhang[1] and Qunchen Zhang[2]✉

[1]Department of Thoracic Surgery, The First Affiliated Hospital of Shantou University Medical College, Shantou City, Guangdong Province, P.R. China; [2]Department of Breast, Jiangmen Central Hospital, Jiangmen City, Guangdong Province, P.R. China

Purpose Ferroptosis and cuproptosis are both metal-dependent regulated cell death that play an important role in cancer. However, the expression patterns and the prognostic values of ferroptosis-related genes (FRGs) associated with cuproptosis in breast cancer (BC) are largely unknown. This study aims to explore the prognostic value of cuproptosis-related FRGs and their relationship with tumor microenvironments in BC. **Methods** The clinical and RNA sequencing data of BC patients from TCGA, METABRIC and GEO databases were analyzed. The least absolute shrinkage and selection operator regression analysis was used to establish prognostic signatures based on cuproptosis-related FRGs. The overall survival between risk subgroups was assessed by Kaplan-Meier analysis. The changes in risk score during neoadjuvant chemotherapy, and differences in immune cells, immune checkpoints, and drug sensitivity between risk subgroups were also analyzed in this study. **Results** A successful development of a prognostic signature based on cuproptosis-related FRGs in the TCGA cohort was achieved and it was validated in the METABRIC cohort. Gene set enrichment analysis results revealed the enrichment of steroid biosynthesis and ABC transporters in the high-risk group. Moreover, the signature was also found to be associated with immune cells and immune checkpoints. Lower risk score in patients after neoadjuvant chemotherapy and higher sensitivity of the high-risk group to AKT inhibitor VIII and cisplatin was also observed. **Conclusion** Cuproptosis-related FRGs can be used as a novel prognostic signature for predicting the overall survival of BC patients. This can provide meaningful insights into the selection of immunotherapy and antitumor drugs for BC.

Keywords: breast cancer, ferroptosis, cuproptosis, immune microenvironment, prognosis

INTRODUCTION

Breast cancer (BC) is one of the most frequently diagnosed cancer in women worldwide, with an extremely high rate of mortality (Azamjah *et al.*, 2019). Its incidence and death rates have increased over recent years making it the second most common cause of mortality in women (DeSantis *et al.*, 2019). Its progressive impact on younger individuals is a cause of concern. Although the etiology and mechanism of BC are not completely understood, biological features including cell infiltration and genetic abnormalities are thought to be the major causes associated with the progression and metastasis of the disease (Feng *et al.*, 2018; Loibl *et al.*, 2021). Although there have been advancements in diagnosis, chemotherapy, endocrine and targeted therapies, the median survival in the case of advanced BC is only 31.8 months (Caswell-Jin *et al.*, 2018; Sung *et al.*, 2021). Early diagnosis and intervention are of paramount importance. Therefore, research on novel prognostic markers and therapeutic targets will provide improved opportunities for individualized treatment of BC.

Metals are essential components of metabolic processes. A significant portion of the proteases requires binding to metals, such as calcium, magnesium, iron, and copper for proper functioning (Waldron *et al.*, 2009). However, dysregulation of metal metabolism can lead to cell death. Ferroptosis, unlike apoptosis and autophagy, is an iron-dependent process of regulated cell death that is characterized by intracellular buildup of reactive oxygen species (ROS) and products of lipid peroxidation (Huang *et al.*, 2020). The primary mechanism of ferroptosis is the catalysis of the highly expressed unsaturated fatty acids on the cell membrane to produce liposome peroxidation, resulting in cell death, under the influence of divalent iron or ester oxygenase (Dixon *et al.*, 2012). Ferroptosis-related genes (FRGs) play an important role in the development of various cancers, including lung cancer, melanoma, renal cell carcinoma, BC, etc. (Friedmann Angeli *et al.*, 2019; Wang *et al.*, 2020; Zhao *et al.*, 2022). Activation of ferroptosis has been shown to prevent the growth and proliferation of tumors (Hassannia *et al.*, 2019). Therefore, ferroptosis can be a potential target for cancer therapy, especially in patients who have grown resistant to conventional forms of therapy (Hassannia *et al.*, 2019; Zhang *et al.*, 2022). For example, the sensitivity of triple-negative BC cells to gefitinib was enhanced by the inhibition of *GPX4* activation of Ferroptosis (Song *et al.*, 2020). Cuproptosis is a method of copper-induced regulated cell death. The direct interaction between copper ions and lipidated protein compo-

nents in the tricarboxylic acid cycle interferes with the iron-sulfur cluster proteins in the respiratory chain complex which ultimately leads to proteotoxic stress and cell death (Kahlson & Dixon, 2022). This could be another regulatory mechanism for the development of cancer (Jiang *et al.*, 2022). Iron-sulfur cluster proteins are able to maintain iron homeostasis in mitochondria (Pain & Dancis, 2016). Several mitochondrial proteins (including NFS1, ISCU, CISD1, and CISD2) require iron for iron-sulfur cluster biogenesis reactions for the negative regulation of ferroptosis (Yuan *et al.*, 2016; Alvarez *et al.*, 2017; Kim *et al.*, 2018; Du *et al.*, 2019). Moreover, elesclomol stimulates copper retention and the subsequent buildup of ROS via the degradation of ATP7A, which promotes ferroptosis in colorectal cancer cells (Gao *et al.*, 2021). Cuprizone, which is a copper chelator, regulates demyelination by the stimulation of ferroptosis and eventually leads to the loss of oligodendrocytes (Jhelum *et al.*, 2020). Therefore, an association between iron and copper metabolism has been well-established in scientific literature. These findings highlight the role of ferroptosis and cuproptosis as potential targets for the treatment of cancer.

In this study, a predictive model based on cuproptosis-related FRGs was built successfully to evaluate the prognosis of patients with BC and the predictive performance of the model was further validated. The findings of this study may enhance the effectiveness of individualized treatment and prognostic evaluations in patients with BC.

MATERIALS AND METHODS

Patient and gene set data collection

Clinical and RNA-sequencing data of 1097 BC patients were obtained from the cancer genome atlas (TCGA) database and 1053 patients containing complete clinical data including overall survival, age, gender, T stage, N stage, M stage, and TNM stage, were obtained after screening, while 44 patients who lacked complete clinical data were excluded. The intrinsic subtype was defined by PAM 50 (Parker *et al.*, 2009). Moreover, 1904 cases of RNA-sequencing and corresponding clinical data were obtained from the molecular taxonomy of breast cancer international consortium (METABRIC) database as the validation set for prognosis, and datasets GSE18728 and GSE87455 from gene expression omnibus (GEO) database were used to compare changes in risk score before and after neoadjuvant chemotherapy. Furthermore, 13 cuproptosis-related genes were obtained from the cuproptosis-related study (Tsvetkov *et al.*, 2022), and 259 FRGs were downloaded from the FerrDb website (Zhou & Bao, 2020).

Identification and prognosis of cuproptosis-related FRGs

The correlation between the expression of cuproptosis-related genes and FRGs was determined using the Pearson correlation coefficients. The criteria used to identify cuproptosis-related FRGs was of P value <0.001 and the absolute value of the Pearson correlation coefficient >0.3($|R|>0.3$). The univariate Cox regression analysis was used to screen the prognosis-related genes.

Building and validation of a prognostic model

Based on the outcome of univariate Cox regression analysis, the least absolute shrinkage and selection opera-

tor (LASSO) regression method was used for the identification of the best survival-related genes via glmnet R package (Tibshirani, 1997; Wang & Liu, 2020). The prognostic risk score formula was created using the coefficients obtained from LASSO regression and the expression levels of genes. The formula can be mathematically represented as: Risk Score = $\sum$ corresponding regression coefficient * expression of the gene. The risk scores of the patients with BC were determined and the patients were grouped into two groups: the high-risk group and the low-risk group using the median risk score as the cutoff. The Kaplan-Meier survival analysis was used to demonstrate the presence of survival differences between the two groups. A receiver operator characteristic (ROC) curve via survivalROC R package was constructed to evaluate the effectiveness of the prognostic model and the METABRIC cohort was used for further validation.

Establishment of a nomogram based on risk score and clinical characteristics

Univariate and multivariate COX regression analyses were used for the evaluation of risk scores and clinical characteristics as independent prognostic factors. A nomogram based on risk score and clinical characteristics was established to predict the probability of 3-, 5- and 10-year overall survival (OS) for patients with BC, and the performance of the nomogram was assessed by calibration curves.

Functional enrichment analysis, protein-protein interaction (PPI), and gene set enrichment analysis (GSEA)

The Gene Ontology (GO) analysis was carried out for the identification of biological activities, molecular mechanisms, and cellular components via clusterprofiler R package. Additionally, the signaling pathways were observed using the Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. Cuproptosis-related FRGs were submitted to the STRING database (http://www.string-db.org/) for obtaining insights into PPI. The Cytoscape program was used to build and render PPI networks. Using the MCODE plug-in, the most important modules were selected based on MCODE score >5. GSEA was carried out to investigate potential enrichment pathways in the high- and low-risk groups. P value <0.05 was considered statistically significant.

Immune cell analysis

Different algorithms including CIBERSORT (Newman *et al.*, 2015), CIBERSORT-ABS, EPIC (Racle *et al.*, 2017), MCP-counter (Becht *et al.*, 2016), QUAN-TISEQ (Finotello *et al.*, 2019), TIMER (Li *et al.*, 2017), and XCELL (Aran *et al.*, 2017) were compared to assess the level of immune cell infiltration between the high- and low-risk groups. The correlation between immune cells and cuproptosis-related FRGs was identified by using the TIMER database. Potential immune checkpoints were obtained from scientific literature and differences in expression in immune checkpoints among high- and low-risk groups were explored using the ggpubr and limma packages.

Drug sensitivity analysis

To compare the difference in drug sensitivity between the two groups, the half-maximal inhibitory concentration (IC50) of drugs was assessed by the pRRophetic

Figure.1 Flow chart of this study.

Figure 2. Identification of prognostic cuproptosis-related FRGs. FRGs, ferroptosis-related genes.

package. *P* value <0.05 was considered statistically significant.

Statistics analysis

Statistical analysis was performed using R version 4.2.1. The Wilcoxon test was used to compare expression differences between the two groups. *P* value <0.05 was considered to be a statistically significant difference.

RESULTS

Identification of cuproptosis-related FRGs and their prognostic value in the TCGA cohort

The design of the study has been depicted using the flowchart (Fig. 1). A total of 125 FRGs were confirmed to be correlated with cuproptosis-related genes in the TCGA dataset (Supplementary Fig. S1 at https://ojs.ptbioch.edu.pl/index.php/abp/). Univariate Cox regression analysis was used to explore the prognostic value of these cuproptosis-related FRGs, and the results revealed that 15 genes had prognostic value (Fig. 2).

Establishment and validation of cuproptosis-related FRG signature

Based on the 15 cuproptosis-related FRGs of prognostic value described above, LASSO Cox regression analysis was performed at the minimum λ value to create a risk model consisting of 11 genes (Supplementary Fig. S2 at https://ojs.ptbioch.edu.pl/index.php/abp/). The risk score for each patient was calculated using the following formula:

Risk Score = 0.187 * *ANO6* + 0.099 * *CHAC1* + (−0.075) * *CHMP6* + 0.115 * *CS* + 0.305 * *EMC2* + 0.195 * *G6PD* + (−0.024) * *GPX4* + 0.178 * *PANX1* + 0.055 * *PIK3CA* + 0.048 * *SLC7A5* + (−0.197) * *SOCS1*.

Patients with BC were divided into the high-risk group (n=526) and the low-risk group (n=527) based on the median risk score. Overall survival was significantly shorter in the high-risk group than in the low-risk group (*P*<0.001), suggesting a negative correlation between risk

score and prognosis (Fig. 3A). Time-dependent ROC curve analysis verified the accuracy of the prognostic signature of patients with BC, with AUCs reaching 0.669 for 3 years, 0.643 for 5 years, and 0.711 for 10 years (Fig. 3B).

To verify the stability of the cuproptosis-related FRG signature, risk scores were calculated for patients in the METABRIC cohort by using the risk score formula ob-

tained from the TCGA cohort. K-M survival analysis revealed a poor prognosis in the high-risk group (Fig. 4A, $P<0.001$). The result obtained was consistent with the TCGA dataset. The time-dependent ROC curves showed AUCs of 0.587 at 3 years, 0.596 at 5 years, and 0.559 at 10 years (Fig. 4B).

The signature based on cuproptosis-related FRGs was an independent indicator of BC prognosis

For further assessment of the independent prognostic value of cuproptosis-related FRG signature, univariate and multivariate Cox regression analyses of clinical characteristics, including age, gender, and TNM stage were performed. Univariate analysis revealed that higher risk scores, T stage, N stage, and M stage were significantly associated with adverse OS in patients with BC (Fig. 5A), and negative estrogen receptor (ER) and progesterone receptor (PR) were suggestive of poor prognosis. The risk score, age, N stage, and M stage were shown to be independent risk factors for OS in the multivariate Cox analysis (Fig. 5B). Therefore, the cuproptosis-related FRG signature was an independent prognostic indicator for patients with BC.

Association between the risk score and clinical characteristics

For the assessment of the impact of cuproptosis-related FRG signature in the development and progression of BC, the association between risk score and clinical characteristics was explored. Chi-square test analysis revealed significant differences between risk groups in T stage, N stage, TNM stage, PR, ER, human epidermal growth factor receptor (HER-2), and intrinsic subtype (Fig. 6). In addition, HER-2-enriched, ER-negative, PR-negative, HER-2-positive, higher N stage, and TNM stage indicated a higher risk score (Fig. 7). Stratified analysis was carried out for the identification of the prognostic value of the cuproptosis-related FRG signature in subgroups. The results revealed that this signature had significant prognostic efficacy in age ≤ 65 ($P=0.001$), age >65 ($P=0.009$), female ($P<0.001$), T1 stage ($P=0.011$), T2-T4 stage ($P=0.001$), N0 stage ($P<0.001$), N1-N3 stage ($P=0.018$), M0 stage ($P<0.001$), stage I ($P=0.047$) and II-IV ($P<0.001$). However, no significant prognostic value was observed in the male patients and the M1 stages ($P>0.05$) (Fig. 8).

Figure 5. Cuproptosis-related FRG signature was shown to be an independent risk factor for OS in TCGA.
(**A**) Univariate Cox regression analysis between OS and various prognostic parameters. (**B**) Multivariate Cox regression analysis between OS and various prognostic parameters. FRG, ferroptosis-related gene; OS, overall survival; TCGA, the cancer genome atlas.

Establishment of nomogram

A nomogram was constructed using risk score and clinical characteristics, including age, T stage, N stage, and M stage (Fig. 9A). The nomogram predicted the survival of BC patients at 3, 5, and 10 years. The calibration curves further validated the consistency of the actual OS of the patients with the predictions of the nomogram (Fig. 9B).

Functional enrichment and PPI of cuproptosis-related FRGs

The potential biological functions involved in 125 cuproptosis-related FRGs were analyzed using the GO and KEGG databases. GO analysis revealed the association of FRGs with biological processes like response to oxidative stress, cellular response to chemical stress, and response to nutrient levels (Supplementary Fig. S3A at https://ojs.ptbioch.edu.pl/index.php/abp/). In addition, in the KEGG pathway, the results revealed the involvement of FRGs in lipid and atherosclerosis, autophagy, FoxO signaling pathway, central carbon metabolism in cancer, and ferroptosis (Supplementary Fig. S3B at https://ojs.ptbioch.edu.pl/index.php/abp/). STRING database revealed that the PPI network of cuproptosis-related FRGs consisted of 125 nodes and 276 edges (Supplementary Fig. S3C at https://ojs.ptbioch.edu.pl/index.php/abp/). The most significant module consisted of 11 cuproptosis-related FRGs, including 11 nodes and 66 edges.

GSEA

GSEA was used to further explore the potential mechanisms of cuproptosis-related FRG signature. The results revealed the enrichment of steroid biosynthesis, ABC transporters, base excision repair, glycosaminoglycan biosynthesis, other glycan degradation, and protein export in the high-risk group (Supplementary Fig. S3D at https://ojs.ptbioch.edu.pl/index.php/abp/). In contrast, ascorbate and aldarate metabolism, olfactory transduction, pentose and glucuronate interconversions, and systemic lupus erythematosus were mainly enriched in the low-risk group (Supplementary Fig. S3E at https://ojs.ptbioch.edu.pl/index.php/abp/).

Immune infiltration level of cuproptosis-related FRG signature

The heatmap depicted the relationship between the cuproptosis-related FRG signature and immune cell subgroups according to the analysis of CIBERSORT, CIBERSORT-ABS, EPIC, MCP-counter, QUANTISEQ, TIMER, and XCELL algorithms (Fig. 10). The CIBERSORT result showed a higher proportion of CD4+ memory T cells, resting NK cells, M0 macrophages, M1 macrophages, M2 macrophages, eosinophils, and neutrophils in the high-risk group, whereas the low-risk group had higher proportions of memory B cells, CD8+ T cells, T follicular helper cells, Tregs, activated NK cells, monocytes, myeloid dendritic cells, activated mast cells, and resting mast cells (Supplementary Fig. S4 at https://ojs.ptbioch.edu.pl/index.php/abp/). In addition, the TIMER database was used to analyze the correlation between each FRG and immune cells. *ANO6*, *CS*, *EMC2*, *PANX1*, and *PIK3CA* were found to be positively correlated with multiple immune cells such as CD8+ T cells, macrophages, neutrophils, and dendritic cells. *CHAC1*, *SLC7A5*, and *SOCS1* were positively correlated with B cells, neutrophils, and dendritic cells. *CHMP6* was nega-

Figure 8. Kaplan-Meier curves of OS differences between high- and low-risk groups stratified by age, gender, T stage, N stage, M stage or TNM stage. OS, overall survival.

tively correlated with CD8+ T cells while positively correlated with CD4+ T cells. *GPX4* was negatively correlated with B cells, CD8+ T cells, macrophage, neutrophil, and dendritic cells. *G6PD* was positively correlated with B cells (Supplementary Fig. S5-6 at https://ojs.ptbioch.edu.pl/index.php/abp/).

Due to the importance of immunotherapy, the differences in immune checkpoints between risk score subgroups were analyzed. The results indicated higher expression of most immune checkpoints including *PDCD1*, *LAG3*, etc. in the low-risk group, suggesting a greater benefit of immune checkpoint suppression therapy in low-risk patients. The high expression of *CD80*, *PD-L2*, and *TNFSF4* in the high-risk group can aid in guiding the study for the optimization of immune checkpoint inhibitors (Fig. 11).

Neoadjuvant chemotherapy and drug sensitivity analysis

To investigate whether the risk score of tumors changes during neoadjuvant chemotherapy. We used two chemotherapy BC cohorts. A significant reduction in risk score was observed in patients treated with docetaxel and capecitabine by comparing paired patients from GSE18728 (Fig. 12A). In the GSE87455 cohort treated

with epirubicin and docetaxel, 69 paired patients who received two cycles of treatment had significantly lower risk score than before treatment (Fig. 12B). Meanwhile, 57 paired patients who received six cycles of treatment had significantly lower risk score than before treatment (Fig. 12C). To further optimize chemotherapy in patients with BC, potential antitumor drugs were screened to compare the differences in drug sensitivity between the high- and low-risk groups. The results of sensitivity analysis showed that the IC50 values of drugs including AUY922, docetaxel, etoposide, imatinib, mitomycin C, paclitaxel, and SL 0101-1 were significantly reduced in the low-risk group, suggesting a higher sensitivity of the patients in the low-risk group to these drugs (Fig. 13A-G). Patients in the high-risk group were found to be more sensitive to AKT inhibitor VIII and cisplatin (Fig. 13H-I).

DISCUSSION

With the development of molecular diagnostic studies, medical professionals are increasingly resorting to the clinical practice of molecular diagnostics in BC, such as Oncotype dX and MammaPrint (Li *et al.*, 2017; Barzaman *et al.*, 2020). BC is a systemic disease and has

evolved from the conventional surgical treatment to the current combination therapy including radiotherapy, chemotherapy, hormonal therapy, and biological therapy (Ben-Dror *et al.*, 2022). Patients with BC may have to choose among different options for postoperative systemic therapy. Therefore, it is imperative to find more effective biomarkers to adapt adjuvant therapies to individualize treatment for patients.

To the best of our knowledge, this is the first study to explore the correlation between FRGs and cuproptosis-related genes in patients with BC. Unlike other regulatory cell death processes, cuproptosis is primarily associated with adiposity of the tricarboxylic acid cycle and in-

Figure 10. Analysis of immune cells between high- and low-risk groups.
* for *P*<0.05; ** for *P*<0.01; *** for *P*<0.001.

volves the loss of iron-sulfur cluster proteins and induction of ROS (Li *et al.*, 2022; Tsvetkov *et al.*, 2022). Gao and others (Gao *et al.*, 2021) reported the accumulation of ROS due to copper retention, which inhibited the *SLC7A11* levels, thereby enhancing oxidative stress and ferroptotic cell death in colorectal cancer. Thus, FRGs

may cause regulated cell death through the cuproptosis-related mechanism.

In this study, the relationship between 259 FRGs and 13 cuproptosis-related genes in BC was comprehensively evaluated and screened for cuproptosis-related FRGs. The relationship between cuproptosis-related FRGs and OS in BC was analyzed and a novel prognostic model containing 11 cuproptosis-related FRGs was constructed. The accuracy of the model was verified by the ME-TABRIC cohort. Survival and ROC analyses revealed a good predictive ability of the model. Univariate and multivariate Cox analysis established the risk score of cuproptosis-related FRG signature to be an independent prognostic indicator for BC. The risk score was further found to be correlated with immune infiltrating cells and the expression of immune checkpoints between risk subgroups was analyzed. Finally, two neoadjuvant chemotherapy cohorts were used to show that the risk score was significantly reduced over the course of treatment, and nine antitumor drugs were screened for the treatment of patients with BC in different risk subgroups.

A significant difference between cuproptosis-related FRG signature and the clinical stage was observed, suggesting that higher risk scores were concentrated in more advanced tumor stages, ER-negative, PR-negative, and HER-2-positive, which further validates the poorer prognosis in the high-risk group. Meanwhile, the prognosis of cuproptosis-related FRG signature was confirmed in different subgroups with different clinical characteristics, except for male patients and patients with distant metastases, which could be because of the small sample size in these two subgroups. Therefore, the proposed model has demonstrated generalizability in different strata of patients with BC.

The cuproptosis-related FRG signature included *ANO6*, *CHAC1*, *CHMP6*, *CS*, *EMC2*, *G6PD*, *GPX4*, *PANX1*, *PIK3CA*, *SLC7A5*, and *SOCS1*. These genes included ferroptosis driver genes (*ANO6*, *CHAC1*, *CS*, *EMC2*, *G6PD*, *PANX1*, and *PIK3CA*) and ferroptosis suppressor genes (*CHMP6*, *PGX4*, and *SOCS1*). Currently, SLC7A5 is an unclassified regulator whose role in ferroptosis is unclear. There is growing evidence of the involvement of *ANO6* in multiple forms of cell death, including necroptosis, pyroptosis, and ferroptosis (Ousingsawat *et al.*, 2017; Ousingsawat *et al.*, 2018; Simões *et al.*, 2018). As a non-selective Ca^{2+}-activated ion channel, lipid scramblase *ANO6* plays a critical role in the induction of ferroptotic cell death by disrupting the stability of membrane phospholipids (Ousingsawat *et al.*, 2019). Chen et al. reported that *CHAC1* contributes to cystine starvation and thereby induces ferroptotic cell death in triple-negative BC cells via the GCN2-eIF2α-ATF4 pathway (Chen *et al.*, 2017). Overexpression of CHAC1 has been linked to the enhanced sensitivity of prostate cancer cells to docetaxel, but the effect was reversed after co-treatment with ferroptosis inhibitors, suggesting that *CHAC1* functions as a potential therapeutic target for castration-resistant prostate cancer by inducing ferroptotic cell death (He *et al.*, 2021). Ferroptosis activators such as erastin and RSL3 increased *CHMP6* accumulation by triggering calcium influx. Silencing of *CHMP6* expression sensitized cancer cells to lipid peroxidation-mediated ferroptosis but did not affect iron accumulation (Dai *et al.*, 2020). *CS* increased the accumulation of citrate in hypoxic triple-negative BC cells, which promoted the migration and invasion of cancer cells (Peng *et al.*, 2019). The overexpression of *G6PD* suggests a poor prognosis in hepatocellular carcinoma and inhibits ferroptotic cell death of the tumor by targeting cytochrome

oxidoreductase (Cao *et al.*, 2021). Luo et al. reported the resistance of *G6PD* for doxorubicin-induced apoptosis in triple-negative BC cells by the maintenance of high glutathione levels (Luo *et al.*, 2022). Genetic models were used for the identification of *GPX4* as a key regulator of ferroptosis and that inhibition of GPX4-induced ferroptosis enhanced the sensitivity of triple-negative BC cells to gefitinib (Seibt *et al.*, 2019; Song *et al.*, 2020). A recent study reported that high expression of *PANX1* induced local immunosuppression in tumor microenvironment of basal-like BC, as evidenced by high infiltration levels of neutrophils and adenosine production (Chen *et al.*, 2022). *SLC7A5* supported the proliferation and growth of tumor cells by increasing mTORC1 activity through the upregulation of regulatory transcription factors under hypoxic conditions (Nachef *et al.*, 2021). In addition, *SLC7A5* inhibitors were used to treat patients with advanced biliary tract cancer such that no disease progression occurred for two years (Hayes *et al.*, 2015). *SOCS1* sensitizes cells to ferroptosis by the activation of p53 target gene expression and glutathione level reduction (Saint-Germain *et al.*, 2017).

The results of GO analysis and KEGG pathway analysis revealed the relation of 125 cuproptosis-related FRGs to certain biological functions or pathways, such as response to oxidative stress, cellular response to chemical stress, autophagy, FoxO signaling pathway, and central carbon metabolism in cancer. Therefore, lipid peroxidation, a key to the induction of ferroptosis, is mediated by oxidative and antioxidant systems, along with autophagy (Chen *et al.*, 2021).

Tumor-associated macrophages have been shown to promote tumor invasion in BC by promoting angiogenesis and remodeling the tumor extracellular matrix while evading the host immune response and suppressing the antitumor effects of cytotoxic T cells (Choi *et al.*, 2018; Mehta *et al.*, 2021). The results of this study revealed higher levels of macrophage infiltration in the high-risk group, accrediting the poor prognosis in the high-risk group to the immunosuppression of the tumor microenvironment. It was also found that patients in the low-risk group had a higher likelihood of benefitting from immunotherapy, while patients in the high-risk group may be more sensitive to immunosuppressive agents targeting *CD80*, *PD-L2*, and *TNFSF4*. Risk score was found to become lower after treatment through the neoadjuvant cohort, which may suggest a remission of the tumor. Finally, the sensitivity of high- and low-risk groups to different antitumor drugs was explored and results revealed that patients in the high-risk group were more sensitive to AKT inhibitor VIII and cisplatin. The results obtained from this study combined with the data available in the literature will aid the facilitation of the optimization of chemotherapy regimens for patients with BC.

However, the objects of this study were from public databases, and clinical data is essential for further validation. Although 125 cuproptosis-related FRGs have been identified, the correlation between FRGs and cuproptosis-related genes was not established. Finally, subgroup-related pathways, immune infiltration, and drug sensitivity require further experimental validation.

Circ-PGPEP1 augments renal cell carcinoma proliferation, Warburg effect, and distant metastasis

PeiRui Wang[1#], Jin Chen[2#], Xin Ye[3], RuYi Wang[4], Lin Chen[4] and HanChao Zhang[4✉]

[1]Department of Urology, Affiliated Hospital of Zunyi Medical University, Zunyi City, Guizhou Province, 563000, China; [2]Department of Pediatric Surgery, Affiliated Hospital of Zunyi Medical University, Zunyi City, Guizhou Province, 563000, China; [3]Department of Urology, Institute of Urology, West China Hospital of Sichuan University, Chengdu City, Sichuan Province, 610000, China; [4]Department of Urology, Affiliated Hospital and Clinical Medical College of Chengdu University, Chengdu City, Sichuan Province, 610081, China

Circular RNAs (circRNAs) contribute to the malignant phenotype and progression of several types of human cancers, including renal cell carcinoma (RCC). This study probed the molecular mechanism of circPGPEP1 regulating RCC proliferation, Warburg effect, and distant metastasis by targeting the miR-378a-3p/JPT1 axis. Here identified higher circPGPEP1 expression in RCC tissues and cells by RT-qPCR, and high levels of circPGPEP1 were positively correlated with high histological grade and distant metastasis in RCC patients. Furthermore, patients with high levels of circPGPEP1 had a worse survival prognosis. Functional assays presented that knockdown of circPGPEP1 inhibited RCC proliferation, invasion, migration, EMT, and Warburg effect. Dual-luciferase reporter assay, RNA immunoprecipitation, nucleoplasmic RNA isolation, and functional rescue experiments confirmed that circPGPEP1 induced JPT1 expression by sponging miR-378a-3p, thereby promoting RCC malignant phenotype. Xenograft assays and metastasis models further demonstrated that down-regulation of circPGPEP1 effectively inhibited tumor growth and distant metastasis of RCC. Taken together, circPGPEP1, a prognostic circRNA in RCC, acts through the miR-378a-3p/JPT1 axis to regulate RCC progression.

INTRODUCTION

Renal cell carcinoma (RCC) is the second leading cause of death in patients with urinary system tumors, accounting for about 3% of all adult malignant tumors (Scelo & Larose, 2018). Although partial and radical nephrectomy is the most effective treatment for early or localized RCC, approximately one-third of RCC patients are primarily diagnosed with advanced disease, and despite aggressive treatment, RCC at this stage has a low overall survival rate (Li *et al.*, 2020). In addition, recurrence and metastasis occur in approximately 30% of RCC patients (Choueiri & Motzer, 2017; Lara & Evans, 2019). RCC proliferation is a complex network involving

multiple carcinogens and diverse genetic backgrounds, resulting in alterations in tumor suppressors or oncogenes (Moch *et al.*, 2014). There is a need to identify molecular mechanisms of RCC progression.

Circular RNAs (circRNAs) can be formed through back splicing events, in which upstream splice acceptor sites join with downstream splice donor sites, resulting in exon circularization (Yu *et al.*, 2020; Zhang *et al.*, 2014). Due to the stability and abundance of circRNAs, an increasing number of circRNAs have been identified to be aberrantly expressed in RCC (Zhou *et al.*, 2022). Mechanistically, these circRNAs act as sponges for microRNAs (miRNAs), thereby protecting downstream mRNAs from miRNAs-mediated degradation (Han *et al.*, 2018). For example, circ_0005875 knockdown suppresses RCC progression by regulating the miR-502-5p/ETS1 axis (Luo *et al.*, 2022). circNUP98, a potential biomarker, acts as an oncogene in RCC through the miR-567/PRDX3 axis (Yu *et al.*, 2020). circ_PGPEP1 is a sponge for miR-1297 and is involved in gastric carcinogenesis (Wang *et al.*, 2021). However, the role and mechanism of circPGPEP1 in RCC development remain to be explored.

Most malignancies are characterized by the Warburg effect (aerobic glycolysis), a unique mode of cellular metabolism in cancer cells that exhibits increased rates of glucose uptake and lactic acid fermentation in an aerobic environment (Cao *et al.*, 2020). Warburg effect has been intensively studied in the cellular progression of cancer cells over the past decade (Liberti & Locasale, 2016). circRNAs have been identified that can modulate the Warburg effect in human cancers (Li *et al.*, 2021), such as circRNA-FOXP1 (Fang *et al.*, 2021) and circ_0091579 (Chen *et al.*, 2021).

This study focused on the biological role of circPGPEP1 in RCC progression, and the Warburg effect, in combination with the regulatory network of circPGPEP1/miR-378a-3p/JPT1 involved in RCC. Taken together, these findings may provide new insights into the treatment of RCC.

MATERIALS AND METHODS

Clinical samples

Specimens were RCC tissue and adjacent normal renal tissue (>5 cm from cancer tissue) collected by radical or partial nephrectomy from 48 cases of RCC patients (no radiation or chemotherapy or other tumors) between 2013 and 2015 at Affiliated Hospital and Clinical Medical College of Chengdu University. Histological features of the specimens were confirmed by 2 pathologists. Dis-

tant metastases of tumor cells were evaluated by examining the lungs, liver, bone, intestine, and pancreas of patients with RCC. Samples were rapidly frozen at -80°C after enucleation for subsequent studies. This work was approved by the Ethics Committee of Affiliated Hospital and Clinical Medical College of Chengdu University and all patients gave written informed consent.

RT-qPCR

Total RNA acquisition was done with TRIzol® Reagent (Invitrogen, Thermo Fisher Scientific). RNA reverse transcription was performed at 37°C for 60 min using M-MLV buffers, dNTP and random primers, and Moloney Mouse leukemia virus RT kits (all from Promega, USA). Next, on a Bio-Rad CFX96 system (BioRad), PCR was done with SYBR Green Real-time PCR Master Mix (Solarbio, Beijing, China). Relative gene expression was determined using the $2^{-\Delta\Delta ct}$ method. The primer sequences are listed in Table 1. GAPDH and U6 were used as endogenous controls for genes.

Table 1. Primers in PCR

	Primer sequence (5′-3′)
GAPDH	Forward: 5′-GGAGCGAGATCCCTCCAAAAT-3′
	Reverse: 5′-GGCTGTTGTCATACTTCTCATGG-3′
U6	Forward: 5′-CTCGCTTCGGCAGCACA-3′
	Reverse: 5′-AACGCTTCACGAATTTGCGT-3′
CircPEPGP1	Forward: 5′-GTCTCGAACTCCTGACCTCA -3′
	Reverse: 5′-CACGGTGTGTTCCCCAAAAG-3′
miR-378a-3p	Forward: 5′-CGCGACTGGACTTGGAGTC-3′
	Reverse: 5′-AGTGCAGGGTCCGAGGTATT-3′
JPT1	Forward: 5′-AAGAACAGGTTTCTCTCTGTCCT-3′
	Reverse: 5′-AGCTTTCCCTCCAATCTACTACT-3′

Cell culture

Human renal tubular epithelial cell line (HK-2) and human RCC cell lines (786-O, ACHN, Caki1, Caki2, and 769-P) were obtained from ATCC and maintained in RPMI 1640 medium containing 10% FBS (Gibco), penicillin (100 U/ml) and streptomycin (100 µg/ml).

RNase R and Actinomycin D treatment

Extracted RNA (2 µg) from ACHN cells was treated with 3 U/µg RNase R (Epicenter Technologies). For the RNA stability assay, RNA extracted from ACHN cells was incubated with actinomycin D (Sigma-Aldrich) at 5 µg/ml for the indicated times. circPGPEP1 RNA expression levels were detected by RT-qPCR.

Cell transfection

To overexpress circPGPEP1 and JPT1, the overexpression plasmids of circPGPEP1 and JPT1 were constructed using the pcDNA 3.1 vector (Green Seed Biotech). siRNAs targeting circPGPEP1 and JPT1 were synthesized by Genepharm, while mimic/inhibitor (oligonucleotides) of miRNA and negative control were by RiboBio. The transfection reagent was Lipofectamine 2000 (Invitrogen).

Colony formation assay

Cells were maintained in DMEM containing 10% FBS for 2 weeks and those fixed in methanol were dyed with 1% crystal violet and counted under a microscope (Olympus).

Proliferation assay

A certain amount of 5-ethynyl-2'-deoxyuridine (EdU) solution (RiboBio) was added to each well containing 1×10^4 cells and incubated for 2 h. After being fixed with 4% paraformaldehyde, cells were reacted with glycine, 0.5% Triton X-100, and Apollo reaction solution until Hoechst 33342 staining and imaging under a fluorescence microscope.

Glucose uptake and lactate production

Cellular glucose uptake was quantified by Glucose Uptake Colorimetric Assay Kit (BioVision) (Qin et al., 2021), while lactate concentration was by Lactate Assay Kit (K627, BioVision).

Extracellular acidification rate (ECAR)

ECAR (mpH/min) was determined by Seahorse Extracellular Flux Analyzer XF96 (Seahorse Bioscience) to reflect glycolytic activity in cells. 2×10^4 cells were grown overnight in 96-well plates and treated accordingly. Data were analyzed using Seahorse XF-96 Wave software.

Transwell

Cell migration and invasion were detected by transwell chambers with or without Matrigel (Corning Life Sciences, USA) (Zhu et al., 2021). First, cells were added to 100 ml serum-free medium and seeded into the upper chamber, then 500 ml of DMEM with 10% serum were seeded into the lower chamber. Cells attached to the lower surface were then fixed with 4% paraformaldehyde after 24 h of incubation. After crystal violet staining, the samples were observed under a microscope and analyzed statistically.

Western blot

RIPA Lysis Buffer was utilized for the lysis of cells or tissues. Total protein was extracted and analyzed by the bicinchoninic acid assay (BCA) method to determine the protein quantity. The samples separated by 10% SDS-polyacrylamide gel electrophoresis were loaded onto a polyvinylidene fluoride membrane which was then supplementary to primary antibodies and the secondary antibody. Followed by visualization using ECL reagents (Millipore), the bands were evaluated by Image-Pro Plus 6.0 software. JPT1 (ab126705, Abcam), E-cadherin (3195, Cell Signaling Technology), N-cadherin (ab18203, Abcam), Snail (ab53519, Abcam), Ki-67 (ab15580, Abcam), HK2 (ab209847, Abcam), PKM2 (4053, Cell Signaling Technology), GAPDH (ab8245, Abcam) were used in the assay.

Nucleoplasmic RNA isolation

A nucleoplasmic RNA purification kit (Norgen Biotek Corp) was adopted to locate circPGPEP1 in cells. Afterward, concentrations of nuclear and cytoplasmic circPGPEP1 RNA were determined by RT-qPCR.

Dual-luciferase reporter assay

The circPGPEP1 and JPT1 3' UTR wild-type sequences (circPGPEP1/JPT1-WT) and their corresponding mutant sequences (circPGPEP1/JPT1-MUT) containing the miR-378a-3p binding site were synthesized. These sequences were each subcloned into psiCHECK2 (Promega) for subsequent co-transfection in ACHN cells using Lipofectamine 2000. Relative luciferase activity was determined using a dual luciferase assay system (Promega).

RNA immunoprecipitation (RIP)

RIP assays were implemented using the EZ Magna RIP kit (Millipore). Cell lysates were mixed with anti-Ago2 or anti-IgG (Millipore) before protein A/G (Thermo Fisher Scientific)-conjugated magnetic beads were added. Before the RT-qPCR assay, RNA purification was done with proteinase K.

Nude mouse xenograft experiments

The animal experiments were carried out after obtaining the approval of the Animal Ethics Committee of the Affiliated Hospital and Clinical Medical College of Chengdu University. ACHN cells (3×10^6 cells) stably transfected with si-NC or si-circPGPEP1 were inoculated subcutaneously into the right upper back of BALB/c mice (female, 6-week-old; n=5/treatment). The width and length of the tumor were measured at an interval of 1 week to calculate tumor volume as (length×width^2)/2. Tumor weight was assessed when the tumor was excised after 5 weeks. Gene expression was analyzed by IHC (Wang, Deng, *et al.*, 2020) or Western blot.

ACHN cells (2.5×10^6) stably knocked down circPGPEP1 were injected into the tail vein of nude mice. Livers and lungs were excised 7 weeks later to carry out HE staining to assess the number of metastatic nodules (Liu *et al.*, 2020).

Data analysis

Statistical analysis was performed using GraphPad Prism 9.0. Data are presented as mean ± standard deviation (S.D.). Chi-square testing assessed the association of circPGPEP1 with clinicopathological features, while the Kaplan-Meier method evaluated that of circPGPEP1 with RCC patients' survival. Statistical analysis between two groups was performed by Student's *t*-test, and that of multiple groups was by one-way analysis of variance (ANOVA). All experiments were performed with at least three biological replicates. $P<0.05$ was considered statistically significant.

RESULTS

High circPGPEP1 level is associated with poor prognosis in RCC patients

To investigate whether circPGPEP1 has a biological function in RCC, circPGPEP1 expression in RCC tissues was evaluated by RT-qPCR. As measured, circPGPEP1 expression was up-regulated in patients' tumor tissues compared with normal tissues (Fig. 1A). circPGPEP1 in RCC cell lines was subsequently evaluated. The results showed that circPGPEP1 expression in the five RCC cell lines was higher than in HK-2 cells, and circPGPEP1 expression was the highest in ACHN cells (Fig. 1B).

In accordant with the bioinformatics website circbase, circPGPEP1 is located on chromosome 19p13.11 with a length of 557 bp (Fig. 1C). RNase R and actinomycin D treatment identified the ring structure of circPGPEP1. As reflected in Fig. 1D, E. RNase R and actinomycin D treatments decreased the expression and half-life of the linear RNA GAPDH mRNA, respectively, but not circPGPEP1.

Subsequently, RCC patients were divided into a high circPGPEP1 expression group and a low circPGPEP1 expression group according to the median expression of circPGPEP1 in RCC patients. The association of circPGPEP1 with clinicopathologic features in patients with RCC was evaluated. As listed in Table 2, high levels of circPGPEP1 were positively correlated with high histological grade and distant metastasis in RCC patients. The relationship between circPGPEP1 and survival outcomes in patients with RCC was evaluated by Kaplan-Meier. Patients with high levels of circPGPEP1 had a worse survival prognosis (Fig. 1F). Briefly, aberrant ex-

pression of circPGPEP1 is related to the malignant progression of RCC.

Knockdown of circPGPEP1 inhibits RCC cell proliferation, invasion, migration, EMT, and Warburg effect

Next, the biological function of circPGPEP1 in RCC cells was explored. CircPGPEP1-targeting siRNA was transfected into ACHN cells to knock down circPGPEP1 (Fig. 2A). The proliferation ability of cells was first evaluated by colony formation assay and EdU assay. The clonogenic ability of cells decreased and the ratio of EdU-positive cells decreased after the down-regulation of circPGPEP1 (Fig. 2B, C). The invasive and migratory abilities were subsequently assessed by Transwell, and it was found that knocking down circPGPEP1 reduced the number of cells invaded and migrated (Fig. 2D). Since EMT is a key process in the distant metastasis of cancer

cells, EMT-related proteins were evaluated by immunoblot. It was presented that knockdown of circPGPEP1 suppressed N-cadherin and Snail and promoted E-cadherin expression (Fig. 2E). Warburg effect is an important way for cancer cells to acquire capacity through aerobic glycolysis (Vaupel & Multhoff, 2021). Therefore, changes in the Warburg effect were observed in RCC cells after interfered with circPGPEP1. As reported in Fig. 2F–H, ECAR, glucose uptake, and lactate production were reduced after the knockdown of circPGPEP1

(Fig. 2F–H). The expression of proteins associated with aerobic glycolysis was then evaluated. Knockdown of circPGPEP1 inhibited the expression of HK2 and PKM2 proteins (Fig. 2I).

Competitive adsorption of miR-378a-3p by circPGPEP1

Our research focus was shifted to the downstream molecules of circPGPEP1. The subcellular localization of circPGPEP1 was first assessed, finding that circPG-

PEP1 was mainly localized in the cytoplasm of ACHN cells (Fig. 3A), which suggested that circPGPEP1 mediates gene expression mainly by targeting and adsorbing miRNAs. The bioinformatics website https://starbase.sysu.edu.cn predicted 10 miRNAs with potential binding sites for circPGPEP1, which were screened by RIP experiments to find that miR-378a-3p and circPGPEP1 were enriched in the Ago2 precipitation complex (Fig. 3B, C). Their targeting relationship was further examined by dual-luciferase, showing that when miR-378a-3p was overexpressed, the luciferase activity decreased in circPGPEP1 WT (Fig. 3D). Subsequently, the expression of miR-378a-3p in RCC was evaluated. Both RCC tissues and RCC cell lines expressed miR-378a-3p at a low level (Fig. 3E, F). Interestingly, miR-378a-3p expression was effectively restored in ACHN cells after knockdown of circPGPEP1 (Fig. 3G). These data suggest that circPGPEP1 binds to miR-378-3p in RCC and regulates miR-378a-3p expression.

miR-378a-3p contributes to a reversal of the effects of si-circPGPEP1 on RCC

miR-378a-3p inhibitor was simultaneously transfected in ACHN cells transfected with si-circPGPEP1 to determine whether circPGPEP1 affects RCC development by regulating miR-378a-3p. The promoting effect of si-circPGPEP1 on miR-378a-3p expression was restrained by miR-378a-3p inhibitor (Fig. 4A). Furthermore, functional experiments observed that the preventive effects of si-circPGPEP1 on ACHN cell proliferation, invasion and migration, EMT, and aerobic glycolysis were all blocked after co-transfection of miR-378a-3p inhibitor (Fig. 4B–I). These data suggest that circPGPEP1 affects the biological behavior of RCC by regulating the expression of miR-378a-3p.

miR-378a-3p targets JPT1 expression

Next, the downstream target genes of miR-378a-3p were explored. The bioinformatics website https://starbase.sysu.edu.cn found 10 mRNAs with potential binding sites for miR-378a-3p. Among them, JPT1 was found to be significantly enriched with miR-378a-3p in the Ago2 precipitation complex in ACHN cells (Fig. 5A, B). Dual

luciferase reporter experiments showed that co-transfection of JPT1 WT with miR-378a-3p mimic mediated a decrease in the luciferase activity (Fig. 5C). Subsequently, the expression of JPT1 in RCC was explored by immunoblot. JPT1 protein expression was higher in RCC tissues and cells than in normal tissues or cells (Fig. 5D, E). In addition, decreased or increased expression of JPT1 was detected in ACHN cells overexpressing or knocking down miR-378a-3p, respectively (Fig. 5F). These data suggest that targeting miR-378a-3p regulates JPT1 expression.

circPGPEP1 affects RCC progression via miR-378a-3p/JPT1 axis

To test the conjecture that circPGPEP1 affects RCC progression by miR-378a-3p/JPT1 axis, si-JPT1 was introduced in ACHN cells overexpressing circPGPEP1. Overexpressing circPGPEP1 promoted circPGPEP1 and JPT1 levels and inhibited miR-378a-3p expression. si-JPT1 decreased JPT1, but did not affect circPGPEP1 and miR-378a-3p levels (Fig. 6A, B). Furthermore, circPGPEP1 overexpression increased cell colony-forming ability and EdU-positive cell rate but knocking down JPT1 prevents these changes (Fig. 6C, D). Transwell assay and immunoblot showed that circPGPEP1 overexpression increased the number of invasive and migratory cells and N-cadherin and Snail protein expression, but JPT1 knockdown reversed these phenomena (Fig. 6E, F). Furthermore, the stimulative effect of circPGPEP1 overexpression on aerobic glycolysis was impeded by knocking down JPT1 (Fig. 6G–J). These data suggest that circPGPEP1 promotes RCC proliferation, invasion, migration, EMT, and Warburg effect by regulating the miR-378a-3p/JPT1 axis.

circPGPEP1 promotes RCC tumor growth and distant metastasis in vivo

In vivo experiments were included to further support the above in vitro results. Tumor growth and distant metastasis were assessed by subcutaneous inoculation or tail vein injection of ACHN cells stably knocking down circPGPEP1 into nude mice. Depleting circPGPEP1 suppressed tumor volume and weight (Fig. 7A–C).

IHC staining showed that knockdown of circPGPEP1 inhibited JPT1 and Ki-67 positive cell ratio in tumors (Fig. 7D). Immunoblot found that depleting circPG-PEP1 reduced N-cadherin, Snail, HK2, and PKM2 protein levels, and elevated E-cadherin protein levels (Fig. 7E). HE staining exhibited that silencing circPG-PEP1 reduced the number of lung and liver metastatic nodules (Fig. 7F). These data suggest that down-regulating circPGPEP1 effectively inhibits tumor growth and distal metastasis of RCC.

DISCUSSION

RCC is a malignancy in the urinary system that has a poor prognosis despite improved treatments (15). The plight of RCC treatment makes it necessary to further explore its mechanism and find effective RCC therapeutic targets. Recently, circRNAs have been intensively studied as a promising direction for gene-targeted therapy (Wang et al., 2020). In line with this, the circPG-PEP1-oriented mechanism in RCC was probed through miR-378a-3p/JPT1.

CircPGPEP1 was stably and highly expressed in human RCC tissues and cells, and high levels of circPG-PEP1 were associated with poor clinicopathological features and prognosis in RCC patients. Recently, a large number of studies have proposed that circRNAs are involved in the malignant progression in RCC, such as circNUP98 (Yu et al., 2020), Circ_0005875 (Luo et al., 2022), Circ-EGLN3 (Zhang et al., 2021), etc., which are highly expressed in RCC cells and are closely related to the growth and metastasis of RCC. Wang et al., disclosed that circPGPEP1 silencing hampers pro-apoptosis, migration, and invasion of cancer cells, and reduces tumor growth in vivo (Wang et al., 2021). In the present study, circPGPEP1 silencing led to a reduction of cell proliferation, invasion, and migration in RCC cells. Influences of circPGPEP1 on EMT-related proteins were studied since EMT is a key process in the distant metastasis of cancer cells (Piva et al., 2016), which showed that circPGPEP1 silencing inhibited EMT progression. Tumor cells obtain energy through the Warburg effect to maintain tumor development (Liberti and Locasale 2016) and circRNAs enable themselves to mediate the Warburg effect in RCC (Li et al., 2021). Here, our study confirmed that down-regulated circPGPEP1 inhibited the Warburg effect in RCC cells. Additionally, inhibiting circPGPEP1 could effectively inhibit the tumor growth and distant metastasis of RCC, further reflecting the tumor-promoting action of circPGPEP1 in RCC. Recently, it has been gradually discovered that circRNAs in exosomes act in intercellular communication, tumor immune response, tumor cell migration, and invasion (Liu et al., 2021). Therefore, RCC cell exosomes can be a study target in subsequent studies.

CircRNAs have been widely demonstrated to act as ceRNAs to counteract the effects of miRNAs (Jorgensen and Ro 2022). Accumulated miRNAs have conferred regulatory influences on RCC metastasis, implicated in a variety of cellular processes, including proliferation, migration, invasion, EMT, and Warburg effect (Abozed et al., 2017). It is known that miR-378a-3p expresses differentially in cancers, including hepatocellular carcinoma (Li et al., 2022), prostate cancer (Cannistraci et al., 2022), breast cancer (Niu et al., 2021), etc. Notably, miR-378a-5p is considered a tumor suppressor in RCC and correlates with a good prognosis for patients (Pan et al., 2019). The present study focused on miR-378a-3p and

revealed that miR-378a-3p was down-regulated in RCC. miR-376a-3p could be targeted and regulated by circR-NA and then involved in cancer progression (Mao et al., 2020). More importantly, the present study confirmed that circPGPEP1 mainly mediates gene expression by absorbing miRNAs, and circPGPEP1 affects RCC development by regulating miR-378a-3p. In detail, the preventive influences of silencing circPGPEP1 on RCC cells were all hampered when miR-378a-3p was inhibited.

miRNAs are widely involved in cancer promotion and repression by regulating cancer-related genes (Abozed et al., 2017). JPT1 is a ~16 kDa protein (Q9UK76, uniprot. org) that was originally identified as an abundant transcript in mouse hematopoietic and brain cells (Bateman et al., 2020; Tang et al., 1997). Notably, JPT1 is abnormally high expressed in cancers. For example, JPT1 expression is 3 times higher in ovarian cancer cells than in normal ovarian epithelial cells (Lu et al., 2004). In glioma, lowering JPT1 reduces tumor growth (Laughlin et al., 2009). In addition, JPT1 can interact with STMN1 to promote the growth and metastasis of thyroid anaplastic carcinoma (Pan et al., 2021). Likewise, the present study noted that JPT1 was upregulated in RCC and JPT1 acted as an oncogene in RCC. Knockdown of JPT1 reversed the promotion effect of circPGPEP1 overexpression on proliferation, invasion, migration, EMT, and glycolysis of RCC cells. This suggests that circPGPEP1 plays a role in promoting cancer by up-regulating JPT1 expression.

Although the circPGPEP1/miR-378a-3p/JPT1 axis-related mechanism in RCC progression has been partially elucidated, further investigation is still required. For example, it is necessary to further determine circPGPEP1 pattern in the serum of RCC patients and to determine the potential of circEHD2 as a diagnostic biomarker for RCC. Furthermore, the downstream pathways of JPT1 in RCC cell progression need to be further elucidated.

CONCLUSION

Our findings suggest that circPGPEP1 is an "oncogene" in RCC. Highly circPGPEP1 promotes cell proliferation and metastasis through miR-378a-3p-mediated JPT1. Our findings not only explain the mechanism of circPGPEP1 in regulating RCC cell progression but also provide potential therapeutic targets for RCC.

Circular RNA sirtuin-1 restrains the malignant phenotype of non-small cell lung cancer cells *via* the microRNA-510-5p/SMAD family member 7 axis

ZiRan Zhao[1#], HongYan Zhang[2#], Fan Zhang[1], Ying Ji[1], Yue Peng[1], Fei Wang[3] and Liang Zhao[1✉]

[1]Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, People's Republic of China, BeiJing, 100021, China; [2]Department of Oncology, The Third Medical Center of PLA General Hospital, BeiJing, 100143, China; [3]Department of Oncology, The Seventh Medical Center of PLA General Hospital, BeiJing, 100010, China

Circular RNA (circRNA) sirtuin-1 (SIRT1) is differentially expressed in non-small cell lung cancer (NSCLC), but its specific mechanism is still uncertain. The study was to figure out the latent molecular mechanism of circSIRT1 in NSCLC. The results clarified that circSIRT1 and SMAD family member 7 (SMAD7) were downregulated, but microRNA (miR)-510-5p was upregulated in NSCLC. Circ-SIRT1 expression was linked with tumor–node–metastasis staging and tumor size in NSCLC patients. Elevating circSIRT1 or suppressing miR-510-5p refrained NSCLC cell activities and glycolysis and inactivated the wnt/β-catenin pathway, while knockdown of circSIRT1 promoted the malignant behavior of NSCLC cells. Besides, inhibition of malignant behavior in NSCLC cells by elevating circSIRT1 was reversed by knockdown of SMDA7. circ-SIRT1 bound to miR-510-5p to target SMAD7. In short, circSIRT1 represses NSCLC cell malignant development *via* miR-510-5p to target SMAD7, making it a latent target for NSCLC treatment.

INTRODUCTION

Lung cancer (LC) takes up 17% of new cancer cases and 23% of cancer deaths (de Sousa *et al.*, 2018). Owing to smoking and environmental pollution, the number of new cases of LC and relevant deaths in China is elevated (Cao *et al.*, 2019). Non-small cell lung cancer (NSCLC) is the major kind of LC, taking up about 85% (Subramaniam *et al.*, 2013). The cure for metastatic liver cancer has long been a challenge for clinicians and researchers, and the molecular mechanisms are not well understood.

Circular RNAs (circRNAs) are a new class of ubiquitous endogenous RNA. Unlike linear RNA, circRNA forms a continuous ring with no 5' or 3' covalent closure (Meng *et al.*, 2017; Yang *et al.*, 2020). Abnormal expression of circRNAs is associated with the occurrence and development of tumors. For instance, circPTK2 is crucial in the growth and metastasis of colon cancer (CC), making it supposed to be a latent target for CC metastasis treatment, and a biomarker for early diagnosis of metastasis (Su *et al.*, 2019). A study by Su *et al.* clarifies that circRNA Cdr1 promotes LC development (Qin *et al.*, 2016). HSA_circ_0001649 expression is downregulated in LC tissues and is associated with tumor size and tumor embolism in hepatocellular carcinoma. While circ-ABCB10 motivates NSCLC cell proliferation, it refrains apoptosis *via* depressing KISS1 (Kong *et al.*, 2019). Circ-sirtuin-1 (SIRT1) controls NF-κB activation through sequence-specific interactions and enhances SIRT1 expression *via* combining with microRNA (miR)-132/212 in vascular smooth muscle cells (Li *et al.*, 2021). Meanwhile, circSIRT1 is discovered to be a tumor suppressor gene in gastric cancer (GC) (Sun *et al.*, 2020). However, the function and mechanism of circSIRT1 in NSCLC have not been figured out yet.

The purpose of this study was to explore the potential molecular mechanism of circSIRT1 in NSCLC. It was assumed that circSIRT1 was a tumor suppressor gene in NSCLC. The potential downstream factor of circSIRT1 was identified by the dual luciferase reporting assay and bioinformatics website. In addition, in this work, it was confirmed that circSIRT1 blocks the activation of the wnt/β-catenin pathway in NSCLC cell lines.

MATERIALS AND METHODS

Clinical tissues obtaining

54 NSCLC patients were recruited and have signed the informed consent. No preoperative chemotherapy or radiotherapy was performed on the recruited patients. The study was approved by the Ethics Committee of Chinese Academy of Medical Sciences and Peking Union Medical College (Approval Number C201612M11). All clinicopathological factors of NSCLC patients were shown in Table 1. NSCLC tissues were confirmed by two histopathological experts. Cancer and adjacent nor-

mal tissues (>5 cm from the tumor) were harvested from 54 cases of NSCLC patients. Afterward, the tissues were immediately frozen in liquid nitrogen and stored in a refrigerator at –80°C.

Cell culture

NSCLC cell lines (A549, H1975, H1650, and HCC827) and non-cancerous bronchial epithelial cell lines (BEAS-2B) (American Type Culture Collection, Manassas, VA, USA) were cultured in Roswell Park Memorial Institute (RPMI)1640 (Thermo Fisher Scientific, Waltham, MA, USA) consisting of 100 U/mL penicillin, 100 U/mL streptomycin (Invitrogen, Carlsbad, CA, USA) and 10% Fetal Bovine Serum (FBS) (Thermo Fisher Scientific).

Actinomycin D and RNase R treatments

To verify the stability of circSIRT1 in A549 cells, actinomycin D and RNase R assays were conducted (Chen *et al.*, 2020). For actinomycin D treatment, A549 cells were cultured in a complete medium supplemented with 2 µg/mL actinomycin D (Sigma, St Louis, MO, USA) or dimethyl sulfoxide (Sigma). For RNA detachment, total RNA from A549 cells was incubated with 3 U/µg RNase R (Geneseed, Guangzhou, China) or diethyl pyrocarbonate-treated water (Sigma). CircSIRT1 or glyceraldehyde-3-phosphate dehydrogenase (GAPDH) expression was detected by reverse transcription quantitative polymerase chain reaction (RT-qPCR).

Cell transfection

siRNA targeting circSIRT1 and SMAD family member 7 (SMAD7) (si-circSIRT1: AGTTTGCAAAGA-TAACCTTCT; si-SMAD7: CTCCAGATACCCGATG-GATTTTC) or pcDNA3.1 (pcDNA3.1-circSIRT1), si-negative control (NC) and pcDNA3.1 NC were purchased from GenePharma (Shanghai, China), and miR-510-5p mimic (UCUCUGGGCCUGUGUCUUAGGC)/inhibitor (GCCUAAGACACAGGCCCAGAGC) and mimic/inhibitor NC were purchased from Sangon (Shanghai). At 80% confluence, cells were transfected in a 6-well plate using lipofectamine 2000 (Invitrogen). Cells were then collected for subsequent experiments.

Colony formation assay

Transfected NSCLC cells (5×10^2/well) were seeded in a 6-well plate (Thermo Fisher) containing FBS. After incubation at 37°C with 5% CO_2 for 10 days, the colonies were stained with 0.1% crystal violet solution (Sigma). Colonies (over 50 cells) were then counted under a microscope (Nikon Eclipse E600, Nikon Instruments, Melville, NY, USA) (Li *et al.*, 2020).

5-ethynyl-2'deoxyuridine (EdU) analysis

A549 and H1650 cells (1×10^4) were seeded in a 96-well plate. Each well was added with 10 µM EdU solution (Genecopoeia, USA). After incubation, the cells were fixed with 4% paraformaldehyde, incubated with glycine, and then washed with phosphate-buffered saline consisting of 0.5% TritonX-100. The cells were incubated with Andy Fluor™ 555 azide (A004, Genecopoeia, USA) or 4',6-diamidino-2-phenylindole. EdU-positive cells were observed under a fluorescence microscope (XSP-BM13C, Shanghai CSOIF. Co., China). Cell proliferation rate = the number of proliferating cells/total number of cells ×100% (Zhu *et al.*, 2021).

Transwell detection of invasion and migration

For invasion detection, Matrigel (BD Biosciences, San Jose, CA, USA) was coated in the Transwell chamber (BD Biosciences). The lower chamber was added with 600 µL RPMI1640 medium consisting of 10% FBS (Thermo Fisher Scientific), and the upper chamber was supplemented with 200 µL serum-free medium consisting of 1×10^5 cells. Cells not passing through the membrane were removed, and the remaining cells were fixed with methanol, stained with crystal violet, and observed under a microscope. Five fields of view were randomly selected to calculate the average number of cells. A Transwell chamber not coated with matrigel was used in the migration assay, and the remaining steps were the same as the invasion (Tang *et al.*, 2021).

Glycolysis test

In line with the manufacturer's instructions, a glucose measurement kit and a lactic acid measurement kit

Table 2. RT-qPCR primer sequence

(Biovision, San Francisco, CA, USA) were utilized to evaluate cellular glycolysis. Absorbance was measured using an automated microplate reader (Molecular Devices LLC, Sunnyvale, CA, USA).

Flow cytometry detection of apoptosis

Annexin V-fluorescein isothiocyanat (FITC) apoptosis detection kit (Sigma-Aldrich, St. Louis, MO, USA) was utilized for analysis of cell apoptosis (Huang *et al.*, 2020). NSCLC cells were resuspended in a 1× binding buffer. After staining with Annexin V-FITC and propidium iodide, cells were evaluated to analyze the apoptosis rate on a flow cytometer (BD Biosciences).

RT-qPCR

RNA was extracted from tissues and cells using the RNeasy Mini Kit (Qiagen, Duesseldorf, Germany). RNase-free treatment was used to avoid RNA contamination. RNA was quantified using a NanoDrop ND-1000 device (Thermo Fisher Scientific). RNA was reverse-transcribed into complementary DNA (cDNA) using M-MLV Reverse Transcriptase Kit (Invitrogen). After mixing cDNA with SYBR GreenER qPCR SuperMix Universal (Invitrogen), RT-qPCR was performed in the PCR system (Applied Biosystems PCR Thermal Cyclers, thermo fisher). GAPDH or U6 was the loading control gene for mRNA and miRNA, respectively. The $2^{-\Delta\Delta CT}$ method was applied for data analysis. Primer sequences were manifested in Table 2.

Western blot

Total proteins were extracted from tissues and cells using Radio-Immunoprecipitation assay lysis buffers containing protease inhibitors. Proteins were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis, and 30 μg sample was electro-blotted onto a polyvinylidene fluoride membrane (Millipore), blocked with 5% skimmed milk, and incubated with primary antibodies and the secondary antibody. Primary antibodies were SMAD7 (25840-1-AP, Proteintech, 1:1000), HK-2 (22029-1-AP, Proteintech,1:1000), GLS1 (ab156876, Abcam, 1:1000), β-catenin (ab32572, Abcam, 1:1000), GAPDH (ab8245, Abcam, 1:1000), *c*-myc (M4439, Sigma, 1:1000), with goat anti-rabbit Immunoglobulin G (7076, Cell Signaling Technology) as the secondary antibody. Protein signals were detected by the BeyoECL Star ECL

kit (Beyotime) and analyzed by ImageJ software (National Institutes of Health, Maryland, USA).

Luciferase activity assay

circSIRT1 and SMAD7 wild-type (WT) and mutant (MUT) luciferase reporter vectors (circSIRT1/SMAD7 WT/MUT) consisting of putative binding sites of miR-510-5p were purchased from Promega (Madison, Wisconsin, USA). A549 and H1650 cells were seeded in a 48-well plate (4.5×10^4/well) and cultured to 70% confluence. Co-transfection of the above vectors was done with miR-510-5p mimic or mimic NC in A549 and H1650 cells using lipofectamine 2000. Luciferase activities were measured in the dual luciferase reporter gene detection system (Promega).

Statistical analysis

Statistical analysis was performed by GraphPad Prism software (La Jolla, CA, USA). Data were shown as mean ± standard de*via*tion (S.D.). Student's t-test or one-way analysis of variance (ANOVA) followed by Tukey's post-hoc test was utilized to analyze two or more groups. $P<0.05$ emphasized obvious statistical meaning. The relationship between circSIRT1 and the clinical features of patients was determined using Spearman correlation tests. All experiments were carried out with at least three biological replicates (N=3).

RESULTS

CircSIRT1 is reduced in NSCLC and is associated with NSCLC clinicopathological features

In order to clarify the potential characteristics of circSIRT1 in NSCLC, circSIRT1 expression was examined in NSCLC. CircSIRT1 in NSCLC tissues and the four NSCLC cell lines were reduced compared with normal tissues and the bronchial epithelial cell line BEAS-2B (Fig. 1A, B). Subsequently, the circular structure of circSIRT1 in A549 cells was examined by actinomycin D and RNase R assay. As shown in Fig. 1C and 1D, circSIRT1 had a longer half-life period and was not degraded by RNase R compared to linear GAPDH mRNA.

Figure 1. CircSIRT1 expression is reduced in NSCLC
(**A, B**) RT-qPCR detection of circSIRT1 expression in NSCLC tissue and adjacent normal tissue, NSCLC cell lines A549, H1975, H1650, HCC827 and non-cancerous bronchial epithelial cell line BEAS-2B; (**C, D**) Actinomycin D and RNase R assay test of circular structure of circSIRT1. The data were manifested as the mean ± S.D. (N=3); *$P<0.05$.

Figure 2. CircSIRT1 performs as a key gene to suppress the malignant phenotype of NSCLC cells
(**A**) RT-qPCR detection of circSIRT1 expression; (**B**) Colony formation assay detection of cell proliferation; C: EdU assay detection of DNA replication; (**D**) Flow cytometry detection of cell apoptosis; (**E**) Transwell detection of cell invasion and migration; (**F, G**) Glycolytic ability of cells; (**H**) Western blot detection of HK-2 and GLS1; In A549 and H1650 cells after transfection of pcDNA 3.1 and siRNA targeting circ-SIRT1. The data were manifested as mean ± S.D. (N=3); *$P<0.05$.

To determine whether circSIRT1 was associated with clinicopathological features of NSCLC patients, patients were divided into circSIRT1 low expression group and circSIRT1 high expression group according to the median expression of circSIRT1, and Spearman correlation analysis was performed. CircSIRT1 was associated with tumor–node–metastasis (TNM) staging and tumor size of NSCLC patients (Table 1). These results indicated that circSIRT1 expression was reduced in NSCLC and was supposed to be related to NSCLC development.

CircSIRT1 performs as a key gene to suppress the malignant phenotype of NSCLC

As circSIRT1 expression levels were the lowest in A549 and H1650 cells, these two cell lines were selected for subsequent experiments. Subsequently, whether circSIRT1 was associated with the malignant phenotype of NSCLC was explored. circSIRT1 was upregulated and

inhibited in A549 and H1650 cells, respectively, by transfection of circSIRT1-targeted overexpression plasmid and siRNA (Fig. 2A). Functional tests clarified that up-regulating circSIRT1 was available to repress A549 and H1650 cell proliferation, invasion, migration and DNA replication, but elevated the apoptosis rate (Fig. 2B–E). Cancer cells usually require a lot of energy to survive. Next, it was explored whether circSIRT1 controls the glycolysis capacity of NSCLC cells. Up-regulation of circSIRT1 suppressed glucose consumption and lactate production in A549 and H1650 cells (Fig. 2F, G). Meanwhile, upregulating circSIRT1 also repressed glycolytic rate-limiting enzyme HK-2 and glutamine hydrolase GLS1 in A549 and H1650 cells (Fig. 2H). However, after the elimination of circSIRT1, the exact opposite result was shown (Fig. 2B–H). Overall, circSIRT1 performed as a tumor suppressor gene in NSCLC cells.

Figure 3. MiR-510-5p accelerates the malignant behavior of NSCLC
(**A, B**) RT-qPCR detection of miR-510-5p expression in NSCLC tissue and adjacent normal tissue, NSCLC cell lines A549, H1975, H1650, HCC827 and non-cancerous bronchial epithelial cell line BEAS-2B; (**C**) RT-qPCR detection of miR-510-5p expression; (**D**) Colony formation assay detection of cell proliferation; (**E**) EdU assay detection of DNA replication; (**F**) Flow cytometry detection of apoptosis; (**G**) Transwell detection of cell invasion and migration; (**H, I**) Glycolytic ability of cells; (**J**) Western blot detection of HK-2 and GLS1 expression; C–J, in A549 and H1650 cells after transfection with miR-510-5p inhibitor. The data were manifested as mean ± S.D. (N=3); *$P<0.05$.

circSIRT1 binds to miR-510-5p to target SMAD7

CircSIRT1 can perform as a sponge of miRNA to modulate protein expression and impact disease development. Subsequently, downstream miRNAs absorbed by circSIRT1 were analyzed. It was found that circSIRT1 had a potential binding site with miR-510-5p through bioinformatics website query (Fig. 3A). Subsequently, a dual luciferase reporting assay was carried out. The results showed that wild-type circSIRT1 lowered the luciferase activity in the miR-510-5p mimic group, while mutant circSIRT1 had no effect on the luciferase activity in the miR-510-5p mimic group (Fig. 3B). After elevation or knockdown of circSIRT1, miR-510-5p expression in A549 and H1650 cells was enhanced or repressed,

respectively (Fig. 3C). This indicated that miR-510-5p might be a downstream target of circSIRT1.

Potential binding sites between SMAD7 and miR-510-5p were found on the bioinformatics website (Fig. 3D). WT SMAD7 could reduce the luciferase activity of the miR-510-5p mimic group (Fig. 3E). Former studies have noted that SMAD7 is under-expressed in various cancers, including LC. Consistent results were also gained in this study (Fig. 3F, G). Meanwhile, SMAD7 was promoted or inhibited in A549 and H1650 cells with downregulated or upregulated miR-510-5p, respectively (Fig. 3H). Therefore, SMAD7 was supposed to be a target gene of miR-510-5p.

Figure 4. circSIRT1 binds to miR-510-5p to target SMAD7
(**A**) RT-qPCR detection of miR-510-5p expression in A549 and H1650 cells after transfection of pcDNA 3.1 and siRNA targeting circSIRT1; (**B**) Bioinformatics website http://starbase.sysu.edu.cn/ to predict binding sites between circSIRT1 and miR-510-5p; (**C**) The luciferase activity assay for verification of the targeting relationship between circSIRT1 and miR-510-5p; (**D**) RT-qPCR detection of SMAD7 mRNA expression in NSCLC tissue and adjacent normal tissue; (**E**) Western blot detection of SMDA7 protein expression in NSCLC cell lines A549, H1975, H1650, HCC827 and non-cancerous bronchial epithelial cell line BEAS-2B; (**F**) Western blot detection of SMAD7 protein expression in A549 and H1650 cells introduced with miR-510-5p mimic/inhibitor; (**G**) Bioinformatics website http://starbase.sysu.edu.cn/ to predict the binding site of SMAD7 and miR-510-5p; (**H**) The luciferase activity assay for verification of targeting relationship between SMAD7 and miR-510-5p; The data were manifested as mean ± S.D. (N=3); * $P<0.05$.

MiR-510-5p motivates the malignant behavior of NSCLC cells

Former studies have confirmed the promoting effect of miR-510-5p on renal cell carcinoma and thyroid cancer development (Liu *et al.*, 2019; Zhan *et al.*, 2020). miR-510-5p expression was evaluated in NSLCL. As manifested in Fig. 4A, B, higher miR-510-5p was presented in NSCLC patients and cell lines. Subsequently, miR-510-5p was knocked down in A549 and H1650 cells after transfecting with miR-510-5p inhibitor (Fig. 4C). Downregulating miR-510-5p repressed A549 and H1650 cell proliferation, DNA replication, migration and invasion, elevated apoptosis rate, and reduced glucose consumption, lactate production, HK-2 and GLS1 protein expression (Fig. 4D-J). Briefly, miR-510-5p motivated the malignant behavior of NSCLC cells.

CircSIRT1 represses the malignant behavior of NSCLC cells by controlling the miR-510-5p/SMAD7 axis

Next, the researchers explored whether circSIRT1 influences the malignant behavior of NSCLC through the miR-510-5p/SMAD7 axis. pcDNA 3.1-circSIRT1 and si-SMDA7 were co-transfected into A549 and H1650 cells. It came out that pcDNA 3.1-circSIRT1 elevated SMDA7 expression, and after co-transfection with si-SMAD7, SMDA7 expression was repressed (Fig. 5A). The suppressive effects of upregulating circSIRT1 on A549 and H1650 cell proliferation, DNA replication, migration, invasion, and glycolysis, as well as the promoting effect on apoptosis, were turned around after knocking down SMDA7 (Fig. 5B–H). In short, circSIRT1 repressed the malignant behavior of NSCLC cells by controlling the miR-510-5p/SMAD7 axis.

CircSIRT1 refrains the wnt/β-catenin signal activation *via* the miR-510-5p/SMAD7 axis

The activation of Wnt/β-catenin signaling is able to accelerate NSCLC proliferation, migration, invasion, and stem cell maintenance (Chen *et al.*, 2016). Next, it was examined whether circSIRT1 affected the wnt/β-catenin pathway. Upregulating circSIRT1 or silencing miR-510-5p could reduce β-catenin and c-myc expression, a downstream target gene of the Wnt pathway, in A549 and H1650 cells. The repressive impacts of elevated circSIRT1 on the Wnt/β-catenin pathway were reversed by upregulating miR-510-5p and knocking down SMDA7 (Fig. 6A, B). The findings clarified that circSIRT1 refrained from the activation of the Wnt/β-catenin pathway in NSCLC *via* miR-510-5p/SMAD7 axis.

DISCUSSION

LC is a very familiar tumor in clinical practice, and it is also the malignant tumor with the highest mortality rate in the world. NSCLC is characterized by a high degree of malignancy and a very low 5-year survival rate. This is mainly due to a lack of understanding of the basic biology of NSCLC, which in turn leads to a

Figure 5. CircSIRT1 refrains the malignant behavior of NSCLC *via* controlling the miR-510-5p/SMAD7 axis
(**A**) Western blot detection of SMAD7 expression; (**B**) Colony formation assay detection of cell proliferation; (**C**) EdU assay detection of DNA replication; (**D**) Flow cytometry detection of cell apoptosis; (**E**) Transwell detection of cell invasion and migration; (**F, G**) Glycolytic ability of cells; (**H**) Western blot detection of HK-2 and GLS1 expression; In A549 and H1650 cells after co-transfection of pcDNA 3.1-circ-SIRT1 and si-SMDA7. The data were manifested as mean ± S.D. (N=3); *$P<0.05$.

lack of reliable biomarker tests and effective therapeutic drugs (Tang *et al.*, 2016). The prognosis of patients with advanced or metastatic LC is quite unpleasing (Gupta *et al.*, 2006). Hence, understanding the pathogenesis of LC is essential for the development of therapeutic targets. The research of circRNA in LC has attracted much attention recently. At present, the key characteristics and latent functions of circRNAs are not well understood (Qu *et al.*, 2015; Hansen *et al.*, 2013). Certain circRNAs are crucial in cancer. For instance, hsa_circRNA_102958 expression in GC tissues is up-regulated and is positively linked with TNM staging (Wei *et al.*, 2020). Hsa_circRNA_102034 motivates LC progression *via* activating NR2F6 (Wang *et al.*, 2019); In NSCLC, a former study has discovered that hsa_circRNA_012515 expression in

NSCLC tissues is overexpressed and is closely implicated in the lymph node metastasis and TNM staging of NSCLC. In the meantime, NSCLC patients with elevated hsa_circRNA_012515 have a clearly shorter survival time (Fu *et al.*, 2020). In the research, it was discovered that circSIRT1 overexpression was available to repress NSCLC proliferation, invasion, migration and glycolysis, but promotes apoptosis.

Subsequently, we further clarified the function of circ-SIRT1 from the molecular mechanism. CircRNA frequently serves as a ceRNA for miRNA. A former study has clarified that miR-510-5p induces renal cell carcinoma and thyroid cancer cell proliferation, invasion and migration (Wang *et al.*, 2021; Zhang *et al.*, 2020). In this study, it was discovered that miR-510-5p, as a down-

A case-control study in *NAT2* gene polymorphism studies in patients diagnosed with acute myeloid leukemia

Abdullah Farasani[1,2]✉

[1]Biomedical Research Unit, Medical Research Center, Jazan University, Saudi Arabia; [2]Department of Medical Laboratory Technology, Faculty of Applied Medical Sciences, Jazan University, Saudi Arabia

Introduction: Acute myeloid leukemia (AML) is a clinically defined heterogeneous disease whose pathophysiology is currently unknown. The association of NAT2 acetylation profiles with human cancer risks, particularly with AML, was investigated in molecular epidemiological studies. Additionally, the *NAT2* gene was carried out with acute lymphoid leukemia and other cancers. **Aim:** In this case-control study, C481T (rs1799929) and G857A (rs1799931) polymorphism studies were investigated in diagnosed AML patients in the Saudi population. **Methods:** This case-control study included 100 AML patients and 100 control subjects recruited in Saudi Arabia. The C481T and G857A polymorphisms were genotyped using specific primers and restriction enzymes. Statistical analysis was performed on the AML patients and controls using chi-square tests, genotyping, and allele frequencies (odds ratios, 95% of confidence intervals, and *P*-values). **Results:** Hardy Weinberg Equilibrium was determined to be both within and outside of the G857A and C481T polymorphisms. The allele and genotyping frequencies in AML and control subjects were analyzed, and the results corroborated the unfavorable connection with C481T (CC *vs* CT+TT; OR-1.12; (95% CIs: 0.64–1.96); *P*=0.67 and T *vs* C; OR-0.89; (95% CIs: 0.59–1.35) and *P*=0.60) and G857A polymorphisms (GG *vs* GA+AA; OR-1.50; (95% CIs: 0.83–2.71); *P*=0.17 and A *vs* G; OR-0.71; (95%CIs: 0.43–1.19) and *P*=0.19) in the *NAT2* gene. **Conclusion:** The study results revealed a negative correlation as well as a protective factor for AML with the C481T and G857A polymorphisms in the *NAT2* gene.

INTRODUCTION

Acute myeloid leukemia (AML) is classified as an aggressive condition in which too many immature, nonlymphoblastic, white blood cells in the bone marrow and blood are identified. AML is also known as acute myelogenous leukemia or acute nonlymphocytic leukemia (Cucchi *et al.*, 2021). Myeloid malignancies are a subset of hematopoietic stem/progenitor cell tumors that include AML and myelodysplastic syndromes (MDS) (Döhner *et al.*, 2015). An estimated 21 450 cases were reported in 2019, representing between 15–20% of leukemias in the United States (Sasaki *et al.*, 2021). The prognosis for AML patients beyond the age of sixty has not changed significantly in decades and remains bleak (Docking *et al.*, 2021). AML is a clonal hematopoiesis condition defined by genetic and epigenetic changes that lead to a block of myeloid progenitor development in the bone marrow and blood and the accumulation of leukemia. Although the overall survival rate of AML patients is poor, around 20% to 30% of them never achieve complete remission, and 50% of them relapse beyond complete remission, often within 2-3 years after diagnosis (Bhatnagar *et al.*, 2021). AML can also be caused by a growing MDS, such as a clonal condition of hematopoietic stem cells (Chamseddine *et al.*, 2016). Despite efforts to enhance the clinical result of AML, current medications fail to eradicate the leading leukemic stem cells (Pegoraro *et al.*, 2020). Based on the French and American classification, AML is classified into eight subtypes, M0-M7, depednding on the type of leukemia that develops and the stage of leukemia maturity (Lafuente *et al.*, 1993).

AML is the most frequent acute leukemia in adults, which causes many deaths from malignancy. Fatigue owing to anemia, easier bleeding due to thrombocytopenia, increasing leukopenia and bone soreness are further symptoms of AML. Acute leukemia may be myeloid or lymphoblastic depending on the type of cells impacted. The specific etiology of AML is not fully understood, although risk factors for the development of AML are also present. In the great majority of AML cases, genetic mutations are discovered. Some AML-associated chromosomal translocations include t(15:17) and t (8:21). Risk factors include patients with a hematologic condition underlying AML, people who underwent alkylating or radiation chemotherapy in previous cancer treatments, genetic disorders such as Down's syndrome and increased age (Kaser *et al.*, 2021). New predictors of diseases like cancer and indications of efficacy of chemotherapy response were developed in single nucleotide polymorphisms (SNPs). To date, most SNPs in AML have been identified with oncological therapy responses (Castro *et al.*, 2021). Over the last three decades, genomic aberrations have dominated the pathogenesis of AML, and diagnostic and prognostic indications of cytogenesis have emerged. The Cancer Genome Atlas project has reported a small number of mutations in often disrupted pathways including *NPM1, FLT3, CEBPA, DNMT3A, IDH1,* and *IDH2*, as well as genes recently implicated in leukemogenesis like *EZH2, U2AF1, SMC1A,* and *SMC3. NPM1, CEPBA,* and *RUNX1* mutations are frequent in AML (Bullinger *et al.*, 2017). Apart from this multi-

ple single nucleotide polymorphisms were documented in the AML. N-acetyl transferase 2 (NAT2) is a phase II metabolizing enzymes that are vital in the acetylation and detoxification of various hazardous metabolites and carcinogenic agents such as aryl or aromatic amines and hydrazines, which are implicated in the development of carcinogenesis (Yarosh *et al.*, 2014). Several molecular epidemiological studies have investigated the link between NAT2 acetylation profiles and the risk of human cancer. In addition, a significant study showed that persons with the NAT2 phenotype are at greater risk of developing AML. Furthermore, SNPs in the *NAT2* gene also control human sensitivity to different cancers such as pulmonary cancer, bladder cancer, gastric cancer etc (Zou *et al.*, 2017). Growing evidence revealed that *NAT2* polymorphic diseases were combined with higher vulnerability to other diseases, notably acute lymphoblastic leukemia and lung squamous carcinoma. In addition, various studies have shown the relationship of distinct NAT2 polymorphisms with a high risk for acute development of leukaemia, notably AML, with contradictory results (AbdelGhafar *et al.*, 2019).

Leukemia is the third and sixth most common malignancy in Saudi men and women, respectively. In 2013, 12% of newly reported leukemia cases were AML patients. AML is an age-related disease in Saudi Arabia, with a median age of 70 years. AML is the most common adult leukemia, with an increased frequency with age. In 2013, 684 new cases of adult leukemia were reported in the most recent cancer-incidence report in Saudi Arabia in every 100 000 persons and this represents 5.9% of all new adult malignancies (Gaafar *et al.*, 2018). Presently, limited studies have been carried out in the Saudi population and unfortunately there are no documented studies on the C481T and G857A polymorphism in the NAT gene in patients diagnosed with AML in the Saudi population. Therefore, the present study aimed to investigate the case-control study in C481T and G857A polymorphism with *NAT* gene in Saudi patients diagnosed with AML.

MATERIALS AND METHODS

The Ministry of Health provided an ethical grant for this study, which was carried out in accordance with the Helsinki Declaration. In this case-control study, 200 Saudi individuals were recruited as 100 patients were diagnosed with AML and 100 were non-AML (healthy subjects). All of the recruited samples were obtained from the Riyadh regional laboratory in Saudi Arabia's capital city. Both cases and controls were chosen based on the inclusion and exclusion criteria discussed in the earlier publication (Farasani, 2019). The inclusion criteria for AML subjects were recruited based on the diagnosis of the AML with histopathological and cytogenetic confirmation, signed informed consent and Saudi adults. The exclusion criteria for AML cases were patients diagnosed with other cancers, unsigned consent form with non-Saudi subjects. The AML cases were diagnosed with bone-marrow examination, complete blood count and flow cytometry. Additionally, cytogenetics and FISH tests were implemented for reconfirmation. The inclusion criteria for healthy controls did not include any type of cancer or other diseases. The exclusion criteria were non-Saudi subjects.

Sample selection

2 ml of EDTA blood was obtained from each patient (n=200) and utilized for DNA extraction and molecular analysis (Alshammary *et al.*, 2023).

Molecular analysis

Genomic DNA extraction was done with the specific kits used for separation of the DNA and nanodrop was used to measure the DNA quantification (Alshammary *et al.*, 2023). Genotyping was performed with C481T and G857A polymorphism in the *NAT2* gene using the precise primers as described in the Table 1. Genotyping was carried out with polymerase chain reaction (PCR) which was performed with a total reaction mix of 50 µl microliters consisting of 4 µl genomic DNA and 30 µl PCR mixes, which contain 10X, $MgCl_2$, dNTPs and 10× Taq DNA polymerases. The Master Mix was complemented by 10pmoles of 2 µL of forward and reverse primers followed by 12 µL of distilled water. For the final amount of 50 µL, the PCR reaction has been standardized (Alshammary & Khan, 2021). Both the C481T and G857A primers from earlier studies have been used. After PCR 35 cycles were performed starting with initial denaturation running 5 min at 95°C, 30 s at 95°C for denaturation, various annealing temperatures for both the polymorphisms at 65/60°C – 30 s, extension at 72°C – 45 s and final extension at 72°C – 5 min. The 910bp of PCR products were digested with *KpnI and BamHI* enzymes at 37°C for 18 hours and further samples were loaded on 3% agarose gel stained with ethidium bromide. Further details were shown in the Table 1.

Statistical analysis

SPSS software (version 20) was used to examine the clinical data. Hardy-Weinberg Equilibrium (HWE) was

Table 3. The studies distribution genotype frequencies of C481T and G857A polymorphisms

NAT2 (rs1799929)	Cases (n=100)	Controls (n=100)	OR (95%CI)	*P*-Value
CC	51 (51%)	48 (48%)	Position	Position

used for comparing the observed and anticipated genotype frequencies using control subjects. The odds ratios, upper, and lower ranges of 95% confidence intervals (95% CI) for C481T and G857A polymorphisms in the NAT2 gene were used in the genotype differences between AML cases and healthy control subjects. The $P<0.05$ were considered statistically significant (Khan *et al.*, 2019).

RESULTS

Clinical details for AML cases and controls

Table 2 documents the clinical characteristics between AML and non-AML (controls) involved in this study. In this case-control study, 100 AML cases and 100 healthy controls were selected within the Saudi population. 38.9±15.1 and 39.9±12.06 was the known mean age for AML cases and control subjects documented with non-signifcant association ($P=0.60$). Between 19–82 is the minimum and maximum age for AML cases and 18–63 is the minimum-maximum age for the control subjects documented in this study. The male and female patients in the AML cases were 61% and 39%, respectively, whereas the male and female participants in the controls were 54% and 46%.

HWE analysis

HWE analysis was performed in both the C481T and G857A polymorphisms and HWE was not in accordance with the control subjects for C481T; VAF=0.37; χ^2=10.98 and $P=0.0009$ and for G857A is in accordance with the control subjects VAF=0.21; χ^2=0.60 and $P=0.80$.

Genotype analysis for C481T and G857A polymorphisms

The genotype frequencies between CC, CT and TT were found to be 51%, 30% and 19% in the AML cases, whereas in the control subjects 48%, 31% and 21% were documented as CC, CT and TT genotypes. 66% of the C allele and 34% of the T alleles have been documented in AML cases and in the control subjects, 0.365% of the T allele and 0.635% of the C allele were confirmed. The genotype [CT *vs* CC; OR-0.91; (95% CIs: 0.48–1.72) and

$P=0.77$ and TT *vs* CC; OR-0.85; (95% CIs: 0.40–1.77) and $P=0.66$] and dominant model also showed the non-signifcant association (CC *vs* CT+TT; OR-1.12; (95% CIs: 0.64–1.96); $P=0.67$ allele frequencies [T *vs* C; OR-0.89; (95% CIs: 0.59–1.35) and $P=0.60$] was also confirmed and non-significantly associated. Table 3 confirms the genotype distribution as well as allele frequencies in AML cases and control subjects. The GG, GA, and AA genotype frequencies of G857A polymorphism were 71%, 26%, and 3% in AML cases, respectively, and 62%, 34%, and 4% in control genotypes. The allelic discrimination between G and A alleles in AML cases was found to be 84% and 16%, respectively, whereas in control subjects it was 79% and 21%. The genotype [GA *vs* GG; OR-0.66; (95% CIs: 0.36–1.23) and $P=0.19$ and AA *vs* GG; OR-0.65; (95% CIs: 0.14-3.04) and $P=0.58$] and dominant model also showed the non-signiifcant association (GG *vs* GA+AA; OR-1.50; (95% CIs: 0.83–2.71); $P=0.17$ allele frequencies [A *vs* G; OR-0.71; (95% CIs: 0.43–1.19) and $P=0.19$] was also confirmed and non-significantly associated.

DISCUSSION

In this case-control study, C481T and G857A polymorphisms in the *NAT2* gene were studied in the Saudi patients diagnosed with AML and the study results confirmed the negative association with any of the allele or genotype frequencies. AML is one of a particular type of cancer that modifies the drug-metabolization enzymes and mainly because of genetic heterogeneity of the various human populations in the fields of drug metabolism and disease sensitivity, NAT2 is a key subject in pharmacogenetic study. Seven SNPs of the *NAT2* gene were studied in human diseases at 191, 282, 590, 857, 481, 803 and 314 positions, and many more SNPs have been reported in worldwide studies (Adole *et al.*, 2016). The NAT2 isoform is encoded by the *NAT2* gene, which is situated on chromosome 8 (8p22), and this gene is positioned combined with the *NAT1* gene and the pseudogene *NATP*. the observed variety of the described alleles derives from the combination of single-base mutations selected from among the several bases. Enzyme activity, affinity for substrate, and stability of resultant protein can all be affected by existing SNPs in

the coding region of the gene. The C481T (rs1799929), G590A (rs1799930), G857A (rs1799931), and G191A (rs1801279) have been useful in the context of NAT2 as an acetylator phenotype to detect them (Santos *et al.*, 2016). C481T polymorphism is a synonymous SNP frequently associated with T341C, which occurs in clusters NAT2*5, as A, B, F, G, H, I, L, and M in the variant alleles 6E, 11A&B, 12 and 14 C. C481T (NAT2*11A) is exceedingly rare, and has not been found in over 2600 individuals of European descent (Garcia-Martin, 2008). G857A substitution results in a change in the amino acid glutamate in the protein (G286E). This mutation alters the active site of the enzyme, lowering its selectivity and capacity to operate as a catalyst. The polymorphism in the *NAT2* gene identified in the G857A variant reduces aromatic and heterocyclic amines. Only 11 NAT2 alleles have the mutation G857A, and two of these are the result of a slow acetylator phenotype, while the others have not yet been identified (Rajasekaran *et al.*, 2011). In this study, only C481T and G857A polymorphisms have been studied in the Saudi patients confirmed with the AML disease. The current study results with G857A polymorphism were associated with a previous study documented in the Jordanian population (Jarrar *et al.*, 2010).

A function for *NAT2* gene polymorphism in several cancer types has been proposed, and AML has been documented in multiple studies in the global population (Gra *et al.*, 2008; Majumdar *et al.*, 2008; Zanrosso *et al.*, 2012; Zou *et al.*, 2017). Limited studies have been recorded in the Saudi population with the *NAT2* gene in different diseases. C481T and G857A polymorphisms have been linked to T2DM in the Saudi Arabian population, and the study results validated the favorable connection with G857A polymorphism. However, none of the SNPs was shown to be positively associated in this study, which may be due to the function of the specific disease (Al-Shaqha *et al.*, 2015). A previous study in the Arab control population in Saudi Arabia with both the C481T and G857A polymorphisms in the *NAT2* gene was performed (Bu *et al.*, 2004). A similar study on the *NAT2* gene was conducted in the Saudi Arabian population in Al-Ahsa, where it was discovered that persons with the *NAT2* gene had an elevated risk of slow acetylators, potentially impacting the efficacy and vulnerability to numerous diseases (Zahra *et al.*, 2020). A similar pattern of this study was replicated in the Jordanian population (Jarrar *et al.*, 2018). The frequency of *NAT2* gene polymorphism in Saudi Arabia, Oman, and Emirati populations varies(Al-Ahmad *et al.*, 2017; Tanira *et al.*, 2003; Zahra *et al.*, 2020). The *NAT2* gene was screened in the Egyptian population in children diagnosed with lymphoblastic leukemia, and the study results indicated that the *NAT2* gene is slowly related with the acetylator phenotype with ALL risk in pediatric children (Kamel *et al.*, 2015). In the NCBI dbSNP *NAT2* C481T and G857A database, the worldwide Minor All Frequency was T=0.27 and A=0.08. G857A is a rather infrequent polymorphism, according to these frequencies (Fayez *et al.*, 2018). The proportion of mutant alleles was validated in this study as 0.34 in T-allele and 0.16 in A-allele of both described polymorphisms in the *NAT2* gene.

A meta-analysis of *NAT2* gene variants in isoniazid-induced hepatotoxicity (IIH) found that these genetic variants had a substantial impact on IIH. The *NAT2* genotyping test can help with a better knowledge of drug-enzyme metabolism as well as an earlier prediction of IIH (Khan *et al.*, 2019). A documented meta-analysis found rs1799931 to be a protective factor against cancer development (Tian *et al.*, 2014), which was consist-ent with the current report's results as well as those of others (Zou *et al.*, 2017). A meta-analysis study on acute leukemia with the NAT2 gene was conducted (Zhu *et al.*, 2019). This study has added strengths and limitations and one of the strengths of this study was opting for a minimum of 100 Saudi patients diagnosed with AML cases and 100 healthy Saudi controls involved in this study. Opting for only 2 SNPs involved in this study is one of the major limitations of this study. Missing of anthropometrical and clinical data was another limitation of this study.

CONCLUSION

In conclusion, the current study findings revealed a negative correlation as well as a protective factor for AML with the C481T and G857A polymorphisms in the *NAT2* gene. The current study findings verified the comparable correlation found in Chinese studies.

Smoking is a main risk factor for bladder cancer (BC). NAT2 is a drug-metabolizing enzyme that catalyses the detoxification of many xenobiotics and carcinogens. Single nucleotide polymorphism (SNP) in *NAT2* results in different acetylation phenotypes (fast, intermediate or slow). Certain *NAT2* SNPs were associated with BC and/or modified the association of BC with smoking. However, limited evidence is available among BC patients or smokers from Jordan. This study aimed to discover novel SNPs in *NAT2* and to assess the association with BC. This was a case-control study among 120 BC patients and 120 controls. Amplification of a 446 bp fragment of *NAT2* encoding the N-catalytic domain was conducted using a polymerase chain reaction. Gene sequencing was done using Sanger-based technology. A total of 40 SNPs were detected. Two variants were significantly associated with BC (*p*<0.05); namely a novel c.87G>A and the reported c.341T>C. Regarding c.87G>A, genotype distribution was significantly associated with BC and subgroup analysis confirmed that this was significant in both smokers (*p*=0.007) and non-smokers (*p*=0.001). Regression subgroup analysis suggested GA as a risk factor among smokers (AOR= 2.356). The frequencies of TC and CC genotypes of c.341T>C were significantly higher in BC (*p*<0.05). This was statistically significant among smokers only (*p*=0.044), upon subgroup analysis. Multivariate analysis showed that subjects with TC genotype are 6.15 more likely to develop BC and regression subgroup analysis revealed TC as a risk factor among smokers (AOR=5.47). This is the first study from Jordan to report the association of smoking and two *NAT2* variants with BC. The data supports the use of GA and TC genotypes of the novel c.87G>A and the reported c.341T>C SNPs, respectively as potential biomarkers of BC, particularly among smokers. Future investigations with a larger population are required to support our findings.

✉e-mail: lmelsalem@just.edu.jo

INTRODUCTION

Globally, bladder cancer (BC) ranks as the 10th most common malignancy (Bray *et al.*, 2018) with tobacco smoking being a main risk factor for the disease development (Freedman *et al.*, 2011, Saginala *et al.*, 2020). Studies reported a 4-folds increased risk for BC among smoker individuals in comparison to non-smokers (Colombel *et al.*, 2008). In addition, more invasive phenotypes of BC were described in smoker patients compared with non-smokers (Jiang *et al.*, 2012). It is well known that tobacco contains more than 4000 chemicals, 60 of which are listed as carcinogens (Richter *et al.*, 2008). Examples of carcinogenic chemicals that are found in cigarette smoking are aromatic and heterocyclic amines (Turesky and Le Marchand 2011). These chemicals are detoxified by different drug-metabolizing enzymes including *N*-acetyltransferase 2 (NAT2) (Sanderson *et al.*, 2007).

Human NAT2 is a Phase II drug metabolizing enzyme that is involved in the detoxification of many xenobiotics and carcinogens by catalyzing the transfer of an acetyl group from acetyl CoA as a donor to the acceptor compound (Grant *et al.*, 1992). Many studies reported inter-individual variations in the rate of acetylation, with subjects classified as fast, intermediate or slow acetylators (Werely *et al.*, 2007; Garcia-Martin 2008; Sabbagh *et al.*, 2011; Al-Ahmad *et al.*, 2017; Aklillu *et al.*, 2018). Phenotypic differences in acetylation rate explain some of the variation observed in the therapeutic/side effect profile of drugs metabolized by NAT2 such as isoniazid, sulfonamides and others (Werely *et al.*, 2007; Ladero 2008; Sim *et al.*, 2014; Adole *et al.*, 2016). Moreover, many reports suggested that the above differences may also modify the risk of developing BC (Hein 2006) and/or modify the association of BC with smoking (Tao *et al.*, 2010; Moore *et al.*, 2011; Ribouh-Arras *et al.*, 2019). Tao *et al.*, showed that environmental tobacco smoke increased the risk of BC among slow NAT2 acetylators (Tao *et al.*, 2010). In addition, a large population-based study from the US revealed that exposure intensity to tobacco smoking was correlated with BC risk in patients with slow acetylation (Moore *et al.*, 2011). A recent study among the Lebanese population has shown that patients

with high BC risk were mainly males, current smokers, alcohol drinkers and those with occupational history of exposure to aromatic amines (Nasr *et al.*, 2017). Further investigations have shown a strong association between NAT2 slow acetylator phenotype and smoking which is attributed to higher BC risk among the Algerian population (Ribouh-Arras *et al.*, 2019).

The NAT2 acetylation phenotype is largely determined by genetic variations in the sequence of the gene encoding the NAT2 enzyme. This gene, also known as *NAT2*, is located on chromosome 2 and has two exons separated by one intron (Blum *et al.*, 1990). Transient heterologous transfection of constructs that contain only the second exon of *NAT2* is sufficient to produce a fully functional enzyme upon its translation (Boukouvala *et al.*, 2003). Not surprisingly, most of the sequence variations in *NAT2* that result in phenotypic differences in acetylation are located within the second exon which is 873 bps in length (Boukouvala *et al.*, 2003; Ribouh-Arras *et al.*, 2019).

Jordan is a Third World Middle Eastern country with one of the highest numbers of cigarette smokers per capita worldwide (Jaghbir *et al.*, 2014). BC is considered the third most cancer in male patients and accounts for almost 5% of all cancer cases diagnosed in Jordan (Directorate-MOH 2014). In addition, BC is a foremost cause of cancer related death in Jordan. Up to our knowledge, no research group in Jordan has ever sequenced the coding region of *NAT2* to search for novel population specific polymorphisms, despite the importance of having such a database from a pharmacogenetic and personalized medicine standpoint. In addition, no studies to date examined the association between genetic variants of *NAT2* and BC risk in Jordan.

The N-catalytic domain of the NAT2 enzyme is found within the second exon of *NAT2*. Several reports found that most of the genetic variation in the *NAT2* gene that leads to changes in acetylation activity is located within the above domain (Boukouvala *et al.*, 2003; Ribouh-Arras *et al.*, 2019). Given the above gaps, we sequenced a stretch of the second exon of the *NAT2* gene from subjects of a BC case-control study to discover novel sequence polymorphisms in *NAT2*, test their association with BC in Jordan, and examine if these polymorphisms modify the link between BC and smoking.

MATERIALS AND METHODS

Ethical approval

This study has the approval of the Deanship of Research and the Institutional Review Board committees of (Jordan University of Science and Technology, King Abdullah University Hospital (KAUH)), (University of Jordan, Jordan University Hospital (JUH)) and (King Hussein Cancer Center (KHCC)), (IRB numbers 25/112/2018, 2018/127 and 30/2018, respectively). Subjects were enrolled in this study after providing an informed consent form.

Study Settings and Subjects Enrolment

This was a case-control study among 120 BC patients from Jordan who attended the Urology clinics of KAUH located in the North of Jordan. Patients were also enrolled from the Urology clinics of JUH and the Oncology clinics of KHCC, both located in the capital city.

Patients were included if they were diagnosed with transitional cell carcinoma (TCC) of BC as their primary cancer and were being treated for BC at the time of enrolment at each respective hospital. On the other hand, patients were excluded if they have BC of other subtypes rather than TCC or if BC was a secondary tumor.

Patients were interviewed by a clinical research coordinator who described the study's objectives and clarified that the study will include the collection of demographic, anthropometric measurements and clinical data as well as a blood sample.

Demographic data included the patient age, gender and smoking status, while anthropometric data included the patient height and weight needed to calculate the Body Mass Index (BMI). Clinical data including the pathological stage of the tumor at the time of its diagnosis was obtained from the electronic medical records.

Regarding the control group, it included 120 subjects who attended Family Medicine clinics of KAUH and JUH without a medical history of bladder disease. Control subjects were matched with cases by gender, BMI and smoking status. Subjects in the control group were excluded if they had a medical history of any urology-related symptoms (difficulty upon urinating, blood and other discharges in the urine, burning upon urination).

Of note, all interviews of both groups were conducted by the same coordinator for the duration of patient recruitment.

Blood sample collection

A single venous blood sample (3 ml) was collected from each subject using ethylenediamine tetraacetic acid (EDTA) tubes (AFCO, Amman, Jordan). Tubes were mixed properly to prevent clotting. Blood samples were stored at 4°C for the subsequent DNA extraction.

DNA extraction, PCR and sequencing

Genomic DNA extraction was carried out using the QIAamp DNA Blood Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. Following the final step of the protocol, DNA concentration was measured using an ND-2000 Nanodrop (Thermo Scientific, Waltham, MA, USA). DNA samples were stored at –80ºC for further processing (i.e. amplification followed by sequencing).

Using the Ensembl genome browser 98 (http://www. ensembl.org/index.html), the location of the N-catalytic domain was mapped on the nucleotide sequence of the second exon. A primer pair that flanks the N-catalytic domain was then designed using Primer 3 software (http://primer3.ut.ee). Primers were designed to amplify a 446 bp fragment. The sequence of the forward primer was (5' to 3'): CTTGCTTAGGGGATCATGGA while the sequence of the reverse primer was (5' to 3'): GGCTGATCCTTCCCAGAAAT.

Conventional polymerase chain reaction (PCR) was then used to amplify the aforementioned 446 bp fragment. The details of the PCR reaction mixture were as Alfaqih and others (Alfaqih *et al.*, 2018). The PCR reaction mixture was then incubated in a T100 thermal cycler (Biorad, Berkeley, CA, USA) under the following reaction conditions; (i) initial denaturation step (95ºC, 3 minutes), (ii) 35 denaturation cycles (95ºC, 3 minutes), (iii) annealing (65ºC, 30 seconds) and (iv) extension (72ºC, one minute) and (v) a final extension (72ºC, 5 minutes).

Prior to sequencing the PCR products, 5 μls of the PCR mixture were loaded into a 2% agarose gel stained with ethidium bromide. The electrophoresis was run at

Table 1. Distribution of study subjects by independent variables and by disease status

Variable	Controls (n=120)	Bladder cancer (n=120)	*p*-value
Gender (n) (%)			
Males	106 (88.3%)	104 (86.7%)	0.423
Females	14 (11.7%)	16 (13.3%)	
Smoking (n) (%)			
Yes	68 (56.7%)	79 (65.8%)	0.093
No	52 (43.3%)	41 (34.2%)	
Age (years)α	60.46 (12.02)	64.80 (12.32)	0.006
BMI (kg/m2) α	28.50 (5.00)	28.60 (7.20)	0.906

αmean ± standard deviation; BMI, body mass index. The *p*-values were calculated by Pearson Chi-square test for gender, and smoking (%), while the student's *t*-test was used for Age, BMI

140 volts for 40 minutes. Ultraviolet light was used to visualize the products. PCR products of the previous step were sent to (Center Name) for sequencing using Sanger=based technology. Sequencing was performed from both ends of the fragment using the forward and reverse primers of the original PCR reaction.

The Chromas Pro Software (http://technelysium.com.au/wp/chromas) was used to visualize sequence chromatograms. The above software was also used for sequence alignment with a reference sequence of the second exon of *NAT2* to identify genetic variants in the sequence. The NCBI (http://www.ncbi.nlm.nih.gov) and Ensemble genome browsers were used to indicate if any of the identified genetic variants are new or previously reported.

Of note, the alleles and genotypes were successfully determined for all SNPs among all enrolled subjects. The allele and genotype frequencies of each SNP were calculated using standard methods. Deviations from Hardy Weinberg equilibrium were tested using a chi-square test.

In-silico predictions for the effect of genetic SNPs on NAT2 protein

Four web-based applications; PolyPhen 2.0 (http://genetics.bwh.harvard.edu/pph2/), SIFT (https://sift.bii.a-star.edu.sg/), PROVEAN (http://provean.jcvi.org/index.php) and Mutation Taster (http://www.mutationtaster.org/) were used to predict the effect of NAT2 SNPs on protein structure and function.

Statistical analysis

The minimum sample size required to meet the study objective was estimated based on Pourhoseingholi and others (Pourhoseingholi *et al.*, 2013): BC prevalence in Jordan (5%), a margin of error which was set to be ±5% and, a confidence level that was set to be 95%, with 5% alpha level, and power level of 80%. Based on the above information, the minimum sample size required was 73. The number of BC patients who enrolled was 120.

Statistical analysis was carried out using the Statistical Package for Social Studies (SPSS) software (version 23, IBM, NY). Student *t*-test was used to evaluate if significant differences exist between cases and controls in terms of age and BMI, while Pearson Chi-square was used for gender and smoking status. Pearson's Chi-square was also used to evaluate the association of allele or genotype distributions with BC risk. Subgroup analysis was also done according to smoking status. Results were considered significant if *p*≤0.05.

Multivariate logistic regression analysis was done to define the association of c.341T>C and c.87G>A SNPs with BC risk in the presence of potential confounders including age, gender, smoking, and BMI. Results were considered significant if *p*≤0.05 with a confidence limit of 95%. Regression subgroup analysis was also conducted according to smoking status.

RESULTS

Subject characteristics

A total of 240 subjects were recruited in this study; 120 BC cases and 120 controls. The characteristics are summarized in Table 1. Among cases, the majority (86.7%) were males and 65.8% were smokers. The majority of the cases were in earlier stages of BC; non-muscle-invasive (Ta=48.33% and T1=36.67%) and muscle-invasive (T2=7.5%, T3=5% and T4=2.5%).

Among controls, 88.3% were males and 56.7% were smokers. While significant differences in case status by gender, smoking status, and BMI were not statistically significant, the mean age of cases (64.80 (12.32)) was significantly higher than that for controls (60.46 (12.02)) (*p*=0.006).

Mutational analyses of a 446 bp fragment of the second exon of the *NAT2* gene among study subjects

A total number of 40 variants were detected in our sample. These were a substitution in one single nucleotide (SNPs) and we did not detect any insertions or deletions (Fig. 1 Supplementary at https://ojs.ptbioch.edu.pl/index.php/abp/). Out of the 40 SNPs detected in our population, 12 SNPs were previously reported while 28 SNPs were not reported in any of the publicly available databases (GenBank or Ensembl) (Table A Supplementary at https://ojs.ptbioch.edu.pl/index.php/abp/). None of the SNPs detected in this study had a minor allele frequency of less than 0.2. All of the SNPs were in agreement with Hardy Weinberg Equilibrium except for the two novel SNPs (c.147G>C) and (c.162T>C) (P< 0.05). These two SNPs were thus excluded from further analysis. All of the remaining SNPs were brought forward for further evaluation of their association with the risk of BC.

The association of genotypic and allelic frequencies of *NAT2* SNPs with bladder cancer

The relationship between 38 SNPs discovered in the sequenced region of the *NAT2* gene and BC was evaluated. Out of 38 SNPs that fit these criteria, only two SNPs showed a significant relationship with BC case status (*p*<0.05); the reported SNP (c.341T>C) and the novel SNP (c.87G>A).

Table 2. Genotype frequencies of *NAT2* SNPs in study subjects.

SNP ID	Genotype	Control n (%)	Bladder cancer n (%)	*p*-value
c.341T>C	TT TC CC Total	15 (12.5%) 105 (87.5%) 0 (0.0%) 120 (100%)	3 (2.5%) 113 (94.2%) 4 (3.3%) 120 (100%)	0.0097
c.87G>A	GG GA AA Total	66 (55.0%) 54 (45.0%) 0 (0.0%) 120 (100%)	53 (44.2%) 51 (42.5%) 16(13.3%) 120 (100%)	0.001

The *p*-values were calculated by the Pearson Chi-square test

Table 3. Allele frequencies of *NAT2* SNPs in study subjects.

SNP ID	Allele	Control n (%)	Bladder cancer n (%)	*p*-value
c.341T>C	T C	135 (56.2%) 105 (43.8%)	119 (49.6%) 121 (50.4%)	0.143
c.87G>A	G A	186 (77.5%) 54 (22.5%)	157 (65.4%) 83 (34.6%)	0.003

The *p*-values were calculated by the Pearson Chi-square test

Genotype distribution of c.341T>C by case status was statistically significant (*p*=0.0097). The frequency of the heterozygous TC and the homozygous CC genotypes was higher among BC cases than their control counterparts (Table 2). Similarly, the genotype distribution of c.87G>A was significantly different by case status (*p*=0.001). The homozygous GG and the heterozygous GA were higher among controls compared to cases, while the homozygous AA genotype was higher in BC cases (Table 2).

Regarding the analysis of alleles association with BC (Table 3), it was found that for c.341T>C, the frequency of the T allele was higher among controls, compared to BC cases, while the frequency of the C allele was higher in cases. For c.87G>A, the frequency of the G allele was significantly higher among controls, while the frequency of the A allele was significantly higher in BC cases (*p*=0.003).

Upon subgroup analysis of genotype frequency among smokers and non-smokers, separately (Table 4), the genotype distribution of c.341T>C showed a significant association with disease status, cases vs. controls, among smokers only (*p*=0.044). Among non-smokers,

the distribution of c.341T>C by disease status, cases vs. controls, was not statistically significant (*p*=0.063) (Table 4). Regarding the genotype distribution of the novel SNP c.87G>A by case status among smokers and non-smokers, statistically significant differences were detected between genotype and case status among both smokers and non-smokers.

Multivariate regression analysis of *NAT2* SNPs with bladder cancer

BC patients in this study were significantly older than controls and the percentage of smokers was higher in BC patients than in controls but not statistically significant. Accordingly, a multivariate regression analysis was done to assess if any of the *NAT2* SNPs significantly modulates BC risk upon adjustment of potential confounders. Table 5 represents all variables in the model to assess the effect of genotypes on BC after controlling the effects of age, gender, BMI, and smoking.

It was found that smoking and age increased the risk of BC (*p*<0.05). Upon controlling for the effect of gender, age, BMI, and smoking status, the genotype distribution of c.341T>C was significantly involved in BC

Table 4. The Genotyping frequencies and smoking status

Smoking status	SNP ID	Genotype	Control n (%)	Bladder cancer n (%)	*p*-value
Smokers	c.341T>C	TT TC CC Total	7 (10.3%) 61 (89.7%) 0 (0.0%) 68 (100%)	2 (2.5%) 74 (93.7%) 3 (3.8%) 79 (100%)	0.044

AOR, adjusted odds ratio; CI, confidence interval; *Distorted AOR.

development. Subjects with the TC genotype were 6.15 more likely to develop BC compared to TT (*p*=0.007 and 95% C.I.=1.6 to 22.9). Regarding the c.87G>A genotype distribution, the *p*-value indicated no significant difference (*p*>0.05).

Regression subgroup analysis with smoking status

We further conducted the analysis by smoking status Table 6. Regarding the c.341T>C SNP, the TC was a risk factor among smokers (5.47 times), (*p*=0.044 and 95% C.I.=1.044 to 28.679). Regarding c.87G>A, GA was a risk factor only among smoker patients (AOR= 2.356, *p*=0.019 and 95% C.I.=1.152to 4.819).

Prediction of the effect of *NAT2* SNPs on protein function and phenotype

All SNPs effects were predicted depending on different in-silico predictions websites which are Mutation Taster, PROVEAN, Polyphen-2 and Sift. Table 7 represents the prediction of the reported SNP c.341T>C and the novel SNP c.87G>A. For c.341T>C, Isoleucine amino acid was changed to Threonine at position 114 of the amino acids sequence. It was predicted as being polymorphism, deleterious, affecting the protein function and reflecting slow acetylator phenotype. Regarding c.87G>A, no change was detected in the amino acid sequence (Glutamine amino acid), however, it was predicted as a disease-causing, neutral and tolerated.

DISCUSSION

Globally, BC is considered the 10th most common malignancy, and the 13th most fatal cancer, accounting for 2.1% of all cancer fatalities (Halaseh *et al.*, 2022). In Jordan, BC was found to be the fourth most prevalent cancer and accounting for 4.1% of all cancer deaths (Abdo *et al.*, 2021). NAT2 is an important enzyme that metabolizes xenobiotics, via acetylation reactions, hence,

modulating susceptibility to environmental carcinogens and toxins that arise from tobacco products, diet, or other environmental exposures (Mittal *et al.*, 2004).

NAT2 gene is a polymorphic gene that encodes for NAT2 enzyme (Magalon *et al.*, 2008). Genetic variations in this gene result in three different phenotypes; rapid, intermediate, and slow acetylators affecting the drug metabolism, therapeutic effects and adverse effects, as well as the vulnerability of the individual to several carcinogens (Garcia-Martin, 2008; Ladero, 2008; Sabbagh *et al.*, 2011). Genetic polymorphisms of *NAT2* have been found to be associated with susceptibility to develop different cancer types with various degrees (Avirmed *et al.*, 2021; Zhu *et al.*, 2021). It has been hypothesized that the increased susceptibility to BC among smokers is caused by genetic polymorphisms in the *NAT2* gene that results in slow acetylation of the aromatic molecules that exist in tobacco (Tao *et al.*, 2010; Ribouh-Arras *et al.*, 2019), thus we aimed to test this hypothesis in our study.

To the extent of our knowledge, this study was the first to explore *NAT2* polymorphism and its association with BC among the Jordanian population. Moreover, in our study, the effect of single nucleotide polymorphism of the *NAT2* gene was stratified by smoking status to identify the effect of genetic variations regardless of smoking status.

Our study revealed – as expected – that the majority of BC patients were males and smokers. BC patients were found to be overweight, which is a previously known risk factor for BC in addition to the male gender and smoking (Kirkali *et al.*, 2005; Nasr *et al.*, 2017; Rezaei *et al.*, 2019).

We have investigated the association of several SNPs in the N-terminal catalytic domain in the *NAT2* gene with the risk of BC. The results of our genetic analysis

Table 7. Prediction of novel *NAT2* SNPs on NAT2 protein function and phenotype

SNP ID	NP	Mutation taster	PROVEAN	Polyphen-2	Sift
c.341T>C	p.Ile114Thr	Polymorphism	Deleterious	Benign	Affect protein function
c.87G>A	P.Glu29=	Disease causing	Neutral	Benign	Tolerated

showed that the frequency of the A allele and the AA genotype of the novel SNP c.87G>A was significantly higher in BC. Since tobacco smoking is a major risk factor for the development of BC we performed a stratified analysis. Interestingly, the analysis showed that these results were significant in both smokers and non-smokers, Regression subgroup analysis, however, showed that GA genotype was a risk factor for BC among smokers only. This may indicate that smoking modifies the association between BC and GA genotype of this SNP.

Individuals with the TC genotype of c.341T<C SNP are 6 times more likely to have BC compared to those with the TT genotype. This is consistent with findings of previous studies that revealed c.341T>C SNP with its slow acetylation phenotype to increase the risk of BC especially among smokers (El Desoky et al., 2005; García-Closas et al., 2005; Quan et al., 2016; Song et al., 2020). Furthermore, our results found that only smoking individuals carrying the C allele in our population could be at a higher risk of BC in view of their slower acetylation of tobacco smoking confirming the results of others (Marcus et al., 2000), while contrasting other studies that indicate no difference in BC risk between different genotypes (Mittal et al., 2004; Saleh et al., 2019).

The reported SNP c.341T>C was predicted as polymorphism, benign, and affecting protein function with deleterious effects. In addition, this SNP is linked to slow acetylator phenotype. As mentioned earlier, this SNP increased the risk of BC among smokers. This is in accordance with other studies, where SNPs with slow acetylation are associated with a higher risk for different cancer types including BC, and mainly among smokers (Zhu et al., 2015; Marcus et al., 2000; Kabir & Rehman, 2018).

Our sequence analysis was limited to a short stretch (446 bp) of the second exon of the coding region of the NAT2 gene; an area that only encompassed the N- catalytic functional domain of the enzyme. Sequence analysis of the entire coding region of the gene is required in future studies. This is especially important since previous studies from other populations showed that genetic areas outside the area sequenced in this investigation may contain genetic variants that affect enzyme function and acetylation phenotype (Boukouvala et al., 2003; Ribouh-Arras et al., 2019).

A high degree of polymorphism was discovered in this gene across a short stretch of the coding sequence. Previous studies also reported the NAT2 gene as being highly polymorphic upon gene sequencing (Sekine et al., 2001; Matimba et al., 2009). Considering that more than half of the genetic variants discovered in this investigation were not previously reported, a more comprehensive evaluation of the NAT2 gene polymorphism should be conducted on a larger number of individuals representing different geographic areas and ethnic backgrounds present in Jordan.

This report highlights the discovery of a novel SNP in the NAT2 gene and its association with BC. Studies that examine the effect of the above SNP on enzyme function and/or structure should be conducted using purified enzyme preparations or mammalian cells transfected with vectors carrying the coding region of the enzyme. The above investigations could be coupled with in vivo assays which examine the acetylation kinetics of individuals that carry the different genotypes using safe and well tolerated substrates (for example, caffeine).

Considering that NAT2 polymorphisms may affect the therapeutic dose and safety profile of many of the most commonly prescribed medications and the high degree of polymorphism discovered in NAT2 (at least among the Jordanian population), we suggest to build a national database of the most frequent alleles of the NAT2 gene in Jordan including their effect on the metabolism of various drugs and medications. This database can then be used as a tool to promote NAT2 pharmacogenetic profiling of patients as part of their treatment protocol.

The major strengths of this study include being the first study in Jordan in which a gene of pharmacogenetic importance was sequenced. This population-based study could represent the first step toward establishing a database of NAT2 gene variants in Jordan – this gene is known to have wide variations across ethnicities (Yee et al., 2020). Moreover, our study was not limited to investigating the effects of already reported polymorphisms but rather attempted to discover novel – not previously reported – variants. This might set up the stage for future population-based studies in the region. Moreover, stratifying our analyses according to smoking status enabled us to control smoking as a potential confounder. Our sample was retrieved from three major centers, one of them is the only specialized cancer center in Jordan, in which cancer patients are treated from all over the country. This makes our results generalizable to all Jordanians with BC.

Yet, this investigation is subject to several limitations. First, the relatively small sample size limits our ability to attain sufficient statistical power and increases the risk of type II error. Second, we acknowledge that we were not able to quantitatively assess the smoking status of participants in order to assess its dose-response relationship with BC, compared to what was done by Moore and others (Moore et al., 2011). Third, this study did not investigate the acetylation activity of the enzyme nor evaluated the acetylation phenotype (by measuring N-acetylated metabolites after administration of drugs like isoniazid, or caffeine) (Grant et al., 1984) distribution among study participants. Since this information is also lacking in Jordan, future studies investigating NAT2 phenotype and genotype associated with BC in the Jordanian population are needed. The lack of enzyme modelling studies assessing the effects of newly discovered variants was another limitation. Finally, despite controlling for smoking status as a confounder, causal inferences still cannot be made due to the nature of observational studies, such as case-control studies, where a temporal sequence is lost.

CONCLUSION

This case-control study demonstrated that smoking and genetic variation in the NAT2 gene are associated with BC risk. Although several investigations across multiple populations explored the association of NAT2 polymorphism with the risk of BC, this is the first study from Jordan. Furthermore, this is the first report from the region to present genomic sequence data on the N-catalytic domain of the NAT2 gene. This genomic-based approach allowed us to identify a novel variant c.87G>A that was not reported before and was found here to be associated with BC risk. In addition, we detected the previously reported SNP (c.341T>C) that was related to slow acetylation phenotype and was also found to increase BC risk. Our data supports the use of TC and GA genotypes of c.341T>C and c.87G>A SNPs, respectively as potential biomarkers of BC, particularly among smokers. However, further investigations with a larger

population are needed to validate our findings. Given the high prevalence of tobacco smoking in Jordan, the initiation of awareness campaigns that explain the implications of cigarette smoking on health and disease is strongly recommended.

Alpha mangostin (AM), isolated from G. mangostana, showed beneficial effects in several disorders due to its antioxidant and anti-inflammatory properties. Acute kidney injury (AKI) due to different etiologies can develop into severe complications, resulting in high mortality rates. In this work, AM is tested for its ability to alleviate AKI in glycerol-induced AKI rat model, where 30 Male Sprague-Dawley rats were assigned to a healthy group, glycerol-treated group and AM-treated group. Glycerol- and AM groups received a single dose of glycerol (per IM, 50% glycerol in saline, 8 ml/kg), whereas control group was injected with saline. AM treatment (a single daily dose, per IP, 175mg/kg) was accomplished for three days. Animals were executed to collect blood samples and kidney tissue for biochemical and histological examination. It was found that glycerol induced increase in serum creatinine, blood urea nitrogen (BUN), lipid peroxidation, serum magnesium, TNF-α and IL-6. It also induced renal edema and hypocalcemia along with histopathological renal damage. AM treatment improved renal histological features and alleviated increase in serum creatinine, BUN, serum magnesium, TNF-α and IL-6 levels, as well as renal edema and lipid peroxidation but did not affect serum calcium levels. This suggests AM as a potential therapeutic agent for treating AKI mainly via its antioxidant and anti-inflammatory properties.

INTRODUCTION

Fruits are highly consumed and largely appreciated throughout the world. They represent a wealthy pool of diverse bioactive compounds, which have shown variable health benefits in reducing the incidence of various diseases such as hyperlipidemia, cancer, oxidative stress, inflammation and heart disease in addition to their effects as anti-diabetic, antimicrobial, neuroprotective, immune-stimulant and anticonvulsant (Karasawa & Mohan, 2018). *Garcinia mangostana* together with nearly 400 other species belongs to *Garcinia* genus; the biggest genus of the *Clusiaceae* family (Magadula, 2010). *G. mangostana's* round, reddish- to dark purple fruits have a sweet, slightly acidic flavor and have been used to treat a wide variety of medical conditions (Ovalle-Magallanes *et al.*, 2017). *G. mangostana* fruit is reported to be rich in xanthones; tricyclic oxygenated compounds (Fig. 1) that exhibit nu-

Figure 1. Structure of α-mangostin (AM).

merous bioactivities such as α-amylase inhibitory, anti-HIV, antimicrobial, antioxidant, anti-inflammatory, antimalarial, and antihypertensive effects in addition to its cytotoxic effect on various tumor cell lines (Mohamed *et al.*, 2017; Ibrahim *et al.*, 2019a; Ibrahim *et al.*, 2019b; Gutierrez-Orozco & Failla, 2013). α-Mangostin (AM, Fig. 1) is one of the major xanthones isolated from *G. mangostana* that has antioxidant properties and possesses diverse bio-activities, such as anti-tumor, anti-inflammatory, cardio-protective, anti-diabetic, larvicidal, antifungal, α-amylase inhibitory, anti-parasitic, anti-obesity, and antioxidant (Chen *et al.*, 2008; Devi Sampath & Vijayaraghavan, 2007; Watanabe *et al.*, 2018; Larson *et al.*, 2010; Perez-Rojas *et al.*, 2016; Chen *et al.*, 2018).

Despite the number of reports suggesting a beneficial effect for AM in alleviating nephropathy (Perez-Rojas *et al.*, 2009; Sanchez-Perez *et al.*, 2010), no reports investigating its role in the management of acute kidney injury (AKI) are yet available. AKI is a high mortality rate clinical condition characterized by a sudden renal impairment; with multiple complicated underlying causes including hemorrhagic shock, infection, rhabdomyolysis, and urethral obstruction (Chawla *et al.*, 2014; Bosch *et al.*, 2009). Epidemiological screening showed that the incidence rate in ICU for AKI-patients was 30–50% and the mortality rate among those patients was 63% (Glodowski & Wagener, 2015). Surviving patients need 6–12 months to completely recover their kidney functions (Li *et al.*, 2020a), whereas 19-31% of AKI patients reach end-stage renal failure (Goldberg & Dennen, 2008; Venkatachalam *et al.*, 2015). Therefore, early intervention to improve kidney functions and treat AKI plays a key role to ameliorate the progression to chronic nephropathy (Homsi *et al.*, 2010).

Intramuscular Glycerol injection is one of the most common protocols used in rats to induce rhabdomyolysis (RM) that ends by AKI, one of the most severe complications of RM (Al Asmari *et al.*, 2017; Sun *et al.*, 2018). RM is a condition caused by extensive skeletal muscle breakdown due to ischemia, toxins, physical effects and infections, resulting in leakage of overwhelming amounts of intracellular contents including myoglobin accessing the blood circulation. Myoglobin exerts toxic effect on the kidneys, where it induces oxidative stress due to production of ROS and inflammation ending by apoptosis. When myoglobin becomes filtered through the kidneys, it is engulfed into the tubular cells via endocytosis, where the ferrous-myoglobin is converted to ferric-myoglobin releasing highly reactive hydroxyl radicals. These radicals induce lipid peroxidation and affect membrane integrity, resulting in AKI (Panizo *et al.*, 2015). ROS-induced inflammation results in infiltration of immune cells to the site of inflammation, where these cells start producing proinflammatory mediators, such as TNF-α and different interleukins that further aggravate the inflammatory response. Both TNF-α and IL-6 have been linked to disease severity in case of AKI and are used as markers for predicting the clinical outcome and mortality (Shimazui *et al.*, 2019; Ramesh & Reeves, 2004).

In the current work, we aimed at evaluating the therapeutic potential of AM against glycerol-induced AKI via assessing its anti-inflammatory, antioxidant and tissue protective effects.

METHODS

Materials

All materials utilized in the current study were of analytical grade and were purchased from local suppliers unless otherwise stated. AM was isolated and purified from fruit bulb and purity was estimated to be 98% (see supplementary data).

Animals and Treatment

Thirty Male Sprague-Dawley rats, 8 weeks-old (180–200 g), were housed in controlled temperature under 12hrs light/dark cycle with free access to food and water and were allowed to accommodate for one week before initiating the experimental procedure. Animals were assigned randomly into three groups with 10 animals in each; a healthy control group, a positive control group (AKI-group) and AKI-AM treated group.

To induce the AKI model in the second and third groups, rats in these groups were deprived of water for 24 hrs before being injected with a calculated dose of 50%, v/v glycerol/saline divided equally on both hind limbs (IM, 8 ml/kg body weight). Healthy control animals were treated similarly to AKI animals but received an equivalent volume of sterile saline instead of glycerol. One hour before inducing the AKI model, animals of AKI-AM group received AM (175 mg/kg in DMSO, IP injection), and the AKI group animals received a corresponding amount of DMSO, and the treatment was repeated once a day for three consecutive days.

Twenty four hours after the last dose of AM, animals were weighed then sacrificed under anesthesia. Blood was collected by cardiac puncture and kidneys were promptly collected, rinsed in ice-cold saline and weighed individually and the recorded weight was used for calculating KW/BW ratio. The right kidney from each animal was stored in 10% neutral formalin solution for further histological examination, whereas the left one was homogenized in Tris-buffer and frozen for further biochemical evaluation.

All animal handling protocols were approved by the local Institutional Animal Care and Use Committee, faculty of pharmacy, Minia university (project code number: ES10/2022), and were in compliance with the International Guidelines for the Care and Use of Laboratory Animals.

Kidney weight-to-body weight ratio

The average weight of the freshly isolated kidneys was divided by the corresponding animal body weight and the value was multiplied by 100 to represent it as a percentage.

Biochemical analysis

Renal parameters. Collected blood samples were allowed to clot at room temperature for 15–20 minutes before being centrifuged at 3000 rpm at 4°C for 10 min to separate the serum. Assessment of blood urea nitrogen (BUN), creatinine, calcium (Ca^{2+}), and magnesium (Mg^{2+}) levels were performed spectrophotometrically using the commercially available kits according to the manufacturer's instructions (Randox®, UK).

Lipid peroxidation. Kidney homogenates were centrifuged at 5000 rpm for 15 minutes and the supernatants were collected for the quantification of thiobarbituric acid reactive substances (TBARS) in an attempt to assess lipid peroxidation based on the earlier established protocol (Ohkawa *et al.*, 1979) and according to the manufacturer's instructions (Lipid peroxidation (MDA) assay kit, Sigma Aldrich, USA). Kidney lipid peroxidation in tissue was calculated as μmole MDA/g of tissue.

Assessment of TNF-α and ILs using enzyme-linked immunosorbent assay (ELISA). Levels of circulating proinflammatory markers TNF-α and interleukin-6 (IL-6) were evaluated in serum using commercially available ELISA kits according to the manufacturer's instructions (Sigma Aldrich, USA).

Assessment of relative gene expression using qRT-PCR

In brief, primers specific to the genes of interest: glutathione peroxidase (GPx), glutathione reductase (GRs) and superoxide dismutase (SOD) along with that of ribosomal protein S-18 (RPS-18) as a house keeping gene were utilized (as shown in primers list, Table 1) to perform, quantitative RT-PCR analyses. Freshly isolated kidney tissues were homogenized, and RNA was isolated using

Table 1. sequence of the primers used for quantitative evaluation of GPx, GRS, TSOD expression

Gene	Sense	Anti-sense
GPx	GTCCACCGTGTATGCCTTCT	TCTGCAGATCGTTCATCTCG
GRs	CAATTGGCATGTCATCAAGG	CCATCTCGAAATGTTGCGTA
TSOD	TGGTGAACCAGTTGTGGTGT	AAAATGAGGTCCTGCAGTGG
RPS-18	AGTTGGTGGAGCGATTTGTC	GAACGCCACTTGTCCCTCTA

miRNeasy Mini (Qiagen, Germany), followed by reverse transcription to create the cDNA using ImProm-II™ reverse transcription system according to the manufacturer's instructions (Promega, USA). Expression level of target genes mRNA was evaluated based on the cDNA, then the relative target gene expression was calculated by comparative Ct ($2^{-\Delta Ct}$) method using RPS-18 as a house keeping gene. Data were presented as mean ± standard error of means for three independent experiments.

Histopathological examination

After being excised, kidneys were rinsed in saline then fixed in 10% neutral formalin solution for 24 hrs followed by dehydration in a series of increasing alcohol concentrations. Finally, they were embedded in paraffin, and 5-microns sections were cut on a microtome and mounted on glass slides for histological investigation. After being deparaffinized, the sections were rehydrated and stained with Hematoxylin & Eosin to evaluate and quantify the extent of tubular injury, dilatation, vacuolation and necrosis in kidney tissues as previously described (Wu *et al.*, 2017).

Data and Statistical Analysis

All data are expressed as means ± S.E.M. (n=10) for all the experiments. Multiple comparisons of data were analyzed by one-way analysis of variance, as appropriate, and group means were compared using Tukey Kramer post hoc test. *p*-values less than 0.05 were considered as statistically significant.

RESULTS

Effect of glycerol and AM on serum biochemical parameters and lipid peroxidation

Injection of glycerol into the animals resulted in signs of renal injury that was characterized by a significant three-fold elevation of serum creatinine when comparing these animals to healthy control group (*p*<0.05). Glyc-

erol administration also resulted in significant increase in blood urea nitrogen (BUN) compared to healthy control animals (*p*<0.05) (Fig. 2A and B).

Acute renal injury induced by glycerol also resulted in a significant increase in lipid peroxidation (p<0.05) in comparison to healthy control animals. Interestingly, administration of AM in glycerol-induced AKI animals effectively ameliorated the signs of renal injury. It significantly decreased serum creatinine as well as BUN levels to values that are comparable to normal healthy group (1.2±0.01 mg/dL and 43.66±25.66mg/dL respectively, *p*<0.05) (Fig. 2A and B)

In addition, AM was significantly capable of ameliorating glycerol-induced lipid peroxidation when compared to animals receiving glycerol alone (*p*<0.05) as shown in Fig. 2C.

Effect of glycerol and AM on serum calcium and magnesium levels

Analysis of electrolytes in the sera of test animals revealed a significant elevation in serum magnesium (Mg^{2+}) in AKI group compared to the healthy control group (4.1±0.02 mg/dl *vs.* 2.48±0.14 mg/dl, *p*<0.05). In contrast, a significant reduction in serum calcium (Ca^{+2}) was observed in this group compared to the healthy control (2.39±mg/dl *vs.* 8.56±0.31 mg/dl, *p*<0.05) as seen in Fig. 3A and B. It is worth to note that the treatment with AM significantly ameliorated the increase in serum Mg^{2+} levels induced by glycerol compared to glycerol-treated animals which didn't receive AM (*p*<0.05). In the same time, serum Mg^{2+} levels were significantly indistinguishable when comparing AM-treated animals with the healthy control ones (*p*>0.05). On the other hand, depleted (Ca^{+2}) levels in response to glycerol treatment were not replenished upon AM treatment (*p*>0.05) and remained significantly less than the healthy control (*p*<0.05, Fig. 3).

Effect of glycerol and AM on endogenous antioxidants

The relative expression of GPx, GRs and SOD was assessed to investigate the effect of the different treatments. Glycerol injection resulted in a significant reduction in the relative gene expression of all three enzymes compared to control animals (*p*<0.05; Figs 4A, B and C). Interestingly, treating AKI animals with AM significantly ameliorated the glycerol-induced reduction in GPx, GRs and SOD compared to animals that received glycerol only (*p*<0.05; Figs 4A, B and C). It is to be mentioned that relative gene expression of GPx and GRs was indistinguishable from that of healthy control animals upon AM treatment (*p*>0.2), whereas the relative expression of

Figure 2. effect of glycerol and AM on biochemical parameters.
Glycerol administration induced a significant increase in serum urea (**A**), creatinine (**B**) and lipid peroxidation compared to healthy control (*******p*<0.05). Animals treated with AM show significant reduction in all three parameters compared to glycerol treated animals (**##**). Values are expressed as mean ±S.E.M., n=10, **/##*p*<0.001, */#*p*<0.01.

Figure 3. effect of glycerol and AM treatments on serum calcium and magnesium.
Glycerol administration induced a significant increase in serum Mg^{2+} (**A**, $p<0.05$) and reduction in serum Ca^{2+} (**B**, $p<0.001$) compared to healthy control. Animals treated with AM showed a significant reduction in magnesium levels compared to the glycerol treated group ($p<0.05$) but no significant changes in serum calcium levels ($p>0.0.05$) was achieved compared to the glycerol treated group. In AM treated animals, Mg^{2+} levels are comparable to control but Ca^{2+} levels are significantly lower than control ($p>0.26$ and $p<0.001$ respectively). Values are expressed as mean ± S.E.M., n=10, **/##$p<0.001$, */#$p<0.05$

SOD was still significantly less than that of control after AM treatment ($p<0.05$).

Effect of glycerol and AM on circulating inflammatory markers level

Animals exposed to glycerol treatment revealed a significant increase in levels of circulating TNF-α and IL-6 when compared to healthy control animals (Fig. 5A and B, $p<0.05$). Interestingly, treating animals with AM resulted in significant amelioration in serum levels of both proinflammatory cytokines ($p<0.05$).

Effect of glycerol and AM on kidney index

As expected, glycerol-treated animals suffered from renal edema as observed by a significant increase in kidney index (KW/BW ratio) when compared to the healthy group (0.57% *vs.* 0.31% respectively, $p<0.05$). Interestingly, treating the animals with AM was capable of reducing KW/BW ratio in the corresponding animals compared to the AKI group animals; however, this reduction was not statistically significant (0.42% *vs.* 0.57%, $p>0.05$) (Fig. 6).

Histopathological findings

Administration of glycerol effectively induced AKI as observed in the form of severe degenerative changes in renal corpuscles accompanied with accumulation of protein casts in the mesangial tissue when compared to control group animals (Fig. 7C and D, arrow head). In addi-

tion, marked degeneration of the renal tubules could be detected (arrow) where the lumen of such tubules was obliterated by protein casts. These changes were accompanied by severe congestion of the renal blood vessels (Fig. 7C and D).

Interestingly, treating AKI animals with AM resulted in marked alleviation of the degenerative changes induced by glycerol. Figures 6E and F show normal renal corpuscles (C) and glomerular capillaries. Despite the mild degree of hydropic degeneration that can be detected in some renal tubules (arrow), the majority of the tubules showed normal morphological features (T). It is to be noted that some protein materials can be detected in few tubules but less than that observed in the glycerol-treated animals. A comparison among the test groups regarding these morphological changes is presented in Table 2.

DISCUSSION

AKI is a renal dysfunction that is characterized by prompt loss of renal filtration rate and accumulation of protein debris within the renal tissues, where rhabdomyolysis (RM) is a main cause of AKI (Parekh *et al.*, 2012). Glycerol-induced rhabdomyolysis is an established model that mimics AKI in human as it induces a myoglobinuric condition and a significant reduction in filtration rate that result mainly from oxidative stress, which induces inflammation and consequently apoptosis (Zager, 1996).

In the current study, glycerol injection induced a significant increase in serum creatinine and BUN, indicating renal dysfunction that was associated with renal edema in response to the toxic levels of myoglobin reaching the kidneys as observed by the increased KW/BW ratio. These pathological changes were confirmed by the histological examination that showed signs of tubular necrosis, congestion and protein casts accumulation within the tubules and mesangial tissue. The observed effects of glycerol were reported earlier by several research groups (Al Asmari *et al.*, 2017; Ustundag *et al.*, 2009; Korrapati *et al.*, 2012).

Despite the possibility of recovering the renal functions affected by RM within few months, some reports have shown that structural changes, including fibrosis, possibly take place as a result of excessive extracellular matrix deposition and the released pro-inflammatory and pro-fibrotic factors (Wen *et al.*, 2011). This causes RM-induced AKI to be a serious condition that needs rapid intervention to improve the prognosis and to prevent long term complications.

RM can result from muscle damage caused by direct traumatic insults or excessive muscular effort that dam-

Figure 4. effect of glycerol and AM treatments on endogenous antioxidant enzyme gene expression.
Administration of glycerol significantly reduced the relative expression of GPx (**A**, $p<0.01$), GRs (**B**, $p<0.01$) and SOD (**C**, $p<0.001$) compared to healthy control animals. Treating animals with AM significantly increased gene expression of GPx (**A**, $p<0.05$), GRs (**B**, $p<0.05$) and SOD (**C**, $p<0.05$) compared to glycerol treated animals. No significant difference in relative gene expression of GPx and GRs could be detected between AM treated animals and control ones. Values are expressed as mean ± S.E.M., n=10, **/##/$$$p<0.001$, */#/$$p<0.05$.

Protein casts	–	+++	+
Necrosis	–	+++	–
Hydropic degeneration	–	+++	+

Key: – no pathological change, +mild degree pathological change, ++moderate pathological change, +++severe pathological change

As these factors induce RM, damaged muscle cells start to release unexpectedly large amounts of myoglobin which becomes filtered through the renal tubules, but instead of being excreted, myoglobin is mostly endocytosed inside the renal tubules' cells. These endocytosed myoglobin molecules undergo several oxidation reactions releasing hydroxyl free radicals among other ROS, initiating a cascade of oxidation and peroxidation reactions to generate a condition of oxidative stress (Boutaud & Roberts, 2011). As observed in the current study, glycerol treatment significantly induced peroxidation as one of oxidative stress outcomes that can be evaluated by MDA tissue content, in agreement with several studies reporting lipid peroxidation in AKI models (Al Asmari *et al.*, 2017).

In rodents, it is believed that glycerol-induced AKI is a result of myoglobinuric nephrotoxicity and renal ischemia (Parekh *et al.*, 2012; Zager, 1996), where the molecular events observed in this model are similar to those observed clinically, which causes the glycerol-induced RM a very common model to study AKI (Stein *et al.*, 1978). In other words, pathophysiology of RM-induced AKI includes oxidative stress, cast formation in renal tubules, vasoconstriction and inflammation of renal tissues (Shanu *et al.*, 2013).

In response to oxidative stress, pro-inflammatory cytokines are released activating macrophages and T-lymphocytes at the site of inflammation, which in turn produces various cytokines e.g. TGF-β and TNF-α to propagate the inflammation condition. Released proinflammatory TNF-α interacts with various cell types and induces NFκB activation and nuclear translocation. This activates the transcription of NFκB downstream proinflammatory target genes, resulting in the release of increased amounts of proinflammatory cytokines e.g. Il-6 (Moreno *et al.*, 2012).

Several reports have shown that antioxidants are capable of protecting against myoglobin-induced oxidative stress via scavenging the released ROS, improving the endogenous antioxidant defense mechanisms, preventing lipid peroxidation or ameliorating the inflammatory response, and hence protecting against the renal damage. These molecules included ascorbic acid, vitamin E, polyphenols, suramin, curcumin and quinacrine among others (Al Asmari *et al.*, 2017; Korrapati *et al.*, 2012; Ustundag *et al.*, 2009).

AM, a xanthone isolated from *G. mangostana* fruit, has been implicated in a lot of studies for its wide range of therapeutic effects as previously mentioned (Sanchez-Perez *et al.*, 2010; Devi Sampath and Vijayaraghavan, 2007; Jung *et al.*, 2006). It has been shown to exert its action via its positive effects on the endogenous antioxidant defense mechanisms, as it was previously reported to improve the superoxide dismutase and glu-

tathione peroxidase activity, in addition to replenishing glutathione tissue content (Fang et al., 2016). In addition, AM was shown to combat inflammation and suppress the production of various inflammatory mediators and fibrogenic mediators via scavenging different free radicals like superoxide and peroxynitrite according to *in vivo* and *in vitro* studies investigating its potential effects in nephrotoxicity models (Perez-Rojas et al., 2009; Li et al., 2020b; Muhamad Adyab et al., 2019; Sanchez-Perez et al., 2010). Some reports related the anti-inflammatory effect of AM to its ability to activate SIRT-1, a nuclear histone deacetylase, which inhibits NFκB signaling and consequently its downstream pro-inflammatory effectors (Franceschelli et al., 2016), whereas others reported the ability of AM to inhibit leukocyte migration as well as the production and secretion of inflammatory mediators e.g Il-2, Il-6 and TNF-α from different cell types (Kim et al., 2021; John et al., 2022). Despite these positive effects of AM, its effect on RM-induced AKI in glycerol model is not yet investigated.

In the current research, we found that AM administration to glycerol-induced AKI rats could efficiently alleviate signs of AKI as it normalized BUN and creatinine levels and alleviated renal edema. It also alleviated the oxidative stress induced by glycerol administration as observed in ameliorating MDA tissue content. It significantly reduced serum magnesium levels, however, serum calcium levels were not improved upon treatment. AM treatment also normalized the relative gene expression of the antioxidant enzymes SOD, GPx and GRs, and ameliorated the expected increase in circulating TNF-α and IL-6, which were upregulated upon AKI induction. On the cellular level, AM could reverse most of the histopathological changes induced by glycerol injection, regaining normal corpuscles and renal tubules with minimal protein deposition indicating good signs of recovery from tissue damage.

These effects can be explained by the previously reported ROS scavenging activity of AM and its ability to replenish the endogenous antioxidant mechanism (Fang et al., 2016; Martinez et al., 2011). In this context, AM was reported to achieve its antioxidant effect via increasing the activity of various antioxidant enzymes including SOD and GPx, and retrieving the gene expression of endogenous antioxidant enzymes as well (Perez-Rojas et al., 2009). In addition, its previously reported mitochondrial-stabilizing, antiapoptotic effect prevents cell death and protects against tissue damage, enabling the recovery of renal functions upon its use (Perez-Rojas et al., 2009; Sanchez-Perez et al., 2010). AM has been also reported previously for its anti-inflammatory effect and its ability to reduce/ameliorate TNF-α and other inflammatory cytokines e.g. IL-6 Il-1β and IL-8 in several models including kidney disease models via its inhibitory effect on NFκB and TLR-4 signaling in addition to other signaling pathways linked to inflammation in renal tissues (Tewtrakul et al., 2009; Xu et al., 2017; Zou et al., 2019).

Hypocalcemia is expected in the early stage of AKI where calcium becomes deposited within the cells as a result of Ca^{2+}-ATPase pumps dysfunction and the damaged sarcoplasmic reticulum, leading to a significant decrease in serum calcium levels. In a later response, proteases and phospholipases attack the cell membranes resulting in leakage of cellular contents, which consequently destroy cells in the near proximity. It is to be noted that renal injury-induced hypocalcemia is observed only in the early oliguric phase of AKI (Graziani et al., 2011; Edelstein et al., 1997).

In contrast, the increase in serum magnesium level in AKI could be attributed to the expected hypovolemic condition that may affect magnesium concentrations, and the impaired tubular filtration mechanisms following AKI that could affect its excretion. It is well established that the decline in renal functions is commonly associated with increased serum magnesium levels (Swaminathan, 2003; Quamme, 1989). The observed effect of AM on serum magnesium levels could be attributed to its ability to retrieve the renal functions and hence improved filtration rate leading to decreasing magnesium levels.

TNF-α is a proinflammatory cytokine that is produced by infiltrating immune cells in addition to various cell types within the renal tissue i.e. mesangial cells, podocytes, and endothelial cells of the proximal tubules, collecting ducts and thick ascending limbs (Ramseyer & Garvin, 2013). It is produced in response to different stimuli such as oxidative stress, infections, complement reaction and exposure to lipopolysaccharides. It has been reported earlier that normalizing the oxidative stress levels using superoxide dismutase (SOD) mimics ameliorated TNF-α production and renal pathological changes in a diabetic nephropathy animal model (Ebenezer et al., 2009). TNF-α aggravates the inflammatory process via its effect on activating nuclear translocation of the transcriptional factor NFκB with the subsequent activation of the transcribing its downstream proinflammatory target genes (e.g. TNF-α, IL-6, inducible nitric oxide synthase (iNOS) and adhesion molecules). A large body of evidence has confirmed the role of TNF-α in inducing renal damage (Shahid et al., 2008; Sun & Kanwar, 2015; Mehaffey & Majid, 2017). It has been reported that TNF-α can enhance the expression of the pro-fibrotic factor TGF-β via activating ERK signaling. This cross talking between both cytokines causes both to be crucial players in the process of tissue remodeling and fibrosis as reported earlier (Sullivan et al., 2005; Liu et al., 2021). IL-6 is a proinflammatory cytokine that is produced by immune- as well as renal cells in response to inflammation. Previous reports have correlated its serum levels with the severity of organ failure and dysfunction in ICU-admitted systemic inflammatory conditions (Shimazui et al., 2019). The previously reported ability of AM to reduce the gene expression level of TNF-α, TGF-β and IL-6 allows it to break the vicious circle of oxidative stress- inflammation-tissue damage-remodeling and fibrosis (Yiemwattana & Kaomongkolgit, 2015), resulting in a significant improvement in the renal functions and histology and preventing fibrosis, which is a main complication of AKI as observed in the current study.

In conclusion, this work represents AM as a safe natural product that can be potentially used to ameliorate the devastating renal effects of RM on kidneys directly via its antioxidant and anti-inflammatory effects and indirectly by preventing fibrosis. It can modulate the inflammatory process through its effect on the proinflammatory cytokines, TNF-α and IL-6, bringing the inflammation to a halt and achieve better recovery in the renal tissue. This may provide a medicinal tool to combat the transition of these acute effects into chronic, long lasting damages and hence decrease AKI-related mortality rates.

LIMITATIONS

Despite the interesting findings, there are some limitations to this study. Serum creatinine and blood urea nitrogen were used as biochemical markers to evaluate re-

nal function, and these data were confirmed by the histopathological examination of renal tissue sections. Urine analysis based studies including urine volume, urine creatinine and creatinine clearance tests could have supported the findings that AM attenuates glycerol-induced renal impairment. In addition, further studies are required to understand the molecular mechanism by which AM exerts its nephroprotective effect and to confirm the efficacy of AM to improve kidney functions in AKI.

MiR-375 attenuates sorafenib resistance of hepatocellular carcinoma cells by inhibiting cell autophagy

Dan Wang[1] and Jingbo Yang[2✉]

[1]Department of Neurology, the First Hospital of Changsha, Changsha, Hunan 410011, P.R. China; [2]Department of Gastroenterology, the First Affiliated Hospital of Shenzhen University, Shenzhen Second People's Hospital, Shenzhen, Guangdong 518028, P.R. China

Objective: Sorafenib is the first-line treatment for hepatocellular carcinoma (HCC), but its efficacy is limited by the drug resistance of HCC cells. MiR-375 has been shown to be an inhibitor of autophagy that contributes to sorafenib resistance of HCC cells. In this context, this study probed into the unaddressed molecular target of miR-375 in inhibiting the autophagy of HCC cells under sorafenib treatment. **Methods:** Western blotting and qRT-PCR (quantitative reverse transcription-polymerase chain reaction) have been applied to measure the expressions of miR-375 and SIRT5 in parental HCC cells (HepG2 and Huh7) and sorafenib-resistant HCC cells (HepG2/so and Huh7/so). HepG2/so cells were accordingly transfected with miR-375 mimic, miR-375 inhibitor, sh-SIRT5, pcDNA3.1-SIRT5 or negative control. Expressions of p62, LC3I and LC3II in HCC cells have been measured by Western blotting. Viability and apoptosis of HCC cells have been assessed by CCK-8 (cell counting kit 8) and flow cytometry respectively. Bioinformatics techniques and dual-luciferase reporter assay have been used to predict and verify the targeting relationship between miR-375 and SIRT5. **Results:** MiR-375 was under-expressed and SIRT5 was over-expressed in HCC cells. An autophagy inhibitor impaired the survival of HepG2/so cells transfected with miR-375 inhibitor. An autophagy activator enhanced the drug resistance of HepG2/so cells transfected with miR-375 mimic. MiR-375 suppressed the drug resistance of HepG2/so cells by inhibiting autophagy. SIRT5 enhanced the drug resistance of HepG2/so cells by promoting autophagy and it could be targeted by miR-375. **Conclusion:** MiR-375 suppresses autophagy to attenuate the sorafenib resistance of HCC cells by regulating SIRT5. The findings of this study may provide new therapeutic targets for treating HCC.

Keywords: MiR-375, SIRT5, autophagy, drug resistance, Sorafenib, hepatocellular carcinomacell

INTRODUCTION

Liver cancer belongs to the commonest deadly cancers worldwide. The death rate of liver cancer rose from 2012 to 2016 and the incidence rate continues to increase (Siegel *et al.*, 2019). Hepatocellular carcinoma (HCC) accounts for the vast majority of primary liver cancers, which can be caused by cirrhosis, infection of hepatitis B or C virus, alcohol abuse and other risk factors (Villanueva, 2019). Sorafenib is a multikinase inhibitor that has been considered the first treatment option and standard therapy for advanced-stage HCC for over a decade (Marisi *et al.*, 2018). Sorafenib targets multiple tyrosine kinases and therefore impairs proliferation, migration and angiogenesis and activates apoptosis in HCC (Brunetti *et al.*, 2019). However, a considerable portion of patients with HCC are insensitive to sorafenib, resulting in an unsatisfactory overall efficacy of this widely used drug (Cheng *et al.*, 2020). HCC cells developing sorafenib resistance exhibit significant mesenchymal phenotypes and stemness features (Xia *et al.*, 2020). Therefore, exploration of the mechanisms of sorafenib resistance is important for prolonging the survival of patients with HCC.

Autophagy is a metabolic process that is unavoidably altered in cancers and it can be well manipulated to improve the clinical outcomes of cancer patients (Levy *et al.*, 2017). Autophagy prevents cell damage and improves survival in response to energy or nutrient shortage and various cytotoxic insults (Dikic & Elazar, 2018). An autophagy inhibitor, chloroquine, overcame the resistance of liver cancer cells to drugs targeting hepatocyte growth factor-activated MET kinase which stimulated liver carcinogenesis and tumor metastasis (Huang *et al.*, 2019). Autophagy is also suggested to be an important participant in mediating sorafenib resistance of HCC. For instance, depletion of METTL3, a primary m^{6}A methyltransferase, enhanced the sorafenib resistance of HCC cells by activating autophagy-associated pathways through destabilization of FOXO3 mRNA (Lin *et al.*, 2020). CD24 activated autophagy by regulating PP2A/AKT/mTOR signaling pathway and therefore decreased the sorafenib sensitivity of HCC cells (Lu *et al.*, 2018). MicroRNA (miR)-541 inhibited autophagy-dependent sorafenib resistance of HCC cells by directly targeting autophagy-related gene (ATG) 2A and Ras-related protein Rab-1B (Xu *et al.*, 2020).

In recent years, microRNAs (miRNAs) have shown great promise as therapeutic targets for cancer treatment. MiRNAs regulate gene function in diverse cellular activities including autophagy. MiR-375 is known to be an autophagy inhibitor in many disease conditions. As an example, miR-375 promoted inflammation and apoptosis

of acinar cells in severe acute pancreatitis by inhibiting ATG7-mediated autophagy (Zhao et al., 2020). MiR-375 also inhibited autophagy to facilitate the sorafenib therapy for HCC (Zhao et al., 2018). However, the mechanism of miR-375 in regulating autophagy-dependent sorafenib resistance in HCC remains largely unknown.

SIRT5 is a sirtuin family member that resides primarily in mitochondrial matrix and regulates cellular homeostasis (Kumar & Lombard, 2018). Overexpression of SIRT5 is associated with tumorigenesis in breast cancer, colorectal cancer, HCC and more (Greene et al., 2019; Shi et al., 2019; Zhang et al., 2019). Garva and others found that SIRT5 positively regulated autophagy and proliferation of tumor cells under stress conditions (Garva et al., 2019). However, there is no report on either SIRT5-mediated autophagy in HCC or the interaction between miR-375 and SIRT5. The authors used Jefferson database to predict whether SIRT5 mRNA and miR-375 have binding sites (https://cm.jefferson.edu/) and designed this study to verify the involvement of miR-375/SIRT5 axis in autophagy-mediated sorafenib resistance of HCC cells.

MATERIALS AND METHODS

Cell cultivation

A healthy liver cell line (L-02) and human HCC cell lines (HepG2 and Huh7) were purchased from the American Type Culture Collection. L-02, HepG2 and Huh7 cells were cultured in Dulbecco's modified Eagle medium (DMEM), MEM and high-glucose DMEM, respectively. All media were supplemented with 10% fetal bovine serum and 2 mM glutamine. These cells were incubated in a moist environment (37°C, 5% CO_2) and used for experiments until they reached the logarithmic growth phase.

Establishment of sorafenib-resistant HCC cell models

Sorafenib treatment was given to HepG2 and Huh7 cells at the logarithmic growth phase. The initial dose of sorafenib was set at 1 μmol/L. The culture medium was renewed every 24 hours, in which the sorafenib concentration increased by 0.25 μmol/L each time until reaching a total of 12 μmol/L. The half maximal inhibitory concentration (IC50) >10 μM indicated resistance to sorafenib. Sorafenib-resistant HepG2 and Huh7 cells (HepG2/so and Huh7/so) were continuously treated with sorafenib to enhance the drug resistance. The cells were observed and photographed under an inverted microscope.

Cell transfection and treatment

L-02 or HepG2/so cells were transfected with miR-375 mimic, miR-375 inhibitor, sh-SIRT5, pcDNA3.1-SIRT5 or their negative control (mimic NC, inhibitor NC, sh-NC or pcDNA3.1) in 3.5 cm culture dishes ($2×10^6$ cells per dish) using Lipofectamine 2000 (Invitrogen, California, USA). The plasmids and RNAs were provided by GenePharma (Shanghai, China). All other experiments were carried out 48 hours after the transfection.

For analyzing the effect of autophagy on sorafenib resistance of HCC cells, HepG2/so cells transfected with miR-375 mimic were treated with an autophagy activator rapamycin (RAP, 0.2 μg/10 μl; Cell Signaling Technology, MA, USA) for 24 hours and HepG2/so cells transfected with miR-375 inhibitor were treated with an autophagy inhibitor 3-Methyladenine (3-MA, 50 μM; Selleck, USA) for 24 hours. The use of RAP and 3-MA was based on existing literature (Ding et al., 2021; Lendvai et al., 2021).

CCK-8 assay

The assay was applied to measure the IC50 of parental and sorafenib-resistant HCC cells. The survival rates of HCC cells were measured 24 hours after treatment with sorafenib of different concentrations (1, 2, 4, 8, 16, 32 μmol/L). The influence of miR-375 or SIRT5 on the survival of sorafenib-resistant HCC cells was also assessed. Cells of each group were cultured in a 96-well plate where every well contained $1.5×10^4$ cells. Cells in each well were incubated with 10 μl of CCK-8 reagent at 37°C for 3 hours. The absorbance value was measured at 450 nm.

Flow cytometry

Cells in each group were made into suspension for centrifugation at 2000 r/min. The cells were washed twice with phosphate-buffered saline (PBS) and then resuspended in binding buffer. Cell suspension (195 μL, about $1×10^5$ cells) was mixed with 5 μL of Annexin-V-fluorescein isothiocyanate (FITC) and propidium iodide (PI) solution. The cells were incubated in the dark for 10 minutes and their apoptosis rates were measured by a flow cytometer (BD Biosciences, Suzhou, China).

qRT-PCR

Total RNA was obtained from 4 ~ $5×10^4$ cells per well using a TRIzol kit. cDNA reverse transcribed from the RNA was used as the template for qRT-PCR. The reaction was performed according to the instruction of SYBR Prime Script RT-PCR kit. The total reactants consisted of 0.8 μl of cDNA, 5.0 μl of SYBR Primix Ex Taq, 1.0 μl of primers and 3.2 μl of RNase H_2O. The thermal cycling was set as follows: 5 minutes at 95°C; 30 cycles of 15 seconds at 95°C, 30 seconds at 95°C and 40 seconds at 72°C. GAPDH served as a reference gene. Each sample had three duplicates. The results were analyzed using the $2^{-\Delta\Delta CT}$ method: $\Delta\Delta Ct = (Ct_{target\ gene} - Ct_{reference\ gene})_{experimental\ group} - (Ct_{target\ gene} - Ct_{reference\ gene})_{control\ group}$. Sequences of the primers used in the PCR are presented in Table 1.

Table 1. Primer sequences

miR-375-F	CACAAAATTTGTTCGTTCGGCT
miR-375-R	GTGCAGGGTCCGAGGT
SIRT5-F	ACAATGGCTCGTCCAAGTTC
SIRT5-R	CCAGTAACCTCCTGCTCCTCT
GAPDH-F	GACAGTCAGCCGCATCTTCT
GAPDH-R	GCGCCCAATACGACCAAATC

Note: F, forward; R, reverse.

Western blotting

Cells were cultured for 48 h before Western blotting analysis in which 1 ~ $2×10^6$ cells per well were used. After two PBS washes, the cells were lysed in lysis buffer on ice for 45 minutes and shaken at 15-minute intervals. After quantification by a bicinchoninic acid (BCA) kit, proteins extracted from the cells were mixed with loading buffer and transferred onto a polyvinylidenefluoride

(PVDF) membrane after SDS-PAGE electrophoresis. Non-specific binding was blocked in 5% skim milk for 2 hours (room temperature). After that, the membrane was incubated with primary antibodies of SIRT5 (#8779, 1:1000), LC3II/I (#12741, 1:1000), p62 (#88588, 1:1 000), acetylated-lysine (#9814, 1:500) (Cell Signaling Technology, Beverly, MA, USA) or LDHB (ab53292, Abcam, Cambridge, MA, USA) at 4°C overnight and washed with PBS Tween 20 (PBST) for 3×15 minutes. The proteins were then incubated with the secondary antibody (ab6728, 1:2000, Abcam, Cambridge, MA, USA) for 1 hour. Protein expressions were reflected by chemiluminescence. GAPDH (Cell Signaling, #5174, 1:1000) acted as a reference protein.

Dual-luciferase reporter assay

MiR-375 was found to have a binding site on the 3'UTR of SIRT5 mRNA based on the analysis of jefferson (https://cm.jefferson.edu/). Wild and mutant SIRT5-3'UTR (WT-SIRT5 and MUT-SIRT5) were synthesized and cloned to luciferase reporter vectors and then co-transfected with miR-375 mimic or mimic NC into HEK-293T cells. Luciferase activities in the cells were assessed 48 hours after transfection using a fluorescent luminescence detector based on the instruction of the dual-luciferase reporter assay kit (Beyotime, Shang-

hai, China). Relative luciferase activity = Firefly luciferase activity/Renilla luciferase activity.

Statistical analysis

SPSS 18.0 (IBM Corp., Armonk, NY, USA) and GraphPad Prism 7.0 (GraphPad Software Inc.) were applied for statistical analysis. Data were finally presented as mean ± standard deviation (S.D.). T-test and one-way analysis of variance were used to analyze the differences of two groups and multi-groups, respectively. Differences were deemed statistically significant when $P<0.05$.

RESULTS

MiR-375 is under-expressed in sorafenib-resistant HCC cells

The parental strains of HCC cells (HepG2 and Huh7) were continuously cultured in sorafenib of increasing concentrations to obtain sorafenib-resistant HCC cells (HepG2/so and Huh7/so). The morphology of HepG2 and Huh7 cells under the inverted microscope were changed from a plump, pebble-like shape (epithelial phenotype) into a spindle shape (mesenchymal phenotype) (Fig. 1A). CCK-8 assay detected that the IC50 of sorafenib in HepG2/so and

Huh7/so cells was higher than in HepG2 and Huh7 cells (Fig. 1B, $P<0.05$), suggesting stronger tolerance of HepG2/so and Huh7/so cells to sorafenib.

MiR-375 was under-expressed in HepG2/so and Huh7/so cells compared to HepG2 and Huh7 cells (Fig. 1C, $P<0.05$). To investigate the potential effect of miR-375 expression on sorafenib resistance and on healthy liver cells, HepG2/so and L-02 cells were trans-fected with miR-375 mimic or miR-375 inhibitor. MiR-375 was up-regulated in the miR-375 mimic group and down-regulated in the miR-375 inhibitor group (Fig. 1D–E, $P<0.05$, *vs* the mimic NC or inhibitor NC group), sug-gesting successful cell transfection. The results of CCK-8 assay showed that transfection of miR-375 mimic/inhibi-tor had no significant impact on the survival of heathy liver cells (Fig. 1F). After the transfection, HepG2/so cells were exposed to sorafenib for 24 hours. Sorafenib treat-ment impeded the survival of HepG2/so cells (Fig. 1G, $P<0.05$). The survival of HepG2/so cells was further damaged by miR-375 mimic while improved by miR-375 inhibitor (Fig. 1G, $P<0.05$). The results of flow cytometry showed that miR-375 mimic promoted sorafenib-induced apoptosis of HepG2/so cells while miR-375 inhibitor at-tenuated the apoptosis (Fig. 1H, $P<0.05$).

Autophagy acts on miR-375-mediated drug resistance of HCC cells

The autophagy level in transfected HepG2/so cells was inhibited by 3-MA or activated by RAP. CCK-8 as-say detected that 3-MA treatment impaired the viability of HepG2/so cells transfected with miR-375 inhibitor, while RAP treatment enhanced the viability of HepG2/so cells overexpressing miR-375 (Fig. 2A, $P<0.05$, *vs* the miR-375 inhibitor group or miR-375 mimic group). The apoptosis of HepG2/so cells was reduced in the miR-375 inhibitor group, while enhanced in the miR-375 in-hibitor + 3-MA group (Fig. 2B, $P<0.05$, *vs* the inhibitor

NC group and miR-375 inhibitor group, respectively). The apoptosis of HepG2/so cells was promoted in the miR-375 mimic group, while inhibited in the miR-375 mimic + RAP group (Fig. 2B, $P<0.05$).

Meanwhile, according to the Western blotting measure-ment of the expressions of p62, LC3I and LC3II, the au-tophagy of HepG2/so cells was inhibited in the miR-375 inhibitor + 3-MA group, while enhanced in the miR-375 mimic + RAP group (Fig. 2C, $P<0.05$, *vs* the miR-375 in-hibitor group and miR-375 mimic group, respectively).

MiR-375 attenuates sorafenib resistance by mediating autophagy in HCC cells

According to the CCK-8 analysis of cell viability, HepG2/so cells were less susceptible to sorafenib than HepG2 cells ($P<0.05$). The drug resistance of HepG2/so cells was enhanced by miR-375 inhibitor and reduced by miR-375 mimic (Fig. 3A, $P<0.05$). The apoptosis rate of HepG2/so cells was significantly reduced compared to that of HepG2 cells ($P<0.05$). The number of apop-totic HepG2/so cells was decreased after transfection of miR-375 inhibitor, while increased after transfection of miR-375 mimic (Fig. 3B, $P<0.05$).

Furthermore, the LC3II/LC3I ratio was increased and p62 was decreased in HepG2/so cells compared to HepG2 cells ($P<0.05$). The above mentioned expres-sion trends of p62, LC3I and LC3II in HepG2/so cells were promoted by miR-375 inhibitor, while perturbed by miR-375 mimic (Fig. 3C, $P<0.05$).

SIRT5 is targeted and down-regulated by miR-375

SIRT5 was detected to be a downstream target of miR-375 based on the bioinformatics analysis of jef-ferson (Fig. 4A). Dual-luciferase reporter assay was de-signed to confirm the potential regulation between miR-375 and SIRT5. miR-375 mimic attenuated the relative

N=3; *$P<0.05$, **$P<0.01$, ***$P<0.001$; data were presented as mean ± S.D.; one-way analysis of variance was for multi-group comparison; the Tukey test was for *post hoc* multiple comparisons after ANOVA.

Figure 5. SIRT5 is over-expressed in sorafenib-resistant HCC cells and reverses the suppressive effect of miR-375 on sorafenib resistance
(**A–B**) The expression of SIRT5 in HepG2, Huh7, HepG2/so and Huh7/so cells. After HepG2/so cells were transfected with pcDNA3.1-SIRT5 or sh-SIRT5, qRT-PCR (**C**) and Western blotting (**D**) measured the expression of SIRT5 in HepG2/so cells; (**E**) CCK-8 assessed the survival rate of HepG2/so cells; (**F**) Annexin-V-FITC/PI staining and flow cytometry assessed the apoptosis of HepG2/so cells; Western blotting measured the expressions of p62, LC3I and LC3II (**G**) and the acetylation level of LDHB (**H**) in HepG2/so cells. N=3; *$P<0.05$, **$P<0.01$, ***$P<0.001$; data were presented as mean ± S.D.; T-test was for comparison between two groups; one-way analysis of variance was for multi-group comparison; the Tukey test was for *post hoc* multiple comparisons after ANOVA; HCC, hepatocellular carcinoma.

luciferase activity of WT-SIRT5 (Fig. 4B, $P<0.01$), but did not affect that of MUT-SIRT5. In cells, the expression of SIRT5 was negatively regulated by miR-375 (Fig. 4C–D, $P<0.01$).

SIRT5 is over-expressed in sorafenib-resistant HCC cells and reverses the suppressive effect of miR-375 on sorafenib resistance

According to the results of qRT-PCR and Western blotting, HepG2/so and Huh7/so cells had higher expressions of SIRT5 than HepG2 and Huh7 cells (Fig. 5A–B, $P<0.05$). To investigate the effect of SIRT5 on sorafenib resistance, SIRT5 was either knocked down or over-expressed in HepG2/so cells *via* transfection of sh-SIRT5 or pcDNA3.1-SIRT5 (Fig. 5C–D, $P<0.05$). SIRT5 inhibition aggravated the damage to the survival of HepG2/so cells whereas SIRT5 overexpression im-

proved the survival (Fig. 5E, $P<0.05$). The suppressive or promotive effect of SIRT5 inhibition or overexpression on sorafenib resistance of HepG2/so cells was reversed by miR-375 inhibitor or miR-375 mimic (Fig. 5E, $P<0.05$). SIRT5 inhibition exacerbated sorafenib-induced apoptosis of HepG2/so cells, which was later attenuated by miR-375 inhibitor (Fig. 5F, $P<0.05$). SIRT5 overexpression ameliorated the deaths of sorafenib-treated HepG2/so cells, while the apoptosis rate was increased in the pcDNA3.1-SIRT5 + miR-375 mimic group (Fig. 5F, $P<0.05$).

SIRT5 promotes autophagy by catalyzing the deacetylation of LDHB (Shi *et al.*, 2019). The ratio of LC3II/LC3I was reduced, the expression of p62 was up-regulated and the acetylation level of LDHB was increased in the sh-SIRT5 group (*vs* the sh-NC group) and pcDNA3.1-SIRT5 + miR-375 mimic group (*vs* the

pcDNA3.1-SIRT5 + mimic NC group); different expression patterns of LC3II, LC3I and p62 and a decreased acetylation level of LDHB were found in the pcDNA3.1-SIRT5 group (*vs* the pcDNA3.1 group) and sh-SIRT5 + miR-375 inhibitor group (*vs* sh-SIRT5 + inhibitor NC group) (Fig. 5G–H, $P<0.05$).

The above experiment data exhibited that SIRT5 knockdown inhibited autophagy to augment the susceptibility of HCC cells to sorafenib, and miR-375 down-regulation abolished the assistance of SIRT5 knockdown to sorafenib treatment. In addition, SIRT5 overexpression enhanced the resistance to sorafenib via autophagy activation in HCC cells, while miR-375 up-regulation improved the sensitivity of SIRT5 overexpressing HCC cells to sorafenib. Taken together, miR-375 mediated the tolerance of HCC cells to sorafenib by regulating SIRT5.

DISCUSSION

HCC is the predominant primary liver cancer caused by both intrinsic and extrinsic risk factors (Ghouri *et al.*, 2017). As the first-line treatment option for HCC, sorafenib significantly improves the overall survival of HCC patients but the drug efficacy has been greatly limited by high its resistance rate (Niu *et al.*, 2017). Some biological processes in tumor microenvironment, including angiogenesis, inflammation, fibrosis, autophagy and viral reactivation, are associated with sorafenib resistance (Chen *et al.*, 2015). To further explore the molecular mechanisms underlying sorafenib resistance-related biological processes would help amplify the benefits of sorafenib. The present paper elucidates the regulatory mechanism of miR-375 in autophagy-mediated sorafenib resistance of HCC cells.

First of all, sorafenib-resistant HCC cells (HepG2/so and Huh7/so) were established. HepG2/so and Huh7/so cells obtained increased cell viability and decreased apoptosis compared to HepG2 and Huh7 cells. MiR-375 was found to be down-regulated in HepG2/so and Huh7/so cells compared with parental HepG2 and Huh7 cells. Sorafenib impaired the survival of HepG2/so cells and miR-375 overexpression further enhanced sorafenib-induced cell death. To confirm the potential regulation of endogenous miR-375 in HCC cells under sorafenib treatment, the expression of miR-375 was either up-regulated or down-regulated in HepG2/so cells. According to the measurement of cell viability and apoptosis, miR-375 inhibition made HepG2/so cells more resistant to sorafenib, while miR-375 overexpression increased the drug sensitivity. The assistance of miR-375 in anti-tumor therapy has already been uncovered. MiR-375 augmented the susceptibility of HCC cells to sorafenib by targeting the autophagy-related gene, ATG14 (Yang *et al.*, 2020). MiR-375 also inhibited the survival of fulvestrant-resistant breast cancer cells by restraining autophagy (Liu *et al.*, 2018).

Numerous existing scientific reports have authenticated that autophagy inhibition results in suppression on sorafenib resistance of HCC cells. For instance, SNHG16 promoted sorafenib resistance by enhancing autophagy via the miR-23b-3p/EGR1 axis in HCC (Jing *et al.*, 2020). LncRNA HANR enhanced autophagy-dependent sorafenib resistance of HCC cells by competing with ATG9A for miR-29b (Shi *et al.*, 2020). The LC3II/LC3I ratio was increased and p62 was decreased in HepG2/so cells in comparison with HepG2 cells, suggesting activated autophagy in sorafenib-resistant HCC cells. After transfection of miR-375 inhibitor or miR-375 mimic, the autophagy level was promoted or inhibited in HepG2/so cells. Autophagy activated or inhibited in HepG2/so cells by miR-375 inhibitor or miR-375 mimic was thereafter inhibited by 3-MA or promoted by RAP. The results of viability and apoptosis tests showed that autophagy manipulation counteracted with the effect of miR-375 on sorafenib resistance. Therefore, miR-375 inhibited sorafenib resistance by regulating autophagy in HCC cells.

Based on the bioinformatics analysis and dual-luciferase reporter assay, SIRT5 was found to be targeted and down-regulated by miR-375. SIRT5 was up-regulated in HepG2/so and Huh7/so cells compared with parental cells. SIRT5 is a vital metabolic regulator and promotes the progression of HCC in some cases (Chang *et al.*, 2018; Dang *et al.*, 2018; Tang & Yang, 2020). In the present study, SIRT5 inhibition suppressed autophagy and increased apoptosis of HepG2/so cells, while SIRT5 overexpression had the opposite effects. Down-regulation of miR-375 reversed the effects of SIRT5 inhibition, promoting sorafenib resistance of HepG2/so cells. On the other hand, up-regulation of miR-375 inhibited autophagy activated by SIRT5 overexpression and suppressed sorafenib resistance of HepG2/so cells.

Collectively, miR-375 mediates autophagy to enhance the sorafenib resistance of HCC cells partially by directly down-regulating SIRT5. MTDH, also known as AEG-1, is another target of miR-375 in mediating multidrug resistance of HCC cells (Xue *et al.*, 2017; Provvisiero *et al.*, 2019; Li *et al.*, 2021). Therefore, downregulation of MTDH may also contribute to miR-375-induced sorafenib sensitivity of HCC cells. Moreover, sorafenib can directly inhibit SLC7A11 (also called System Xc-) and consequently impede glutathione biosynthesis to induce ferroptosis in HCC cells (Li *et al.*, 2021). MiR-375 may also sensitize HCC cells to sorafenib-induced ferroptosis. Sorafenib resistance exists in most cases of HCC treatment. Despite this unsatisfactory outcome, sorafenib is still a potent drug for advanced HCC. The miR-375/SIRT5 axis discovered in the present study may serve as a new target for increasing sorafenib sensitivity and therefore improve the outcomes of HCC treatment.

Long noncoding RNA LGALS8-AS1 promotes angiogenesis and brain metastases in non-small cell lung cancer

Jian Zhong[1,2] and Bo Wang[1,2]✉

[1]Department of Thoracic Surgery, Affiliated Brain Hospital of Nanjing Medical University, Nanjing City, Jiangsu Province, 210000, China; [2]Department of Thoracic surgery, Affiliated Nanjing Brain Hospital, Nanjing Medical University, Nanjing 210029, China

Brain metastases (BM) are associated with poor prognosis in patients with non-small cell lung cancer (NSCLC). Considering that, LGAS8-AS1-mediated progression of BM was probed in NSCLC. The clinical characteristics of 60 NSCLC patients (30 without BM and 30 with BM) were analyzed. NSCLC patients with BM had higher levels of LGALS8-AS1 than NSCLC patients without BM. Depleting LGALS8-AS1 prevented NSCLC cell proliferation, migration, invasion, and angiogenesis *in vitro,* and NSCLC tumorigenesis and BM *in vivo*. LGALS8-AS1 targeted miR-885-3p to mediate Fascin actin-bundling protein 1 (FSCN1) expression. Restoring miR-885-3p inhibited NSCLC growth, angiogenesis, and BM, and FSCN1 induction rescued the performance of LGALS8-AS1 depletion on NSCLC cells. Our results provide new insights into LGALS8-AS1-mediated NSCLC metastasis and suggest that LGALS8-AS1 may be a useful biomarker for identifying NSCLC with metastatic potential.

INTRODUCTION

Non-small cell lung cancer (NSCLC) is one of the deadliest malignancies, accounting for more than 80% of lung cancer cases worldwide, with a current 5-year survival rate of only 15% (Salehi *et al.*, 2020). Patients with advanced NSCLC generally die within 18 months of diagnosis mainly due to metastatic spread (Wood *et al.*, 2014). Brain metastases (BM) are a common complication of advanced NSCLC (Chen *et al.*, 2012), for which the management always involves systemic therapy (Fang *et al.*, 2021). Since angiogenesis is associated with aggressiveness in NSCLC (Schettino *et al.*, 2012), targeting inhibition of angiogenesis is promising in the treatment of NSCLC and many clinical trials have evaluated the addition of anti-angiogenic therapy to standard therapy in patients with NSCLC (Alshangiti *et al.*, 2018). Therefore, exploring the regulatory mechanism of angiogenesis is helpful for understanding the pathogenesis of NSCLC and developing new therapeutic drugs.

Long non-coding RNAs (lncRNAs) are of significance in the physiological and pathological processes of diseases (Xie *et al.*, 2018; Zhang *et al.*, 2019). The occurrence of human malignant tumors is often accompanied by the deregulation of lncRNA (Kondo *et al.*, 2017). More and more studies have shown that lncRNAs play a key role in tumorigenesis and metastasis (Hanniford *et al.*, 2020; Yang *et al.*, 2018; Gupta *et al.*, 2010). LncRNAs usually regulate their downstream target genes by competing endogenous RNAs with microRNAs (miRNAs), which can affect the proliferation and metastasis of various cancer types (Zheng *et al.*, 2019; Wang *et al.*, 2018; Hao *et al.*, 2019). For example, lncRNA GAN1 inhibits tumor progression in NSCLC *via* decoying miR-26a-5p; lncRNA LINC00473 promotes proliferation, migration, invasion, and inhibition of apoptosis of NSCLC cells by acting as a sponge of miR-497-5p (Xu *et al.*, 2021). LGALS8-AS1 has been confirmed to be highly expressed in breast cancer and promotes breast cancer metastasis by targeting miR-125b-5p (Zhai *et al.*, 2021). However, the expression and role of LGALS8-AS1 in NSCLC remain unclear.

MiRNAs are a group of short endogenous non-coding RNAs with a length of about 18-22 nucleotides, which can regulate post-transcriptional gene expression by binding to the 3'-UTR of target gene mRNA to inhibit mRNA translation and reduce mRNA stability (Ahn *et al.*, 2020). MiRNAs are involved in almost all biological processes, including tumor angiogenesis (Mao *et al.*, 2015). For example, miR-543 promotes tumorigenesis and angiogenesis in NSCLC (Wang *et al.*, 2020) whereas miR-20a-5p inhibits tumor angiogenesis (Han *et al.*, 2021). It is studied that miR-885-3p can architect cell autophagy and apoptosis in squamous cell carcinoma cells (Huang *et al.*, 2011). However, the biological function of miR-885-3p in NSCLC has not been fully elucidated.

Therefore, this study aims to explore the role of LGAS8-AS1 in NSCLC metastasis and angiogenesis through regulating miR-885-3p expression and its potential mechanism. The study identified a lncRNA, LGALS8-AS1, which is associated with NSCLC metastasis and angiogenesis and elucidated the molecular regulatory mechanism of LGALS8-AS1 in NSCLC and provides a new reference for the treatment of NSCLC patients.

METHODS

Tissue sampling

This study was approved by the ethics committee of Affiliated Brain Hospital of Nanjing Medical University. Written informed consent was obtained from all sub-

jects, 60 patients who were histologically confirmed with NSCLC. BM are confirmed by whole-brain CT scan or MRI. Tumor tissues and adjacent normal tissues were collected during surgery.

Cell culture

Human lung cancer cells (A549) and human umbilical vein endothelial cells (HUVECs) were purchased from the Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences. Under humidified air conditions of 37°C and 5% CO_2, cells were cultured in Roswell Park Memorial Institute (RPMI)-1640 (Gibco, USA) medium supplemented with 10% fetal bovine serum, 100 U/ml penicillin, and 100 mg/ml streptomycin (Invitrogen, USA).

Cell transfection

Both miR-885-3p mimic and mimic negative control (NC) were purchased from RiboBio (Guangzhou, China). The shRNA sequence targeting LGALS8-AS1 was purchased from Genepharma (Shanghai, China). Fascin actin-bundling protein 1 (FSCN1) was cloned into the pcDNA3.1 vector (Invitrogen). Cells were transiently transfected with RNAiMax and Lipofectamine 3000 with Plus reagent (Thermo Fisher Scientific).

Cell counting kit (CCK)-8

Cells growing on the 96-well plates were tested by a CCK-8 kit (Liji, Shanghai, China) to determine proliferative activity. Quantitative results were obtained on a microplate reader (SAFAS Xenius XL, Ruixuan, Shanghai, China) at 450 nm.

Flow cytometry

Cells were stained with annexin V-fluorescein isothiocyanate and propidium iodide according to the manufacturer's instructions (Bioscience, Shanghai, China). Then the apoptosis rate was detected by flow cytometry (Beckman, USA). The percentage of cells in the Q3 quadrant represents early apoptosis, and the percentage of cells in the Q2 quadrant represents late apoptosis (Wang *et al.*, 2020).

Transwell assay

Transwell chambers (8-μm pore size; Corning Costar, Cambridge, MA, USA) measure cell migration and invasion capacity. For cell invasion, cells suspended in serum-free RPMI-1640 medium were seeded into the upper chamber pre-coated with Matrigel. The lower chamber was PMI-1640 medium with 20% serum as a chemotactic agent. After 24 h culture, the cells were fixed with 90% formaldehyde and stained with 0.1% crystal violet. The cells were photographed under a microscope and counted. In the cell migration experiment, there was no matrigel coating, and the other operations were the same as the invasion experiment (Yang *et al.*, 2018).

Tube formation

Matrigel (0.5mmol/L) was coated with pre-cooled 96-well plates. HUVECs were starved without serum for 1 h and then re-suspended in Dulbecco's modified Eagle medium to make a cell suspension. Next, cell suspensions (1×10^5 cells/mL) were inoculated into a matrigel coating containing cell conditioned culture-medium with 3 repeat wells per treatment. The plates were then incubated at 37°C for 6 to 8 h. The tube formation was observed under a microscope (Olympus). The number of tubes in a branch (a branch point is a skeleton part where three or more tubes meet) and the number of rings (a ring is a background area surrounded by [or almost] tubular structures) were counted.

Real-time reverse transcriptase-polymerase chain reaction (RT-qPCR)

Total RNA was extracted using a Trizol reagent according to the manufacturer's instructions (Invitrogen, Carlsbad, CA, USA). RNA purity was determined using a NanoDrop spectrophotometer (Thermo Fisher Scientific, Waltham, MA, USA). cDNA reverse transcription kit (Promega, Madison, WT, USA) was used to reverse transcribed 1 μg total RNA into the first strand cDNA. Power SYBR Green PCR Master Mix (Promega) quantitative PCR was used to detect RNA levels. LncRNA and protein-coding gene were normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA, and miRNA was normalized to U6. The primer sequences used are presented in Table 1.

Western blot

Total protein lysates were subjected to 10% or 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis, loading on a polyvinylidene fluoride membrane (Millipore, USA), and blocking the membrane with 5% nonfat milk. After that, primary antibodies FSCN1 (1:1000, sc-21743, Santa Cruz Biotechnology) and GAPDH (1:1000, ab8245, Abcam) were supplemented, and Immunoreactive bands were visualized after incubation with secondary antibody (Invitrogen) by enhanced chemiluminescent detection system (Thermo Fischer Scientific).

Luciferase reporter gene assay

pGL3 luciferase reporters for LGALS8-AS1 and FSCN1 were designed by Genomeditech (Shanghai, China), named LGALS8-AS1-wild type (WT), LGALS8-AS1-mutant type (MUT), FSCN1-WT, and FSCN1-MUT. These reporters and miR-885-3p mimic or mimic NC were co-transfected into A549 cells, thus measuring luciferase activity with a luciferase assay kit (Promega) (Wu *et al.*, 2021).

Table 1. Primer sequences

N2	9 (30.0%)	9 (30.0%)
N3	15 (50.0%)	14 (46.7%)

Xenograft models in nude mice

For xenograft models, 4-week-old BALB/c nude mice (Cyagen Biosciences) bred under pathogen-free conditions were subcutaneously injected with A549 cells stably transfected with sh-LGALS8-AS1 and sh-NC (5×10^6, n=6/group). A549 cells were pre-diluted in 200 µL phosphate-buffered saline (PBS) + 200 µL Matrigel (BD Biosciences). During 28-h housing, mice were measured for longitudinal diameter and lateral diameter at an interval of 7 days to calculate tumor volume as $0.5 \times L \times D^2$. On day 28, xenograft tumors were dissected from mice and weighed.

A lung cancer BM model was established according to previous studies (Li *et al.*, 2017; Nguyen *et al.*, 2009). A549 cells after transfection were resuspended in 100 µL of PBS and injected into the right ventricle of mice (1×10^6, n=6/group). Finally, brain tissues were collected and prepared for HE staining and observations of metastatic nodules.

Statistical analysis

The selected way to perform statistical analysis was SPSS 19.0, and that to construct graphs was GraphPad Prism 6. Two-tailed paired Student's *t*-test and one-way analysis of variance were of utility for data comparison of two groups and more than two groups, respectively. Tukey's post hoc test validated pairwise comparisons.

Figure 1. LGALS8-AS1 is more expressed in NSCLC patients with BM
LGALS8-AS1 expression in clinical samples (A–B); the values were expressed as mean ± standard deviation (n=60).

Pearson correlation analysis assessed gene correlation. $P<0.05$ was considered to indicate a statistically significant difference.

RESULTS

LGALS8-AS1 is more expressed in NSCLC patients with BM

A total of 60 patients with NSCLC were included in the study, of which 30 had BM and the remaining 30 did not. The clinical characteristics are shown in Table 2. Examinations of LGALS8-AS1 found that LGALS8-AS1

Figure 2. Targeting suppression of LGALS8-AS1 blocks NSCLC development
Based on sh-LGALS8-AS1-induced knockdown of LGALS8-AS1 (**A**), assays were to determine proliferation (**B**), apoptosis (**C**), migration (**D**), invasion (**E**), and angiogenesis (**F**); values are presented as mean ± standard deviation (N=3) *P<0.05 *vs.* sh-NC.

was increased in tumor tissues, and it was higher in tumor tissues of NSCLC patients with BM (Fig. 1A, B).

Targeting suppression of LGALS8-AS1 blocks NSCLC development

Firstly, the effect of LGALS8-AS1 on the progression of NSCLC cells was investigated. A549 cells were transfected with sh-LGALS8-AS1 to silence the expression of LGALS8-AS1, and the transfection was verified by RT-qPCR (Fig. 2A). Cell proliferation was then detected by CCK-8, and it was found that A549 cell proliferation decreased after down-regulating LGALS8-AS1 (Fig. 2B). Apoptosis was detected by flow cytometry, and the results showed that apoptosis of A549 cells increased after downregulation of LGALS8-AS1 (Fig. 2C). Transwell was used to detect cell migration and invasion,

and it was found that A549 cell migration and invasion decreased after downregulating LGALS8-AS1 (Fig. 2D, E). Angiogenesis was also examined by tube formation assays, which showed that angiogenesis was attenuated after down-regulating LGALS8-AS1 (Fig. 2F). These results indicate that down-regulation of LGALS8-AS1 inhibits proliferation, migration, invasion, and angiogenesis of NSCLC cells, and promotes cell apoptosis.

LGALS8-AS1 deficiency suppresses tumor growth and BM *in vivo*

Based on our findings that LGALS8-AS1 is involved in NSCLC cell progression, the study further explored its role in tumor growth and brain metastasis *in vivo*. Tumor growth was studied by subcutaneous injection of A549 cells stably transfected with sh-LGALS8-AS1 into

Figure 3. LGALS8-AS1 deficiency suppresses tumor growth and BM *in vivo*
In nude mice injected with sh-LGALS8-AS1, tumor volume and weight were measured (**A–B**) and BM was evaluated (**C–D**); values are presented as mean ± standard deviation (n=6) *P<0.05 *vs.* sh-NC.

Figure 4. miR-885-3p expression is controlled by LGALS8-AS1
A potential binding relationship between LGALS8-AS1 and miR-885-3p was predicted (**A**) and confirmed by detecting luciferase activity (**B**) miR-885-3p expression in clinical samples (**C**) and its correlation with LGALS8-AS1 expression (**D**) miR-885-3p expression was altered by sh-LGALS8-AS1 in A549 cells (**E**); values are presented as mean ± standard deviation (N=3) *$P<0.05$ vs. sh-NC.

nude mice. As measured, LGALS8-AS1 down-regulation reduced tumor volume and weight (Fig. 3A, B). BM were explored by injecting A549 cells stably transfected with sh-LGALS8-AS1 into the right ventricle of nude mice. As presented in HE staining results, the number of brain metastatic nodules was reduced in sh-LGALS8-AS1-treated mice (Fig. 3C, D).

miR-885-3p expression is controlled by LGALS8-AS1

Next, LGALS8-AS1 was predicted to have binding sites with miR-885-3p through the RNA22 database (Fig. 4A). Subsequently, dual luciferase assay was performed to verify their targeting relationship, and the results showed that the luciferase activity of A549 cells could be significantly reduced by co-transfection of LGALS8-AS1-WT with miR-885-3p mimic (Fig. 4B). In addition, the expression of miR-885-3p in clinical samples was detected, and it was found that miR-885-3p in lung cancer tissues was down-regulated (Fig. 4C) and negatively correlated with LGALS8-AS1 expression (Fig. 4D). Moreover, after downregulating LGALS8-AS1, it was found that miR-885-3p expression was increased in A549 cells (Fig. 4E). The results showed that LGALS8-AS1 inhibited miR-885-3p expression by targeting miR-885-3p.

miR-885-3p represses NSCLC development *in vitro*

In order to investigate the effect of miR-885-3p on NSCLC cells, miR-885-3p mimic or mimic NC was transfected into A549 cells, and successful transfection was verified by RT-qPCR (Fig. 5A). In A549 cells over-expressing miR-885-3p, it could be recognized that proliferative, invasive, migratory, and an-apoptotic activities were all in a weakened status, and the same was true for angiogenic capacity (Fig. 5B–F). These results suggest that up-regulation of miR-885-3p inhibits proliferation, migration, invasion, and angiogenesis of NSCLC cells, and promotes cell apoptosis.

miR-885-3p targets FSCN1

Subsequently, the RNA22 database predicted that miR-885-3p and FSCN1 had binding sites (Fig. 6A).

Then, dual luciferase assay was performed to verify the targeting relationship between them. The results showed that the luciferase activity of A549 cells could be significantly reduced by co-transfection of FSCN1-WT with miR-885-3p mimic (Fig. 6B). RT-qPCR detected FSCN1 mRNA expression in lung cancer tissues, and the results showed that FSCN1 mRNA expression was up-regulated (Fig. 6C) and was negatively correlated with the expression of miR-885-3p (Fig. 6D). Moreover, mRNA and protein expression of FSCN1 in A549 cells decreased after up-regulation of miR-885-3p (Fig. 6E). These results suggest that targeting miR-885-3p regulates FSCN1 expression.

LGALS8-AS1-mediated impairments of A549 cell activities can be rescued by FSCN1

To verify the regulatory role of LGALS8-AS1/miR-885-3p/FSCN1 axis in lung cancer cells, sh-LGALS8-AS1 + pcDNA3.1-FSCN1 and sh-LGALS8-AS1 + pcDNA3.1-NC were transfected into A549 cells. RT-qPCR and Western blot results showed that pcDNA3.1-FSCN1 reversed the inhibition effect of sh-LGALS8-AS1 on FSCN1 expression (Fig. 7A). The results of CCK-8, flow cytometry, Transwell and tube formation experiments showed that up-regulation of FSCN1 mitigated the impact of down-regulation of LGALS8-AS1 on proliferation, apoptosis, migration, invasion, and angiogenesis of A549 cells (Fig. 7B–F). In conclusion, LGALS8-AS1 promotes NSCLC cell progression by regulating the miR-885-3p/FSCN1 axis.

DISCUSSION

As studies indicate, 90% of lung cancer deaths are caused by distant metastasis, and BM is a common site of distant metastasis in NSCLC (Rybarczyk-Kasiuchnicz *et al.*, 2021). LncRNA dysregulation is fundamental for tumorigenesis and distant metastasis of NSCLC and serves as a biomarker for NSCLC (Pan *et al.*, 2020). In the present study, LGALS8-AS1 was up-regulated in NSCLC patients' tumor tissues and was more expressed in NSCLC patients with BM. Silencing LGALS8-AS1

A potential binding relationship between FSCN1 mRNA and miR-885-3p was predicted (**A**) and confirmed by detecting luciferase activity (**B**); FSCN1 mRNA expression in clinical samples (**C**) and its correlation with miR-885-3p expression (**D**) FSCN1 mRNA and protein expression was altered by miR-885-3p mimic in A549 cells (**E**); values are presented as mean ± standard deviation (N=3) *P<0.05 *vs*. mimic NC.

blocked the malignant phenotype and angiogenesis in NSCLC cells, as well as inhibiting tumor growth and BM *in vivo*. Overall, LGALS8-AS1 plays a critical role in NSCLC metastasis and serves as a potential therapeutic target for NSCLC metastasis.

Abnormally expressed lncRNAs are involved in regulating NSCLC development by acting as miRNA sponges. For example, lncRNA plasmacytoma variant translocation 1 promotes angiogenesis in NSCLC by competitive absorption of miR-29c (Wang *et al*., 2018). LncRNA

DNAH17 antisense RNA 1 induces the occurrence and metastasis of NSCLC by binding to miR-877-5p (Du *et al*., 2020). LGALS8-AS1 has only been reported in breast cancer considered an oncogenic gene regarding its potential to induce malignant phenotype and metastasis. Here, the study observed high LGALS8-AS1 expression in NSCLC, and LGALS8-AS1 expression was able to discriminate whether NSCLC patients developed BM. Cell and animal experiments consistently confirmed that LGALS8-AS1 knockdown played a negative role in

Figure 7. LGALS8-AS1-mediated impairments of A549 cell activities can be rescued by FSCN1.
Based on pcDNA3.1-FSCN1-induced elevation of FSCN1 expression in sh-LGALS8-AS1-treated A549 cells (**A**), assays were to determine proliferation (**B**), apoptosis (**C**), migration (**D**), invasion (**E**), and angiogenesis (F); values are presented as mean ± standard deviation (N=3) *P<0.05 *vs.* sh-LGALS8-AS1 + pcDNA3.1-NC.

NSCLC for cell growth, angiogenesis, and tumor growth and metastasis. In addition, the RNA22 database predicted that LGALS8-AS1 had a binding site with miR-885-3p.

miR-885-3p was mediated by LGALS8-AS1 in this study. miR-885-3p has received academic attention in the field of cancer. miR-885-3p expression decline has previously been found in lung adenocarcinoma to be associated with pathological stage and poor survival in patients (Yang *et al.*, 2021). Functionally discussed, miR-885-3p impairs gastric cancer cell activities and oxidative stress (He *et al.*, 2021), and tumor angiogenesis in colon cancer (Xiao *et al.*, 2015). This study confirmed the reduction in miR-885-3p expression in NSCLC, and the suppressive effects of miR-885-3p on NSCLC cell growth and angiogenesis.

miRNAs usually function by binding to target gene mRNAs (Datta *et al.*, 2019). Here, FSCN1 was selected to be a target of miR-885-3p. FSCN1 is a structurally unique and highly conserved actin cross-linking protein that mediates cellular interaction (Liu *et al.*, 2019). It has been described that dysregulation of FSCN1 aggrandizes tumor motility and invasiveness by altering the structure of cell protrusions and focal extracellular matrix adhesions (Gao *et al.*, 2019). Therefore, FSCN1 is considered an oncogene in cancers, including adrenocortical carcinoma (Liang *et al.*, 2019), ovarian cancer (Li *et al.*, 2018), laryngeal squamous cell carcinoma (Gao *et al.*, 2018), and NSCLC (Xiao *et al.*, 2016). Here, FSCN1 was overexpressed in NSCLC and can mitigate the effects of LGALS8-AS1 knockdown, promoting NSCLC cell growth and angiogenesis.

This study did not address a possible direct relationship between LGALS8-AS1 expression and clinical factors, including tumor node metastasis staging and survival analysis, due to insufficient clinical sample size and lack of a long-term follow-up of all included patients. Also, this study did not further explore the effects of overexpression of LGALS8-AS1 and downregulation of miR-885-3p alone on NSCLC cells. In addition, FSCN1 has been confirmed to mediate NSCLC cell migration and invasion by altering the Mitogen-activated protein kinase pathway (Zhao *et al.*, 2018). Whether the MAPK pathway or other signaling pathways are involved in the regulation of LGALS8-AS1 in NSCLC still needs to be further explored to determine detailed and comprehensive mechanics.

CONCLUSION

Our study provides new insights into the mechanism by which lncRNAs regulate NSCLC progression. Our findings suggest that the LGALS8-AS1/miR-885-3p/FSCN1 axis is an essential signaling pathway for NSCLC cell growth, angiogenesis, and BM.

Declarations

Ethical statement. All procedures performed in this study involving human participants were in accordance

with the ethical standards of the Affiliated Brain Hospital of Nanjing Medical University research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. All subjects were approved by the Affiliated Brain Hospital of Nanjing Medical University.

OPEN ACCESS

Clinical features and risk factors for primary Sjögren's syndrome combined with interstitial lung disease: a retrospective study

Zhixia Yang[1], Hao Zhao[2], Lei Shan[1] and Dan Wang[1]*

[1]Department of Rheumatology, Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China, [2]Department of Emergency, Shanghai Traditional Chinese Medicine—Integrated Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Objective: To analyze the clinical characteristics of primary Sjögren's syndrome (pSS) combined with interstitial lung disease (ILD), so as to provide a theoretical basis for the early diagnosis, treatment and prevention of PSS-ILD.

Methods: From October 2017 to January 2022, patients with pSS who were admitted to the Department of Rheumatology at Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine were included in this retrospective study. Patients were divided into the pSS-ILD (102 cases) and pSS-non-ILD groups (154 cases) based on the presence or absence of ILD on high-resolution computed tomography (HRCT). Demographics information, clinical symptoms, laboratory indicators and HRCT features were compared, and the logistic regression analysis was utilized to identify the risk factors.

Results: A total of 256 patients were included. Patients with pSS-ILD were more often female, and their age and disease duration were significantly higher than those in the pSS-non-ILD group ($p < 0.05$). The HRCT imaging classification included ground glass-like shadow (78.4%) and patchy solid shadow (17.6%), and Non-specific interstitial pneumonitis (NSIP) (72.5%) was the predominant typology. Regarding the laboratory indexes, the positive rates of erythrocyte sedimentation rate, C-reactive protein, white blood cell count, neutrophil/lymphocyte ratio, triglycerides, total cholesterol, and anti-SS-A52 antibodies were significantly higher in the pSS-ILD patients than in the pSS-non-ILD group, while the positive rates of anti-synaptic antibodies were lower than in the pSS-non-ILD group, and the differences between two groups were statistically significant ($p < 0.05$). Logistic regression showed that age >60 years, longer duration of disease, higher triglycerides, and cholesterol were risk factors for pSS-ILD patients.

Conclusion: The clinical features of pSS-ILD patients were xerophthalmia, cough and shortness of breath, and HRCT can help to diagnose the disease at an early stage. Age over 60 years, chronic course of disease, and elevated lipid levels are risk factors for ILD in pSS patients, and the relationship between autoimmune antibody levels and the occurrence of ILD needs to be further

confirmed in follow-up studies with large sample sizes. These findings have the potential to provide useful information for early diagnosis, treatment, and prevention of the development of pSS-ILD.

Introduction

Primary Sjogren's syndrome (pSS) is a common chronic autoimmune disease with a prevalence of 0.33%–0.77%, which is characterized by exocrine lymphocyte infiltration, mainly involving salivary glands and lacrimal glands (Zhang et al., 1993; Mariette and Criswell, 2018). Due to the presence of multiple autoantibodies in the patient's serum, pSS is a complex heterogeneous autoimmune disease with a diverse clinical face, with almost three-quarters of patients developing extraducular lesions, including the lungs, kidneys, liver, and nervous system (Martin-Nares and Hernandez-Molina, 2019; Yayla et al., 2020; Manfre et al., 2022). Pulmonary lesions are one of the most common extraglandular manifestations of pSS, with an incidence of 9%–75% (Palm et al., 2013; Reina et al., 2016; Manfredi et al., 2017; Roca et al., 2017; Lee et al., 2021), of which the incidence of Interstitial Lung Disease (ILD) can reach 30.1% (Zhao et al., 2020). Moreover, pulmonary involvement is closely related to the prognosis of pSS patients. Compared to pSS patients without lung involvement, patients with lung involvement have a significantly lower quality of life (Dogru et al., 2017). It is reported that patients with pSS-ILD have a mortality rate of up to 39% and a 4-fold increase in mortality after 10 years (Parambil et al., 2006; Palm et al., 2013). Therefore, early screening of patients with high risk for the development of ILD is of great significance for prompt intervention in order to improve prognosis.

Prior studies have found that male gender, older age, and elevated levels of C-reactive protein (CRP) are risk factors associated with the development of interstitial lung disease in patients with primary Sjögren's syndrome (He et al., 2020). However, there is still limited reporting on the comprehensive assessment of ILD in pSS patients, which combines the patients' immune antibody levels and high-resolution computed tomography (HRCT) manifestations. Thus, this study aimed to analyzed the clinical characteristics of pSS-ILD and identified the risk factors related to the development of interstitial lung lesions in pSS patients.

Materials and methods

Study design and participants

This retrospective study started with identification of pSS patients by searching the electronic medical records. We enrolled patients with pSS who were admitted to the Department of Rheumatology at Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine between October 2017 and January 2022.

Inclusion criteria for participants were as follows: 1) age over 18 years old; 2) meeting the 2012 American College of Rheumatology (ACR) recommended SS classification criteria (Shiboski et al., 2012); 3) presence of respiratory symptoms or lung abnormalities on HRCT; 4) at least one HRCT examination within 1 year.

The exclusion criteria were as follows: 1) secondary dry syndrome or combined with other rheumatic diseases; 2) combined pulmonary infections, chronic obstructive pulmonary disease, pneumoconiosis and lung diseases such as tumors, tuberculosis, and pulmonary nodules; 3) patients with severe primary diseases of the heart, lungs, liver, kidneys and other organs; 4) patients with incomplete clinical information. Then all patients were divided into pSS-ILD group and pSS-non-ILD group based on whether their HRCT features showed ILD or not. pSS patients whose imaging features supporting ILD in HRCT (e.g., ground-glass opacity, reticulation, consolidation, nodules, traction bronchiectasis, honeycombing) were diagnosed as pSS-ILD (Lohrmann et al., 2004). Altogether 256 pSS patients were screened in this study and divided into the pSS-ILD (102 cases) and pSS-non-ILD groups (154 cases). This study was approved by the Ethics Committee of Shanghai University of Traditional Chinese Medicine (No. 2018-014) and was registered at Chinese Clinical Trial Registry (No. ChiCTR2000037057).

Data collection

Demographic and clinical data were collected from patients' medical records, including age, sex, disease duration. Clinical features associated with pSS and pSS-ILD were fully recorded as well, such as xerostomia, xerophthalmia, cough, shortness of breath. Moreover, the blood biochemical data were also collected, including complete blood cell count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), blood lipids, rheumatoid factor (RF), immunoglobulin, complement 3 (C3), complement 4 (C4), antinuclear antibody (ANA) spectrum, cytokine.

Blood biochemical data testing methods: Complete blood cell count: The BC-6800 automatic hematology analyzer (mindray,

China) was used for testing. The mindray series analyzer's auto hematology analyzer reagent (mindray, China) was used.

Erythrocyte sedimentation rate (ESR): The TEST 1 Automatic Rapid Blood Sedimentation Analyzer (Alifax, Italy) was used for determination. EDTA anticoagulant was used for blood collection.

C-reactive protein (CRP): The high-sensitivity human C-reactive protein detection kit (mindray, China) was used for the determination of C-reactive protein in human whole blood samples by latex-enhanced immunoscattering turbidimetric assay.

Blood lipids: Enzyme method was used for testing, including total cholesterol (TC), triglycerides (TG), high-density lipoprotein (HDL), and low-density lipoprotein (LDL) testing. Reagent brands: glucose oxidase-cholesterol dehydrogenase method TG kit, glucose oxidase-peroxidase method TC kit, Direct HDL-cholesterol (HDL-c) assays Kit and Direct LDL-c kit (Beckman, United States).

Rheumatoid factor (RF): The N Latex RF Kit (Siemens healthineers, Germany) was used for testing.

Immunoglobulin (Ig), complement 3 (C3), complement 4 (C4): The Scattering turbidimetric method was used for testing. The reagent kit brand was N Antiserum to Immunoglobulin A (IgA), immunoglobulin M (IgM), immunoglobulin G (IgG), complement C3 and complement C4 reagent kit (Siemens healthineers, Germany).

Antinuclear antibody (ANA) spectrum: The EUROLINE ANA profile 3 (Euroimmun Medizinische Labordiagnostika, Germany) was used for testing.

Cytokines: Luminex® xMAP (Luminex Corporation, United States) technology was used for quantitative detection of tumor necrosis factor-α (TNF-α), Interleukin 2 receptor (IL-2R), IL-6 and IL-8. The reagent kit brand was 12 Human Cytokine assay kit (RAISECARE, China).

In addition, all patients underwent HRCT examination. Approach to Radiological Analysis: The Philips iCT 256 spiral computed tomography (CT) scanner was used for image analysis. The tracheal level was selected as the starting position, and the scan was conducted downwards until the bottom of the lungs (excluding the lung apex). The scan parameters were as follows: pitch 1, reconstruction slice thickness of 1.0 mm, interlayer spacing of 1.0 mm, tube current of 40–120 mA, voltage of 120 KV, and reconstruction with a wide window level setting of 2000 HU/-600 HU. All imaging data were reviewed by two experienced radiologists in batches. For high-resolution CT images, a qualitative analysis method and reproducible calculated measurement parameters, including the morphology, extent, and severity of interstitial lung disease (such as linear, nodular, reticular, honeycombing, traction bronchiectasis lesions) were used for classification, counting, and scoring. The maximum diameter and area of all lesions were measured, and the CT density value (CT value) was calculated to evaluate the degree and type of lesion. During

the analysis process, independent assessments were performed first, followed by a consensus reached through discussion.

For HRCT abnormalities, different HRCT features of pSS-ILD patients were image-typed according to the American Thoracic Society/European Respiratory Society (2013) International Multidisciplinary Classification of idiopathic interstitial pneumonia (Travis et al., 2013), including Non-specific interstitial pneumonitis (NSIP), Unusual interstitial pneumonia (UIP), Lymphocytic interstitial pneumonitis (LIP), Organizing pneumonia (OP). Additionally, we refer to the literature to stage the severity of fibrosis by chest HRCT in pSS-ILD patients into stages 1, 2, and 3 (Qiu et al., 2008). Stage 1 is defined as early or active lesion with ground glass shadow, increased interlobular stroma and thickened interlobular septa; stage 2 is defined as progressive or chronic prolonged lesion with stage 1 manifestations and interface signs, subpleural arcuate shadow, intrapulmonary lamellar solidity and small nodular shadow; stage 3 is defined as advanced lesion with stage 1, stage 2 and reticular shadow, fibrous streak shadow, honeycomb shadow, multiple large alveoli, distended bronchial dilatation and diffuse fibrosis. Determination of HRCT results were determined by both radiologists and rheumatologist.

Statistics

All data were statistically analyzed using SPSS 24.0 statistical software. Continuous variables were presented as mean ± standard deviation (SD) for normally distributed data; if the variance had chi-square, two independent samples t-test was used, and if the variance was not chi-square, approximate t-test was used. Median (interquartile spacing) was used for non-normally distributed data and non-parametric test was used for statistical analysis. Categorical variables were presented as the percentages and were compared using chi-square test or Fisher's exact test. Logistic regression analysis was used to identify the factors associated with the development of ILD in patients with pSS. All reported p-values were two sided and $p < 0.05$ was considered to be statistically significant.

Results

Demographic and clinical features in patients with pSS-interstitial lung disease (ILD)

This study included a total of 256 patients with pSS. Of these, there were 102 patients in the pSS- ILD group, with a mean age of 63.36 ± 9.22 years, of whom 66 (64.71%) were over 60 years old. The pSS-non-ILD group consisted of 154 patients, with a mean age of 57.16 ± 12.72 years, of whom 73 (47.40%) were over

60 years old. Generally, there were significant differences between the pSS-ILD and total pSS-non-ILD groups related to age ($p < 0.01$) and disease duration ($p < 0.001$) characteristics studied (Table 1).

Next, clinical symptoms of the two groups were analyzed. Among 256 patients with pSS, the most common clinical manifestations were xerostomia, xerophthalmia, and arthralgias. Fever, fatigue, Raynaud's phenomenon, cough and sputum, chest tightness and shortness of breath, skin rash, muscle aches and pains have been observed in a few patients. Patients with pSS-ILD have a significantly higher proportion of clinical manifestations of xerophthalmia (85.2%), cough (25.4%), and shortness of breath (22.5%) compared with patients without ILD ($p < 0.05$) (Table 1).

Laboratory metrics

As shown in Table 1, ESR, CRP, white blood cell count (WBC), neutrophil/lymphocyte ratio (NLR), TC, and TG were significantly higher in the pSS-ILD group than in the pSS-non-ILD group ($p < 0.05$). As for the immunologic index, the positivity for different autoantibodies in pSS-ILD groups was as follows: 87 cases (85.29%) for ANA, 65 cases (63.73%) for Ro52, 65 cases (63.73%) for Ro60, 39 cases (38.24%) for SSB, and 9 cases (8.82%) for anti-centromere antibodies. By chi-square test, patients in the pSS-ILD group had a higher rate of anti-Ro52[+] and a lower rate of anti-centromere[+] than those in the pSS-non-ILD group, and the differences between the two groups were statistically significant ($p < 0.05$) (Table 1).

In addition, among all pSS patients, cytokines were measured and analyzed in 222 patients showed that IL-6 was significantly higher in the pSS-ILD group than in the pSS-non-ILD group ($p < 0.05$), while no statistically significant differences between the remaining cytokines in the two groups ($p > 0.05$) (Table 1).

HRCT features

HRCT provides superior evaluation of the lung compared with conventional radiographs. If HRCT findings are characteristic, lung biopsy is not necessary to confirm ILD in humans. In our study, all 256 patients underwent HRCT and 102 of them showed interstitial lung lesions on HRCT. For HRCT abnormalities, the percentages of different patterns were showed in Table 2. Of note, ground glass-like shadow described as a hazy increased opacity of the lungs was the most common, followed by patchy solid shadow. The percentages of different stages were as follows: 38 patients (34.3%) were in stage 1 (early stage), 35 patients (34.3%) were in stage 2 (chronic prolongation), and 29 patients (28.4%) were in stage 3 (late stage). And then HRCT imaging classification of pSS-ILD patients were showed as follows: 74 cases (72.5%) with NSIP, 10 cases (9.8%) with UIP, 6 cases (5.9%) with LIP, and 2 cases (2.0%) with OP. However, due to atypical HRCT imaging manifestations that could not be clearly defined to which imaging type they belonged, or the presence of two or more types of imaging manifestations at the same time, they were categorized as other in our study results (10 cases, 9.8%) (Table 2).

Additionally, we investigated the features for ILD detected by HRCT in pSS patients with or without respiratory symptoms. It is noteworthy that 50 percentage of patients without obvious pulmonary symptoms exhibited abnormalities, consistent with ILD symptoms, in HRCT-scan. We further observed the characteristics of HRCT in these patients without respiratory symptoms (imaging performance, staging and classification). Obviously, HRCT features in pSS-ILD patients without obvious pulmonary symptoms are predominantly early compared to patients with obvious pulmonary symptoms (Figure 1). This suggests that regular HRCT should also be performed in patients with pSS without respiratory symptoms.

Stage 2	35 (34.3)
Stage 3	29 (28.4)

NSIP, non-specific interstitial pneumonia; UIP, usual interstitial pneumonia; LIP, lymphocytic interstitial pneumonia; OP, organizing pneumonia.

Risk factors for the development of ILD and predictive model

Furthermore, we also performed logistic regression analysis to investigate the independent risk factors of interstitial lung lesions in patients with pSS. In the univariate logistic regression analysis comparing the pSS-ILD cohort with the control cohort, several variables showed statistically significant odds ratios. The pSS-ILD cohort had an odds ratio (OR) of 2.034 (95% CI 1.216–3.414, $p = 0.007$) for age>60 years, 1.006 (95% CI 1.003–1.010, $p < 0.001$) for disease duration, 0.103 (95% CI 0.024–0.446, $p = 0.002$) for shortness of breath. Among the laboratory metrics, the following ORs were observed: ESR (OR = 1.010, 95% CI 1.000–1.020, $p = 0.046$); CRP (OR = 1.951, 95% CI 1.008–3.776, $p = 0.047$); WBC (OR = 1.150, 95% CI 1.032–1.281, $p = 0.011$); NLR (OR = 1.179, 95% CI 1.043–1.333, $p = 0.008$); TG (OR = 1.793, 95% CI 1.191–2.700, $p = 0.005$); TC (OR = 1.329, 95% CI 1.038–1.702, $p = 0.024$); Anti-Ro52[+] (OR = 1.949, 95% CI 1.167–3.255, $p = 0.011$); Anti-centromere[+] (OR = 0.369, 95% CI 0.168–0.811, $p = 0.013$).

Based on the results and clinical relevance, 11 variables were a step forward included in the multivariate logistic regression analysis. The finally results showed that older than 60 years (OR = 2.381, 95% IC 1.302–4.355, $p < 0.05$), longer duration of disease (OR = 1.007, 95% IC 1.003–1.012, $p < 0.001$), higher TG (OR = 1.652, 95% CI 1.014–2.691, $p < 0.05$), higher TC (OR =

1.424, 95% CI 1.059–1.915, $p < 0.05$) and anti-Ro52[+] (OR = 1.949, 95% CI 1.167–3.255, $p = 0.011$) were risk factors for ILD in pSS patients. Interestingly, we also found a protective factor for ILD in pSS patients was anti-centromere[+] (OR = 0.402, 95% CI 0.17–0.935, $p < 0.05$) (Table 3).

Discussion

The pathogenesis of pSS-ILD is not fully elucidated. An early study revealed that the combined involvement of genetic, environmental and infection susceptibility factors result in recruitment of inflammatory cells into the interstitial and alveolar spaces of the lung, releasing inflammatory factors and causing alveolar epithelial damage. Consequently, fibroblasts and myofibroblasts in the interstitial spaces of the lung become activated and produce extracellular matrix proteins, leading to lung fibrosis (Wells and Denton, 2014; Panagopoulos et al., 2021). In our study, patients in the pSS-ILD group had significantly higher WBC counts than patients in the pSS-non-ILD group. WBC, as an inflammatory cell, can activate inflammatory responses in certain pathological conditions, so is it possible that patients in the pSS-ILD group had higher inflammatory indicators? We then further analyzed the inflammatory indexes in both groups and found that CRP, ESR, NLR, and IL-6 were significantly higher in the pSS-ILD group than that in the patients without ILD. NLR, as a new inflammatory index that can reflect the systemic inflammatory status, is commonly used in the diagnosis and assessment of prognosis of infectious diseases. It includes lymphocyte and neutrophil counts, which has the advantages of being simple, easy to operate, inexpensive and reproducible. And it is more clinically meaningful than single lymphocyte and neutrophil counts, and can be widely used in clinical practice to assess the inflammatory status of diseases in combination with CRP, ESR and other indexes. IL-6 is a multifunctional cytokine with multiple immunomodulatory effects, and its elevation is positively correlated with inflammation. Previous study (Boumba et al., 1995; Mavragani, 2017) reported that IL-6, IL-8, IL-10, and TNF-α may be involved in the occurrence and development of ILD in patients with pSS, suggesting that the occurrence of pSS-ILD is closely related to the inflammatory response and needs clinical attention.

In addition, pSS also can attack blood lipids and promote the development of atherosclerosis (Vaudo et al., 2005). Previous study reported that pSS patients had a strong trend to present dyslipidemia when compared to healthy individuals (Cruz et al., 2010). Consistently, our study showed that TG and TC were significantly higher in the pSS-ILD group than in the pSS-non-ILD group. As for the reasons, the elevation of TG and TC may be related to the older age of patients. On the other hand, it also suggested that pSS-ILD patients were more likely to have abnormal TG and TC than patients without ILD. In clinical

FIGURE 1
Characteristics of HRCT in pSS-ILD patients with or without respiratory symptoms. **(A,B)** Percentage of different HRCT staging **(A)** and classification **(B)** in ILD patients with and without respiratory symptoms.

treatment, we need to pay more attention to and monitor the lipid profile of patients in order to reduce the risk of cardiovascular and cerebrovascular adverse events in patients. Certainly, glucocorticoid can also cause dyslipidemia in patients, which could be a potential confounding factor.

Moreover, immunological factors also play an important role in the pathogenesis of pSS-ILD, and multiple immune cells are jointly involved in the pathogenesis (Ytterberg et al., 2015). We further analyzed the immunological indicators between the two groups, and the results showed that the anti-RO52[+] rate in pSS-ILD group was significantly higher than that in non-ILD group, while the positive rates of immunoglobulin and complement were not significantly different, indicating that anti-Ro52[+] pSS patients were more prone to ILD. Davidson et al. (2000) have reported that lung involvement occurs primarily in pSS patients who are positive for anti-RO antibodies and can occur early in the disease. This suggests that early screening should be conducted for such patients in clinical practice.

pSS-ILD is asymptomatic and easy to be missed, and some patients have no obvious clinical symptoms in the early stage. HRCT can detect abnormal changes in the lungs of pSS patients at an early stage with a specificity of 90%, which is the same as the pathological findings of lung biopsy. In this study, 256 patients underwent HRCT of the lung, and 102 of them showed interstitial lung lesions, which mainly consisted of ground glass-like shadow, patchy solid shadow, fibrous streak shadow, lattice shadow and honeycomb shadow, among which ground glass-like shadow was the most common, followed by patchy solid shadow. HRCT staging of patients based on imaging presentation revealed that NSIP was the most common type of ILD in patients with pSS. Abrasive glassy shadow is an early manifestation of interstitial lung changes, mostly reversible, while lattice-like and honeycomb-like changes are indicative of intermediate and advanced stages of irreversible fibrosis. In addition, it is noteworthy that 50% patients without obvious pulmonary symptoms exhibited abnormalities, consistent with ILD features in HRCT-scan, although these were relatively early. Therefore, HRCT can help to diagnose the disease at an early stage so that we can better grasp the timing of treatment. In addition, respiratory symptoms appeared later than pulmonary imaging findings in some patients, which requires clinicians to judge whether there is pulmonary involvement in pSS patients, not only based on respiratory symptoms, but also regular imaging examinations to achieve the purpose of early diagnosis.

Pulmonary involvement increases the 10-year mortality of pSS patients by 4 times (Palm et al., 2013). Early diagnosis and treatment can prevent pulmonary lesions from progressing from reversible inflammatory stage to irreversible pulmonary fibrosis stage, and significantly improve the prognosis of patients. After single factor screening, eleven clinical variables were found to be significantly different between two groups. These factors were age, course of disease, CRP, ESR, WBC, NLR, TG, TC, anti-Ro52[+], anti-centromere[+], and IL-6. The multivariate analysis showed that age ≥60 years, chronic disease, high TG and high

TC were the high risk factors for ILD in pSS patients, which was consistent with previous studies (Gao et al., 2018). Analysis of the reason may be induced in older adults with the body immune function change matter more, thus easier to cause the change of immune, eventually lead to the occurrence of ILD. Surprisingly, our study also found that anti-centromere[+] is a protective factor for ILD, which is similar to what has been reported in previous studies, the antibodies against the centromere has protective effect to the organs in the diffuse systemic sclerosis (dsSSc) (Caetano et al., 2018). However, in our literature review, we found no reports of anti-Ro52[+] and ILD in pSS patients. The correlation between the level of autoimmune antibodies in pSS patients and the incidence of ILD is worthy of further investigation.

In addition, there were some limitations in our study. First of all, this study was a retrospective, single-center, and small-scale study, which may affect the universality and practical clinical significance of the results. Second, there was a correlation between some of the indicators, such as high age and elevated lipid levels, which may have led to potential confusion. Third, some results with statistical differences lacked appropriate clinical interpretation, which affected the authenticity of the results. In the next step, we will conduct a multi-center study with a large sample size and collect more comprehensive patient clinical data to reduce controllable interference factors and provide advantages for early diagnosis, treatment and prognosis of pSS-ILD.

Conclusion

The clinical features of pSS-ILD patients were xerophthalmia, cough and shortness of breath, and HRCT can help to diagnose the disease at an early stage. Age over 60 years,

chronic course of disease, and elevated lipid levels are risk factors for ILD in pSS patients, and the relationship between autoimmune antibody levels and the occurrence of ILD needs to be further confirmed in follow-up studies with large sample sizes.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Ethics statement

The studies involving humans were approved by the Ethics Committee of Shanghai University of Traditional Chinese Medicine (No. 2018-014) and was registered at Chinese Clinical Trial Registry (No. ChiCTR2000037057). Informed consent was obtained from all the study subjects before enrollment. The studies were conducted in accordance with the local legislation and institutional requirements. The participants provided their written informed consent to participate in this study.

Author contributions

ZY and DW contributed to the conception and design of the study; HZ, LS, and ZY performed the experiments, collected and analyzed data; ZY wrote the manuscript; All authors contributed to the article and approved the submitted version.

Clinical study: the impact of goal-directed fluid therapy on volume management during enhanced recovery after surgery in gastrointestinal procedures

Ming Gao, Minggan Chen, Gang Dai, Dengfeng Zhu and Yiting Cai*

Department of Gastrointestinal Surgery, Chongming Hospital Affiliated to Shanghai University of Medicine and Health Sciences, Shanghai, China

Background: Goal-directed fluid therapy, as a crucial component of accelerated rehabilitation after surgery, plays a significant role in expediting postoperative recovery and enhancing the prognosis of major surgical procedures.

Methods: In line with this, the present study aimed to investigate the impact of target-oriented fluid therapy on volume management during ERAS protocols specifically for gastrointestinal surgery. Patients undergoing gastrointestinal surgery at our hospital between October 2019 and May 2021 were selected as the sample population for this research.

Results: 41 cases of gastrointestinal surgery patients were collected from our hospital over 3 recent years. Compared with T1, MAP levels were significantly increased from T2 to T5; cardiac output (CO) was significantly decreased from T2 to T3, and significantly increased from T4 to T5; and SV level was significantly increased from T3 to T5. Compared with T2, HR and cardiac index (CI) were significantly elevated at T1 and at T3–T5. Compared with T3, SVV was significantly decreased at T1, T2, T4, and T5; CO and stroke volume (SV) levels were increased significantly at T4 and T5. In this study, pressor drugs were taken for 23 days, PACU residence time was 40.22 ± 12.79 min, time to get out of bed was 12.41 ± 3.97 h, exhaust and defecation time was 18.11 ± 7.52 h, and length of postoperative hospital stay was 4.47 ± 1.98 days. The average HAMA score was 9.11 ± 2.37, CRP levels were 10.54 ± 3.38 mg/L, adrenaline levels were 132.87 ± 8.97 ng/L, and cortisol levels were 119.72 ± 4.08 ng/L. Prealbumin levels were 141.98 ± 10.99 mg/L at 3 d after surgery, and 164.17 ± 15.84 mg/L on the day of discharge. Lymphocyte count was 1.22 ± 0.18 (10^9/L)

Abbreviations: ERAS, enhanced recovery after surgery; TAP, transabdominal plane; GDFT, goal-directed fluid therapy; CO, cardiac output; CI, cardiac index; SV, stroke volume; SVV, stroke volume variation; MAP, mean arterial pressure; HR, heart rate.

at 3 d after surgery, and 1.47 $\pm$ 0.17 (10^9/L) on the day of discharge. Serum albumin levels were 30.51 $\pm$ 2.28 (g/L) at 3 d after surgery, and 33.52 $\pm$ 2.07 (g/L) on the day of discharge.

Conclusion: Goal-directed fluid therapy (GDFT) under the concept of Enhanced Recovery After Surgery (ERAS) is helpful in volume management during radical resection of colorectal tumors, with good postoperative recovery. Attention should be paid to the influence of pneumoperitoneum and intraoperative posture on GDFT parameters.

Introduction

During gastrointestinal surgery, patients are influenced by various factors, such as their psychological state, anesthesia, surgical procedures, and pain. As a result, they may experience different levels of illness-related effects. These effects manifest in the form of a robust surgical stress response, leading to the production of significant amounts of stress hormones in patients' bodies. Consequently, symptoms such as elevated blood pressure, inadequate oxygen supply, and accelerated heart rate may arise, ultimately impacting the surgical outcomes (Pu et al., 2020; Daca-Alvarez et al., 2022; Ding et al., 2022; Erdem et al., 2022). Therefore, it is particularly important to implement effective perioperative management for patients undergoing gastrointestinal surgery (Ayala et al., 2022).

Fluid therapy plays a crucial role in ensuring the safety of patients during surgery and facilitating postoperative recovery within the context of Enhanced Recovery After Surgery (ERAS) protocols (Ashok et al., 2020). Consequently, this factor has garnered significant attention not only from surgeons but also from anesthesiologists (Feldheiser et al., 2016). In recent years, with the widespread adoption of the ERAS concept, there has been a surge in the number of medium-to high-risk patients requiring surgical interventions, as well as an increase in the complexity and volume of surgeries performed. This trend has led to a growing interest among scholars in exploring and researching various aspects of fluid therapy (Gustafsson et al., 2019). Building upon traditional fluid replacement and restrictive fluid therapy approaches, the concept of goal-directed fluid therapy (GDFT), which offers more precise and accurate administration, has gained widespread recognition (Arena et al., 2021).

GDFT, or goal-directed fluid therapy, refers to an individualized rehydration approach that relies on monitoring hemodynamic indicators to assess the body's fluid requirements (Di et al., 2020). The effectiveness of GDFT within the ERAS framework often hinges on various common risk factors associated with both the surgery and the patient (Giusto et al., 2021). Previous research has demonstrated that personalized GDFT during surgical procedures can yield significant benefits for patients categorized as medium-to-high risk (Bisgaard et al., 2020; Jiang et al., 2021). Consequently, recent studies have primarily focused on investigating the application of GDFT in ERAS protocols for major surgery involving middle- and high-risk patients (Aaen et al., 2021). This present study aimed to examine the impact of goal-directed fluid therapy on volume management during ERAS in gastrointestinal surgery.

Materials and methods

General information

This study was approved by the Medical Ethics Committee of our hospital (NO: 2020051617), and all patients signed an informed consent form. Adult patients who were scheduled to undergo surgery in Gastrointestinal Procedures under general anesthesia from October 2019 to May 2021 were selected, regardless of gender and ASA score (class I or II).

Exclusion criteria

Severe uncontrolled cardiovascular, endocrine, or respiratory disease; severe digestive tract obstruction; significant liver and kidney dysfunction; abnormal blood coagulation function; contraindications for artery puncture and central vein catheterization prior to surgery; severe nervous system disease; abnormal mental states; inability to communicate normally.

Exit criteria

Active request by the patient to withdraw during the study; failure to effectively cooperate with the treatment plan, leading to the failure of normal research protocols; serious accidents during

treatment; transfer to an intensive care unit (ICU) for monitoring and treatment after operation.

Before the withdrawal of any subject, the reason for withdrawal was recorded accurately, and a new subject was not included instead.

Procedures under the research program

Before the surgery, the doctor informed the patient about possible anesthesia methods, possible complications and solutions during anesthesia, and postoperative analgesia strategy. One day before surgery, the patient took laxatives orally to clean the intestines, without undergoing mechanical enema. Solid food was fasted from 6 h before the operation; 2 hours before anesthesia induction, patients took 4 mL/kg of multidimensional carbohydrate drink orally (surgical energy).

After entering the room, patients were monitored for non-invasive blood pressure, electrocardiogram, SpO2, respiratory rate, and body temperature; depth of anesthesia was monitored using a Narcotrend monitor. A FloTrac/Vigileo sensor was connected after radial artery catheterization under local anesthesia to monitor cardiac output (CO), cardiac index (CI), stroke volume (SV), and stroke volume variation (SVV). Before anesthesia induction, midazolam 0.05 mg/kg, pentoxiquine hydrochloride 0.4–0.6 mg, and lansoprazole 30 mg were injected intravenously. Anesthesia induction consisted of etomidate 0.3 mg/kg, sufentanil 0.4–0.6 μ G/kg, cisatracurium 0.15 mg/kg, and mask-assisted respiration, nitrogen removal, and oxygen delivery; the anesthesia machine was connected after endotracheal intubation, with respiratory parameters FiO 30%–50%, tidal volume 6–8 mL/kg, respiratory rate 12–15 times/min, and I:E = 1:2. Subsequently, the right subclavian vein was punctured and catheterized. Ultrasound-guided transabdominal plane (TAP) block was given at the head end of the bilateral iliac crest, with 0.375% ropivacaine 20 mL on each side. Propofol rate was 3–6 mg/(kg/h), remifentanil was 0.05–0.2 μG/(kg/min), and 1%–1.5% sevoflurane was inhaled. During the operation, the concentration of sevoflurane was adjusted according to the Narcotrend value, and the Narcotrend value was maintained at 37–45. Muscle relaxants were added according to the needs of the operation. Ulinastatin 5 000 U/kg was injected into the crystal solution during the operation.

Fluid management plan

(1) (Daca-Alvarez et al., 2022) Compensatory dilatation (5 mL/kg) was supplemented 30 min before anesthesia induction. Crystalloid solution (Ringer Lactate) was used as the background infusion. Before laparotomy, crystalloid solution (2 mL/kg/h) was input. At the laparotomy stage, 5 mL/(kg/h) was used as the background infusion until the

end of the operation (Ding et al., 2022). SVV ≤13% was taken as the reference range of volume reactivity. If SVV >13% at a measured time point, this was defined as a low-volume time point, and volume-loading treatment was carried out: that is, 150 mL of hydroxyethyl starch 130/0.4 sodium chloride injection was given intravenously for 10 min, and SVV was re-evaluated until SVV ≤ 13%. If SVV ≤13% at a measured time point, CI was further evaluated. (Erdem et al., 2022). If CI < 2.5 L/(min/m2), dobutamine 2.5–10 μg/(kg/min) was used. When the heart rate (HR) was higher than 100 beats/min, dobutamine was reduced or stopped. (Pu et al., 2020). Central venous oxygen saturation (ScvO2) was evaluated. When ScvO2 < 73% and Hb < 10 g/dL, concentrated red blood cells were infused to bring Hb ≥ 10 g/dL. If it was still the case that ScvO2<73%, dobutamine 2.5–20 μ G/ (kg • min) was used until ScvO2 ≥ 73%.

Intraoperative management and analgesia plan

When MAP <65 mmHg, intravenous infusion of norepinephrine 40 μg was administered; arterial blood samples were taken every 60 min for blood gas analysis. During the operation, blood glucose was maintained between 5.6 and 10 mmol/L. During the operation, central temperature (nasopharynx temperature) was maintained no lower than 36°C by means of air heater and liquid heating; this was maintained until the patient was transferred back to the ward. Before the end of the operation, 5 mg of dizosine, 6 mg of tropisetron, 5 mg of dexamethasone, 1.5 mg of droperidol, and 0.375% ropivacaine were given for local infiltration anesthesia.

The PCIA formula for postoperative analgesia consisted of deszocin 0.4–0.5 mg/kg, flurbiprofen lipid 5 mg/kg, tropisetron 12–18 mg, background dose 2 mL/h, pressing dose 0.5 mL, locking time 15 min. After the operation, the patient was decannulated and transferred to the PACU. Once the patient was awake, respiration and circulation were stable, and VAS was less than 3 points, he was transferred back to the ward.

Observed indicators

Mean arterial pressure (MAP), HR, CO, CI, SV, and SVV were recorded after endotracheal intubation (T1), after skin incision (T2), 60 min after pneumoperitoneum (T3), 5 min after laparotomy (T4), at the end of surgery (T5). For this study, the intraoperative fluid infusion volume (crystalloid/colloid), intraoperative blood loss, surgical duration, and amount of vasoactive drugs used during the procedure were recorded. The patient's time of awakening, status of gas/bowel movements, and postoperative hospital stay were also documented.

TABLE 1 General information of gastrointestinal surgery.

Group	
Number	41
Age	61.56 ± 10.74
Sex	23 (Man)/18 (Woman)
BMI	23.52 ± 3.52
Cancer category	
Colon cancer	28
Rectal cancer	13

ASA-I	17
ASA-II	24

Statistical methods

SPSS 21.0 statistical software was used for statistical analysis. Measurement variables that followed a normal distribution are expressed in the form of x ± s, and repeated-measures ANOVA was used to compare different time points. Differences were regarded as statistically significant if $p < 0.05$.

Results

Comparison of patient characteristics

A total of 41 patients who underwent gastrointestinal surgery at our hospital were included in this study, covering a span of 3 years. Table 1 presents demographic data for the patients, including gender, age, and disease type. Statistical analysis revealed no significant differences in these variables among the patient groups ($p > 0.05$).

Hemodynamic changes during surgery

In comparison to the baseline measurement (T1), there was a significant increase in mean arterial pressure (MAP) from T2 to T5 ($p < 0.05$, Table 2). Cardiac output (CO) was significantly decreased from T2 to T3, but notably increased from T4 to T5 ($p < 0.05$, Table 2). Stroke volume (SV) levels exhibited a significant increase from T3 to T5 ($p < 0.05$, Table 2). Heart rate (HR) and cardiac index (CI) were significantly higher at T1 and T3–T5 than at T2 ($p < 0.05$, Table 1). Moreover, systolic volume variation (SVV) was significantly decreased at T1, T2, T4, and T5 in comparison to T3 ($p < 0.05$, Table 2). At T4 and T5, both CO and SV demonstrated a significant increase ($p < 0.05$, Table 2). These data indicate that GDFT-significant hemodynamic changes were observed during the surgical procedure. GDFT can significantly improve postoperative cardiac function and has potential cardiac protective effects.

Postoperative follow-up

The duration of pressor drug administration was recorded as 23 days in this study. The average time spent in the post-anesthesia care unit (PACU) was 40.22 ± 12.79 min, while the time taken for patients to mobilize and get out of bed was 12.41 ± 3.97 h. The interval prior to bowel movement/defecation was observed to be 18.11 ± 7.52 h. The average length of the postoperative hospital stay was determined to be 4.47 ± 1.98 days (Table 3). GDFT can significantly improve the duration of PACU stay, time to mobilize and get out of bed, and length of hospital stay.

Surgical stress indices

Assessment of surgical stress indices revealed an average HAMA score of 9.11 ± 2.37. Additionally, C-reactive protein (CRP) levels were measured at 10.54 ± 3.38 mg/L, adrenaline levels at 132.87 ± 8.97 ng/L, and cortisol levels at 119.72 ±

4.08 ng/L (Table 4). GDFT can significantly improve surgical stress index measurements.

Nutritional status

Regarding patients' nutritional status, prealbumin levels were found to be 141.98 ± 10.99 mg/L at 3 days after surgery; levels increased to 164.17 ± 15.84 mg/L on the day of discharge from the hospital (Table 5). Lymphocyte counts at 3 days after surgery were reported as 1.22 ± 0.18 (10⁹/L), rising to 1.47 ± 0.17 (10⁹/L) on the day of discharge (Table 5). Serum albumin levels at 3 days after surgery were recorded as 30.51 ± 2.28 g/L, increasing to 33.52 ± 2.07 g/L on the day of discharge. GDFT can significantly improve postoperative nutritional status.

Discussion

Gastrointestinal surgery is characterized by significant trauma, a high risk of blood loss, and a high proportion of elderly patients or those with multiple comorbidities (Harada et al., 2022). The application of Enhanced Recovery After Surgery (ERAS) principles in gastrointestinal surgery has received extensive scholarly attention, and this framework been implemented extensively in clinical practice, gradually reaching a mature stage (Jabłońska et al., 2022). However, fluid management during gastrointestinal surgery is critical, as both fluid overload and inadequate circulating blood volume can have adverse effects on patient outcomes. Specifically, fluid

TABLE 5 Nutritional status.

overload can lead to an increased incidence of postoperative complications such as anastomotic leakage and delayed recovery of gastrointestinal function (Pu et al., 2021; Lata et al., 2022). Conversely, insufficient effective circulating blood volume can result in inadequate tissue perfusion, hypoxia, and an elevated risk of postoperative complications and mortality (Mao et al., 2022). In gastrointestinal surgery, devices such as Esophageal Doppler (ED) and FloTrac/Vigileo, among others, are commonly used for real-time monitoring of stroke volume (SV), systolic volume variation (SVV), and pulse pressure variation (PPV) to assess dynamic changes in fluid status and optimize fluid management (Ross et al., 2022). In this study, we collected data from 41 patients who underwent gastrointestinal surgery at our hospital over the past 3 years. Table 1 presents the general characteristics of these patients, including gender, age, and disease type. Makaryus et al. showed that optimization of perioperative fluid management is crucial for Enhanced Recovery Pathways (ERPs), as this helps improve lung function, tissue oxygenation, gastrointestinal motility, and wound healing (Makaryus et al., 2018). Therefore, in this study, data were collected from 41 patients who underwent gastrointestinal surgery to examine the impact of goal-directed fluid therapy on volume management during ERAS in gastrointestinal surgery.

While there has been limited research on the application of goal-directed fluid therapy (GDFT) in gastrointestinal surgery under the ERAS framework, it is worth noting that existing studies have small sample sizes and provide only weak evidence (Scott et al., 2015; Pędziwiatr et al., 2018; Low et al., 2019). Intraoperative GDFT plays a crucial role in perioperative fluid therapy within the ERAS management approach (Sica et al., 2020). Most studies related to ERAS include intraoperative GDFT as a component (Wobith and Weimann, 2021). Therefore, this article aimed to review and discuss the current application and research progress of GDFT in gastrointestinal

surgery within the context of ERAS, drawing on high-quality studies. In this study, we observed a significant increase in mean arterial pressure (MAP) from T2 to T5, while cardiac output (CO) was decreased from T2 to T3 but increased from T4 to T5. Grass et al. showed that among these 5,155 patients, 2,320 patients (45.1%) received more than 3 L of intravenous fluids on postoperative day 0 (Grass et al., 2020). Thus, these data also show the encouraging efforts of GDFT, as it has been found to be associated with better outcomes and indicates potential for customization in specific patient populations.

Goal-directed fluid therapy (GDFT) utilizes various observational indicators, including traditional static measurements such as SvO2, central venous pressure, pulmonary capillary wedge pressure, and lactic acid, as well as functional hemodynamic indicators such as stroke volume (SV), SV variation (ΔSV), systolic volume variation (SVV), and pulse pressure variation (PPV) (Wobith and Weimann, 2021). Recently, there has been a growing interest in studying SV, ΔSV, SVV, and PPV, and similar parameters measured by equipment such as the FloTrac/Vigileo and LiDCO, as they provide new insights into the cardiac preload of the body (Joosten et al., 2021). It is important to note that SVV or PPV should be evaluated when patients are mechanically ventilated and free from complications such as thoracotomy, arrhythmia, or myocardial disease. In contrast, SV and ΔSV are not influenced by tidal volume or rhythm and can be evaluated in awake patients or those with arrhythmias (Liu et al., 2021). In our study, we observed a significant increase in SV from T3 to T5, while HR and cardiac index (CI) values were notably elevated at T1 and T3–T5. Moreover, CO and SV demonstrated a significant increase at T4 and T5. Makaryus et al. showed that GDFT improves blood flow intraoperatively, and ultimately reduce LOS and complications (Makaryus et al., 2018). Therefore, this treatment method improves pulmonary function, tissue oxygenation, gastrointestinal motility, and wound healing. The clinical demand for evidence-based Enhanced Recovery After Surgery (ERAS) programs is increasing with the rise in the number of patients undergoing major surgeries with medium to high risk levels (McLain et al., 2021). Early research on ERAS has shown that optimizing intraoperative fluid management can significantly benefit patients (Mizunoya et al., 2019). The debate surrounding intraoperative fluid management schemes has evolved from traditional rehydration approaches to restrictive rehydration and ultimately to individualized goal-directed fluid therapy (GDFT) supported by evidence-based medicine (Mohammed El-Hadi Shoukat Mohammed et al., 2021). Numerous high-quality studies have demonstrated the significant advantages of GDFT for medium-to high-risk patients undergoing major surgery, including a reduction in the incidence and mortality of postoperative complications, shorter hospital stays, lower medical costs, faster postoperative recovery, and improved quality of life, aligning with the principles of ERAS (Rollins et al., 2020). It is worth noting

that perioperative fluid management under the ERAS model should encompass the entire diagnostic and treatment process, including the stages before, during, and after surgery, as fluid management at each stage can significantly impact patient prognosis (Turi et al., 2021). In this study, the duration of pressor drug administration was recorded as 23 days, while the average time spent in the post-anesthesia care unit (PACU) was 40.22 ± 12.79 min. Patients took an average of 12.41 ± 3.97 h to mobilize and get out of bed, and 18.11 ± 7.52 h for bowel movements/defecation; the average length of the postoperative hospital stay was 4.47 ± 1.98 days. Additionally, the average HAMA score was determined to be 9.11 ± 2.37; CRP levels were measured at 10.54 ± 3.38 mg/L, adrenaline levels at 132.87 ± 8.97 ng/L, and cortisol levels at 119.72 ± 4.08 ng/L. Lee et al. reported that goal-directed fluid therapy is associated with earlier progression to a postoperative soft diet, reduced acute postoperative pain intensity, and less rescue analgesics (Lee et al., 2021). Thus, these data also illustrate the fact that goal-directed fluid therapy leads to better postoperative recovery and a better renal protective effect.

However, it is important to acknowledge that inappropriate treatment at any stage of the diagnostic and treatment process can undermine the entire ERAS pathway and affect the final outcome (Turi et al., 2022). This article has primarily focused on intraoperative fluid management within the ERAS framework, without delving into preoperative and postoperative fluid management schemes (Virág et al., 2022). Due to the current medical model and the roles assigned in implementing the overall ERAS program, anesthesiologists are primarily responsible for controlling and accurately managing the intraoperative stages of fluid management, while preoperative and postoperative fluid management is often carried out by surgeons (Xie et al., 2021). This approach contradicts the concept of continuous and unified fluid management advocated by anesthesiologists during the perioperative period (Weinberg et al., 2019; Zorrilla-Vaca et al., 2021). Regarding nutritional status, in this study, prealbumin levels were found to be 141.98 ± 10.99 mg/L at 3 days after surgery, increasing to 164.17 ± 15.84 mg/L upon discharge from the hospital. Lymphocyte counts at 3 days after surgery were reported to be 1.22 ± 0.18 (109/L), increasing to 1.47 ± 0.17 (109/L) on the day of discharge. Serum albumin levels at 3 days after surgery were recorded as 30.51 ± 2.28 g/L, increasing to 33.52 ± 2.07 g/L on the day of discharge. These data indicate that goal-directed fluid therapy has a better effect at discharge.

While the concept of perioperative fluid management has been established for some time, its implementation in clinical practice lacks uniformity within the current medical development model. However, with the emergence of perioperative medicine as a specialized discipline, it is expected that a standardized approach to managing the perioperative process will be developed in the future. This may enable anesthesiologists to implement continuous and

consistent fluid management for patients undergoing elective surgery.

It is worth mentioning that this article has specifically focused on the application of GDFT in gastrointestinal surgeries under the ERAS model, without covering its utilization in other areas. Additionally, this article has not delved extensively into preoperative and postoperative fluid management schemes and their impact on patients. Finally, due to the limited sample size of 41 cases from the author's institution, further validation through larger-scale studies is required to confirm the findings of this study.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Ethics statement

The studies involving humans were approved by the Ethics Committee of the Chongming Hospital Affiliated to Shanghai University of Medicine and Health Sciences. The studies were conducted in accordance with the local legislation and institutional requirements. Written informed consent for participation in this study was provided by the participants' legal guardians/next of kin.

Author contributions

MG designed the experiments. MC and GD performed the experiments. DZ and YC collected and analyzed the data. MC and YC drafted manuscript. All authors contributed to the article and approved the submitted version.

Funding

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Protective effect of tretinoin derivative and TXNRD1 protein on streptozotocin induced gestational diabetes *via* an age-rage signaling-pathway

Wensheng Wang✉ and Lin Wang

Department of Nursing, Hebi Polytechnic, Changjiang Street QibinHebi, Henan 458030, China

Background: In the present study effect of tretinoin derivative was investigated on the pathogenesis of gestational diabetes mellitus (GDM) in mice model *in vivo*. **Materials and Methods**: Diabetes was induced in mice by injecting Streptozotocin (STZ) for 5consecutive days at a dose of 65 mg/kg body weight through the intraperitoneal route. Tretinoin derivative was given to the mice at 0.12 and 0.25 mg/kg doses through gavage in normal saline alternately for one week after STZ injection.**Results**: The results demonstrated that tretinoin derivative administration to the diabetic mice significantly (*P*<0.05) alleviated the blood FBG and FINS levels. Administration of tretinoin derivative to the diabetic mice significantly (*P*<0.05) promoted the blood HDL level and alleviated TC and TG levels. The administration of tretinoin derivative to the diabetic mice significantly (*P*<0.05) alleviated the CRP, IL-6and TNF-α production in pancreatic tissues. Tretinoin derivative administration to the diabetic mice significantly (*P*<0.05) elevated the SOD activity, and CAT level and lowered the MDA level in pancreatic tissues. The TXNRD1 expression in diabetic mice was comparable to that in the normal group after administration of tretinoin derivativeat the dose of 0.25 mg/kg dose. *In silico* data demonstrated that tretinoin derivativeinteracts with TXNRD1 protein with the binding affinity ranging from –10 to 9.4 kcal/ mol. **Conclusion**: In conclusion, tretinoin derivative administration effectively regulated streptozotocin-induced changes in fasting blood glucose, insulin level, high-density lipid level and triglyceride level in diabetic mice *in vivo*. The streptozotocin-induced excessive production of C-reactive protein and inflammatory cytokines was also down-regulated in diabetic mice on administration of tretinoin derivative. Therefore, tretinoin derivative can be investigated further as a therapeutic agent for the treatment of gestational diabetes mellitus.

INTRODUCTION

Gestational diabetes mellitus (GDM) is a leading medical complication in pregnant females characterized by high glucose level (Metzger *et al.*, 1998). It has been observed that the bodies of pregnant females react differently to elevated sugar levels. In most cases high blood glucose level during pregnancy leads to miscarriage or premature birth (Metzger *et al.*, 1998). Despite being the leading life threat to pregnant females and their babies the pathogenesis of GDM is yet to be fully known (Johns *et al.*, 2018). Studies have revealed that one of the major factors involved in the development and pathogenesis of GDM is insulin resistance (IR) (Hajifaraji *et al.*, 2018; Sha *et al.*, 2019). Furthermore, the pathogenesis of GDM is complicated by the excessive release of inflammatory factors and induction of oxidative stress pathways during pregnancy (Hajifaraji *et al.*, 2018; Sha *et al.*, 2019). During type-2 diabetes, the expression of the antioxidant gene, thioredoxin reductase-1 cytoplasmic (TXNRD1) is markedly elevated which complicates the disorder (Baig *et al.*, 2020; Nazem *et al.*, 2019). The activity of superoxide dismutase (SOD) is also found to be higher in patients suffering from type-2 diabetes (Baig *et al.*, 2020; Nazem *et al.*, 2019). It is reported that elevated levels of inflammatory factors persistently in pregnant females play a prominent role in the pathogenesis of GDM (Sudharshana *et al.*, 2018).

The TrxR1, a member of the thioredoxin system which is encoded by TXNRD1 plays a vital role in regulating the redox system. It also constitutes an important part of the antioxidant defense system and inhibits Trx expression to maintain the reduced state of intracellular proteins (Cebula *et al.*, 2015). Up-regulation of TXNRD1 plays a crucial role in increasing the resistance of cells to oxidative stress by neutralizing hydrogen peroxide and inactivation of apoptotic pathway. Thus, increasing the expression of TXNRD1 is believed to be of therapeutic significance for the treatment of diabetes (Kabuyama *et al.*, 2008; Chang *et al.*, 2018). The TrxR/Trx system has been demonstrated to be associated with inhibition of oxidative stress, inactivation of apoptosis, DNA synthesis and regulation of NF-κB pathway (Park *et al.*, 2015; Raninga *et al.*, 2016; Matsui *et al.*, 1996). It is also reported that inflammatory response in cells is regulated by TXNRD1 expression (Shi *et al.*, 2020).

Triazoles are known for various pharmaceutical activities, such as anti-cancer, antioxidant, anti-inflammatory, anti-HIV, anti-diabetic, and anti-protozoal properties. Structural-activity relationship investigations have revealed that the 1,2,3-triazole part is the most active pharmacophoric group in numerous bioactive compounds.

Figure 1. Chemical structure of tretinoin derivative.

The pharmacological activity of 1,2,3-triazoles is mainly attributed to various types of interactions such as hydrogen bonds, van der Waals forces, and dipole–dipole bonds with proteins, enzymesand different receptors in living organisms (Bonandi *et al.*, 2017; Bozorov *et al.*, 2019). The compounds containing 1,2,3-triazole scaffold have been found to exhibit various pharmaceutical activities like antibacterial (Zhang, 2019; Chu *et al.*, 2020), antimalarial (Chu *et al.*, 2019; Feng *et al.*, 2020), anti-tubercular (Yan *et al.*, 2020), anti-viral (Feng *et al.*, 2021), and anti-cancer (Slavova *et al.*, 2020) properties. The present study was designed to investigate the therapeutic effect of a tretinoin derivative on gestational diabetes mellitus and understand the underlying mechanism.

MATERIALS AND METHODS

Mice model of gestational diabetes

Male C57BL/6 mice eighty in number (body weight 18–30 g and around 10 weeks old) were supplied by the Experimental Animal Center belonging to the Hospital in Shanghai, China [Registration number 09/2020]. The mice were kept in cages in the animal center at a regulated temperature of $24\pm1°C$, humidity of 65%, and exposed to 12/12-hour light/dark cycles. Mice in the normal group were fed a normal diet and those in the model GDM groups were given fat rich and sucrose diet. The animal experimental procedures were conducted in compliance with the guidelines of the institutional laboratory and Guide of the National Institute of Health for Care and Use of Laboratory Animals [Ethical clearance certificate number 102/2020].

The female mice were caged overnight with male mice at the proestrus stage and microscopy was performed to confirm the pregnancy on the following day. Diabetes was induced in mice by injecting STZ (Sigma-Aldrich, St. Louis, MO, USA) for 5 consecutive days at a dose of 65 mg/kg body weight through intraperitoneal route. Induction of diabetes in mice was confirmed by measuring the glucose blood for 8weeks after STZ injection. The mice having elevated level of blood glucose (16.7 mmol/L) and suffering from polyuria, polyphagia and weight loss were considered to be diabetic (John *et al.*, 2012). The mice were divided into four groups of 10 each; normal, model diabetes and two tretinoin derivative treatment (administered with 0.12 and 0.25 mg/kg body weight) groups. Tretinoin derivative was given to the mice by gavageat doses of 0.12 and 0.25 mg/kg in normal saline alternately for one week after STZ injection.

Mice were fasted for 10 hours and then injected with 1% pentobarbital sodium (50 mg/kg) anesthesia after completion of the treatment. The blood samples were collected from the abdominal aorta of the mice for biochemical analysis of the various parameters. The collected blood samples were stored overnight in a refrigerator and thencentrifuged at 4°C for 25 minutes at 12000×*g* to collect the serum. Tissue samples were extracted from the pancreatic islets and placental for investigation of pathological changes.

Assay for FBG, FINS, IR, HDL and TG determination

The blood samples collected from the mice abdominal aorta were analyzed for FBG level using the commercially available glucose test strips (Nova Biomedical Corporation) according to the supplier's instructions. The enzyme-linked immunosorbent assay kits (Shanghai Huzhen Biological Technology Co., Ltd.) were used for the measurement of FINS in the mice blood samples as per manufacturer's guidelines. BK-400 automatic biochemical analyzer (BioBase) was used for the measurement of TG and HDL levels in the mice blood samples. The HOMA-IR was calculated using the reported formula [FBG (mmol/l)×FIN S (mU/l)] /22.5.

Measurement of oxidative stress factors in mice pancreatic tissues

The tissue sections from the pancreas of the mice were extracted, sliced into thin sections and then homogenized. The lysate obtained was subjected to centrifugation at 2000×*g* for 15 min at 4°C to separate the supernatant for measurement of various oxidative factors. The commercially available UV-visible spectrophotometer assay kits (Beyotime Institute of Biotechnology) were used for the measurement of CAT, MDA levels, and activity of SOD in mice pancreatic tissues.

Western blot analysis

The pancreatic tissue samples of the mice were lysed on treatment with RIPA lysis buffer (Sigma-Aldrich; Merck KGaA) to obtain the tissue lysate. The protein content in the tissue lysates was estimated using the Bradford method. Protein samples (30 µg) in equal quantities were separated on 10% SDS-PAGE gel and then transferred onto the PVDF membranes. Incubation of the membranes was performed with 5% skimmed milk powder for 2 hours at 4°C to block the non-specific sites. Membranes were incubated overnight with anti-CRP (cat. no. ab207756), anti-TNF-α (cat. no. ab205587), anti-IL-6 (cat. no. ab208113), anti-TXNRD1 (cat. no. ab124954) and anti-GAPDH (cat. no. ab9485; all purchased from Abcam) primary antibodies at 4°C. After washing with PBS the membranes were incubated again at room temperature for 1 hour with HRP-conjugated secondary antibodies (cat. no. ab7090; 1:10,000; Abcam). Expression of protein bands was visualized using the Chemiluminescence enhancement reagent (Thermo Fisher Scientific, Inc.) and analyzed by the ImageJ software (version 1.46r; National Institutes of Health).

Statistical analysis

The presented data are the mean ± S.D. of the three independently conducted experiments. Analysis of the data was performed using the Graph-Pad Prism software (version 8; Graph-Pad Software, Inc.). The difference between the groups was determined using the Student's test and ANOVA followed by Tukey's post hoc test. The values at $P<0.05$ were considered to represent the statistically significant differences.

RESULTS

Tretinoin derivative administration alleviates FBG and FINS levels in diabetic mice

In diabetic mice, the FBG as well as FINS levels were significantly ($P<0.05$) elevated in blood compared to the

Figure 2. Effect of tretinoin derivative on blood FBG and FINS levels in diabetic mice.
Diabetic mice were administered Tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). Commercially available glucose test strips and enzyme-linked immunosorbent assay kits were used for the determination of blood FBG and FINS levels, respectively in mice. *P<0.05,**P<0.01 vs model group.

Figure 4. Effect of tretinoin derivative on blood TC and TG levels in diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). The BK-400 automatic biochemical analyzer was used for the determination of blood TC and TG levels, respectively in mice. *P<0.05,**P<0.01 vs model group.

Figure 3. Effect of tretinoin derivative on blood HDL level in diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). A commercially available BK-400 automatic biochemical analyzer was used for the determination of blood HDL in mice. *P<0.05, **P<0.01 vs model group.

Figure 5. Effect of tretinoin derivative on CRP, IL-6 and TNF-α production in pancreatic tissues of diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). Western blotting assay was performed to assess the production of CRP, IL-6 and TNF-α in mice pancreatic tissues. *P<0.05,**P<0.01 vs model group.

normal group (Fig. 2). Tretinoin derivative administration to the diabetic mice significantly (P<0.05) alleviated the blood FBG as well as FINS levels in a dose-dependent manner. The FBG and FINS levels in diabetic mice were reduced more closely to those in the normal group after treatment with 0.25 mg/kg tretinoin derivative compared with the 0.12 mg/kg group.

Tretinoin derivative administration promotedHDL level in diabetic mice

The HDL level showed a significant (P<0.05) decrease in blood samples of diabetic mice compared to the normal group (Fig. 3). Administration of tretinoin derivative to the diabetic mice significantly (P<0.05) promoted the blood HDL level in a dose-dependent manner. The HDL level in diabetic mice was promoted more comparable to those in the normal group after treatment with tretinoin derivativeat a dose of 0.25 mg/kg compared to the group receiving 0.12 mg/kg.

Tretinoin derivative administration alleviates TC and TG levels in diabetic mice

In diabetic mice, the TC and TG levels were significantly (P<0.05) elevated in blood compared to the normal group (Fig. 4). Administration of tretinoin derivative to the diabetic mice significantly (P<0.05) alleviated the

blood TC and TG levels in a dose-dependent manner. The TC and TG levels in diabetic mice were reduced more comparable to the normal group on treatment with 0.25 mg/kg dose tretinoin derivative compared to the 0.12 mg/kg group.

Tretinoin derivative administration alleviates inflammation of pancreatic islets in diabetic mice

In diabetic mice, the CRP and IL-6 production showed a significant (P<0.05) increase in pancreatic tissues compared to the normal group (Fig. 5). Additionally, the TNF-α level in diabetic mice pancreatic tissues was also significantly (P<0.05) increased compared to the normal group. However, the administration of tretinoin derivative to the diabetic mice significantly (P<0.05) alleviated the CRP and IL-6 production in pancreatic tissues in a dose-dependent manner. The tretinoin derivative administration also suppressed the TNF-α level in diabetic mice pancreatic tissues comparable to the normal group.

Figure 6. Effect of tretinoin derivative on SOD activity and CAT and MDA levels in pancreatic tissues of diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). The UV-visible spectrophotometer was used for the determination of SOD activity and CAT and MDA levels in mice pancreatic tissues. $*P<0.05, **P<0.01$ vs model group.

Figure 7. Effect of tretinoin derivative on the expression of AGEs in dermal tissues of diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). Immunohistochemical staining was used for the determination of the expression of AGEs in mice.

Tretinoin derivative administration alleviates inflammatory response in diabetic mice

The SOD activity and CAT level showed a significant ($P<0.05$) decrease in pancreatic tissues of diabetic mice compared to the normal group (Fig. 6). Moreover, the level of MDA showed a significant ($P<0.05$) increase in diabetic mice pancreatic tissues in comparison to the normal group. Administration of tretinoin derivative to the diabetic mice significantly ($P<0.05$) elevated the SOD activity and CAT level in pancreatic tissues in a dose-dependent manner. The SOD activity and CAT level in diabetic mice were elevated comparable to the normal group on the administration of 0.25 mg/kg dose of tretinoin derivative. The tretinoin derivative administration lowered the MDA level in diabetic mice pancreatic tissues close to the normal group. The MDA level in diabetic mice pancreatic tissues was lowered to the level of the normal group on administration of tretinoin derivative at 0.25 mg/kg dose.

Figure 8. Effect of tretinoin derivative on TXNRD1 expression in serum samples of diabetic mice.
Diabetic mice were administered tretinoin derivative at 0.12 and 0.25 mg/kg doses or physiological saline (normal and model groups). The western blotting assay was used for the determination of TXNRD1 protein in mice serum samples. $*P<0.05, **P<0.01$ vs model group.

Figure 9. The in silico interaction between tretinoin derivative and TXNRD1 protein.
The binding of tretinoin derivative with TXNRD1 protein was investigated using the AutoDock Vina and Discovery Studio software.

Figure 10. Demonstration of binding between tretinoin derivative and TXNRD1 protein through two-dimensional diagram.
AutoDock Vina and Discovery Studio software were used for understanding the binding of tretinoin derivative with TXNRD1 protein.

Tretinoin derivative targets AGEs in diabetic mice

The expression of AGEs was prominently higher in the dermal tissues of diabetic mice compared to the normal group (Fig. 7). However, the administration of tretinoin derivative effectively alleviated the expression of AGEs in dermal tissues of diabetic mice in a dose-dependent manner. The expression of AGEs in diabetic mice was reduced comparable to the normal group on

administration of 0.25 mg/kg dose tretinoin derivative compared to the 0.12 mg/kg group.

Tretinoin derivative administration elevates TXNRD1 expression in diabetic mice

The TXNRD1 expression showed a remarkable decrease in diabetes mice serum samples compared to the normal group (Fig. 8). However, administration of tretinoin derivative to the diabetic mice led to a prominent increase in TXNRD1 expression in serum samples in a dose-dependent manner. The TXNRD1 expression in diabetic mice was promoted comparable to the normal group on administration of 0.25 mg/kg dose of tretinoin derivative compared to the 0.12 mg/kg group.

Tretinoin derivative interacts with TXNRD1 protein

It was observed from *in silico* data that trizoleinteracts with TXNRD1 protein (3EAN) with the binding affinity ranging from –10 to 9.4 kcal/ mol (Fig. 9). The binding of tretinoin derivative with TXNRD1 protein involves arginine (ARG C:416) andtryptophan (TRP C:411) amino acid residues of TXNRD1 *via* conventional hydrogen bonds (Fig. 10). Moreover, the protein interacts with tretinoin derivative *via* pi-alky and alkyl interactions involving leucine (LEU D:75), tryptophan (TRP D:411), leucine (LEU D:76) and alanine (ALA C:79) amino residues.

DISCUSSION

Expecting mothers have a serious life threat to themselves as well as to their children because of gestational diabetes mellitus (Johns *et al.*, 2018). Unfortunately, the incidence of the disorder has been increasing every year over the past decade in Chinese women (Johns *et al.*, 2018). High blood glucose levels during pregnancy have been found to be responsible for premature deliveries and increased abortion rate (Poston *et al.*, 2016). The present study was designed to understand the effect of tretinoin derivative on gestational diabetes in mice model *in vivo*. Initially, it was observed that streptozotocin administration in the mice caused a significant increase in FBG and FINS levels compared to the normal group. Other specific features of diabetes such as polyuria, polydipsia, polyphagia and weight loss were also observed in the mice administered with streptozotocin. Thus, these features confirmed the induction of diabetes in mice model. However, the administration of tretinoin derivative to the diabetic mice significantly ($P<0.05$) alleviated the blood FBG and FINS levels in a dose-dependent manner. Further, it was observed that FBG and FINS levels in diabetic mice were alleviated comparable to the normal group on treatment with 0.25 mg/kg dose of tretinoin derivative. In diabetic mice, the HDL level showed a significant ($P<0.05$) decrease in blood samples compared to the normal group. On the other hand, tretinoin derivative administration effectively promoted the blood HDL level in diabetic mice in a dose-dependent manner. The TC and TG levels were also elevated significantly in blood samples of the diabetic mice compared to the normal group. However, the administration of tretinoin derivative to the diabetic mice significantly ($P<0.05$) reversed the streptozotocin-induced increase in TC and TG levels in blood samples in a dose-dependent manner. Thus, initial data clearly showed that tretinoin derivative reverses streptozotocin-induced changes in FBG, FINS, lipoprotein and triglyceride levels in the

mice and therefore needs to be investigated further for possible role in the treatment of diabetes.

The increased expression of C-reactive protein (CRP) in diabetic patients is an indicator of inflammatory reactions and it is also associated with insulin resistance (Bateman*et al.*, 2016). It is reported that CRP promotes activation of various substrates of insulin receptors and inhibits tyrosine kinase activity (Kaushik *et al.*, 2009). Thus, insulin synthesis and its secretion are inhibited by CRP thereby leading to the development of resistance to the insulin action. Additionally, excessive secretion of TNF-α has been found to down-regulate the expression of glucose transporter-T4 and consequently increase insulin resistance. Studies have also demonstrated that elevated IL-6 production is associated with a decrease in insulin sensitivityand an increase in secretion of glucocorticoids and growth hormones. Thus, excessive IL-6 level in diabetic patients promotes insulin resistance and increase the level of blood glucose (Skórzyńska-Dziduszko *et al.*, 2016; Roca-Rodríguez *et al.*, 2017; Khaliq *et al.*, 2018; Bhat *et al.*, 2018; Dar *et al.*, 2016; Ansari *et al.*, 2018). In the present study, the CRP and IL-6 production was elevated in diabetic mice pancreatic tissues compared to the normal group. The TNF-α level in diabetic mice pancreatic tissues was also increased remarkably compared to the normal group. On the other hand, tretinoin derivative administration indiabetic mice effectively alleviated the CRP and IL-6 production in pancreatic tissues in a dose-dependent manner. Further, tretinoin derivative administration also led to a prominent reduction in TNF-α level in diabetic mice pancreatic tissues. In diabetic mice, SOD activity and CAT level showed a prominent decrease in pancreatic tissues than those of the normal group. The level of MDA also showed a remarkable increase in diabetic mice pancreatic tissues in comparison to the normal group. Fortunately, administration of tretinoin derivative to diabetic mice effectively elevated the SOD activity and CAT level in pancreatic tissues. It was found that tretinoin derivative administration lowered the MDA level in diabetic mice pancreatic tissues. Administration of tretinoin derivative to the diabetic mice also reversed the streptozotocin-induced increase in TXNRD1 protein expression effectively.

CONCLUSION

In conclusion, tretinoin derivative administration effectively regulated streptozotocin-induced changes in fasting blood glucose, insulin level, high-density lipid level and triglyceride level in diabetic mice *in vivo*. The streptozotocin-induced excessive production of C-reactive protein and inflammatory cytokines was also down-regulated in diabetic mice on administration of tretinoin derivative. Furthermore, the activity of SOD and the level of CAT in diabetic mice were elevated by triazole administration. Tretinoin derivative administration suppressed TXNRD1 protein expression and *in silico* data revealed that it binds to arginine (ARG C:416) and tryptophan (TRP C:411) amino acid residues of the protein *via* conventional hydrogen bonds. Therefore, tretinoin derivative can be investigated further as a therapeutic agent for the treatment of gestational diabetes mellitus.

Identification of AHNAK expression associated with the pathogenesis of chronic obstructive pulmonary disease by bioinformatic analysis

Chunhui Zhang and Yu Liu✉

Department of Respiratory and Critical Care Medicine, Fujian Geriatric Hospital, Fuzhou 350003, China

Background: Chronic obstructive pulmonary disease (COPD) was a risk factor for lung cancer tumorigenesis. This study aimed to discover novel diagnostic biomarkers for COPD patients and determine their underlying pathogenetic mechanisms. **Materials and methods**: Differentially expressed genes (DEGs) in COPD samples and normal controls were analyzed and utilized to construct a network associated with a high risk for COPD occurrence. Enrichment analysis was applied on the strength of Gene Ontology (GO) annotations and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis. The RT-qPCR analysis was performed to determine 10 hub genes in COPD. ELISA assay was utilized to measure IL-1β, IL-6, and IL-10 levels. Spearman's correlation analysis was conducted to detect the correlation between inflammatory cytokines and AHNAK expression. Cell proliferation and apoptosis were evaluated by CCK-8 and flow cytometry assays. **Results**: AHNAK was significantly increased in COPD serum samples compared with non-COPD smokers and strongly correlated with inflammation. AHNAK level could also discriminate COPD from non-COPD with high accuracy. **Conclusion**: AHNAK may be a feasible biomarker playing crucial functions in the diagnosis and progression of COPD.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) was a classic chronic respiratory disease with a global average prevalence of 13.1% (Blanco *et al.*, 2019). In 2015, about 3.2 million people died of COPD (Jolliffe *et al.*, 2019); by 2030, COPD is expected to be the fourth most common cause of death and the fifth most common cause of disability worldwide (Barnes, 2007). Its main features included persistent airflow limitation and recurrent airway inflammation, including emphysema, parenchymal emphysema destruction, and mucus overproduction due to capillary bronchitis (Hogg *et al.*, 2009). However, the molecular pathogenesis of COPD remains unclear, and effective prevention and treatment methods were lacking. Therefore, further research on the molecular mechanisms of COPD was needed to identify new drug targets.

Patients with COPD frequently presented with abnormal lung inflammation characterized by increased numbers of inflammatory cells (neutrophils, macrophages, and t-lymphocytes) and the release of multiple inflammatory mediators (lipids, chemokines, cytokines, and growth factors) (Guiedem *et al.*, 2018; Barnes, 2016). The main cause of COPD is exposure to noxious gases or particles, with smoking being one of the major risk factors (Salvi, 2014). The increase in inflammatory response cells and subsequent release of mediators further amplified the normal inflammatory response to smoking in COPD disease (Barnes, 2017). Up to now, nearly 1 billion people worldwide were smokers (Propper, 2020). However, only a minority of smokers eventually developed COPD, and the exact molecular and cellular pathogenesis of this complex process was not fully understood.

In this study, we used differential analysis from the NCBI Gene Expression Omnibus (GEO) database to screen for AHNAK, a critical gene that was highly expressed in COPD. Furthermore, bioinformatics analysis was utilized to explore its potential pathogenesis. Collectively, these results suggested that AHNAK may be a useful biomarker for COPD.

MATERIALS AND METHODS

Subject enrollment

68 healthy non-COPD smokers who underwent physical examination, 79 stable-COPD patients, and 83 acute exacerbation COPD (AECOPD) patients admitted to Fujian Geriatric Hospital between August 2017 and May 2020 were enrolled in our study. There was no significant difference in gender and age between the two groups ($P>0.05$). COPD was diagnosed according to the standard of the Global Initiative for Chronic Obstructive Lung Disease (GOLD). The specific manifestations were: pulmonary function first-second force exhalation volume (FEV1) to force spirometry (FVC) ratio less than 0.7 after an inhaled bronchodilator (salbutamol 200 ug), combined with clinical symptoms and signs, excluding irreversible obstructive pulmonary ventilation dysfunction caused by other factors. Exclusion criteria: (1) cases with bronchial asthma, bronchiectasis, interstitial pneumonia, lung cancer, and other definite severe lung diseases were excluded from this study; (2) cardiovascular diseases, metabolic diseases, rheumatic immune diseases, and acute and chronic inflammatory diseases in

Table 1. Clinical information on COPD patients and healthy controls

	Control (n=68)	Stable COPD (n=79)	acute exacerbation COPD (n=83)	P value
Age (years)	65.11±7.83	64.84±6.98	65.25±7.92	0.9412
Gender (Male/Female)	38/30	46/33	51/32	0.7835
BMI (kg/m2)	21.62±3.51	21.75±2.99	21.06±2.37	0.2914
FEV1/FVC (%)	83.59±9.22	60.33±6.41	53.47±7.25	<0.0001
CRP (mg/L)	5.19±1.67	25.71±13.36	51.28±27.49	<0.0001
Smoking history(Yes/No)	45/23	75/4	80/3	<0.0001

other parts of the body were excluded; (3) those who had been treated with antibiotics, systemic corticosteroid therapy, or immunosuppressive drugs within 3 months.

All included subjects were drawn 10 ml of venous blood after 8 h fasting, and all samples were sent to the laboratory department for centrifugation. The upper serum layer was taken, and the samples were stored at –80°C until use. All the subjects' information was shown in Table 1. This study was approved by the Ethics Committee of Fujian Geriatric Hospital and followed the Declaration of Helsinki. All participants were informed of the study plan and signed a written informed consent form.

Data download and differentially expressed genes (DEGs) analysis

We used the 'chronic obstructive pulmonary disease' search term as the keyword and limited the search scope to 'expression profile by array' to search the GEO database. In our study, our dataset included 10 samples from COPD patients and 10 control samples. All the data were downloaded and analyzed by R and GEOquery. After analysis, 122 up-regulated DEGs were found in COPD, which was used for subsequent analysis.

Gene Ontology (GO) annotations and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis

GO annotations and the Database conducted KEGG analysis of the integrated DEGs in COPD for Annotation, Visualization, and Integrated Discovery (DAVID; v 6.7).

Identification of protein-protein interaction (PPI) network

A hub gene was considered a gene with an absolute value of clinical trait relatio0.8ip of more than 0.2 and an absolute value of Spearman's correlation value of more than 0.8. The interaction of the hub gene and the DEGs were deemed to be key genes.

Real-time quantitative polymerase chain reaction analysis

Total RNAs were extracted from serum samples and cells using TRIzol reagent (Invitrogen, Carlsbad, CA). Then, reverse transcription was conducted to synthesize cDNA from RNA using a PrimeScript RT reagent kit (Takara, Japan). Finally, RT-qPCR was performed on a 7500 Real-time PCR System (Applied Biosystems, Beijing, China) using SYBR Premix EX Taq reagent (Takara, Japan) following the protocol. U6 functioned as an internal control, and data were analyzed relative to GAPDH based on the $2^{-\Delta\Delta CT}$ aquation. The primers sequences were as follows: AHNAK forward, 5'-AGCGTCTGTAGCTTCCTTGT-3', and reverse 5'-GGCAGCCTCAGTCGTGTATT-3'; GAPDH forward, 5'-TGGCACCGTCAAGGCTGAGA-3', and reverse, 5'-TGGTGAAGACGCCAGTGGACTC-3'.

ELISA assay

IL-1β and IL-6 levels in serum samples were determined by corresponding ELISA kits obtained from Solarbio Life Sciences (Beijing, China). The detailed infor-

mation of all ELISA kits was as follows: IL-1β (SEKH-0002), IL-6 (SEKH-0013).

Statistical analysis

GraphPad Prism 6.0 and R version 3.5.3 were applied to analyze the data. All the data were presented as mean ± standard deviation (S.D.). Differences between the two groups were compared and analyzed using Student's *t*-test followed by Tukey's posthoc test. A *P*-value of less than 0.05 was considered to be statistically significant.

RESULTS

DEGs of COPD

122 up-regulated genes were identified in our study and presented as a Volcano map (Fig. 1A). Figure 1B displayed the heatmaps of the 122 DEGs in our dataset.

GO functional analysis and pathway-enrichment KEGG analysis of DEGs

Three functional groups of GO analysis consisted of biological processes (BP), cell composition (CC), and molecular function (MF). As shown in Fig. 2A, with the BP results, the up-regulated DEGs were enriched in the categories of regulation of inflammatory response, positive regulation of the small molecular, metabolic process, negative regulation of lymphocyte-mediated immunity, regulation of purine nucleotide biosynthetic process, and regulation of nucleotide biosynthetic process. As for the CC functional groups, the up-regulated DEGs were concentrated at the cell-cell junction, phagocytic vesicle, apical junction complex, myelin sheath, nuclear chromosome, telomeric region, and bicellular tight junction. Finally, with the MF groups, the up-regulated DEGs were enriched at cell adhesion molecule binding, actin filament binding, SH3 domain binding, and calcium-dependent protein binding.

Figure 4. The AHNAK expression in COPD.
(**A**) Expression of AHNAK in COPD serum samples. (**B**) ROC analysis of AHNAK in COPD. COPD, chronic obstructive pulmonary disease

In addition, as shown in Fig. 2B, the KEGG pathways analysis of the DEGs in COPD unveiled that they were mostly concentrated in the categories of amyotrophic lateral sclerosis, neurotrophin signaling pathway, tight junction, and RNA transport.

PPI results of DEGs

The PPI network for integrated DEGs was shown in Fig. 3A and Fig. 3B. The 10 hub genes that extensively interacted with other genes in COPD were AHNAK, S100A6, S100A4, ANXA8, GSN, DDB1, PSMD4, USP5, COPE, and UBQLN2.

Up-regulation in COPD patients

Furthermore, patients were divided into stable COPD and acute exacerbation COPD groups, and the clinical information of the patients and healthy controls were shown in Table 1. Next, after collecting COPD and non-COPD serum samples, we found that AHNAK expression was significantly increased in COPD patients (Fig. 4A, $P<0.001$); moreover, compared with stable-COPD patients, AHNAK was up-regulated in serum samples of acute exacerbation COPD patients ($P<0.05$). the area under the curve (AUC) of AHNAK concerning discriminating COPD from non-COPD smokers was 0.8789 (Fig. 4B, cut-off value >1.454, sensitivity 75.95, specificity 92.65).

Figure 5. Correlation between AHNANK expression and inflammatory cytokines.
Correlation with AHNAK expression and IL-1β (**A**) and IL-6 (**B**) levels in COPD.

Association between AHNAK and inflammation in COPD

To determine the correlation between AHNAK and inflammation in COPD, we measured inflammatory cytokines levels and performed Spearman's correlation analysis accordingly. As shown in Figs 5A and B, AHNAK was strongly correlated with IL-1β and IL-6 levels in COPD.

DISCUSSION

High-throughput sequencing made rapid progress in the past decade, and advances in bioinformatics deepened our understanding of disease mechanisms and facilitated drug target development, including COPD (Scherer et al., 2017; Dorn et al., 2014; Regan et al., 2019; Matsson et al., 2016). Several studies have identified hundreds of DEGs based on mRNA gene expression profiles in COPD (Huang et al., 2019; Zhu et al., 2020; Morrow et al., 2017). A hub gene was a gene playing a critical role in biological processes, and the regulation of other genes in a related pathway was often influenced by this gene. Therefore, the hub gene was often an important target and a hot spot for research. In this study, we screened 122 up-regulated DEGs and analyzed the expression profiles using WGCNA. Among them, we identified 10 hub genes, of which AHNAK was the shared central gene and DEG. These results suggested that AHNAK may play an important role in the progression of COPD.

AHNAK was a large structural scaffold protein with 700 kDa, which was implicated in blood-brain barrier formation, cardiac calcium channel regulation, and tumor metastasis (Alvarez et al., 2010; Gentil et al., 2005; Haase et al., 2005; Sohn et al., 2018). What we all know is that AHNAK has been proved to be implicated in various diseases, functioning as a potential biomarker for disease detection or predicting the prognosis. For instance, Zhao and others (Zhao et al., 2017) reported that AHNAK was down-regulated in glioma cell lines, inhibiting glioma tumor growth and associated with poor prognosis. Lee and others (Lee et al., 2018) revealed that AHNAK was a crucial candidate for bladder urothelial carcinoma diagnosis based on in-depth proteomics. Dumitru and others (Dumitru et al., 2013) discovered that AHNAK was dysregulated in laryngeal carcinoma and significantly correlated with poor clinical outcomes in laryngeal carcinoma patients. Sudo and others (Sudo et al., 2014) proposed that AHNAK was highly expressed in several mesothelioma cell lines, playing a key role in regulating mesothelioma cell migration and invasion. Zhang and others (Zhang et al., 2019) suggested that high AHNAK expression was strongly correlated with short disease-free survival and poor prognosis, exerting as an oncogene in pancreatic ductal adenocarcinoma. More importantly, Nedeljkovic and others (Nedeljkovic et al., 2018) implied that AHNAK abnormal expression could be novel candidate variants in COPD. The data we obtained from clinical samples also confirmed the specific high expression of AHNAK in COPD patients, which was consistent with the comprehensive bioinformatic analysis. Therefore, this study provided new insights into the complex pathogenesis of COPD.

In order to explore the mechanisms involved in disease progression, we performed a PPI dynamic analysis. Based on KEGG and GO's enrichment results, we identified 38 pathways enriched in the dynamic PPI network. The top 12 processes were inflammation response, small molecular, metabolic process, cell-cell junction, phagocytic vesicle, apical junction complex, cell adhesion

molecular binding, actin filament binding, SH3 domain binding, amyotrophic lateral sclerosis, neurotrophin, tight junction, and RNA transport. Thus, we verified the relationship between AHNAK and inflammatory factors in COPD, and the outcome demonstrated that AHNAK was closely associated with IL-1β and IL-6 levels in COPD patients. These results support that AHNAK represents a sensitive biomarker for the diagnosis of COPD.

Nevertheless, this study maintains some limitations. First, the specific mechanism of action of AHNAK in COPD requires further in vivo studies. In addition, the sample size in this study was relatively small, and the DEGs between the different stages of COPD could not be determined due to the sample size. In future studies, we will use a larger sample size consisting of samples from patients with different stages of COPD to avoid accidental errors. Finally, long-term follow-up investigations of COPD patients are recommended to determine the impact of abnormal AHNAK expression on COPD prognosis.

CONCLUSION

AHNAK was significantly elevated in COPD, functioning as a potential biomarker for COPD detection and treatment.

LINC00707 promotes multidrug resistance of ovarian cancer cells by targeting the miR-382-5p/*LRRK2* axis

Min-Wen Zhao[1][#], Chang-Jie Lin[2][#] and Jian-Ping Qiu[1]✉

[1]Department of Obstetrics and Gynecology, The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University. Suzhou, Jiangsu 215000, China; [2]Department of General Surgery, The Second Affiliated Hospital of Soochow University, Suzhou, Jiangsu 215000, China

Multidrug resistance severely limits the efficacy of ovarian cancer (OC) treatment. Recent studies have revealed the carcinogenic role of *LINC00707* RNA. However, the role of *LINC00707* in the development of multidrug resistance in OC has not been clarified. Therefore, the aim of this study was to investigate the relationship between *LINC00707* and multidrug resistance in OC, which can facilitate the development of new therapeutic agents for effectively addressing this issue. The RNA expression of *LINC00707*, *miR-382-5p* and leucine-rich repeat kinase 2 (*LRRK2*) in SKOV3 (a human OC cell line) cells was detected by qRT-PCR. The effects of *LINC00707* on the proliferation and viability of SKOV3 cells were determined by MTT assay and colony formation assay. The interaction of *LINC00707*, *miR-382-5p*, and *LRRK2* was bioinformatically predicted and verified with dual-luciferase reporter assay. In addition, the effect of *LINC00707* on drug resistance in SKOV3 cells through targeting the *miR-382-5p/LRRK2* axis was explored. The expression of *LINC00707* and *LRRK2* was significantly increased in SKOV3 cells, while *miR-382-5p* expression was significantly decreased. The results of bioinformatic prediction and colony formation assay demonstrated that *LINC00707* could regulate *LRRK2* expression in SKOV3 cells by targeting *miR-382-5p*. Additionally, knockdown of *LINC00707* markedly increased expression of miR-382-5p and decreased that of *LRRK2*, increased cell proliferation and viability, as well as sensitivity to chemotherapeutic agents in SKOV3 cells. Notably, these manifestations were more obvious with simultaneous knockdown of *LINC00707* and *miR-382-5p* compared with knockdown of *LINC00707* alone. *LINC00707* is overexpressed in SKOV3 cells and promotes SKOV3 cell proliferation and resistance to chemotherapeutic drugs via targeting the *miR-382-5p/LRRK2* axis.

INTRODUCTION

Ovarian cancer (OC) is one of the deadliest malignancies in women. Global cancer statistics in 2020 reported more than 310,000 new cases and nearly 210,000 deaths of OC, with increasing morbidity and mortality rates each year (Kuroki & Guntupalli, 2020; Sung *et al.*, 2021). Although more than a third of OC patients can be diagnosed at an early stage (Sadeghi *et al.*, 2011), distant metastases usually occur in about 60% of these patients, which results in a five-year survival rate of only 30% (Siegel *et al.*, 2020). In addition, surgical resection of the tumor and cisplatin-based chemotherapy are the two major standard treatments for newly diagnosed OC patients in clinical settings. Unfortunately, clinical data have shown that with prolonged treatment, OC loses sensitivity to cisplatin and can even completely acquire resistance to it, resulting in treatment failure (Luo *et al.*, 2020). Consequently, resistance, particularly multidrug resistance, continues to be the primary challenge when employing chemotherapeutic drugs for OC. Therefore, it is important to explore the mechanism of drug resistance in OC cells.

To date, multiple studies have shown that the acquisition of drug resistance in OC is affected by multiple factors, of which genetic and epigenetic factors are the most significant (Bast *et al.*, 2009). Particularly, long non-coding RNAs (lncRNAs), a class of RNA transcripts with more than 200 nucleotides but no capacity for protein coding, play a key role in the development of multidrug resistance. By interacting with chromatin, RNA, and proteins, lncRNAs affect numerous processes in a cancer cell such as cell proliferation, anti-apoptosis, and migration (Raveh *et al.*, 2015). Moreover, lncRNAs have also been reported to be associated with acquired resistance in cancer cells. When paclitaxel-resistant cells were subjected to lncRNA sequencing, Xu and others speculated that five upregulated lncRNAs and 21 downregulated lncRNAs were linked to multidrug resistance (Xu *et al.*, 2018). Wang *et al.* suggested that lncRNA *EPIC1* could promote AKT-mTORC1 signaling and resistance to rapamycin in breast cancer and OC by binding to the transcription factor Myc (Wang *et al.*, 2020). Shi *et al.* discovered a significant increase in the expression of *LINC01118* in paclitaxel-resistant OC tissues, which promoted cell migration and invasion while inhibiting apoptosis (Shi & Wang, 2018). All these data indicate the significance of lncRNAs in the multidrug resistance of OC. Notably, *LINC00707* has been shown to behave as a cancer-promoting factor in both colorectal and cervical malignancies (Guo *et al.*, 2021). A recent study on cisplatin-resistant non-small cell lung cancer (NSCLC) cells showed that knocking down *LINC00707* expression significantly restored the sensitivity of the resistant cells to cisplatin (Zhang *et al.*, 2019). In summary, *LINC00707* not only promotes cancer development, but

also increases the susceptibility of cancer cells to medication resistance.

MicroRNAs (miRNAs), small non-coding RNAs of about 20 nucleotides in size, regulate the expression level of genes by binding to the 3' UTR region of target genes, thereby affecting the regular activities of cells (Sun *et al.*, 2019). MiRNAs may play a direct or indirect role in the progression of cancer and the emergence of drug resistance to chemotherapeutics. A study showed that downregulated *miR-130a* was associated with multidrug resistance in various cancers, and *miR-130a* targeted *MET* and enhanced TRAIL sensitivity in NSCLC cells (Acunzo *et al.*, 2012). According to the results of previous studies, *miR-382-5p* may be a tumor suppressor gene, and reduction of its expression can promote cancer progression (Xie & Pan, 2021). Furthermore, increased *miR-382-5p* expression levels led to significant reduction in iron levels in OC cells (Sun *et al.*, 2021). However, no studies have yet been conducted on the role of *miR-382-5p* in acquisition of multidrug resistance in OC cells. Interestingly, an interaction between *LINC00707* and *miR-382-5p* has been revealed, which is shown to affect cancer progression (Guo *et al.*, 2021), but the role of this relationship in OC remains unclear. We proposed the multidrug resistance mechanism of OC as follows: *LINC00707* acted as a molecular sponge for *miR-382-5p* and increased OC progression and resistance to chemotherapeutic agents by targeting *miR-382-5p*. This hypothesis was further supported by *in vitro* cell experiments.

MATERIALS AND METHODS

Cell culture and treatment

Human normal ovarian surface epithelial cell line (IOSE80) and human OC cell line (SKOV3) were obtained from the American Type Culture Collection (ATCC, VA, USA). The cells were cultured in DMEM/F12 medium supplemented with 100 U/mL penicillin, 0.1 mg/mL streptomycin sulfate, and 10% fetal bovine serum (FBS), then the medium was incubated at 37°C and 5% CO_2

According to the manufacturer's instructions, the following plasmids or fragments were transfected into the cells using Lipofectamine™ 2000 transfection reagent: control shRNA, LINC00707 shRNA, control pcDNA3.1 vector, pcDNA3.1-LINC00707, control mimics, miR-382-5p mimics, control inhibitor, and miR-382-5p inhibitor. Next, LINC00707 shRNA and miR-382-5p inhibitor were transfected into SKOV3 cells together, upon which the following groups were obtained: sh-NC, sh-LINC00707, control vector, LINC00707, miR-NC, miR-382-5p, Anti-NC, Anti-miR-382-5p, and sh-LINC00707 + Anti-miR-382-5p. The medium was replaced with fresh medium six hours after transfection for two days of culture. Finally, the transfection efficiency was verified using qRT-PCR.

Quantitative real-time PCR (qRT-PCR)

The TRIzol™ Plus RNA Purification Kit was used to extract total RNA from SKOV3 cells following the manufacturer's instructions. The concentration and purity of RNA were subsequently measured by NanoDrop One ultramicrospectrophotometer. With the help of Prime-Script RT Master Mix, cDNA was obtained by reverse transcription. qRT-PCR was performed to detect the expression levels of *LINC00707*, *miR-382-5p*, and leucine-

	R: 5'- ACCACCCTGTTGCTGTAGCCAA

rich repeat kinase 2 (*LRRK2*) according to the instructions of the SYBR Premix Ex Taq II kit. *GAPDH* or *U6* served as an internal control, and six replicates were set up for the experiment. The experimental data obtained by qRT-PCR were used to calculate the relative expression of the target gene with the help of the $2^{-\Delta\Delta Ct}$ method. The primer sequences used are shown in Table 1.

MTT assay

The transfected SKOV3 cells were seeded in a 96-well plate at a density of 5×10^3 cells/well, and to each well, 20 μL MTT solution (5 mg/mL) was added. After 4 h of incubation at 37°C, the supernatant was aspirated and 200 μL DMSO was then added into each well. Later, the absorbance values at a wavelength of 490 nm were measured by a microplate reader, and the cell viability was evaluated. In order to observe the drug resistance of cells, the transfected SKOV3 cells were incubated with different concentrations of paclitaxel (PTX, 2, 4, 8, 16, 32 μmol/L), doxorubicin (Dox, 0.5, 1, 2, 4, 8 μmol/L), methotrexate (MTX, 2, 4, 8, 16, 32 μmol/L), and cisplatin (DDP, 0.25, 0.5, 1, 2, 4 μmol/L) for 48 h. Subsequent to the addition of 20 μL MTT solution to each well, the supernatant was aspirated after 4 h of incubation at 37°C. Again, 200 μL DMSO was added to each well, and the absorbance at 590 nm was detected by a microplate reader. Half-maximal inhibitory concentration (IC50) was calculated with the use of GraphPad Prism 7 software.

Colony formation assay

The transfected SKOV3 cells were inoculated into 6-well culture plates at 1×10^6 cells/well and cultured in DMEM/F12 medium containing 10% FBS for two weeks, with the medium replaced every three days. Afterwards, SKOV3 cells were fixed with 4% paraformaldehyde and stained with 0.1% crystal violet.

Dual-luciferase reporter assay

In order to verify the interaction among *LINC00707*, *miR-382-5p*, and *LRRK2*, wild type *LINC00707* and *LRRK2*, or *LINC00707* and *LRRK2* fragments with

Figure 1. *LINC00707* is upregulated in ovarian cancer (OC) cells. The expression levels of *LINC00707* RNA in human normal ovarian surface epithelial cells (IOSE80) and human OC cells (SKOV3) detected by qRT-PCR. **$p < 0.01$, *vs* IOSE80 group.

mutated nucleic acid sequences were constructed and then inserted into the luciferase reporter gene of pMIR-REPORT (pGL3) plasmid (H306, Obio Technology, Shanghai, China) based on the predicted binding sites of *LINC00707* and *LRRK2* with *miR-382-5p*. The cells were accordingly divided into four groups: wild type pGL3-LINC00707 (*LINC00707*-WT) and pGL3-LRRK2 (*LRRK2*-WT) or mutant pGL3-LINC00707 (*LINC00707*-MUT) and pGL3-LRRK2 (*LRRK2*-MUT) vectors. Next, miR-382-5p mimics and pGL3 plasmids were transfected together into SKOV3 cells using Lipofectamine™ 2000. Subsequently, luciferase activity was assessed using the Dual-Luciferase Reporter System Kit (E1910, Promega, USA).

Western blot

The cells were lysed in lysis buffer (RIPA) supplemented with a protease inhibitor (PMSF). Equal amounts of protein (20 μg) were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene fluoride (PVDF) membranes. After that, the membranes were blocked with 5% milk in Tris-buffered saline containing 0.1% Tween-20 for 1 h at ambient temperature. The membranes were subsequently incubated overnight at 4°C with primary LRRK2 antibody (1:1000, ab133474, Abcam, Cambridge, UK), followed by 1 h of incubation at 37°C with peroxidase conjugated goat anti-rabbit immunoglobulin G (IgG) antibody (1:3000; ab97051). Next, immunoreac-

tive bands were visualized using enhanced chemiluminescence reagents (Thermo Fisher Scientific, Waltham, USA) and imaged using a Luminescent Image Analyzer ChemiDoc XRS Plus (Bio-Rad). Optical densitometric quantification of band intensities from four independent experiments was performed using Image-Pro Plus 6.0 software, and relative expression levels of target proteins were normalized to band intensities of GAPDH.

Data analysis

Measurement data were presented as mean ± standard deviation (S.D.). The *t*-test was adopted when comparing only two groups, and one-way analysis of variance with Tukey' test was employed when comparing more than two groups. Pearson correlation was applied to analyze the expression correlation. All statistical analyses were performed using SPSS 26.0 software (IBM, Armonk, NY, USA), with two-tailed $p < 0.05$ as the level of statistical significance. All experiments were performed in triplicate, with at least three independent experiments.

RESULTS

LINC00707 is upregulated in SKOV3 cells

QRT-PCR was used to determine *LINC00707* expression in OC cells in this study. We found that *LINC00707* was expressed at significantly higher levels in SKOV3 than in IOSE80 cells (Fig. 1), which suggests that *LINC00707* may be involved in OC development.

Knockdown of LINC00707 suppresses the proliferation of SKOV3 cells

In order to investigate the effect of *LINC00707* on OC, *LINC00707* was knocked down or overexpressed using plasmids, and the transfection efficiency was detected by qRT-PCR. The qRT-PCR results demonstrated that the expression level of *LINC00707* was significantly decreased in cells in the sh-LINC00707 group compared with that in the sh-NC group and was notably increased

in the LINC00707-oe group compared with the control vector group (Fig. 2A). Later, we examined cell proliferation and viability through MTT and colony formation assays. Combining the results of both assays, we observed that the proliferation and viability of cells in the sh-LINC00707 group were much lower than those in the sh-NC group, and the proliferation and viability of cells in the LINC00707-oe group were much higher than those in the control vector group (Fig. 2B, 2C). Thus, knockdown of *LINC00707* can significantly inhibit SKOV3 cell proliferation.

Knockdown of LINC00707 decreases multidrug resistance in SKOV3 cells

Subsequently, in order to observe the effect of *LINC00707* on chemoresistance of SKOV3 cells, the resistance of LINC00707-knock-down and LINC00707 overexpressing SKOV3 cells to PTX, Dox, MTX, and DDP was studied using MTT assay. The MTT results showed that the IC50 of SKOV3 cells treated with PTX, Dox, MTX, and DDP was markedly decreased in the sh-LINC00707 group compared with the sh-NC group, while being considerably increased in the LINC00707-oe group relative to the control vector group (Fig. 3A–D). In brief, knockdown of *LINC00707* can reduce the resistance of SKOV3 cells to chemotherapeutic agents.

LINC00707 targets miR-382-5p

LINC00707 was predicted to target *miR-382-5p* using lncBASE software (Fig. 4A). According to the findings of dual-luciferase reporter assay, co-transfection of WT-LINC00707 3'-UTR with miR-382-5p mimics in the miR-382-5p group greatly reduced the luciferase activity

compared with the miR-NC group (Fig. 4B). qRT-PCR results indicated that SKOV3 cells in which *LINC00707* was knocked down showed significant increase in the *miR-382-5p* expression compared with the cells in the sh-NC group, and those with *LINC00707* overexpression showed significant downregulation of *miR-382-5p* expression compared with those in the control vector group (Fig. 4C). In addition, the expression level of *miR-382-5p* was much lower in SKOV3 cells than in IOSE80 cells (Fig. 4D). Overall, *LINC00707* targets *miR-382-5p* and sh-LINC00707 can significantly upregulate the *miR-382-5p* expression in OC.

LRRK2 is a target gene of miR-382-5p

Firstly, we generated SKOV3 cells with *miR-382-5p* knock down or overexpression to determine the relationship between miR-382-5p and *LRRK2*. The expression level of *miR-382-5p* in SKOV3 cells was significantly elevated in the miR-382-5p group compared with the miR-NC group and the expression level of *miR-382-5p* was markedly lowered in the Anti-miR-382-5p group relative to the Anti-NC group (Fig. 5A). Subsequently, with the help of starbase2.0 (https://starbase.sysu.edu.cn/starbase2/index.php), *miR-382-5p* was predicted to target *LRRK2* mRNA (Fig. 5B). The dual-luciferase reporter assay results showed that the *miR-382-5p* group presented a significant decrease in luciferase activity after co-transfection of the WT-LRRK2 3'-UTR with miR-382-5p mimics (Fig. 5C). qRT-PCR results indicated that *miR-382-5p* overexpression could considerably reduce *LRRK2* expression compared with the miR-NC group in SKOV3 cells, while *miR-382-5p* knockdown significantly upregulated *LRRK2* expression compared with the Anti-

Figure 6. *LINC00707* promotes proliferation and resistance of ovarian cancer (OC) cells to chemotherapeutic agents by targeting the *miR-382-5p/LRRK2* axis.
(**A**) QRT-PCR results of the expression level of *LRRK2* in SKOV3 cells after simultaneous transfection of *LINC00707* shRNA and *miR-382-5p* inhibitor. (**B**) Western blot results of LRRK2 protein levels in SKOV3 cells after transfection. (**C**) MTT results of the viability of SKOV3 cells after transfection. (**D–G**) MTT results of the tolerance of SKOV3 cells to PTX (**D**), Dox (**E**), MTX (**F**), and DDP (**G**) after simultaneous transfection of *LINC00707* shRNA and *miR-382-5p* inhibitor. **$p<0.01$, *vs*. NC; #$p<0.05$, *vs*. sh-LINC00707; i$p<0.05$, *vs*. Anti-miR-382-5p. sh, short hairpin; NC, negative control.

NC group (Fig. 5D). Additionally, *LRRK2* was expressed at quite higher levels in SKOV3 cells than in IOSE80 cells (Fig. 5E). Collectively, we found that *miR-382-5p* expression and *LRRK2* expression are upregulated in OC, *miR-382-5p* directly targets *LRRK2*, and knockdown of *miR-382-5p* significantly promotes *LRRK2* expression.

LINC00707 promotes proliferation and multidrug resistance of SKOV3 cells by targeting the *miR-382-5p/LRRK2* axis

In order to further investigate the effect of *LINC00707* on OC cell viability and drug resistance, the expression level of *LRRK2* was detected by qRT-PCR and Western blot by targeting the *miR-382-5p/LRRK2* axis, after simultaneous knockdown of *LINC00707* and *miR-382-5p* in SKOV3 cells. The results showed that the sh-LINC00707 + Anti-miR-382-5p group displayed a much higher expression level of *LRRK2* than the sh-LINC00707 group; and the expression level of *LRRK2* was significantly decreased in the sh-LINC00707 + miR-382-5p group compared with the Anti-miR-382-5p group (Fig. 6A, 6B). The MTT assay outcomes indicated that cell viability was considerably increased in the sh-

LINC00707 + Anti-miR-382-5p group compared with the sh-LINC00707 group, but significantly reduced in the sh-LINC00707 + Anti-miR-382-5p group compared with the Anti-miR-382-5p group (Fig. 5C). Next, the resistance of SKOV3 cells to chemotherapeutic agents (PTX, Dox, MTX, and DDP) was detected using MTT assay. We discovered that the sh-LINC00707 + Anti-miR-382-5p group had a much higher IC50 than the sh-LINC00707 group, and the sh-LINC00707 + Anti-miR-382-5p group presented a lower IC50 than the Anti-miR-382-5p group (Fig. 6D–G). These results suggest that *LINC00707* promotes proliferation and resistance of SKOV3 cells to chemotherapeutic agents by targeting the *miR-382-5p/LRRK2* axis.

DISCUSSION

OC, one of the gynecological malignancies with the highest mortality rates, poses a severe threat to female health worldwide. Research suggests that chemoresistance of OC cells significantly contributes to the high mortality (Barriga-Rivera *et al.*, 2016). Currently, the combination of Dox and PTX is typically effective at first, but the

condition relapses in the majority of patients, and is then usually incurable, with just an 18-month-survival rate (Yang *et al.*, 2017). Therefore, a thorough understanding of the molecular mechanism of multidrug resistance in OC is crucial for improving the prognosis. Our study's findings showed that *LINC00707*, which was expressed at a considerably higher level in OC, could boost cellular resistance to chemotherapeutic drugs by targeting the *miR-382-5p/LRRK2* axis.

LncRNAs, described in recent studies, hold promise as potential biomarkers for cancer diagnosis, prognosis, and treatment. Notably, many lncRNAs are dysregulated in OC, which may play crucial roles in the incidence and progression of tumors (Wang *et al.*, 2018). Among them, lncRNA *HOXD-AS1* is an OC-associated lncRNA that is overexpressed in both OC tissues and cells and can indicate poor prognosis in patients (Zhang *et al.*, 2017). Recently, Zahra and coworkers performed high-throughput sequencing and found that *LINC00707* was highly upregulated in OC tissues and has potential as a diagnostic marker (Zahra *et al.*, 2021). Although earlier research indicated that *LINC00707* is a proto-oncogene (Guo *et al.*, 2021), it is not clear how *LINC00707* and OC are related. Therefore, the aim of our study was to investigate the effect of *LINC00707* in OC and its molecular mechanism. In this study, *LINC00707* was overexpressed in SKOV3 cells, and *LINC00707* overexpression markedly increased the proliferation and viability of SKOV3 cells, while *LINC00707* knockdown inhibited the proliferation and viability of cells. Furthermore, studies on several malignancies have shown that lncRNAs have a role in controlling chemosensitivity (Xu *et al.*, 2018). Our findings clearly showed that *LINC00707* overexpression increased resistance to PTX, Dox, MTX, and DDP in SKOV3 cells. These findings are in line with the results of *LINC00707* overexpression in cancer cells in the bladder (Gao & Ji, 2021) and breast (Yuan *et al.*, 2020). Thus, it is clear that *LINC00707* overexpression induces OC resistance to chemotherapeutic agents.

Recent evidence has suggested that the interaction between lncRNAs and microRNAs may have an impact on a number of pathological mechanisms, including the development of cancer and the acquisition of drug resistance. By functioning as a competitive endogenous RNA sponge for miR-17 and altering *STAT3* expression, lncRNA *H19* was discovered by Huang *et al.* to accelerate the development of NSCLC (Huang *et al.*, 2018). Li *et al.* discovered that lncRNA *SNHG1* promoted the resistance of hepatocellular carcinoma cells to sorafenib by increasing *miR-21* expression to activate the Akt pathway (Li *et al.*, 2019). Through bioinformatic predictions and several experiments in our study, we demonstrated that there was a binding site in *LINC00707* for miR-382-5p, and *LINC00707* acted as the molecular sponge of *miR-382-5p*. Interestingly, Guo *et al.* also proved the interaction between *LINC00707* and miR-382-5p (Wang *et al.*, 2020). However, our study is the first to find that *miR-382-5p* expression is significantly downregulated in OC cells and inversely correlated with *LINC00707* expression. Although *miR-382-5p* has only been the subject of a few studies, they have shown that this microRNA suppresses the genes involved in tumor development. For instance, the expression level of *miR-382-5p* is significantly downregulated in colorectal cancer tissues (Xie & Pan, 2021). Likewise, few studies were conducted on the downstream target genes of *miR-382-5p*. In this regard, our study discovered that *miR-382-5p* targeted the *LRRK2*mRNA 3'-UTR region and regulated the expression level of *LRRK2*. Mutations in *LRRK2* were first

thought to be critical for inducing familial Parkinson's disease (Deniston *et al.*, 2020). Interestingly, the expression level of *LRRK2* was found to be significantly downregulated in NSCLC tissues (Ma *et al.*, 2019). However, the role of *LRRK2* in cancer has rarely been reported. In our study, the expression level of *LRRK2* was discovered to be significantly upregulated in SKOV3 cells and was clearly inversely regulated by *miR-382-5p*; *LRRK2* expression level in SKOV3 cells was significantly higher when *LINC00707* and *miR-382-5p* were simultaneously knocked down than that when either of them was knocked down alone. Moreover, SKOV3 cells in the sh-LINC00707 + Anti-miR-382-5p group were significantly more resistant to chemotherapeutic agents than those in the Anti-miR-382-5p group, but significantly less resistant than those in the sh-LINC00707 group. Therefore, *LINC00707* induced multidrug resistance of SKOV3 cells by targeting the *miR-382-5p/LRRK2* axis.

CONCLUSION

In summary, *LINC00707* is highly expressed in SKOV3 cells. *LINC00707* regulates the expression of *LRRK2* by targeting *miR-382-5p*, thereby enhancing the proliferation and viability of SKOV3 cells and inducing multidrug resistance in them. Therefore, knocking down *LINC00707* expression is key for addressing multidrug resistance in OC cells. However, the role of *LINC00707* is multifaceted, and more research is required to fully elucidate its function.

Genetic association between vitamin D receptor gene and Saudi patients confirmed with Familial Hypercholesterolemia

May Salem Al-Nbaheen✉

College of Health Sciences, Saudi Electronic University, Riyadh, Saudi Arabia

Introduction: Familial Hypercholesterolemia (FH) is a common condition caused by inherited genetic abnormalities. Inadequate clearance of the circulating low-density lipoproteins (LDL) is the primary cause of the excessive concentrations of LDL seen in FH patients. The relation with vitamin D deficiency and vitamin D receptor (VDR) gene is well documented in the Saudi Arabia. **Aim**: The aim of this study was to investigate the role of molecular analysis studied between FH patients and fours polymorphisms associated with VDR gene in Saudi Population. **Methods**: In this case-control study, 120 patients were selected, and 50 patients were confirmed as FH and 70 subjects were confirmed as healthy controls. Genotyping was performed with polymerase chain reaction followed by restriction fragment length polymorphism analysis using ApaI, BsmI, TaqI and FokI polymorphisms in the VDR gene. **Results**: The current study results confirmed no association between clinical characteristics studied between FH cases and controls (p>0.05). Hardy Weinberg Equilibrium analysis was present in ApaI and FokI polymorphisms (p<0.05). Only ApaI (C vs A: OR-15.1 (95% CI:5.78-39.41); p<0.001; AC+CC vs AA: OR-6.59 (95% CI:2.42-17.95); p=0.0006) and BsmI (G vs A: OR-2.88 (95% CI:1.54-5.38); p=0.0006 and AG+GG vs AA: OR-3.79 (95% CI:1.72-8.35); p=0.0007) polymorphisms showed both allele and genotype association between FH patients and controls. ANOVA analysis confirmed that TG levels were associated (p=0.02) with combination of heterozygous and homozygous genotypes present in all four polymorphisms studied in this population. **Conclusion**: ApaI and BsmI polymorphisms in the VDR gene showed association with FH patients in the Saudi Population.

Keywords: Familial Hypercholesterolemia, low-density lipoproteins, vitamin D

Abbreviations: BMI, Body Mass Index; DLCN, Dutch lipid clinical network; FH, Familial Hypercholesterolemia; HoFH, Homozygous Familial Hyper-cholesterolemia; HWE, Hardy-Weinberg equilibrium; LDL, low-density lipoproteins; PCR, Polymerase Chain Reaction; TC, total choles-terol; TG, Triglycerides; VDR, vitamin D receptor

INTRODUCTION

Familial Hypercholesterolemia (FH) is defined as a common disorder caused due to inherited genetic defects which is responsible for elevated LDLc levels due to inadequate clearance of the circulating LDL (Hori *et al.*, 2023). The definition of FH is described as elevated levels of LDLc which describes in time the development of atherosclerosis process in the arteries with subsequent high risk of cardiovascular diseases (Maştaleru *et al.*, 2022). Extremely high levels of LDL-c are the result of homozygous familial hypercholesterolemia (HoFH), a severe and rare form of FH. If ignored, HoFH can cause atherosclerotic cardiovascular disease in the early decades of life. An estimated 1 in 300 000–360 000 people in the United States have HoFH. Isolated groups and those experiencing the founder effect also have a higher incidence (Kayikcioglu & Tokgozoglu, 2023). Clinical scoring systems for the diagnosis of FH are widely used and approved, and numerous sets of criteria have been created, encompassing clinical, biochemical, and genetic factors. The most commonly used criteria are Simon Broome, MedPed and Dutch lipid clinical network (DLCN), the last one being used predominantly in the European countries (Huangfu *et al.*, 2023; Todorovova *et al.*, 2023). Some patients have unusual alleles in the minor genes *APOA5, ABCG5, ABCG8, LIPA,* and *STAP1*, whereas the vast majority have mutations in the classically related FH genes *LDLR, APOB*, or *PCSK9*. Interestingly, many FH cases either demonstrate a mixture and accumulation of numerous common variations or have no known genetic etiology. In addition, inflammation, vascular tone, cellular proliferation, and other unknown processes account for 80% of common DNA variations that predispose an individual to coronary artery disease (Ruiz-Pesini *et al.*, 2023). Previous meta-analysis estimates the worldwide frequency of heterozygous FH to be 1:313 (Beheshti *et al.*, 2020). However, the estimated heterozygous FH prevalence in the Arabian Gulf region is 1:112, which is around three times the predicted incidence worldwide (Alhabib *et al.*, 2021). Based on the incidence of 1:200–500, the estimated number of HeFH patients in Saudi Arabia ranges from 63 485 to 158 712. The lack of genetic screening programs and governmental data makes it difficult to determine the true FH incidence in Saudi Arabia and the Middle East (Alzahrani *et al.*, 2020). In Saudi Arabia, information on the genetics of FH is extremely scarce. The literature revealed that 21 variations were linked to *LDLR, APOB* and *PCSK9* genes and 80% of these variants were predicted to influence the *LDLR* gene, and c.1332dup (p.D445*) and c.2026delG (p. G676Afs*33) mutations were confirmed to be novel variants in the *LDLR* gene (Al-Allaf *et al.*, 2014).

In Saudi Arabia, the main causes of vitamin D deficiency are cultural practices, climate, genetic disposition, and skin color. Furthermore, high temperatures are predisposed to this deficiency (Al-Alyani *et al.*, 2018). It was well-established that Vitamin D will be converting into 25-hydroxyvitamin D in liver and kidney will be converting into 1,25-dihydroxyvitamin D3, which has a biological purpose (Bikle, 2014). Expression of *VDR* in mel-

anocytes allows it to control melanin production. Vitamin D is effective at treating a variety of skin conditions in humans (Tang *et al.*, 2018). The vitamin D receptor (VDR) is a nuclear steroid receptor that functions as a DNA-binding transcription factor. Vitamin D activity and metabolic concentrations are both affected by polymorphisms in the *VDR* gene (Guo *et al.*, 2023). The *VDR* gene is present on chromosome 12p13, which has variants in exons 2 and 3 for the enzymes *ApaI, BsmI,* and *TaqI*, and in exon 2 for the enzyme *FokI*. The restriction enzymes for *VDR* gene polymorphisms can be used to analyze the gene's many polymorphic sites in its untranslated region; which influences the functional stability of the transcript. Alleles with and without certain restriction sites are designated A-a, B-b, T-t, and F-f, respectively (Ghada Bin Saif & Imran Ali Khan, 2022). Numerous studies on the *VDR* gene in various human diseases have been conducted in Saudi Arabia, but no studies on the *VDR* gene and FH have been documented. The aim of this study was to investigate the role of *VDR* gene polymorphism studies in FH patients in the Saudi Arabia.

MATERIALS AND METHODS

FH subjects

A case-control study was conducted from King Khalid University Hospital in Riyadh city. The FH cases were confirmed based on Dutch group protocol (Alharbi *et al.*, 2015) which is an inclusion criteria. The FH subjects without Dutch group criteria is considered to be excluded. The Dutch group criteria is defined as the diagnosis of FH based on clinical, genetic and family history. However, in our study, clinicians have confirmed the FH cases based on the previous study (Alharbi *et al.*, 2015).

Healthy controls were selected based on normal levels of lipid profile. In this study, 70 FH cases and 50 healthy controls were recruited based on signing of patient informed consent form. This study was performed based on Declaration of Helsinki and ethical grant was approved within the hospital premises (E-19-1176). All patients (n=120) have signed the informed consent form to enroll in this study.

BMI details

Body Mass Index (BMI) was calculated based on Alshammary *et al* studies using body weight and height (Alshammary & Khan, 2021).

Sample collection

In this study, 5ml of blood was collected from 120 participants. Peripheral blood was separated into 3ml serum sample and 2ml in EDTA tube. Serum blood was used to measure the lipid profile parameters such as LDLc, HDLc, total cholesterol (TC) and triglycerides

(TG). Lipid profile was performed based on the previous study (Batais *et al.*, 2019).

Molecular analysis

EDTA sample was used for extraction of genomic DNA using DNA isolation kit. Extracted genomic DNA was used to quantify the DNA quality using NanoDrop spectrophotometer. VDR gene primers were adapted from the recently published article (Ghada Bin Saif & Imran Ali Khan, 2022) and all 4 single nucleotide polymorphisms were selected. The primer sequence of four polymorphisms were shown below:

(ApaI/TaqI) F: AGAGCATGGACAGGGAGCAAG and R: GCAACTCCTCATG GCTGAGGTCTCA; (BsmI) F: CAACCAAGACTACAACCGCGTCAGTGA and R: AACCAGCGGAAGAGGTCAAGGG; (FokI) F: AACCAGCGGAAGAGGTCAAGGG and R: ATGGAAACACCTTGCTTCTTCTCCCTC

Next, Polymerase Chain Reaction (PCR) was amplified with 4 polymorphisms present in the *VDR* gene. The initial denaturation took place for 10 mins at 95°C, denaturation at 95°C–30s, annealing took place at different temperatures for 4 polymorphisms, extension took place at 72°C–45s and final extension at 72°C–10 mins. The conditions of thermal cycler were followed for 35 cycles. After completion of amplification, PCR products were run on 2% of agarose gel stained with ethidium bromide and then restriction fragment length polymorphism analysis was performed using specific restriction enzymes as discussed in Table 1. Digestion was performed based on previous study (Alharbi *et al.*, 2017) for 24 hours. All types of PCR products were run on 2% agarose gel.

Statistical analysis

The visible data is regularly distributed and reported as mean ± S.D.; this study was conducted as a frequency-based analysis. Chi-square analysis was used to identify statistically significant differences between the case and control groups. Goodness-of-fit analysis was used to establish Hardy-Weinberg equilibrium (HWE). The frequencies of each genotype and allele were computed. Genotype and allelic frequencies comparisons were made between healthy controls and vitiligo patients, and other genetic models. This study was determined as the odds ratio and its 95% CI. In this study, a one-way Anova analysis (Khan *et al.*, 2019) was used in Table 4. However, *p*-values below 0.05 were regarded as statistically significant (*p*<0.05).

RESULTS

In this research, a total of 70 FH cases and 50 healthy control subjects were enrolled. The FH patients were clinically diagnosed based on Dutch group criteria and equally 50% of males and females were selected in both FH cases and controls. The mean age for both study groups were in between 51.98±10.61 in controls

Table 1. List of VDR gene polymorphism and restriction enzymes used in this study

Table 5. Anova Analysis Performed between Heterozygous and Variant genotypes in FH cases with BMI and lipid profile

	rs79785232 (AC=31)	rs1544410 (AG+GG=40)	rs731236 (TC=24)	rs2228570 (CT=17)	*p*-value
BMI (kg/m²)	27.32±2.29	27.08±2.61	26.54±2.69	27.76±1.56	0.12
TG (mmol/L)	2.32±1.63	2.01±1.18	1.91±1.16	2.31±1.96	0.02
TC (mmol/L)	5.34±0.84	5.41±0.91	5.62±0.90	5.42±1.16	0.48
HDLc (mmol/L)	0.67±0.18	0.68±0.20	0.69±0.19	0.65±0.25	0.46
LDLc (mmol/L)	3.74±0.90	3.83±0.82	3.72±0.88	3.90±0.81	0.93

and 52.74±10.51 in FH cases (*p*=0.80). Both cases, FH (26.84+2.49) and controls (26.81+2.53), were found to be overweight (*p*=0.06) and mean levels of weight was found to be an average of 73kg in both groups (*p*=0.35). None of the parameters of lipid profile (TG/TC=0.11; HDLC=0.22 and LDLC=0.80) were associated when compared between FH group and control. Table 2 defines the general characteristics used for FH group and control group.

The polymorphic site studied in VDR gene was in Hardy Weinberg Equilibrium in the whole sample. In this study, *p*-value was measured with one degree of freedom in which *p*<0.05 is considered as non-consistent. In this study, ApaI (*p*=0.70 and X²=0.13) and FokI (*p*=0.008 and X²=6.83) were associated whereas in other polymorphisms such as BsmI (*p*=0.01 and X²=6.55) and TaqI were non-significant. Table 3 consists of HWE analysis details.

Table 4 presents the group of polymorphisms present in the *VDR* gene in FH cases and controls. The ApaI polymorphism was strongly associated with allele (OR-15.1 (95% CI: 5.78-39.41); *p*<0.001), genotypes (AC *vs* AA; OR-7.15 (95% CI: 2.53-20.18); *p*=0.0005) and dominant model (OR-6.59 (95% CI: 2.42-17.95); *p*=0.0006). A similar association was found in BsmI polymorphism (G *vs* A: OR-2.88 (95% CI: 1.54-5.38); *p*=0.0006; AG *vs* AA: OR-3.83 (95% CI: 1.57-9.36); *p*=0.002 and AG+GG *vs* AA: OR-3.79 (95% CI: 1.72-8.35); *p*=0.0007). A negative impact was confirmed in both TaqI (C *vs* T: OR-3.79 (95% CI: 1.72-8.35); *p*=0.0007; TC *vs* TT: OR-0.44 (95% CI: 0.21-0.93); *p*=0.03 and TC+CC *vs* TT: OR-0.45 (95% CI: 0.21-0.94); *p*=0.03) and FokI (T *vs* C: OR-0.92 (95% CI: 0.42-2.01); *p*=0.84; CT *vs* CC: OR-0.91 (95% CI: 0.39-2.11); *p*=0.83 and CT+TT *vs* CC: OR-0.90 (95% CI: 0.39-2.07); *p*=0.81). Yates correction couldn't document the association in any of genotypes or allele in FH groups.

Anova analysis was confirmed in TG group (*p*=0.02) in the lipid profile and BMI parameters. TC (*p*=0.48), HDLC (*p*=0.46), LDLC (*p*=0.93) and BMI (*p*=0.12) were not associated when compared with heterozygous and homozygous mutants in ApaI, BsmI, TaqI and FokI polymorphisms in *VDR* gene. Table 5 shows the ANOVA analysis within FH heterozygous and homozygous mutants in the *VDR* gene.

DISCUSSION

The hypercholesterolemia that runs in families is called familial hypercholesterolemia, and it's inherited in an autosomal dominant pattern. Patients are typically heterozygous, meaning they carry only one copy of the genetic mutation. Homozygosity occurs exceedingly infrequently when a patient gets an erroneous gene from both parents; having homozygous FH results in extraordinarily high blood cholesterol levels. LDLR gene mutations are frequently responsible. Gain-of-function mu-

tations in *ApoB* and *PCSK9* genes, among others, have been reported (Pejic & Lee, 2006). Patients with FH have elevated LDL-c blood levels, which increases the risk of coronary artery disease and heart attack in the future (Alharbi *et al.*, 2015). The relationship between cholesterol and vitamin D is that human skin cells require cholesterol in order to produce vitamin D when exposed to sunlight. The initial phase requires cholesterol, but vitamin D is converted further in the liver and kidneys. Increased risk of cardiovascular disease (CVD) has been associated with low serum 25-hydroxyvitamin D [25(OH)D] levels, which plays an important part in the onset of osteoporosis, but it has also been connected to other health problems. Diabetes (type 1 and 2), multiple sclerosis, autoimmune, and viral diseases have all been linked to vitamin D deficiency. The relation between Vitamin D and cholesterol is connected with 7DHC, making the influence of vitamin D status on blood lipids particularly intriguing, despite conflicting findings from earlier studies (Gumus *et al.*, 2023; Hong, 2022). Documented studies in vitamin D deficiency have been discovered as a potential risk factor for CVD, either independently or in conjunction with other cardiovascular risk factors such as diabetes, hypertension, or obesity (Burgess & Gill, 2022; Norman & Powell, 2014; Pilz *et al.*, 2016). The main cause of vitamin D deficiency include a lack of sun exposure, a sedentary lifestyle, being overweight, having type 2 diabetes, lower HDLC level, being over age, having dark skin, living far from the equator, experiencing winter, being a smoker, being exposed to secondhand smoke, having impaired absorption due to renal and liver disease, and taking certain medications (Mozos & Marginean, 2015).

The aim of this study was to investigate the role of *VDR* gene polymorphism in diagnosed FH patients in the Saudi population. The present study results confirmed that ApaI and FokI polymorphisms were found to be in HWE analysis. Only ApaI and BsmI polymorphisms showed both allele and genotype association between FH patients and controls (*p*<0.05). In our study, ApaI (AC *vs* AA: *p*=0.0005, AC+CC *vs* AA: *p*=0.0006 and C *vs* A: *p*<0.001) and BsmI (AG *vs* AA: *p*=0.002, GG *vs* AA: *p*=0.02, AG+GG *vs* AA: *p*=0.0007 and G *vs* A: *p*=0.0006) polymorphism was associated when compared between FH cases and controls. ANOVA analysis confirmed that TG levels were associated with combination of heterozygous and homozygous genotypes present in all four polymorphisms studied in this population. The first step was measuring the cholesterol and vitamin D levels of healthy women. As a result of Gemfibrozil and Atorvastatin's ability to inhibit HMG-CoA reductase production, blood cholesterol levels have dropped dramatically in the second phase. Within this population, vitamin D levels also went down. Women who took medication for vitamin D, on the other hand, had a low vitamin D level (Han *et al.*, 2021). Other similar studies have been documented between vitamin D and

cholesterol related diseases. One of the Spanish studies measured vitamin D (25(OH)D) levels in hypercholesterolemia patients and found a signiifcant correlation (Cutillas-Marco et al., 2013). Rady and others confirmed that the FF genotype in the VDR gene is associated with a threefold risk of juvenile idiopathic arthritis (Rady et al., 2022). The study by Han and others shows compelling evidence that vitamin D insufficiency is linked to atherogenic dyslipidemia, and in particular, elevated small dense LDL-C levels in middle-aged adults without CVD (Han et al., 2021). Previous studies have linked dyslipidemia (Jorde & Grimnes, 2011) and lipid profile (Ponda et al., 2012) to vitamin D deficiency. Lipid levels in adulthood are also correlated with vitamin D levels, which are in turn linked to the gene's steady association with vitamin D levels in the blood (Jorde & Grimnes, 2011; Nissen et al., 2014; Thongthai et al., 2015).

Vital biological functions like cell proliferation, regulation, and differentiation, bone formation, and immune response modulation are all influenced by the endocrine vitamin D system. VDR is a member of the steroid hormone family of nuclear receptors and is responsible for the transcriptional control of a number of hormone-responsive genes by its binding to the active metabolite calcitriol. Due to the presence of VDRs in all major cardiovascular cell types, including vascular smooth muscle cells, endothelial cells, cardiomyocytes, platelets, and most immune cells, it is possible that *VDR* gene polymorphisms influence CVD. In addition, the VDR plays a crucial role in modulating the expression of several proteins that play a role in controlling the cardiovascular system. These include renin, endothelial nitric oxide synthase, and NADPH oxidase (Abouzid et al., 2021). The role of vitamin D and the VDR gene in Saudi Arabia is critical, as one meta-analysis study conducted in Saudi Arabia revealed that 60% of the healthy population in Saudi Arabia has a vitamin deficiency (Al-Alyani et al., 2018). The normal value of vitamin D deficiency in Saudi Arabia has been confirmed as 24.96 nmol/L which is below the limit (Albaik et al., 2016). The *VDR* gene polymorphism studies were carried out in the Saudi population with different human diseases and confirmed all forms of association (Ali et al., 2018; Alkhayal et al., 2016; Alzaim et al., 2022; Ansari et al., 2021; Mansy et al., 2019; Nemenqani et al., 2015; G. B. Saif & I. A. Khan, 2022; Taha et al., 2019; Zeidan et al., 2022). Additionally, there are limited documented studies of Saudi Arabian patients with confirmed FH. The lack of cholesterol data was one of the study limitations.

CONCLUSION

Both ApaI and BsmI polymorphisms was associated to FH via allele and genotype frequencies in the Saudi population. The Saudi Arabia VDR *gene* polymorphism link was built with FH patients.

Declarations

Conflict of interest: Not applicable for this study.

Formononetin enhances the chemosensitivity of triple negative breast cancer *via* BTB domain and CNC homolog 1-mediated mitophagy pathways

Shan Li[#✉], Linlian Zhu[#], Yufeng He and Ting Sun

Oncology Department, Dongtai People's Hospital, Dongtai City, Jiangsu Province 224200, China

This study aimed to investigate the effects of formononetin on triple negative breast cancer (TNBC). Clinical samples were collected from patients with TNBC. Overall survival rates were evaluated using the Kaplan-Meier method. Gene expression was determined using immunohistochemistry, immunofluorescence and western blot. Cellular functions were determined using CCK-8, colony formation and propidium iodide (PI) staining. Xenograft assay was performed to further verify the effects of formononetin (FM) on TNBC. We found that FM combined therapy suppressed the metastasis of TNBC and increased the overall survival rates of TNBC patients. Moreover, FM suppressed the proliferation and induced mitochondrial damage and apoptosis of TNBC cells. FM increased the expression of the BTB domain and CNC homolog 1 (BACH1) in TNBC tissues as well as cells. However, BACH1 knockdown antagonized the effects of FM and promoted the survival of TNBC cells. FM suppressed the tumor growth of TNBC. Taken together, FM suppressed the aggressiveness of TNBC *via* BACH1/p53 signaling. Therefore, FM may be an alternative strategy for TNBC.

#Shan Li and Linlian Zhu contributed equally in this study.
Abbreviations: BACH1, BTB domain and CNC homolog 1; FM, formononetin; PI, propidium iodide; TNBC, triple negative breast cancer

INTRODUCTION

Breast cancer is the most common tumor among women worldwide (Braden *et al.*, 2014; Burstein *et al.*, 2019). Recent decades witness an increase in the incidence and mortality of breast cancer in China (Ding *et al.*, 2020; Fan *et al.*, 2014). Triple negative breast cancer (TNBC) is characterized by a high proliferative index, histological grade, and metastatic states (Garrido-Castro *et al.*, 2019). Although great advances have been made in chemotherapy, radiotherapy, and surgery for TNBC (Bianchini *et al.*, 2016). However, the overall survival rates of TNBC are still unsatisfactory (Newman and Kaljee 2017). The high recurrence and metastatic properties of TNBC neutralize the clinical outcomes (Xu *et al.*, 2020). Therefore, a new strategy for TNBC is urgently needed.

Traditional Chinese medicine (TCM), with high efficiency and few side effects, is widely applied in the treatment of breast cancer (Chan *et al.*, 2021; Yang *et*

al., 2021). Formononetin (FM), extracted from *astragalus membranaceus* and s*patholobus suberectus* and with anti-inflammatory and anti-carcinogenic properties, is used as adjuvant therapy for breast cancer (Ma *et al.*, 2020; Xin *et al.*, 2019; Yu *et al.*, 2020). Previous studies reveal that formononetin exerts its anti-cancer function *via* modulating several signaling. For instance, formononetin suppresses the chemoresistance of TNBC *via* inactivating autophagy (Li *et al.*, 2021). Formononetin induces prostate cancer cell mitochondrial and apoptosis *via* regulating IGF-1/IGF-1R pathways (Huang *et al.*, 2013). Additionally, formononetin inhibits the immune suppressiveness of cervical cancer through inactivating MYC/STAT3/PD-L1 signaling (Wang *et al.*, 2022). This study explored the effects of NP (vinorelbine and cisplatin) combined with formononetin on TNBC.

MATERIALS AND METHODS

Patients

Clinical samples were collected from patients with refractory TNBC undergoing chemotherapy (vinorelbine and cisplatin, NP) with or without FM. at People's Hospital of Dongtai City from April 1, 2019 to March 31, 2021. The samples were immediately stored in liquid nitrogen at –80°C. This study was approved by the Ethical Committee of People's Hospital of Dongtai City. All patients signed confirmed consent. The inclusion criteria are: (1) the patients diagnosed with mTNBC; (2) women under the age of 70; (3) no serious complications occurred after the operation; (4) general condition score: ECoG 0-2; (5) patients in the combined group insisted on taking formononetin for at least 8 months. The exclusion criteria are: the mTNBC patients with an estimated ≤3 months of survival time; (2) patients accompanied by severe impairment or insufficiency of heart, liver and kidney functions; (3) patients with poor compliance and unable to adhere to treatment.

Immunohistochemistry

Sections were deparaffinized. Then the slides were blocked with 0.1% Triton X-100. After washing with 10 PBS, the section was incubated in 3% H_2O_2. The sections were incubated with primary antibody against BTB domain and CNC homolog 1 (BACH1) (ab128486, 1: 150, Abcam, USA) at 4°C overnight in shade. The next day, the section was incubated with a secondary antibody at 37°C for 1.5 h in the shade. The slices were counterstained using hematoxylin for 10 min. Finally, the sections were visualized using a microscope (Nikon, Japan).

Cell culture and transfection

Breast cancer cell line MCF7 was purchased from ATCC. Cells were incubated with DMEM containing 10% FBS at 37°C in 5% CO_2.

Cells were treated with 1.5 μM of vinorelbine, 2 μM of cisplatin, 80 μmol/L of FM or 10 mM of N-acetyl-cysteine (NAC).

Cells were transfected with shBACH1 (sh1, F: 5'-CCGGCCAGCAAGAATGCCCAAGAAACTC-3' and R: 5'-AATTCAAAAACCAGCAAGAATGCCCAA-GA-3'; sh2, F: 5'-CCGGGCCCATATGCTTGTGT-CATTACTCGA-3'and R: 5'-AATTCAAAAAGCCCAT-ATGCTTGTGTCATT-3', sh-p53 (5'-GACUCCAGUG-GUAAUCUAC-3') and the negative control (NC, F: 5'-CCGGCAACAAGATGAAGAGCACCAACTC-GAGTTGGTGCTCTTCATCTTGTTGTTTTTG-3' and R: 5'-AATTCAAAAACAACAAGATGAAGAGCAC-CAA   CTCGAGTTGGTGCTCTTCATCTTGTTG-3') by using Lipofectamine® 3000 for 48 h.

Western blot

Protein was collected from TNBC tissues and cells. Protein concentrated with BCA kit (Beyontine, Shanghai). The protein was isolated using 12% SDS-PAGE. The separated protein was moved onto the PVDF membrane, which was then blocked using 5% skimmed milk. Afterwards, the membranes were incubated with primary antibodies, such as anti-cyto C (ab133504, 1:2000, Abcam, USA), anti-caspase3 (ab32351, 1:5000, Abcam, USA), anti-Bcl-2 (ab32124, 1:1000, Abcam, USA), anti-Bax (ab32503, 1:1000, Abcam, USA), anti-BACH1 (ab300130, 1:1000, Abcam, USA), anti-p53 (ab32389, 1:10000, Abcam, USA), anti-PARK2 (ab73015, 1:1000, Abcam, USA), anti-PINK1 (ab300623, 1:1000, Abcam, USA) and anti-GAPDH (ab9485, 1: 2000, Abcam, USA), and then with secondary antibodies (ab6721, 1:5000, Abcam, USA). Finally, the bands were captured using an ECL kit and analyzed using ImageJ software.

MDA and SOD determination

The release of MDA and SOD was determined using specific commercial kits (Beyotime, Shanghai).

Immunofluorescence

Cells were fixed with 4% paraformaldehyde and permeabilized with 0.2% Triton X-100. Afterwards, cells were sealed with 5% bovine serum. Then cells were incubated with primary antibodies against Hsp60 (ab190828, 1:200, Abcam, USA), BACH1 (ab300130, 1:100, Abcam, USA), cyto-C (ab133504, 1:100, Abcam, USA) and then with secondary antibody. Then cells were counterstained with DAPI. The results were visualized using an immunofluorescence microscope (Zeiss, Germany).

CCK-8 assay

After 48-hour transfection, cells were collected. Then cells were plated into 24-well plates and cultured for 0, 12, 24, and 48 h. After being supplemented with CCK-8 regents and cultured for another 2 h, cells were detected by a microplate reader at the wavelength of 450 nm.

Colony formation assay

After transfection, cells were plated into a 24-well plate. After 2 weeks of culture, cells were fixed and stained with 0.1% crystal violet. Subsequently, the colonies were visualized using a microscope.

Propidium iodide (PI) staining

After transfection, cells were plated into a 24-well plate. Then cells were treated with PI solution (2 μg/mL). Finally, PI positive cells were captured by a fluorescence microscope (Leica, Germany).

Xenograft assay.

18 BALB/c nude mice (6–8 weeks, 18–22 g) were purchased from the Animal Center of Nanjing Medical University. Mice were randomly divided into three groups: control group, NP+FM group, and NP+FM+CDDO-ME (CDDO-ME) group. Each mouse was inoculated subcutaneously with 3×10^4 cells. The tumor was measured every three days. Tumor size was calculated as followed: $V=lw^2/2$. At 21 days, mice were euthanized, and tumor were collected. This study was authorized by the Animal Care Broad of People's Hospital of Dongtai City.

Statistical analysis

All data were analyzed using SPSS 20.0. The difference was analyzed using the Student t-test and ANOVA assay. The survival rates of patients were analyzed using Kaplan Meier and log-rank test. $P<0.05$ was deemed as a significant difference.

Figure 1. The survival rates of TNBC patients.
The overall survival rates of TNBC patients. **$P<0.01$.

RESULTS

The characteristics of TNBC patients

As shown in Table 1, the participants were all female. 68% of the TNBC patients had increased LDH levels. 45% showed visceral metastasis and 33% with recurrence. Additionally, combined therapy significantly improved the overall survival rate of TNBC patients (Fig. 1).

FM promotes oxidative stress and mitochondrial damage in TNBC

Previous studies reveal that FM suppresses the progression of multiple myeloma *via* inducing oxidative stress. Then we determined the release of oxidative stress in TNBC. FM enhanced the effects of NP on the release of MDA and GSH (Figs 2A and B). FM enhanced mitochondrial aggregation induced by NP (Fig.

2C). Moreover, FM+NP markedly increased cyto C protein expression compared with the NP group (Fig. 2D).

FM suppresses the aggressiveness of TNBC cells.

To further verify the effects of FM on TNBC, we determined the MCF7 cellular functions. Compared to the control group, FM treatment significantly suppressed the cell viability of MCF7 cells (Fig. 3A). This was consistent with the results from the colony formation assay. FM markedly inhibited the proliferation of MCF7 cells (Fig. 3B). Additionally, FM significantly enhanced the apoptosis of MCF7 cells (Fig. 3C). FM remarkably increased the protein expression of BAX and Caspase3 and decreased Bcl2 (Fig. 3D).

FM increases BACH1 expression

BACH1 is evidenced to play a vital role in mitochondrial function. We then determined the potentials of BACH1 in TNBC. The online database showed that BACH1 expression was decreased in invasive breast cancer tumors (Fig. 4A). To further verify this, we determined BACH1 expression in TNBC patients. As shown in Fig. 4B, BACH1 expression in patients administrated with NP+FM. Moreover, the protein expression of BACH1 was markedly increased in cells treated with NP+FM (Figs. 4C and D).

BACH1 transmits ROS signaling to mitochondria

BACH1 suppresses the aggressiveness of cancer cells *via* increasing the release of mitochondrial ROS (Hao *et al.*, 2021). We, therefore investigated the potentials of BACH1 mitochondrial ROS. Figure 5A showed the transcription efficiency of sh-BACH1. BACH1 knockdown antagonized the effects of FM and increased the cell ability of MCF7 cells (Fig. 5B). Moreover, BACH1 knockdown suppressed the protein expression of cyto-C, and cleaved caspase3 and -9 (Fig. 5C). Additionally, BACH1 knockdown suppressed mitochondrial aggrega-

tion (Fig. 5D). The apoptosis rates were significantly decreased in the sh-BACH1 group (Fig. 5E). To further confirm the roles of BACH1 in mitochondrial ROS. Cells were exposed to NAC (an ROS inhibitor). As shown in Fig. 5F, NAC antagonized the effects of FM and decreased the protein expression of BACH1.

FM regulates mitophagy *via* inducing BACH1-mediated activation of p53

We further investigated the potential underlying mechanisms. The online database STING predicted the po-

tential genes interacting with BACH1 (Fig. 6A). Then we found that BACH1 may regulate the expression of p53. To further verify this, cells were treated with FM and/ or sh-p53. As shown in Figs 6B and C, FM promoted p53 translocation from cytoplasm to mitochondria. p53 deficiency suppressed protein expression of cyto C and Caspase9 mitochondrial aggregation (Fig. 6D) as well as mitochondrial aggregation (Fig. 6E). Moreover, p53 knockdown decreased the protein expression of PINK1, PARK2 (Fig. 6F). p53 knockdown promoted the cell

viability and inhibited the apoptosis of MCF7 cells (Figs 6G and H).

FM suppresses the tumor growth of TNBC *via* regulating BACH1

To further verify the effects of FM on TNBC, in vivo assay was performed. As shown in Fig. 7A–C, FM suppressed the tumor size, volume and weight, which was abated by BACH1 deficiency.

DISCUSSION

In this study, FM suppressed improved the clinical outcome of TNBC patients. FM induced oxidative stress and apoptosis of MCF7 cells suppressed tumor growth. Additionally, FM suppressed mitophagy *via* inactivating BACH1/p53 signaling pathways.

Formononetin (FM) possesses anti-tumor properties in various cancers (Tay *et al.*, 2019). For instance, FM suppressed the proliferation and metastasis of ovarian cancer cells (Zhang *et al.*, 2018). FM suppresses the growth and migration of gastric cancer (Yao *et al.*, 2019). In breast cancer, FM induced breast cancer cell cycle rest (Chen *et al.*, 2011). FM inhibits Taxol-chemoresistance of breast cancer cells *via* suppressing autophagy signaling (Wu *et al.*, 2021). However, seldom study focuses on the mitochondrial functions in breast cancer cells. In this study, FM transmitted ROS to mitochondria to release cyto C and induced the cascades of caspase-3 and caspase-9, the activation of which induced the apoptosis of MCF7 cells. These findings suggest that FM may exert its anti-tumor functions *via* impeding the mitochondrial function in breast cancer cells.

BACH1, a member of the cap'n'collar (CNC) b-Zip family, plays a key role in regulating oxidative stress (Wiel *et al.*, 2019). BACH1 is a key regulator of mitochondrial metabolisms in cancer (Lignitto *et al.*, 2019). For instance, BACH1 knockdown induces mitochondrial respiration and increases the chemosensitivity of papillary thyroid cancer cells to metformin (Yu *et al.*, 2022). Moreover, BACH1 is overexpressed in TNBC patients and High levels of BACH1 predict poor overall survival and disease-free survival rates (Ou *et al.*, 2019). Overexpressed BACH1 inhibits glycolysis as well as suppresses lactate catabolism in the tricarboxylic acid (TCA) cycle, and promotes breast cancer bone metastasis (Lee *et al.*, 2019; Padilla *et al.*, 2022). These studies dictate that BACH1 may function as an oncogene in breast cancer. In this study, BACH1 was overexpressed in TNBC patients and MCF7 cells. Moreover, overexpressed BACH1 suppressed the release of oxidative stress and cancer cell apoptosis. Moreover, BACH1 alleviated FM-induced mitochondrial damage.

Mitochondrial metabolism plays a vital role in mitochondrial function, requiring intensive integration of mitochondrial morphology and dynamics (Chan, 2020). Mitophagy, erasing damaged mitochondria *via* autophagy, is a key process to maintaining mitochondrial quality (Srinivasan *et al.*, 2017). However, dysfunction of mitophagy may induce the pathogenesis of cancer, such as hepatocellular carcinoma, colon as well as breast cancer (Chen *et al.*, 2019; Deng *et al.*, 2021; Yin *et al.*, 2021). Therefore, to unraveling the underlying mechanisms may provide a novel target for cancer therapy. In this study, FM treatment induced the overexpression of p53. As a tumor suppressor, p53 suppresses tumorgenesis *via* inducing apoptosis, pyroptosis, ferroptosis as well as autophagy. In this study, FM stimulated p53/PINK1/PARK2 signaling pathways *via* inactivating BACH1, which promoted the release of cyto C and caspases as well as mitophagy-mediated mitochondrial dysfunction.

However, there are several limitations to this study. A large number of patients could make the results more convincing. Therefore, future studies will recruit more metastatic TNBC patients. Additionally, mitochondrial damage and mitophagy may induce other forms of death, such as ferroptosis and pyroptosis. Whether FM induced ferroptosis or pyroptosis. This needs further study.

In conclusion, FM improved the clinical outcomes of TNBC patients. Additionally, FM suppressed the aggressiveness of TNBC *via* regulating BACH1 signaling. Therefore, FM may be an alternative strategy for TNBC.

Poland, [2]Department of Pediatric Laboratory Diagnostic, Medical University of Lublin, Lublin, Poland

Introduction: Proper nutrition in patients with cancer is important for preventing treatment complications and achieving remission. Malnutrition in these patients leads to reduced production of essential structural proteins.

Purpose: The aim of the study was to assess the role of albumin and prealbumin in assessing the nutritional status of cancer patients and in predicting an increased risk of infectious complications during treatment.

Patients and Methods: The study included 40 pediatric patients with newly diagnosed cancer and 30 healthy children serving as controls. Prealbumin, albumin, and C-reactive protein (CRP) levels and the upper arm muscle area (UAMA) were measured before and after treatment in children with cancer and compared with the control group to evaluate nutritional status. Additionally, we assessed associations between these parameters and the incidence of infectious complications during cancer treatment in patients with anthropometric malnutrition, as well as associations with an increased risk of malnutrition related to inflammation before treatment.

Results: At baseline, patients with cancer had lower prealbumin and albumin levels (p< 0.001), higher CRP levels (p < 0.001), and lower UAMA percentiles (p = 0.0245) compared with controls. Cancer treatment resulted in an increase in prealbumin and albumin levels (p < 0.001) and a reduction in CRP levels (p < 0.001), with no change in UAMA (p = 1.000). Prealbumin deficiency was more common than albumin deficiency before and after cancer treatment. Median prealbumin and albumin levels tended to increase with an increasing UAMA percentile range, but these differences were not significant (p> 0.05). The incidence of infectious complications during treatment in patients with risk factors for inflammation-related malnutrition was similar to that in patients with pre-existing anthropometric malnutrition without inflammation (p = 1.000). In a univariable logistic regression model including prealbumin and albumin deficiency, as well as low UAMA percentile, albumin deficiency before treatment was shown to be a significant predictor of 3 or more infectious episodes during treatment (p = 0.02).

Conclusion: Albumin and prealbumin deficiency may predict the risk of malnutrition associated with inflammation in patients with cancer. Hypoalbuminemia may predict an unfavorable course of treatment complicated by frequent infections in these patients.

Introduction

Thanks to advances in pediatric cancer treatment, the number of childhood cancer survivors is growing. In recent years, a reduction in childhood cancer mortality has been observed in Europe, with Poland being one of the countries with the lowest leukemia mortality rates (Bertuccio et al., 2020). On the other hand, the long duration of cancer treatment, the use of cytostatic and biologic drugs, as well as radiotherapy and surgery, may lead to treatment-related complications. The most common complications are infections, which can be life-threatening in immunosuppressed patients, and thus reduce cancer survival (Esbenshade et al., 2023; Zawitkowska et al., 2019). As a result, cancer remains the third leading cause of death (after accidents and injuries) in the pediatric population (Cunningham et al., 2018).

Supportive care in cancer patients is important to prevent serious complications or to mitigate their effects (Esbenshade et al., 2023). One component of supportive care is to improve the nutritional status of patients. Malnutrition at diagnosis increases the risk of mortality during and after treatment (Barr and Stevens, 2020). Proper nutritional status in cancer patients promotes remission and improves patient comfort (Rogers and Barr, 2020). Therefore, it is important to identify patients at risk for malnutrition.

The assessment of nutritional status in children with cancer should include common anthropometric measures such as body weight and body mass index, as well as baseline body composition evaluated by mid-upper arm circumference and triceps skinfold thickness, or by more advanced tests such as bioelectrical impedance analysis and dual-energy X-ray absorptiometry (Ladas et al., 2016). Anthropometric nutritional status can also be determined by the upper arm muscle area (UAMA) index, which represents lean body mass and is calculated using the Frisancho formula (Frisancho, 1990).

Increased catabolism and energy expenditure in cancer patients results in reduced production of structural proteins (Bauer et al., 2011; Co-Reyes et al., 2012; Laviano et al., 2005; Sala et al., 2004; Soeters et al., 2021; Romano et al., 2022). These metabolic processes manifest clinically as muscle wasting and poor muscle function both in adult and pediatric patients (Joffe et al., 2019; Shachar et al., 2016; Cederholm et al., 2017). Malnutrition in cancer is a type of disease-related malnutrition with inflammation, where the degree of disease-induced metabolic response determines the rate of catabolism and the onset of clinically significant malnutrition (Cederholm et al., 2017; Viani et al., 2020). Patients with precachexia are at risk for malnutrition due to the inflammatory response induced by the underlying disease (Sala et al., 2004).

Given that low serum protein levels may predict inflammatory malnutrition, we aimed to assess the protein status of children with newly diagnosed cancer and the effect of pretreatment albumin and prealbumin deficiency on the incidence of infectious complications during treatment (Cehreli et al., 2019; Luo et al., 2019).

Patients and methods

Study design

This observational, prospective, single-center study was conducted in pediatric patients with newly diagnosed cancer who were hospitalized between October 2019 and January 2022 in the Pediatric Department of Hematology, Oncology and Transplantology at University Hospital in Lublin, Poland. In total, 40 children with cancer were included. The results of the study group were compared with the results of the control group, which was recruited from volunteers. The control group included children who were not receiving specialized care for chronic diseases, were not taking any chronic medications, and had no evidence of active infection on enrollment.

Median age at the time of cancer diagnosis was 11.29 years (IQR, 5.25–13.27), and the median age of the control group was 6.5 years (IQR, 4.65–9.96). Most patients were male (67.5%), had a diagnosis of hematological malignancy (75%), and received low-intensity or intermediate-intensity treatment (55%). The median follow-up was 39.93 weeks (IQR, 26.57–48.64), and the median time between the end of cancer treatment and study measurements was 6.07 weeks (IQR, 3.21–11.89). The baseline characteristics of the study are summarized in Table 1.

In all patients, the levels of visceral serum proteins (prealbumin and albumin) and C-reactive protein (CRP) were assessed, and anthropometric measurements were performed before and after cancer treatment to evaluate nutritional status

TABLE 1 Characteristics of 40 children with cancer.

Characteristics of 40 children with cancer	
Sex Female Male	n (%) 13 (32.5) 27 (67.5)
Age, years	Median (Q1-Q3) 11.29 (5.25–13.27) Range 2.08–17.67
Primary diagnosis Hematological malignancies Acute lymphoblastic leukemia Acute myeloid leukemia Non-Hodgkin's lymphoma Hodgkin's lymphoma Solid tumors Central nervous system tumors Wilms tumor Soft tissue sarcoma Ewing sarcoma Germ cell tumors	n (%) 30 (75.0) 15 2 5 8 10 (25.0) 2 2 3 2 1
Intensity of treatment[a] Low/intermediate High	n (%) 22 (55.0) 18 (45.0)

[a]Treatment intensity was defined according to risk group classification or disease stage as follows: SR, standard risk; IR, intermediate risk, stage I, II (low/intermediate intensity of treatment), HR, high risk, stage III, and IV (high intensity of treatment).

as well as associations between these parameters and the incidence of infectious complications during cancer treatment. As malnutrition is a risk factor for infectious complications, we assessed the incidence of complications in patients with anthropometric malnutrition and those with an increased risk of malnutrition related to inflammation before treatment. Patients with anthropometric malnutrition met the following criteria: low UAMA percentile range and low albumin and/or low prealbumin and normal CRP levels, whereas patients with normal/high UAMA and low albumin and/or low prealbumin and elevated CRP levels were suspected of malnutrition with inflammation.

The clinical and demographic data of patients were obtained from hospital medical records. In all patients, cancer was diagnosed based on the International Classification of Childhood Cancer ver. 3 (Steliarova-Foucher et al., 2005). Patients received standard treatment according to the type and stage of cancer.

Detailed clinical, demographic, and social characteristics of study participants were reported previously (Milaniuk and Drabko, 2024).

Informed consent was obtained from parents or legal guardians of each participant included in the study.

Ethics approval

This study was conducted in accordance with the principles of the Declaration of Helsinki. Approval was granted by the Ethics Committee of the Medical University of Lublin (26 Sep 2019/No KE-0254/278/2019).

Biochemical assessment of serum protein levels

Blood samples were collected from patients after an overnight fast during routine sampling for laboratory measurements. Serum prealbumin levels were determined by enzyme-linked immunosorbent assay (IDK® prealbumin ELISA, Immunodiagnostik AG, Germany) in samples previously stored at −20°C. Albumin and CRP levels were determined immediately after sample collection. Albumin deficiency was defined as a level of 3.5 g/dL or lower and prealbumin deficiency as a level of 0.2 g/L or lower. Prealbumin levels of less than 0.1 g/L indicated severe deficiency. CRP levels greater than 0.5 mg/L indicated the risk of inflammation.

Assessment of anthropometric protein-energy undernutrition

In this study, UAMA was used to anthropometrically assess protein-energy undernutrition (PEU) in cancer patients. It was calculated using the Frisancho formula: UAMA (cm^2) = $[MUAC - (TSFT^*\pi)]^2 / (4^*\pi)$, where MUAC is the mid-upper arm circumference and TSFT is the triceps skinfold thickness.

UAMA percentiles were classified into the following categories: low muscle (<5th percentile), below average (5th to <15th percentile), average (15th to <85th percentile), above average (85th to <95th percentile), and high muscle (≥95 percentile) according to age- and sex-adjusted growth charts (Frisancho, 1990).

Assessment of infectious complications

The medical records of participants were reviewed for the history of the following infectious complications during treatment: respiratory infections, gastrointestinal inflammation, stomatitis, soft tissue inflammation, fever of unknown origin (FUO), and sepsis. Standardized International Classification of Diseases, Tenth Revision (ICD-10) diagnostic codes were used in the analysis.

Statistical analysis

Patient characteristics were evaluated using descriptive statistics, categorical variables were described as numbers and percentages, and numerical variables were described as mean, standard deviation, median, quartiles, and range. Differences between groups were assessed using Fisher, χ^2, Mann-Whitney, Wilcoxon, Kruskal-Wallis. A single-variable logistic regression analysis was used to assess prealbumin and albumin deficiency and low percentile ranges of the UAMA as predictors

of infectious complications during treatment. For each explanatory variable OR was calculated. A p-value of <0.05 was considered significant. All statistical analyses were performed using R version 4.1.1.

Results

Protein levels and UAMA percentile ranges in cancer patients and controls

Albumin and prealbumin levels were significantly lower in cancer patients than in controls. In the cancer group, albumin and prealbumin levels were higher after vs. before treatment (Table 2). In contrast, CRP levels were significantly higher in cancer patients than in controls. Cancer treatment led to a significant reduction in CRP levels (Table 2).

Regarding UAMA, there was a significantly higher number of patients with low percentiles in the cancer group compared with the control group. There were no differences in the distribution of UAMA percentiles before vs. after treatment in cancer patients (Table 3).

Protein levels and UAMA values in patients with hematological malignancies and solid tumors

There were no significant differences in protein levels and UAMA values between group of patients with hematological malignancies and those with solid tumors (neither before nor after cancer treatment (p > 0.05). However, the comparison within groups demonstrated that in patients with hematological malignancies prealbumin and albumin concentrations were significantly higher after treatment that before. Similat observation was made in patients with solid tumours, but it regard only to albumin concentrations (Table 4).

Assessment of prealbumin and albumin deficiency

In patients with cancer, prealbumin deficiency was more common before vs. after treatment (p < 0.001). Before treatment, it was noted in 35 patients (87.5%), of whom 23 (57.5%) had severe prealbumin deficiency. After treatment, prealbumin deficiency was reported in 25 patients (67.5%). None of the cancer patients had severe prealbumin deficiency after treatment. Albumin deficiency was found in 5 patients (12.5%) before treatment, while it was not observed in any of the patients after treatment (p = 0.0547). Before treatment, 21 patients (52.5%) had elevated CRP levels, as compared with 8 patients (20%) after treatment (p = 0.0053).

The median prealbumin level across all UAMA percentile ranges was less than 0.2 g/L. However, patients with UAMA below the 85th percentile had the median prealbumin level below 0.1 g/L, what indicated a severe deficiency. The median albumin level for all UAMA percentile ranges was greater than 3.5 g/dL. In addition, median albumin and prealbumin levels tended to increase with an increasing UAMA percentile, but the difference was not significant (p > 0.05). There was no association between CRP levels and UAMA percentile range (Table 5).

Associations between nutritional status at diagnosis and infectious complications

The most common infectious complications during the course of treatment affected respiratory system (n = 17) with almost half of them being pulmonary mycosis (n = 8), and oral cavity (n = 15) with stomatitis reaching grade III and IV of severity (n = 5). The third most common infectious complication were gastrointestinal tract infections (n = 9). Sepsis was diagnosed in 8 patients and FUO occurred in 5. The

remaining infections regard to soft tissue infections, asymptomatic COVID-19 and varicella (Figure 1). Severe mucosal inflammation (typhlitis, stomatitis) required total parenteral nutrition in 2 patients. In the remaining cases, oral nutritional interventions were used.

Infectious complications occurred in 23 patients with cancer (57.5%), with 3 or more infectious episodes reported in 11 patients (27.5%). The incidence of complications was influenced by tumor type, with 3 or more episodes occurring significantly more often in patients with hematological malignancies than in those with solid tumors (63.2% vs. 40%; p = 0.0381). Factors such as sex, intensity of treatment, and patient age had no effect on the incidence of infectious complications (p > 0.05).

Pretreatment prealbumin and albumin levels were slightly lower in patients with infectious complications during cancer treatment compared with patients without complications (Table 6). However, these differences were not significant,

Type of infectious complications

FIGURE 1
Type and frequency of infectious complications.

except borderline significance for prealbumin. Patients with hypoalbuminemia were significantly more likely to have 3 or more infectious episodes (Table 7).

Infectious complications in patients with anthropometric malnutrition and risk of malnutrition with inflammation

The incidence of infectious complications during cancer treatment was compared between patients with anthropometric malnutrition without inflammation and those at risk of malnutrition due to inflammation. Only 4 patients (10%) met the diagnostic criteria for malnutrition without inflammation, while 15 patients (37.5%) were at risk for malnutrition due to inflammation. The remaining 21 patients with cancer (52.6%) did not meet any of the criteria to be included in either subgroup. We found no differences in the incidence of infectious complications between subgroups, and over 50% of patients in both subgroups had 3 or more infectious episodes (Table 8).

Effect of protein deficiency and low UAMA on the incidence of complications during cancer treatment

In a univariable logistic regression model including prealbumin and albumin deficiency, as well as low UAMA percentile, pretreatment albumin deficiency was shown to be a significant predictor of 3 or more infectious episodes during cancer treatment (p = 0.02) (Table 9).

Discussion

This study highlights the importance of identifying malnutrition in children with cancer. We present an analysis of the protein and anthropometric status of protein malnutrition in cancer, which indicates the risk of infectious complications in malnourished patients and those at risk of malnutrition.

Previous studies confirmed that cancer patients have lower blood protein levels than healthy individuals and in addition that protein deficiency affects the treatment course and survival of these patients (Cehreli et al., 2019; Luo et al., 2019; McLean et al., 2020; Sanches et al., 2015; Kuvibidila et al., 2000). In our study, prealbumin and albumin levels were also significantly lower in children at the time of cancer diagnosis compared with healthy control. Moreover, blood protein levels increased after cancer treatment, which may indicate a metabolic switch to anabolic processes in cancer remission.

Protein in the diet is very important for cancer patients, whose metabolic rate is particularly high. Therefore, supportive cancer care should include nutritional management of malnourished patients. For this reason, the Polish Society for Pediatric Clinical Nutrition and the Polish Society for Pediatric Oncology and Hematology have developed guidelines for assessing the clinical risk of malnutrition in children with cancer and the indications for implementing nutritional interventions before and during treatment in patients at risk of malnutrition and malnourished patients (Budka-Chrzęszczyk et al., 2024). The enrichment of meals with foods that are high in protein and calories is a basic principle in the choice of diet for children with cancer. However, during cancer treatment, children's taste and smell preferences often change, and treatment with cytostatic drugs is associated with vomiting

and nausea, making it difficult to follow dietary recommendations. Patients at risk of permanent malnutrition during treatment should therefore be treated with nutritionally complete and energy-rich enteral formulas, this form of management provides uninterrupted nutritional support. In some cases, patients who have developed gastrointestinal mucosal complications may have difficulty with oral intake, and special situations such as acute pancreatitis and bowel obstruction may require temporary parenteral nutrition. The indications for nutritional interventions developed by the above

Polish societies are supported by literature data (Bauer, et al., 2011; Ladas et al., 2016).

In our study group, up to 87% of children were found to be protein deficient before treatment. The results of our study did not confirm significant differences in protein status and the incidence of PEU when comparing the group of patients with solid tumours and hematological malignancies both before and after treatment. In contrast, the results of the analysis showed that there was an increase in protein levels after treatment in both tumour groups, with significantly higher levels of prealbumin

and albumin in the hematological malignancies and significantly higher levels of albumin in the solid tumour group.

In our study, prealbumin deficiency was more common than albumin deficiency before treatment and was present in most patients. Prealbumin (transthyretin) is a transport protein for thyroid hormones. Serum prealbumin levels below 0.1 g/L are considered to indicate a significant risk of malnutrition (Keller, 2019; Beck and Rosenthal et al., 2002; Bharadwaj et al., 2016). In our study, 67.5% of patients had prealbumin deficiency after treatment, but the deficiency was not severe. We also observed that achieving higher prealbumin concentrations after treatment occurred in patients with hematological malignancies, who are at lower risk of malnutrition due to their tumour type. Additionally, most patients with hematological malignancies received low and intermediate intensity treatment due to their low risk group classification (standard risk or-intermediate risk), while most patients with solid tumours received high intensity treatment due to their high stage of disease. Compared with albumin, prealbumin has a short half-life of only 2 days. Due to its favorable amino acid composition, prealbumin can be used to assess changes in the patient's diet, such as insufficient caloric intake or dietary improvement (Keller, 2019; Beck and Rosenthal et al., 2002; Bharadwaj et al., 2016). In our study, a lower percentage of patients with prealbumin deficiency after treatment may indicate an improvement in the nutrition of cancer patients in remission and thus predict an improvement in the nutritional status of patients. However, this hypothesis cannot be confirmed due to the limited duration of the study and the lack of monitoring of nutritional status and prealbumin levels in cancer survivors.

Literature data report a different prevalence of hypoalbuminemia at diagnosis in children with cancer, ranging from 7.4% to 45.8% (McLean et al., 2020; Leraas et al., 2023; Tandon et al., 2015; Yaprak et al., 2021). In our study, albumin deficiency was found in only 12.5% of children before treatment and in no children after treatment. Therefore, albumin was shown to be less useful than prealbumin in predicting malnutrition due to inflammation.

Our study highlights the measurement of UAMA as a simple but important tool for assessing lean body mass, particularly muscle mass, which is a key component of metabolic and immune health. The prevalence of anthropometric malnutrition according to UAMA in our patients did not change during the observation period. A low UAMA percentile was reported in 27.5% of cancer patients at diagnosis, and this rate remained stable until the end of treatment. Iniesta et al. (Revuelta Iniesta et al., 2019) reported a lower prevalence of PEU in their study group including 64 children with cancer. The highest prevalence of 14% was found at baseline and decreased to 10% at 3 months and to 12.5% at 24 months of follow-up. None of the patients had PEU at 30 and 36 months after diagnosis (Revuelta Iniesta et al., 2019). In our study, we did not confirm a significant relationship between PEU and the levels of selected proteins. However, we found that patients with normal and high UAMA percentiles had higher serum prealbumin and albumin levels

than patients with low UAMA. In contrast, Yaprak et al. (2021) reported an association between anthropometric malnutrition in children with cancer and prealbumin deficiency. The rates of low serum prealbumin levels on admission and at follow-up were 54.3% and 39.4%, respectively. Low prealbumin levels were reported in 73% of patients with malnutrition vs. 42% of those without (p = 0.007). In contrast, Gürlek Gökçebay et al. (2015) highlighted significant changes in prealbumin levels following dietary intervention in patients diagnosed with anthropometric malnutrition. At 3 months of follow-up, there was a significant decrease in prealbumin levels in patients with vs. those without malnutrition (p = 0.04), while no significant reduction in the proportion of patients with malnutrition was reported. At 6 months, the proportion of patients with malnutrition was significantly lower than at baseline (p = 0.006) (Gürlek Gökçebay et al., 2015). These results indicate that it is possible to modify the UAMA parameter in those patients who have improved their diet, but that its improvement and increase from deficient values to normal values can be achieved over a longer period of time after completion of oncological treatment. However, this hypothesis also cannot be confirmed due to the limited duration of the study and the lack of monitoring of nutritional status and prealbumin levels in cancer survivors.

Malnutrition can make a person more susceptible to infection, which in turn increases the body's need for energy and also contributes to the onset or worsening of malnutrition (Katona and Katona-Apte, 2008). In the inflammatory condition, protein synthesis processes in the liver correlate inversely with increases in CRP, so visceral protein deficiencies are often found in disease states where acute phase proteins are elevated (Evans et al., 2020). Proteins play an important role in supporting the immune system, and their deficiency can adversely affect immune function. They are essential for the proper functioning of immune cells, including T and B lymphocytes, and influence the production of cytokines that regulate immune responses. An adequate supply of protein is also necessary for the proper functioning of the complement system. In addition, proteins play a role in wound healing and a deficiency can interfere with tissue repair (Morales et al., 2023).

The incidence of infectious complications in cancer is influenced by disease- and treatment-related factors, such as bone marrow suppression, as well as by patient-related factors, such as inadequate nutritional status (Pedretti et al., 2023). Consequently, every patient with cancer is at risk for developing infectious complications during cancer treatment, which leads to a delayed completion of cancer treatment, increased risk of infection-related mortality, and cancer treatment failure. Among the infectious complications analysed in our patient group, some were serious and life-threatening (sepsis, FUO, fungal infections, stomatitis in stages III and IV, typhlitis). However, due to small sample size we did not analyze patients grouped according to infections severity, but we assessed the impact of prealbumin and albumin deficiency and PEU on the incidence of infectious

complications during cancer treatment. We found a significantly higher number of infectious complications in patients diagnosed with hematological malignancies compared with those with solid tumors. Our findings are in line with the study by Zajac-Spychala et al. (2021). In our study, the incidence of infectious complications during treatment in patients with risk factors for inflammatory malnutrition was similar to that in patients with pre-existing anthropometric malnutrition without inflammation. We also found that patients at risk for malnutrition with inflammation were more than 3 times more likely to have known anthropometric malnutrition without inflammation. Although the diagnosis of malnutrition based on protein assessment is not recommended (Evans et al., 2021), our findings confirm that they can be used to identify inflammation leading to malnutrition that increases the risk of infectious complications during cancer treatment to the same extent as the presence of malnutrition itself.

We found lower pretreatment prealbumin and albumin levels in patients with infectious complications, with borderline statistical significance shown for prealbumin. In addition, pretreatment prealbumin deficiency was present in all patients who had more than 3 infectious episodes during treatment. This finding may support the role of proteins, particularly prealbumin, in assessing changes in nutritional status in children with cancer and in recognizing the need to implement supportive nutritional measures during cancer treatment. Liang et al. (2018) reported a significant increase in total protein, albumin, and prealbumin levels after nutritional intervention in children with acute lymphoblastic leukemia during induction treatment. They also showed a lower incidence of infection during induction treatment in patients who received nutritional therapy (Liang et al., 2018). Although most our patients had prealbumin deficiency and hypoalbuminemia was less common, albumin deficiency was shown to be a significant predictor of 3 or more episodes of infectious complications during treatment in our patients. The role of hypoalbuminemia as a negative prognostic factor for treatment outcome was demonstrated by other authors (McLean et al., 2020; Leraas et al., 2023; Tandon et al., 2015; Sonowal and Gupta, 2012).

The study has its strengths and limitations. The strengths include prospective design which enables to collect data in unified way and interdisciplinary approach of the study that combines clinical, nutritional and, in some cases, immunological perspectives relevant to supportive care during oncological treatment of childhood cancer. One of its limitations is the small sample size, which may have affected the statistical significance of the results. However, the number of patients included reflects the capacity of the department where the study was conducted at the time of the study. We are also aware that the study group was heterogeneous regarding diagnosis but subjecting to analyzis only patients with one type of cancer would make the study group even more smaller. The treatment approach is also different, as patients

with hematological malignancies received steroid therapy. However, this is a standard treatment for this type of cancer, so we could not avoid its possible influence on the study results. We did not analyse the effect of nutritional interventions on the biochemical results obtained in this study, but we believe that the questions raised will encourage further research.

Conclusions

The presence of protein-energy malnutrition in children with cancer at the time of diagnosis increases the risk of infectious complications during treatment. In our study, albumin and prealbumin deficiencies were shown to indicate the risk of malnutrition related to inflammation in patients with childhood cancer. Hypoalbuminemia may be useful for identifying cancer patients who are at risk for an adverse treatment course, complicated by frequent infections. Implementing nutritional interventions will be beneficial in patients with PEU and in those with suspected malnutrition with inflammation. Proper nutrition in cancer improves nutritional status and reuduces the risk of infectious complications during treatment.

Data availability statement

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

Ethics statement

The studies involving humans were approved by the Ethics Committee of the Medical University of Lublin (26 Sep 2019/ No KE-0254/278/2019). The studies were conducted in accordance with the local legislation and institutional requirements. Written informed consent for participation in this study was provided by the participants' legal guardians/ next of kin.

Author contributions

AM and KD are responsible for the conception and design of the study. AC conducted laboratory work. Material preparation, data collection and analysis were performed by AM. The first draft of the manuscript was written by AM and all authors commented on previous versions of the manuscript. KD supervised the study. All authors read and approved the final. All authors contributed to the article and approved the submitted version.

Application of the FISH method and high-density SNP arrays to assess genetic changes in neuroblastoma—research by one institute

Dorota Winnicka[†], Paulina Skowera*[†], Magdalena Stelmach*, Borys Styka and Monika Lejman

Independent Laboratory of Genetic Diagnostics, Medical University of Lublin, Lublin, Poland

Neuroblastoma is the most common extracranial solid tumor in children. Amplification of the MYCN gene has been observed in approximately 20%–30% of tumors. It is strongly correlated with advanced-stage disease, rapid tumor progression, resistance to chemotherapy and poor outcomes independent of patient age and stage of advanced disease. MYCN amplification identifies high-risk patients. To assess neuroblastoma tumors with MYCN amplification we used paraffin-embedded tissue sections in 57 patients and intraoperative tumor imprints in 10 patients by fluorescence *in situ* hybridization (FISH). Positive results for *MYCN* amplification have been observed in twelve patients' paraffin-embedded tissue sections and in three patients' intraoperative tumor imprints, which represents 22.4% of all patients tested in the analysis. Fluorescence *in situ* hybridization is a highly sensitive and useful technique for detecting MYCN amplification on paraffin-embedded tissue sections of neuroblastoma tumors and intraoperative tumor imprints thus facilitating therapeutic decisions based on the presence or absence of this important biologic marker. The presence of structural changes, regardless of MYCN gene amplification status, influences the clinical behavior of neuroblastoma. High-Density SNP Arrays have emerged as the perfect tools for detecting these changes due to their exceptional accuracy, sensitivity and ability to analyze copy number and allele information. Consequently, they are proven to be highly valuable in the genomic diagnosis of immature neuroectodermal tumors.

KEYWORDS

neuroblastoma, childhood tumours, MYCN amplification, high-density SNP arrays, FISH

Introduction

Neuroblastoma is a malignant tumor in children aged 0–15 years. It accounts for 8%–10% of all childhood tumors, with 80% affecting children under the age of 5 years and approximately 15% representing all cancer deaths in children (Aygun, 2018; Swift et al., 2018). Approximately 60–70 of the new incidences of neuroblastoma are diagnosed each year in Poland (Whittle et al., 2017).

Neuroblastoma derives from primitive cells of the sympathetic nervous system. It occurs in the retroperitoneum, posterior mediastinum, neck, or pelvis. The clinical symptoms in neuroblastoma depend on the tumor mass, the extent of metastasis and catecholamine and vasoactive intestinal peptide secretion by the tumor cells. The diagnosis of neuroblastoma is based on histopathological results and the presence of tumor cells in the bone marrow accompanied by elevated levels of urinary catecholamines. In addition to clinical, histopathological and laboratory data, genetic test results are crucial in determining prognosis (Adamkiewicz-Drożyńska, 2006; Schulte et al., 2018).

The most common cytogenetic changes include deletions of chromosome 1p, amplification of the oncogene *MYCN*, ploidy changes, gains of chromosome arm 17q and deletion of 11q in tumor cells. Genetic abnormalities are very powerful predictors of response to therapy and outcome and provide important information to guide optimal patient management (Bhat and McGregor, 2017; Lim et al., 2020).

The *MYCN* gene is a cellular protooncogene of the MYC family. *MYCN* maps to the 2p24 chromosome. Structural alterations leading to amplification can manifest in the form of double minute chromosomes (dmins) or homogeneous staining regions (HSRs). Dmins represent extra chromosomal material, while HSRs denote duplicate material within chromosomes. Dmins are commonly observed in tumor-derived cells, whereas HSRs are more prevalent in cell lines. However, without traditional karyotype analysis, we are unable to precisely determine what type of changes we are dealing with (Van Noesel and Versteeg, 2004; Jeison et al., 2010).

MYCN is an oncogenic transcription factor involved in the regulation of proliferation, transformation, differentiation and apoptosis (Swift et al., 2018).

MYCN amplification is detected in 20%–30% of neuroblastoma patients (Yue et al., 2017; Otte et al., 2020). It is strongly correlated with advanced disease stage, rapid tumor progression, resistance to chemotherapy and poor outcomes. The *MYCN* amplification test result is included in medical protocols around the world, it is an independent indicator in the assessment of the patient outcome and it is one of the qualifying factors for a group requiring the most aggressive treatment (Brodeur et al., 1985; Huang and Weiss, 2013; Ahmed et al., 2017; Kaczówka et al., 2018; Croteau et al., 2021). *MYCN* amplification is present in 38% of patients with

stages 3 and 4 (Ahmed et al., 2017) but only in 5%–10% of patients with stages 1, 2, and 4 s (Morandi, 2022). The level of *MYCN* gene amplification is necessary to avoid either under- or over-treating patients (Lee et al., 2018). The gold standard in the assessment of *MYCN* amplification is fluorescence *in situ* hybridization on paraffin-embedded tissue sections and intraoperative tumor imprints.

The independent factors that predict the outcome of treatment are: tumor histology, level of *MYCN* amplification and chromosomal copy number changes (Chicard et al., 2016; Lerone et al., 2021). In addition to these two main genetic markers, a number of segmental aberrations involving different chromosomes have also been described that, in addition to *MYCN* amplification, have a strong effect on the development of neuroblastoma, making it more aggressive and resistant to treatment (Lerone et al., 2021). Currently, the diagnosis of neuroblastoma also relies on molecular methods, such as microarrays, but it is not always possible to isolate good-quality DNA from paraffin-embedded tissue sections. An alternative method to obtain good-quality DNA is the intraoperative collection of tumor scrap from which DNA isolation is performed directly.

SNP array analysis provides comprehensive detection of the presence of deletions and duplications involving chromosomal fragments and allows for simultaneous assessment of DNA copy number.

SNP array analysis can also detect loss of heterozygosity (LOH). Studies of neuroblastoma cells have identified LOH in several chromosomal regions, of which LOH 1p and 4p correlate with poor patient outcomes.

In addition to these relatively large genomic aberrations, deletion aberrations of single genes, parts of genes or point mutations e.g., *TERT*, *ALK*, *ATRX,* and *ARID1A*, have recently been described as having unfavorable clinical outcomes and implications for clinical management (Brunner et al., 2016).

The aim of this study was to demonstrate the effectiveness of the FISH method for the evaluation of *MYCN* amplification on paraffin-embedded tissue sections and intraoperative tumor imprints together with HD SNP array analysis in neuroblastoma patients.

Materials and methods

The study materials consisted of 57 paraffin-embedded tissue sections with freshly removed tumors and 10 intraoperative tumor imprints, along with archival sections from 67 patients with an established clinical diagnosis of neuroblastoma (31 little girls and 36 little boys; median age: 3 years 2 months). All of the children were admitted to the Department of Pediatric Hematology, Oncology and Transplantology, Children's University Hospital, Lublin, Poland between 1994 and 2023.

TABLE 1 Patient characteristics.

	Criterium	Number
Age at diagnosis	<18 m	31
	>18 m	36
Diagnosis	NB	52
	GNB	11
	GN	1
	ND	3
INSS risk group	1	7
	2	3
	3	24
	4s	3
	4	30
Primary site	Abdomen	22
	Adrenal glands	25
	Mediastinum	11
	Pelvis	7
	Cervical	2
MYCN amplification	Yes	15
	No	52

The collected clinical data included the patient's age at diagnosis, stage according to the INSS (International Neuroblastoma Staging System) criteria (Park et al., 2017), tumor location, histopathological diagnosis of the examined tissues and *MYCN* amplification [Table 1]. Detailed patient data can be found in the Supplementary Material. All studies were performed between 1994-2023.

FISH method

We used the Pretreatment Kit (Vysis) and the LSI N-MYC (2p24) SpectrumGreen/CEP 2 SpectrumOrange Probe (Vysis) to estimate *MYCN* amplification.

Paraffin-embedded tissue blocks were cut into 4-micron thick sections on silanized slides and they were baked at 56°C overnight. Slides were soaked twice in xylene for 10 min and dehydrated in ethanol at 100%, 96%, 80%, and 70% for 2–5 min in each solution. Slides were then immersed in 0.2 N hydrochloric acid for 20 min and rinsed in water and wash buffer for 3 min in each of them. The slides were immersed in Pretreatment Solution at 80°C for 30 min and they were washed twice in 2xSSC for 5 min.

In the next step, the tissue sections were digested in protease solution at 37°C for 30 min and then the slides were immersed in 2xSSC cooled to 5°C.

The slides were then fixed in 10% formalin for 10 min. Fixed tissue, washed twice in 2xSSC and dried on a hot plate at 45°C–50°C.

Slides with intraoperative tumor imprints were immersed in a fixative prepared by mixing 3 parts methanol and 1 part acetic acid for 30 min. The slides were then dried at room temperature for 24 h.

To detect the presence of *MYCN* gene amplification, on paraffin-embedded tissue sections and intraoperative imprints of neuroblastoma tumors, we used fluorescence *in situ* hybridization (FISH) on interphase nuclei. Molecular cytogenetics uses the FISH method to identify specific DNA sequences on chromosomes using DNA probes that are directly labeled by the fluorophore. The labeled probe and the target DNA are denatured in the first step of this method. Hybridization is the second step of the FISH method. Combining the denatured probe and target DNA allows for the annealing of complementary DNA sequences.

We used 1 µL of direct fluorochrome-labeled, dual color DNA Probe for the *MYCN* gene locus (2p24) and α-satellite DNA identifying the centromeric region of chromosome 2 (Vysis LSI N-MYC (2p24) SpectrumGreen/CEP 2 SpectrumOrange Probe) combined with the 7 µL Hybridization Buffer and 2 µL water. The probe was placed on a slide, then covered with a coverslip and secured with rubber cement. The slides were incubated at 72°C for 5 min to denature the DNA. Hybridization was performed for 14–18 h at 37°C.

The slides were subsequently immersed in post-hybridization wash buffer at room temperature for 15–20 min until the coverslip fell off. Then they were immersed in post-hybridization wash buffer warmed to 72°C for 5 min. The cells were counterstained with DAPI. The signals were evaluated by eye or captured with Applied Spectral Imaging- ASI- Israel at ×100 magnification on the Nikon epifluorescence microscope equipped with a 100-W mercury arc lamp and an appropriate set of filters (single filters for FITC and TexasRed fluorochromes and a triple bandpass filter for FITC/TR/DAPI). A minimum of 200 nuclei was evaluated for each of the *MYCN* and CEP2 loci. Nuclei with two visible red and two green signals were scored as negative for *MYCN* amplification (Figure 1). According to the guidelines, the cutoff point for *MYCN* amplification was set at 10 signals (amplification ≥10; gain <10) only in the presence of disomy of chromosome 2. In the presence of polysomy of chromosome 2 in tumor cells, confirmation of *MYCN* gene amplification was based on the guideline that the number of tested signals must exceed that of control signals by at least four times (Ambros et al., 2009; Winnicka et al., 2020).

The study was approved by the Ethics Committee of the Medical University of Lublin (KE-0254/229/2012).

HD SNP array method

In eight patients, we isolated DNA from tumor tissue and performed microarray testing using the CytoScan HD array to

FIGURE 1

evaluate additional cytogenetic abnormalities. In one case, the quality of the DNA did not allow for the array procedure.

Genomic DNA was isolated with the QIAamp DNA Blood Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's protocols. DNA samples were stored at −20°C until the next step. The concentration and quality of DNA were determined using a spectrophotometric method (NanoDrop 8000; Thermo Fisher Scientific, Waltham, MA, United States). In total, 250 ng of genomic DNA was used in accordance with the manufacturer's protocols. Microarray testing was performed with the use of a CytoScan HD array [2,670,000 markers, including 750,000 SNP and 1,900,000 non-polymorphic copy number variant (CNV) markers] (Applied Biosystems, part of Thermo Fisher Scientific). All subsequent steps and data analysis were performed as described previously by Lejman et al. (2020). The scanned data file was analyzed with Chromosome Analysis Suite v 3.3 (ChAS; Thermo Fisher Scientific) using the CRCh37 (hg19) reference genome.

Results

Results of *MYCN* amplification by fluorescence *in situ* hybridization (FISH)

Sixty-seven patients participated in this study. Thirty-four (50.7%) of patients had localized neuroblastoma (1–3 stages), 4.5% stage 4S, and 44.8% stage 4 disease. Forty-seven (70.1%) of patients had an abdominal/adrenal mass at diagnosis. Thirty-one (46.3%) patients were <18 months of age, and thirty-six (53.7%) patients were >18 months of age. Of 67 patient samples, including 52 neuroblastomas, 11 ganglioneuroblastomas, and 1 ganglioneuroma, 3 samples had no definitive diagnosis.

Positive results for *MYCN* amplification were observed in twelve patients' paraffin-embedded tissue sections and in three patients' intraoperative tumor imprints which represents 22.4% of all tested patients in the analysis (Figure 2).

There were 9 (60%) little boys and 6 (40%) little girls included in the study. Of the 15 patients, 1 (6.7%) had stage 3 disease, 1

FIGURE 3
Complex copy number gains and losses in the region 2p25.3p21 of chromosome 2 in patient 63. With Neuroblastoma by single-nucleotide polymorphism (SNP) array. (6.7%) had stage 4 s disease, and 13 (86.6%) had stage 4 disease. Of these 15 patients with MYCN amplifications 5 (33.3%) were <18 months of age, and 10 (66.7%) were >18 months of age. Five (33.3%) of the patients with MYCN amplification had a tumor mass in the abdomen and ten (66.7%) had a tumor mass in the adrenal gland.

Molecular karyotype results

To evaluate additional molecular abnormalities we performed microarray testing on 6 patients with different stages of disease, tumor localization and ages at diagnosis.

We performed microarray testing on a patient with stage 4 disease and tumor localization in the adrenal gland. The patient was a girl who was over 18 months of age at the time of diagnosis. Through fluorescence *in situ* hybridization we observed positive results for *MYCN* amplification. Microarray analysis revealed a deletion within the short arm of chromosome 1 (arr [GRCh37] 1p36.33p36.22 (849466_9304205)x1), and a duplication involving a fragment of the short arm of chromosome 1, and the long arm of chromosome 1 (arr [GRCh37] 1p13.3q44 (110062169_249224684)x3). In region 2p25.3p21 we observed chromothripsis (arr [GRCh37] 2p25.3p21 (12770_46642249) cth) (Figure 3). The *MYCN* gene (2p24.3) was amplified in this region (10 copies). In addition, the *ALK* gene (2p23.2-p23.1) was also duplicated. Monosomy of chromosome 3 and trisomy of chromosome 18 were identified (Figure 4).

The second patient was a boy over 18 months of age at diagnosis, with stage 4 disease and tumor localization in the adrenal gland. Through fluorescence *in situ* hybridization we did not observe any amplification of the *MYCN* gene. Microarray analysis identified 3 cell lines with various genetic changes (Figure 5). We present the results in the table below (Table 2).

The third patient was a girl who was over 18 months of age at diagnosis, with stage 3 disease and tumor localization in the abdomen. Through fluorescence *in situ* hybridization we did not observe any amplification of the *MYCN* gene. Microarray analysis revealed mosaic monosomy of chromosome X and duplication of region 22q11.21 (arr [GRCh37] 22q11.21 (18979347_21800471)x3). The Whole Genome View (WGV) showed a decrease in the log2ratio value, which may indicate the presence of monosomy on chromosomes 3, 4, 9, 10, 14, 15, 19, and 21, and an increase in the log2ratio value, which may indicate the presence of trisomy on chromosome 13. An ambiguous assessment of chromosome copy number may be the result of incorrect material collection. The fourth patient was a boy who was over 18 months of age at diagnosis, with stage 3 disease and tumor localization in the abdomen. *MYCN* amplification was negative. With microarray analysis we identified a duplication involving a fragment of the short arm of chromosome 1 (arr [GRCh37]1p36.33p36.32 (849467_3627839)x3 [0.3]) and deletions in the following regions: arr [GRCh37] 12q24.23q24.31 (118233114_125556278)x1 [0.2], 19p13.3p11 (260912_24505049)x1 [0.2]. As with the previous patient the Whole Genome View (WGV) showed a decrease in the log2ratio

FIGURE 4

value, which may indicate the presence of monosomy on chromosomes 3, 4, 9, 10, 14, and 15 and an increase in the log2ratio value, which may indicate the presence of trisomy on chromosome 13. The microarray results for the two patients were normal and did not reveal any additional changes in the molecular karyotype.

Discussion

In recent years, significant progress has been made in understanding the genetic basis of neuroblastoma. Numerous studies have been published on somatic mutations and chromosomal abnormalities associated with the development of neuroblastoma. However, their role in treatment response, prognosis, and the development of metastasis has not been fully elucidated. Based on our

research, we have divided patients into two groups: those with *MYCN* amplification and those without it.

High-risk patients are identified by the presence of *MYCN* amplification. *MYCN* amplification is a powerful prognostic factor for advanced stages and rapid tumor progression (Lau et al., 2015). Interphase FISH analysis provides a direct and rapid method. Only a small number of tumor cells are required, compared with primary tumor biopsies, and FISH is more sensitive by counting the *MYCN* copy number in each single cell (Tibiletti, 2007; Campbell et al., 2017).

The fluorescence *in situ* hybridization (FISH) method is faster to prepare than molecular biology techniques or traditional cytogenetic analysis. FISH can be used on interphase nuclei, in contrast to karyotype analysis, and it can be performed on formalin-fixed nuclei, in cases where a fresh or frozen tumor is not available (e.g., small biopsies or retrospective studies). However, molecular methods, such as microarrays, have

TABLE 2 Molecular changes identified in the microarray analysis of patient 64.

strong limitations when analyzing *MYCN* amplification and other genetic changes in neuroblastoma because molecular methods are based on DNA from a mixture of cells and therefore only provide an average result for a particular tumor. When a tumor is highly amplified, this is not a problem for diagnosis. However, with low levels of *MYCN* amplification, it can be difficult to interpret the results. The first possibility is that there is a heterogeneous population of tumor cells in which a small number of cells are highly amplified or have other anomalies. Or it may be a highly amplified tumor mixed with normal tissue. Finally, it may be a low level of amplification occurring in tumor cells (e.g., a triploid population) (Shapiro et al., 1993; Squire et al., 1996; Thorner et al., 2006).

In the Polish population, tumor imprints are routinely used to assess *MYCN* amplification. However, this is not always possible and then the only material for *MYCN* amplification is a paraffin tissue section. It can be done on both fresh and archived tissues from many years ago.

For this study we used intraoperative tumor imprints and fresh paraffin-embedded tissue sections in addition to archival materials. Fresh material was obtained from a tumor removed from a patient 2 weeks before the study and archival paraffin sections were removed from a patient operated on 8 years and 2 months before the study. In our opinion both fresh tissue and tissue from years before preserved in a paraffin block were adequate materials for the test. The quality of the specimens was similar and the evaluation of both archival and fresh specimens was consistent with previous studies. Intraoperative tumor imprints were taken immediately after their removal. The

quality of these specimens is much better compared to the paraffin-embedded tissue sections, as only the tumor cells are on the slide, with no surrounding tissue. The assessment of *MYCN* amplification on intraoperative tumor imprints does not cause any diagnostic problems.

Microarray testing of neuroblastoma samples provides additional information on other chromosomal changes observed in patients with and without *MYCN* amplification, which has a strong impact on prognosis. In a sample from a patient with *MYCN* amplification we found a deletion within the short arm of chromosome 1 (1p36.33p36.22), and a duplication involving a fragment of the short arm of chromosome 1 and the long arm of chromosome 1 (1p13.3q44). In the literature, deletion or loss of heterozygosity (LOH) of the 1p36 chromosomal band is correlated with high-risk neuroblastoma features, including older age at diagnosis, metastatic disease, *MYCN* amplification and poor prognosis Unfavorable abnormalities also include segmental copy number alterations, such as loss of 3p, deletion or LOH 11q23, 14q23qter and gain of 17q (Marrano et al., 2017). Amplification of the *MYCN* gene was observed only at a level of 10 copies. Unfortunately, this can be considered a limitation of the molecular method because the FISH analysis showed the amplification of the *MYCN* gene at a level of approximately 30 copies. In our opinion, the gold standard for the assessment of *MYCN* amplification is fluorescence *in situ* hybridization on intraoperative tumor imprints. Furthermore, microarray analysis showed a duplication of the 2p23.2p23.1 region, including the *ALK* gene. Anaplastic lymphoma kinase (ALK) is an important regulator of stem cell functions,

including STAT3 dependent self-renewal, and as a transcriptional target of *MYCN*, high expression indicates an unfavorable prognosis (Rosswog et al., 2023). According to studies carried out on genetically engineered mouse models of NB, the *MYCN* and *ALK* genes cooperate to promote oncogenesis (Vivancos Stalin et al., 2019). Additionally, CytoScan HD analysis revealed a monosomy of chromosome 3 and a trisomy of chromosome 18.

In 3 out of 5 patients without changes in *MYCN* amplifications, we observed complex alterations in the microarray pattern. In two samples, discrete changes indicating the presence of monosomy of chromosomes 3, 4, 9, 10, 14, and 15. According to scientific research chromosome 10 is the most frequent loss. On the long arm of chromosome 10, there are tumor suppressor genes such as *PTEN*, *DBMT*, and *LGI1*, while the short arm contains *IDI1*, *AKR1C3*, *DDH1*, *NET1A*, *PRKCQ*, and *GATA*-binding protein 3. Among these, *PTEN* is the second most commonly deleted/mutated gene in human tumors, with a mutation rate of 50%. The GDNF family receptor alpha 2 (GFRA2) promotes the proliferation of NB cells (Li et al., 2019). According to the literature, patients with neuroblastoma and an abnormal chromosome 10 had a significantly lower 3-year OS compared to the group of patients with a normal copy number of chromosome 10 (Jiang et al., 2021). In the same samples we noted an extra copy of chromosome 13, which, according to other researchers (Bilke et al., 2008; Ambros et al., 2014) is a common chromosome in the trisomy of neuroblastoma. Interestingly, some authors show that there are no structural changes on chromosome 13 in neuroblastoma (Bogen et al., 2016). While its prognostic significance in neuroblastoma has not been precisely determined, in other cancers, including ALL, AML, and MDS, trisomy 13 is closely associated with an unfavorable prognosis for the patient. The presence of trisomy 13 in acute leukemia cells indicates a poor response to chemotherapy (Spirito et al., 2003; Herold et al., 2014). Monosomy of chromosome X and duplication of region 22q11.21 have not been described in the literature in patients with neuroblastoma so far. However, our results unequivocally demonstrate that such alterations may also be present in this type of cancer.

According to the Polish "Standards for the genetic diagnostics of solid tumors in children" structural changes involving chromosomal regions 1p, 1q, 2p, 3p, 4p, 6p, 6q, 11q, and 17q are most commonly observed in advanced stages of the disease in older children and represent unfavorable prognostic factors, increasing the risk of disease recurrence, regardless of the specific chromosomal pairs affected (Trubicka et al., 2023). In one of our patients with stage 4 disease, the FISH study found no amplification of the MYCN gene, while the microarray analysis identified 3 cell lines in which some of the above-mentioned structural changes were noted (including: 1p, 2p, 3p, 4p, 6q, 11q, and 17q) stratifying the patient into a group with an unfavorable prognosis.

In the literature, high-risk patients had long-term survival rates of only 10%–20% with combination chemotherapy, surgery, and local radiation therapy (Tolbert and Matthay, 2018). However, treatment approaches that used a combination of induction therapy, myeloablative consolidation therapy with stem cell support, and biological therapy had improved 5-year survival rates from less than 15%–40% (Nakagawara et al., 2018).

Despite many biochemical, molecular and genetic indicators as markers of poor prognosis, *MYCN* amplification is still used to stratify patients into risk groups and is a marker of poor prognosis. These patients respond poorly to conventional therapy. The ability to determine this biological marker is necessary for appropriate clinical management. Unfortunately, treatment failure has been reported in all patient groups, even without *MYCN* amplification, suggesting that additional prognostic markers must be discovered to improve treatment protocols (Feng et al., 2023).

In conclusion, both the FISH technique and microarray testing have their advantages and disadvantages. In addition to *MYCN* gene amplification, cytogenetic abnormalities are also a marker of an unfavorable prognosis in patients diagnosed with neuroblastoma. Therefore, it is very important that the result be based on both, fluorescence *in situ* hybridization and molecular karyotype.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

Ethics statement

The study was conducted according to the guidelines of the Declaration of Helsinki and approved by the Ethics Committee of the Medical University of Lublin (KE-0254/229/2012). The studies were conducted in accordance with the local legislation and institutional requirements. Written informed consent for participation in this study was provided by the participants' legal guardians/next of kin.

Author contributions

DW and ML are responsible for the conception and design of the study. DW and BS conducted laboratory work. BS and PS were responsible for the acquisition of literatures for manuscript. DW and BS were responsible for interpretation of data. DW, PS, MS, and ML prepared final manuscript for publication. All authors contributed to the article and approved the submitted version.

Funding

The author(s) declare that no financial support was received for the research, authorship, and/or publication of this article.

Acknowledgments

Preprint: "Winnicka et al., 2020" is part of this article, which has been enriched with additional research and updated.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Supplementary material

Prevalence of poor nutrition status in multiple sclerosis patients assessed by different diagnostic tools

Natalia Mogiłko[1] and Sylwia Małgorzewicz[2]✉

[1]Department of Neurology and Clinical Neuroimmunology of the Specialist Hospital in Grudziadz, Grudziądz, Poland; [2]Department of Clinical Nutrition, Medical University of Gdansk, Gdańsk, Poland

Patients with multiple sclerosis (MS) present a spectrum of nutritional disorders from obesity to malnutrition. The purpose of this study was an assessment of the nutritional status of MS patients by NRS-2002 and GLIM criteria. Methods: 147 patients were included in the study. The nutritional status was assessed by NRS 2002, GLIM, and body composition analysis. The routine biochemical parameters were measured. Results: Deterioration of the nutritional status was observed in 87.8% of patients. GLIM criteria indicated that 20% of patients were malnourished and 80% were at risk. The percentage of patients with excess body mass was 46.8%, and of underweight patients was 6.6%. The risk of malnutrition was positively associated with low content of adipose tissue (R=−0.24; p=0.00), low BMI (R=−0.22; p=0.00), and higher weight loss in the last 6 months (R=0.47; p=0.00). Additionally, a significant (p<0.05) correlation between malnutrition state and s-albumin (R=−0.2) and CRP (R=0.23) was observed. Conclusion: Overweight and obesity concerned a large proportion of the studied group of MS patients, but this does not exclude the risk of malnutrition. Dietary care and regular outpatient nutritional status assessment should be provided throughout the disease.

INTRODUCTION

Multiple sclerosis is a chronic neurological disease that leads to disability (Oh *et al.,* 2018). At the beginning of the disease, patients often present excess body weight, while in advanced stages, signs of malnutrition appear, and the need to introduce enteral nutrition. It seems that the spectrum of disorders from obesity to malnutrition may be of clinical significance. The symptomatology of MS is very diverse, patients suffer from movement disorders (limb paresis, ataxia), sensory disorders (persistent paraesthesia, hypoaesthesia, hyperesthesia), cranial nerves lesion (oculomotor paralysis, visual disturbances, trigeminal neuralgia), as well as vegetative and mental disorders (cognitive and mood disorders) (Łabuz-Roszak *et al.,* 2013). Depression, mood disorders, mobility limita-tions, and dysphagia directly affect the nutritional status of people suffering from multiple sclerosis.

At the beginning of the disease, mood disorders, lack of proper diet, and the desire to comfort with food result in the consumption of processed foods rich in sugar and saturated fats – which is associated with body composition disturbances, including an increased amount of adipose tissue (Pilutti *et al.,* 2016; Mokry *et al.,* 2016). Additionally, steroid therapy and a sedentary lifestyle due to progressive disability increase the risk of obesity and its characteristic complications. In the later stages, gastrointestinal problems, such as gastroesophageal reflux, delayed gastric emptying, constipation, and dysphagia can be diagnosed. Dysphagia is the cause of dehydration and malnutrition (D'Amico *et al.,* 2018; Ansari *et al.,* 2020).

The dietitian should adjust the composition of the diet and the amount, volume, and consistency of meals and recommend thickeners depending on the patient's current situation. Next, oral nutritional supplementation or enteral or parenteral nutrition may be necessary (Afifi *et al.,* 2021; Burgos *et al.,* 2008). There is a need for the early identification of patients at risk of malnutrition because the therapeutic possibilities are much greater in this stage than in advanced cachexia.

Therefore, our study was aimed at exploring the nutritional status by NRS 2002 and GLIM criteria of patients treated for multiple sclerosis in a stable clinical condition.

MATERIALS AND METHODS

The population of the study consisted of 147 MS patients (M=38), with an average age of 40.4±11.6 years, consecutively admitted to the neurology ward of a Specialist Hospital during a six-month period. All subjects gave their informed consent for inclusion before they participated in the study. The study received the approval of the Ethics Committee of the Medical University of Gdansk. The 57.8% of patients presented the following comorbidities: 18% hypothyroidism, 16% hypertension, 16% hyperlipidemia, 12% depression, 6% Hashimoto's disease, 5% diabetes, 5% allergy or asthma, 3% hyperthyroidism, 3% epilepsy, 2% anemia, and 1% psoriasis. The mean time since MS diagnosis was 6.5±4.9; there is no dysphagia recognized in the study group.

Nutritional status and body composition were evaluated at admission by the NRS 2002 (the Nutritional Risk Screening) and the GLIM (the Global Leadership Initiative on Malnutrition) criteria which were applied by a trained clinical examiner. In addition, each patient underwent an analysis of his/her medical records to obtain information regarding concomitant diseases and anthro-

pometric parameters, such as body mass by electronic weight and body mass index calculation (BMI), and bio-impedance analysis with the use of the InBody 120 analyzer.

The following biochemical parameters were measured by routine laboratory methods: C-reactive protein (CRP), s-albumin level, lipid profile, and whole blood morphology.

Statistical analysis

Results are expressed as mean and standard deviation or percentages (for categorical variables). The Shapiro-Wilk W test was used to evaluate the normal distribution of the tested parameters. On the other hand, the Leven (Brown-Forsythe) test was used to test the hypothesis of equal variances. Pearson and/or Spearman correlation coefficients were used to calculate the correlation between the variables. A p-value <0.05 was considered to be statistically significant. Statistical processing of the results was performed with the use of the statistical software STATISTICA PL v 13.0 (Statsoft, Krakow, Poland).

RESULTS

In the study group, the mean body weight was 72.6 ± 16.9 (range 45.0–130.0 kg) and the mean BMI was 25.1 kg/m^2 (range 16.1–43.4). 6.6% of patients presented as underweight with a body mass index <18.5 kg m^2 (14.4% with BMI <20), and normal body weight was observed in 74 subjects (50.3%). High BMI (BMI >25) was presented in 42.1% of pts. The mean content of % body fat was 30.7 (range 9.9–52.0) – for females – 33.1% and for men 23.7%.

Independently of the BMI, according to the GLIM criteria, the majority of patients (85.5%) were at risk of malnutrition and 15.5% exhibited malnutrition. Based on the NRS 2002, a slight deterioration of the nutritional status was observed in 87.8% of patients, moderate in 9.5% and severe in 2.7%. Analysis showed a strong correlation between both methods (R=0.8; $p<0.05$).

Unintentional body weight loss (UBWL) in the last 6 months was observed in 28% of patients in mean level 1.4 kg (range 0–20 kg). 58% of patients did not change their body weight within the last 6 months. 9% of patients reduced their body weight intentionally by using various diets, including those generally available on the Internet, individual diets from dietitians, or by restricting selected groups of food products. There was also a group of patients who gained weight (5%).

The malnourished patients in comparison to patients "at risk" were older (57.4 ± 12.8 vs 43.3 ± 13.3, $p<0.05$) and presented significantly lower body fat (25.8 ± 7.0 vs 31.3 ± 8.8, $p<0.05$), FFMI (14.8 ± 1.1 vs 17.9 ± 2.6, $p<0.00$), s-albumin (26.0 ± 4.1 vs 39.4 ± 4.0, $p<0.05$) and higher CRP serum level (12.1 ± 3.2 vs 4.4 ± 13.4, $p<0.05$) (see Table 1).

The risk of malnutrition was positively associated with low content of adipose tissue (R=–0.24; p=0.00), low BMI (R=–0.22; p=0.00), and higher weight loss in the last 6 months (R=0.47; p=0.00). However, a statistically significant correlation was observed between the malnutrition diagnosis and s-albumin (R=–0.2; $p<0.05$) and CRP (R=0.23; $p<0.05$).

DISCUSSION

The aim of the study was to estimate the prevalence of risk for malnutrition and malnutrition among MS patients treated on neurology wards assessed with the NRS 2002, routine screening method in hospital patients (Burgos et al., 2008). It was evaluated in comparison to the GLIM criteria, the newest and recommended by the ES-PEN tool for nutritional status assessment, as well as in comparison to BMI (Håkonsen et al., 2015; Cederholm et al., 2020). To our knowledge, there are no other studies that used GLIM criteria in a group of patients with multiple sclerosis.

Our data show that the risk of malnutrition is a significant problem among MS patients. The prevalence of deterioration of nutritional status reached 85.5%, indicating that a considerable number of patients were in need of appropriate nutritional advice.

It is worth emphasizing that regardless of the BMI, there may be observed unfavorable changes in body composition and nutritional status such as UBWL or decreased albumin level in this group of patients. A high BMI should not delay nutritional interventions because, in the early stages, the interventions are much more effective (Atuk Kahraman et al., 2021; Synnot et al., 2016).

In our study, malnutrition was associated with elevated CRP. Some authors (Palavra et al., 2016; Taheri et al., 2017) reported an increase in inflammatory markers in MS patients. For example, interleukin (IL-6) plays a significant role in the development of malnutrition through the catabolism of muscle proteins and the anorectic effect of cytokines (increased leptin production and lipolysis). An increased level of cytokines is characteristic of hypoalbuminemic patients and is associated with shorter survival

Table 1. Selected parameters in study MS groups. Data are presented as mean ± S.D. or %.

in a different group of chronically ill patients (Yalachkov *et al.*, 2021).

Many authors and ESPEN guidelines postulated that the analysis of body composition should be an essential part of the assessment of nutritional status (Burgos *et al.*, 2018; Hedström *et al.*, 2012). In patients with multiple sclerosis, an analysis of body composition may indicate loss / low muscle mass regardless of excess body weight, suggesting an initial stage of malnutrition. Risk factors for sarcopenia or sarcopenic obesity are metabolic disorders due to chronic diseases, treatment with glucocorticosteroids, and reduced physical activity (Kvistad *et al.*, 2015). The research shows that people diagnosed with multiple sclerosis lead a sedentary lifestyle and usually do not engage in physical activity (Cavanaugh *et al.*, 2011; Goldman *et al.*, 2008). Other authors point to poor dietary habits (Bromley *et al.*, 2019).

Additionally, many patients with MS already seek complementary and alternative treatments or diets for their condition. Unfortunately, the Internet remains the central source of information for most patients, frequently leading to choices and behaviors lacking any scientific support. A scientific analysis of different dietary patterns or other gut-oriented interventions is necessary (Synnot *et al.*, 2016; Bromley *et al.*, 2019).

Therefore, in patients with MS diagnosis, the weight loss process in the case of obesity should be controlled by an experienced dietitian in order to maintain muscle mass.

The limitation of our study is the relatively low number of patients. Further studies in patients with MS (e.g., multicenter) are needed to confirm our results.

CONCLUSIONS AND CLINICAL IMPLICATION

Overweight and obesity concerned a large proportion of the studied group of patients with multiple sclerosis, not excluding the risk of malnutrition confirmed by methods such as NRS 2002 and GLIM. This risk may increase or may develop malnutrition as the disease progresses. Therefore, regular nutritional assessment and dietary consultation should be part of the care. In addition to screening methods, an assessment of nutritional status should include body composition and diet estimation to prevent nutritional problems.

Mutational analysis of *FOLR1* and *FOLR2* genes in children with Myelomeningocele

Box 2455, Riyadh 11451, Saudi Arabia

Myelomeningocele (MMC) is a congenital disease. For a long time, molecular mechanism of MMC, the role of folate receptor and transporter proteins remain unclear. Folate from maternal lumen to developing embryo is carried out with the help of folate transporters (SLC46A1, SLC19A1, FOLH1 and SLC25A32) and folate receptor (FOLR1, FOLR2 and FOLR3). Due to the loss of function of these important genes, complications can facilitate the risk of MMC. This study focused on the mutational analysis of *FOLR1* and *FOLR2* genes in children suffering from MMC. Myelomeningocele is a rare disorder so twenty blood samples from the children were collected. Primers of selected exons for *FOLR1* and *FOLR2* genes were designed with the help of PrimerFox software. Extracted DNA was amplified, and PCR based mutational analysis was done to check any type of mutation/SNPs in these genes. Sanger sequencing method was performed to confirm mutation in *FOLR1* and *FOLR2* genes. The results showed that certain environmental factors (smoking, low socio-economic status of mother bearing MMC fetus) were found to be significantly ($P<0.05$) associated with MMC but no mutation in the selected exons of *FOLR1* and *FOLR2* genes was detected. Thus, genetic variations in the folate transporter gene may have no role in the progression of MMC in the studied population.

Keywords: FOLR1, FOLR2, Congenital, Myelomeningocele, phenotype, mutation

INTRODUCTION

One of the most important and congenital forms of spina bifida is Myelomeningocele (MMC). In this disease, two sides of backbone become unable to fuse with one another and forms a gap between them (Hassan *et al.*, 2022). This usually happens after about 2–4 weeks of gestation. Due to the failure of fusion of both backbone side nerves, spinal cord and meninges remain uncovered. This can lead to the partial or complete paralysis of the body. Partial paralysis happens in the lower portion of the body from the point of opening (Moldenhauer & Adzick, 2017). The evidence of this disease in first-degree relatives and second-degree relatives is about 3–4% and 1–2%, respectively (Farmer *et al.*, 2018). Genomic and environmental factors are responsible for this situation. Folic acid plays a vital role in the organ development of fetus in placenta (O'Byrne *et al.*, 2010). Genes involved in folate transport play an important contribution in the development of MMC. Other environmental factors such as deficiency of vitamins, certain medications, tobacco usage, drug addiction, maternal infections, maternal hyperthermia and exposure to some metals play vital role in tube defects in developing fetus (Naveed *et al.*, 2023; Muhammad *et al.*, 2023; Naveed *et al.*, 2022; Tauheed *et al.*, 2017).

Studies on animal models illustrate involvement of about 200 genes in tube defects (Cavalheiro *et al.*, 2021). It is proposed that certain genes and their variants make an interaction with each other and, being affected by environmental factors, cause MMC (Mazumdar *et al.*, 2015). Certain studies highlighted certain mutations and/or SNPs i.e. rs223622 and rs180113 in the MTHFR gene, MTHFDM1 gene, rs13908 in FOLR2 and rs792687, rs792554 and rs792698 in FOLR3 gene (Ntimbani *et al.*, 2020). These mutations have been reported in different ethnic groups, such as Dutch, Italian, and British population. The role of folate transporter genes has already been documented worldwide (Wolujewicz *et al.*, 2021). Unfortunately, little work has been done on this among the Pakistani population so far. The main objective of this study is to check the role of environmental factors and to perform the mutational analysis of *FOLR1* and *FOLR2* genes with reference to Myelomeningocele.

METHODOLOGY

All the patients in this study had less than 2 years of age. Before the procedure, informed consent of the parents was taken. The skin of the patients was sterilized with alcohol swabs. About 2 to 3cc blood of MMC patients was collected with the help of sterilized syringes and stored in refrigerator at 4°C in an EDTA vacutainer. The sample of mothers of MMC patients was also collected when it was possible. DNA extraction was done by using the standard method (Albertsen *et al.*, 2015). Forward and reverse primers were prepared for exons 3–4 and 5 for *FOLR1* gene, and exons 3–4, 5 of *FOLR2* gene. Primers were designed by using PrimerFox Software (Table 1).

Table 1. Forward and reverse primers for exons 3–4 and 5 of *FOLR1* and *FOLR2* genes

Primers	Sequence (5'-3')	Tm (^{o}C)	Length (nt)
FOLR2 exon 5 forward	TCCTGGATGGCCCTTATG	57	19
FOLR2 exon 5 reverse	GCAACAGATGGGTGACAGA	59	20

No	13.0 (65%)	15.0 (75%)		
Age of Mother (Years)				
Under 30	14.0 (70%)	17.0 (85%)	0.411 (0.086–1.95)	0.263
Above 30	6.0 (30%)	3.0 (15%)		
Family income				
Poor	12.0 (60%)	4.0 (20%)	6 (1.45–24.6)	0.013
Middle + affluent	8.0 (40%)	16.0 (80%)		

The standard PCR procedure was followed for the amplification of *FOLR1* and *FOLR2* genes (Lorenz, 2012). The denaturation temperature was 95°C for both *FOLR1* and *FOLR2* genes and it was done for 4 minutes. The annealing temperature for *FOLR1* gene was 58°C for 45 seconds and 51–59°C for *FOLR2* gene and it was done for about 45 seconds. Elongation temperature was 72°C and it was done for one minute and finally for 4 minutes. To get the appropriate amount of PCR product, 35 cycles of PCR were run. Holding temperature of the PCR vials was 4°C. Afterward, the PCR product was loaded on agarose gel and visualized with the help of UV light. To rule out mutation sequencing of the amplified products Sanger Sequencing method was done. Statistical analysis was done with the use of GraphPad Prism software v13.

RESULTS

Current study includes 20 MMC patients. Most of the patients lie within the age group of (1–2 years). Patients usually belong to Northern and Southern Punjab and most of the mothers were malnutritional due to poverty as shown in Fig. 1. The statistical analysis was done to check the association of different environmental factors (Smoking, weight/age of the mother, Folic acid intake, history of abortion and family socio-economic status) with MMC. Smoking and poor socio-economic status of

	1 year or more	less than one year	Southern Punjab	Northern+Southern Punjab	Middle/Affulent	Poor

Figure 7. Amplified DNA Band of exon 5 of *FOLR2* gene in patients

the mother was found to be significantly associated with MMC as the *P*-value is less than 0.05 (Table 2).

If we look at the clinical symptoms, 70% (n=14) of the patients were hydrocephalus. The position of Myelomeningocele varies among patients, 35% (n=7) had in cervical region, 60% (n=12) covered lumbar region while 5% (n=1) showed in both cervical and lumbar regions (Table 3).

Primer was designed for exon 5 of *FOLR1* gene. After performing PCR, PCR product was visualized on 1.5% agarose gel. There was a clear bright band on 494bp location which indicates no mutation in it (Fig. 2). Fur-

ther, sequencing was done, and the chromatogram also showed no mutations (Fig. 3).

Exons 3-4 of *FOLR1* gene primers were also designed and the band of interest was of 679bp. This clearly indicates no mutation in these exons as well (Fig. 4). This was also confirmed by the chromatogram of these exons in *FOLR1* gene (Fig. 5).

Figure 8. Chromatogram showing exons 3–4 sequences of *FOLR2* gene.

Figure 9. Chromatogram showing exon 5 sequences of *FOLR2* gene.

FOLR2 is another important gene involved in MMC. So, primers were designed for exons 3–4, 5 and PCR was performed. The PCR product for exons 3–4 showed a clear band of 686bp (Fig. 6) and exon 5 of 760 bp (Fig. 7) which indicates that there is no mutation in these exons as well and it was confirmed by sequencing (Figs 8 and 9).

DISCUSSION

Myelomeningocele is an important congenital disorder. It usually occurs after the 2–4 weeks of pregnancy. Folic acid deficiency can lead towards the exaggeration of MMC disease. Folate is needed for fetal organ development (Mazumdar *et al.,* 2015). Its demand increases significantly during pregnancy and is found to be significantly associated with MMC. Due to pediatric neuro-degeneration resulting from neural folate deficiency, the role of FR can significantly inhibit folate uptake in the CSF (Canfield *et al.,* 2009). In the present study, various environmental factors like folic acid intake, body weight and age of mother, and history of abortion were found to be insignificantly associated with MMC ($P>0.05$). However smoking habit in mother in the form of huk-kah, cigarettes, sheesha and burning of fossil fuels was found to be significantly associated with MMC. Similarly, a poor family socio-economic status was found to be significantly associated with MMC ($P<0.05$). (Nageen *et al.,* 2023; Hussain *et al.,* 2023).

Defects in folic acid receptor or transport protein can lead towards the MMC disorder. Many studies have been done for the mutational analysis of *FOLR1* and *FOLR2* genes but only a few studies have reported some mutations in these genes. Studies done in 2014 and 2020 indicated some novel mutations in these genes. (Tenpenny *et al.,* 2014; Steele *et al.,* 2020). In 2017, a study was done in the United States of America and it showed the down regulation of *FOLR1* gene in MMC patients (Findley *et al.,* 2017). In 2020, a study confirmed twelve new mutations in Folate receptor genes (Hillman *et al.,* 2020). This

Figure 10. FOLR2 protein structure in MMC patients (n=20)

proved the direct link of FOLR1 protein in the disease. Just like Boyles *et al.,* the present study also showed no mutation in *FOLR1* and *FOLR2* genes (Boyles *et al.,* 2006).

In 2022, another study showed the low level of FOLR1 protein (known as glycosyl-phosphatidylinositol-anchored plasma membrane protein) in MMC patients as compared to healthy people. *FOLR2* gene is present on chromosome 11 and belongs to the folate receptor family, producing folate receptor beta protein. FRβ, is a member of this family of reduced folate (Han *et al.,* 2022). In the present study, MMC patients showed no alteration in the cluster of Folate receptor protein FOLR2 (Fig. 10).

CONCLUSION

This study showed no mutation in *FOLR1* gene exons 3–4 and 5, and *FOLR2* gene exons 3-4 and 5. This study emphasises the significance of maternal health and dietary consumption in determining the trajectory of these receptor genes, especially FOLR1 and FOLR2, given the critical role of folate in satisfying the developmental demands of a growing fetus. The results of this study indicate that genetic variations in the folate receptor genes may not significantly contribute to the development of MMC (Myelomeningocele), but environmental factors are more important in this situation. The limitation of this study includes small sample size, as it is a rare disease. Furthermore, this study lacks ultrasound report of the infants or toddlers, maternal folic acid levels and other blood profile data during and before conceiving.

Selected osteointegration markers in different timeframes after dental implantation: findings and prognostic value

Emir Bayandurov[1], Zurab Orjonikidze[1], Sophio Kraveishvili[1], Ramaz Orjonikidze[1], George Ormotsadze[2], Sophio Kalmakhelidze[2]* and Tamar Sanikidze[2]

[2]Department of Physics, Biophysics, Biomechanics and Informational Technologies, Tbilisi State Medical University, Tbilisi, Georgia

The study aimed to determine the osteointegration markers after dental implantation and evaluate their predictive value. The study was performed on 60 practically healthy persons who needed teeth rehabilitation using dental implants. The conical-shaped implants (CI) and hexagonal implants (HI) were used. The content of Osteopontin (OPN), Osteocalcin (OC), Alkaline Phosphatase (ALP), Osteoprotegerin (OPG), and nitric oxide (NO) was determined in patients' gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF), collected 1, 3, and 6 months after implantation. During the 3–6 months of observation level of OPN increased in patients with CIs (<50 years > 50 years) and HIs (<50 years) (CI: <50 years F = 36.457, $p < 0.001$; >50 years F = 30.104, $p < 0.001$; HI < 50 years F = 2.246, $p < 0.001$), ALP increased in patients with CIs (<50 years: F = 19.58, $p < 0.001$; >50 years: F = 12.01; $p = 0.001$) and HIs (<50 years) (F = 18.51, $p < 0.001$), OC increased in patients <50 years (CI: F = 33.72, $p < 0.001$; HI: F = 55.57, $p < 0.001$), but in patients >50 years - on the 3 days month (CI: F = 18.82, $p < 0.001$; HI: F = 26.26, $p < 0.001$), but sharply decreased at the end of sixth month. OPG increased during 1–3 months of the observation in patients <50 years (CI: F = 4.63, $p = 0.037$; HI: F = 2.8927, $p = 0.046$), but at the end of the sixth month returned to the initial level; NO content in PISF increased in patients with CI (>50 years) during 1–6 months of the observation (F = 27.657, $p < 0.001$). During the post-implantation period, age-related differences in osteointegration were observed. Patients <50 years old had relatively high levels of OPN, ALP, OC, and OPG in PISF, resulting in less alveolar bone destruction around dental implants and more intensive osteointegration. These indicators may be used as biological markers for monitoring implant healing. The process of osseointegration was more intense in CIs due to their comparatively high mechanical loading.

KEYWORDS

osteopontin, osteocalcin, bone alkaline phosphatase, osteoprotegerin, nitric oxide

Introduction

Aesthetic and functional rehabilitation using dental implants offers highly predictable and esthetical results; hence it has become one of the alternatives to be included in the therapeutic options for the treatment of totally or partially edentulous patients. Despite this, the risk of failure remains high but difficult to predict (Scarano et al., 2023).

The implant's stability significantly depends on the osteointegration process between the bone and the implant. Osteointegration is a continuous process of osteoclast and osteoblast activation, necessary for bone repair, formation, and functional recovery (Martin and Sims, 2005).

Bone remodeling is critical to maintaining long-term stable osseointegration. The mechanisms of wound healing around dental implants are characterized by several features. The cellular and molecular mechanisms of the osseointegration process have not yet been fully established and require further research in this direction (Matsuura and Yamashita, 2018).

Early monitoring of sensitive clinical-laboratory indicators of patients with dental implants, correlated with pathological disorders in the osteointegration process in the early stages of the implantation, can be used to identify predictive markers of possible complications and their severity at its later stages. This can be useful for providing guides to treatment strategies and preventing complications, maintaining long-term stable osseointegration.

Since the array of clinical indices of periodontal origin, such as indices recording gingival inflammation, plaque accumulation, and bleeding and probing depths (clinical index) most frequently gives the possibility only determining the soft tissue inflammatory response, rather than detecting its early predictors (Greenstein, 1996), for the determination of peri-implant clinical status, various oral fluids are used, the molecules of which are associated with the inflammatory response, bone metabolism, and proteinases.

The gingival crevicular fluid is the osmotically mediated physiological exudate originating from serum and tissue fluid that seeps through the crevicular and junctional epithelium. Gingival crevicular fluid plays a special part in maintaining the structure of junctional epithelium and the antimicrobial defense of periodontium, reflects the cellular response in the periodontium by the constituents from the gingival crevice, and is an important determinant of the status of periodontal tissues (Akman et al., 2018). The peri-implant sulcus is, anatomically, functionally, and environmentally quite similar to periodontal crevices (Berglundh et al., 1991; Piattelli et al., 1996; Buser et al., 1997); this fluid was termed the peri-implant sulcular fluid. Peri-implant sulcular fluid like gingival crevicular fluid is composed of serum and locally generated materials such as tissue breakdown products, inflammatory mediators (cytokines, prostaglandins), tissue degradation components, mineralized tissue components, bone turnover markers, and antibodies directed against dental

plaque bacteria (Akman et al., 2018; Subbarao et al., 2019). Peri-implant sulcular fluid analysis can potentially reflect the actual status of peri-implant soft and hard tissues (Lang and Berglundh, 2011). GCF and PISF could be useful markers of early inflammation in gingival and peri-implant tissues (Shama et al., 2016).

The study aimed to determine the osteointegration markers in different timeframes after dental implantation and their prognostic value.

Materials and methods

The study was performed on 60 persons (aged from 18 to 65 years) who performed teeth rehabilitation using dental implants based on Dental Clinic and Training-Research Center UniDent and Dental Clinic A1 during 2020–2022 years.

Patient inclusion criteria in the study

Practically healthy male persons (without comorbidities) (60 patients) who needed rehabilitation using dental implants in the chewing teeth in the mandible, with good hygiene of the oral cavity (Board index <20%) (Ainamo and Bay, 1975) were included in the study.

Patients excluding criteria in the study

Females were excluded from the study to avoid the possible influence of pre-menopause/menopause-related hormonal imbalances on the process of osseointegration. Patients with various accompanying diseases (allergy, cancer, hepatitis, diabetes, endocrine system disorders, stomach ulcer, chronic gastritis, colitis, respiratory diseases, and pregnant women), also were patients who, during the last 6 months before implantation, used medications that can change the osseointegration (including anti-inflammatory drugs) were excluded from the study.

The research plan was approved by the Ethics Committee of Tbilisi State Medical University. All subjects signed informed consent.

The conical-shaped implants (CIs) (<50 years—10 patients, >50 years—20 patients) and hexagonal implants (HIs) (<50 years—15 patients, >50 years—15 patients) from the AlphaBio were used.

The selected age range (18–65 years) lowered chronic comorbidity risk. The age limit of 50 years was chosen to equally distribute patients between groups while considering the mean number of patients of different ages. This distribution of the patients will give the possibility to assess the dynamic intensity of osteointegration processes with aging.

The GSF and PSF were collected from patients 1, 3, and 6 months after implantation, and the content of Osteopontin (OPN), Osteocalcin (OC), bone Alkaline Phosphatase (ALP), Osteoprotegerin (OPG), and nitric oxide (NO) was determined.

Collection of gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF)

PISF and GCF were obtained by the method considering minimal mechanical irritation (Rudin et al., 1970). The area to be sampled was treated with sterile cotton swabs to remove dental plaque and then air-dried to prevent plaque and saliva contamination. To obtain a sample PISF strips of standardized paper (Periopaper, no. 593525) were placed at the entrance of the grooves of the implant and healthy teeth and inserted to a standardized depth of 1 mm at each site regardless of probing depth to avoid further mechanical irritation. To obtain a sample GCF strips of standardized paper (Periopaper, no. 593525) were placed at the entrance of the grooves between the healthy teeth and inserted to a standardized depth of 1 mm at each site egardless of probing depth to avoid further mechanical irritation. The sampling time is standardized and equal to 30 s. Samples contaminated with blood were not used.

For safe storage of PISF and GCF samples, the paper strips will be placed in sterile Eppendorf and stored at −80°C until laboratory analysis.

Analysis

After the paper strips in Eppendorf tubes were kept at room temperature for at least 30 min, 100 μL assay buffer included in the kit was added to each Eppendorf tube and put into the shaker device for 45 min. Then the tubes were centrifuged at 11,200 rpm for 15 min. After the GCF/PISF in the paper strips were transferred to the assay buffer, the assay buffer in the Eppendorf was taken using a clean polypropylene pipette, and the levels of OPN, OC, bone ALP, and OPG were measured according to the manufacturer's instructions.

The bone markers in PISF and GCF samples were determined by immuno-enzymatic method (ELISA) using HumaReader SETPROD immune-enzymatic counter. OPG was determined by use of EH0247 Human OPG ELISA Kit OC—EH3468 Human OC/BGP ELISA Kit, OPN—EH0248 Human OPN ELISA Kit, bone ALP—BIOLABO Kit.

For the determination of NO content in PISF and GCF, distilled water (130 μL per sample) was added to the Eppendorfs containing PISF and GCF, and the Eppendorfs were shaken vigorously to dissolve the nitrite in the water. To the 100 μL of the obtained extract, 0.5 mL of freshly prepared Greiss reagent was added; after a 10-minute incubation at room temperature, the

TABLE 1 Statistical significance of OC, OPG, OPN, ALP, and NO in the gingival crevicular fluid alterations after the 6 months after implantation (analysis of variance (ANOVA) F, between-group variability/within-group variability; p, level of significance of Null Hypothesis).

VAR	AGE <50		Age $\geq$ 50	
	F	p	F	p
OC	0.059	0.942	0.366	0.698
OPG	0.022	0.977	0.027	0.972
OPN	0.154	0.858	0.036	0.964
ALP	0.010	0.989	0.130	0.878
NO	0.884	0.438	0.134	0.875

absorbance intensity of each sample placed on the microplate was measured at a wavelength of 540 nm (Grisham et al., 1996). A standard curve was prepared using sodium nitrite to calculate the nitrite (NO_x) concentration in the GSF and PISF.

Statistical analysis

Statistical significance was tested using analysis of variance ANOVA and a two-sample t-test. Relationships yielding p-values less than 0.05 were considered significant. All values were expressed as the mean ± SE.

Results

As follows from the data presented in Table 1 the content of OPN, OC, bone ALP, OPG, and NO in the gingival crevicular fluid did not change statistically significantly during the entire observation period.

Figures 1–5 show alterations of OPN, OC, bone ALP, and OPG, and NO content in the patients' GSF and PISF after 1, 3, and 6 months after implantation.

Figure 1 shows that after the implantation the level of OPN in patients' peri-implant sulcular fluid (PISF) increased in comparison to its level in gingival crevicular fluid (GSF). In the case of the CIs in both age groups the content of OPN in PISF increased during the entire observation period (1–6 months) and reached a maximum by the end of 6 months of observation (<50 years—F = 36.457; p < 0.001; >50 years—F = 30.104; p < 0.001), but in case of HIs, an increase in the OPN content was recorded during the observation period only in patients of the age group <50 years (F = 22.246; p < 0.001); in age group >50 years, an increase in the level of OPN in PISF was not statistically significant.

Figure 2 shows that during the first month after implantation, the content of ALP in peri-implant sulcular fluid (PISF) did not

FIGURE 1
The levels of OPN in the gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF) of patients of different age groups during the post-implantation period (after 1, 3, and 6 months), in cases of conical-shaped implants (CIs) and hexagonal implants (HIs).

FIGURE 2
The levels of ALP in the gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF) of patients of different age groups during the post-implantation period (after 1, 3, and 6 months), in cases of conical-shaped implants (CIs) and hexagonal implants (HIs).

change significantly in comparison to its level in gingival crevicular fluid (GSF) (CI: <50 years—F = 1.15; p = 0.297; >50 years—F = 1.35; p = 0.258; HI: <50 years—F = 2.43; p = 0.135; >50 years—F = 2.99; p = 0.099) and increased in both age groups at 3 months after the implantation. In patients with CIs, this tendency continued for 3–6 months and was statistically

FIGURE 3
The levels of OC in the gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF) of patients of different age groups during the post-implantation period (after 1, 3, and 6 months), in cases of conical-shaped implants (CIs) and hexagonal implants (HIs).

FIGURE 4
The levels of OPG in the gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF) of patients of different age groups during the post-implantation period (after 1, 3, and 6 months), in cases of conical-shaped implants (CIs) and hexagonal implants (HIs).

FIGURE 5
The levels of nitrite (NO$_x$) concentration in the gingival crevicular fluid (GCF) and peri-implant sulcular fluid (PISF) of patients of different age groups during the post-implantation period (after 1, 3, and 6 months), in cases of conical-shaped implants (CIs) and hexagonal implants (HIs).

significant in both age groups (<50 years—F = 19.58; p < 0.001; >50 years—F = 12.01; p = 0.001). In patients with HIs during the 3–6-month period in the age group <50 years the ALP content in PISF increased significantly (F = 18.51; p < 0.001), but in patients older than 50 years the statistical significance of the difference was not high (F = 1.30; p = 0.233).

As follows from Figure 3, 1 month after implantation OC levels in peri-implant sulcular fluid (PISF) did not differ from the corresponding values in gingival crevicular fluid (GCF) (conical: F = 2.065; p = 0.164; hexagonal: F = 1.107; p = 0.304); its content began to increase only 3–6 months after the implantation. In patients under the age of 50 years the level of OC in PISF was high during the 3–6 months of the observation period (CI: F = 33.72; p < 0.001; HI: F = 55.57; p < 0.001), whereas in patients of the age group after 50 years, the level of OC in PISF increased up to the 3 months of observation (conical: F = 18.82; p < 0.001; hexagonal: F = 26.26; p < 0.001), and sharply decreased by the end of 6 months (CI: F = 1.10; p = 0.261; HI: F = 1.71; p = 0.204).

As follows from Figure 4, during the first 3 months of observation (1–3 months) OPG in peri-implant sulcular fluid (PISF) in patients of the age group <50 years increased (CI: F = 4.63; p = 0.037; HI: F = 2.8927; p = 0.046) compared to its level in gingival crevicular fluid (GCF), but by the end of the sixth month it was returned to the initial level (CI: F = 1.03; p = 0.29; HI: F = 1.07; p = 0.31). In patients of the age group >50, the level of OPG in PISF did not change statistically significantly compared to its

level in GCF during the entire follow-up period (CI: F = 1.23; p = 0.246; HI: F = 1.03; p = 0.301).

As follows from Figure 5, in patients of the age group <50 years, the mean values of the nitrite (NO$_x$) concentration in peri-implant sulcular fluid (PISF) did not changed during whole observation period compared with the corresponding values in gingival crevicular fluid (GCF) only at the end (6-th months) after implantation (CI: F = 1.615; p = 0.2443; HI: F = 1.524; p = 0.263). In patients of the age group >50 years with a CIs, the NO$_x$ concentration in PISF increased statistically significantly compared to the corresponding values in GCF during the whole period (1–6 months) of the observation (F = 27.657; p < 0.001), while in the case of a HIs, did not statistically significantly change compared to the corresponding values in GCF (F = 0.596; p = 0.448).

Discussion

The success of the osteogenic process requires careful chronological coordination of molecular signals to drive the proliferation, migration, and differentiation of mesenchymal precursor cells in osteoblasts (Zaidi, 2007). In the last decades, periodontal research has focused on the analysis of potential host markers that can be used to diagnose the healing intensity of implants and determine prognosis (Arikan et al., 2008).

Bone is in a constant state of remodeling, which is important for the maintenance of its normal structure and function. Many types of cells and factors are involved in the process of bone remodeling.

Osteoblasts, responsible for new bone formation, and osteoclasts responsible for bone resorption, are the two main cell types participating in those processes (Matsuoka et al., 2014; Chen et al., 2018). These processes are stable and balanced under physiological conditions; However, bone architecture or function will be disturbed when the balance is disordered.

The process of osseointegration begins after the placement of the dental implant in the jaw bone; the implant integrates with the living bone by healing the bone wound. OPN and OC are major non-collagenous proteins involved in bone matrix organization and deposition. They are produced during bone formation, later in the mineralization process, and involved in organizing the extracellular matrix and coordinating cell-matrix, mineral–matrix interactions, which play key roles in the biological and mechanical functions of bone, regulate whole-bone structure and morphology (Bailey et al., 2017).

At first, OPN is secreted on the hard surface of the bone. This extracellular matrix protein is a major factor affecting osteoclast attachment, wound healing, and angiogenesis, plays an important role in bone mineralization, cell adhesion, differentiation, and foreign body response, since it has several binding sites with implant hydroxyapatite crystals, collagen, and various integrins, through the calcium ions and Arg-Gly-Asp motif (Makishi et al., 2022).

Secretion of OPN at the resorption site during bone remodeling regulates migration, adhesion, differentiation, and activation of osteoclasts to form a bone matrix, also, migration, adhesion, and differentiation of osteoblasts. OPN positively affects osteoblasts in direct osteogenesis after implantation (Dodds et al., 1995; McKee and Nanci, 1995).

As follows from the results of our study level of OPN in patients' PISF increased in comparison to its level in GSF from the early stages after the implantation. In the case of CIs, the content of OPN in PISF was higher compared to the corresponding values in GCF during the entire observation period (1–6 months) and reached a maximum by the end of sixth month at both age groups, but in the case of HIs, an increase in the OPN content in PISF from the beginning to the end of the observation (sixth month), was recorded only in patients of the age group <50 years, in age group >50 years, an increase in the level of OPN in PISF was not statistically significant.

During bone mineralization, osteoblasts secrete a specific membrane-bound glycoprotein, ALP, that catalyzes the hydrolysis of phosphate monoesters and supports a high concentration of phosphate on the surface of osteoblasts (Sharma et al., 2014). Elevated levels of ALP in sulcular fluid are observed as a compensatory mechanism in response to destructive disease processes and indicate active bone formation (Malik et al., 2015).

According to our study results, OC and ALP content increase in PISF began 3 months after implantation. In patients with CIs, ALP remains this statistically significant tendency for 3–6 months in both age groups, however, in patients with HIs in patients older than 50 years the statistical significance of this growth was not high. Regarding OC, under the age of 50 years in patients with conical-shaped and hexagonal implants, the level of OC in PISF was high during 3–6 months after implantation, whereas in patients of the age group after 50 years, the level of OC in PISF increased on to the 3 months of observation, and sharply decreased at the end of 6 months. In literature, age-related decline of OC has been established (Vanderschueren et al., 1990). A weak correlation between the bone markers ALP and OC levels, and the dental implant stability quotient (ISQ) over the healing period was revealed, which is in harmony with the intensification of a gene expression of bone markers in PICF (Tirachaimongkol et al., 2016) and indicates that these biological markers may be used for monitoring of implant healing.

These data indicate that when using CIs, the process of osseointegration proceeds intensively in both age groups, while when using HIs, the intensity of this process in elderly patients decreases. This is due to the comparatively higher mechanical loading produced by the CIs (Bayandurov et al., 2023), as well as age-related characteristics of osteogenesis—in yang (<50 years) patients content of the OPG, ALP, and OC in PISF was especially high.

Osteointegration success is determined by the incorporation of the woven bone and the bone mass adaptation to bearing a load (Parithimarkalaignan and Padmanabhan, 2013). Disruption of the balance of factors regulating host response can induce impairment osteointegration process and bone remodeling, stimulation of osteoclasts activity with consequent alveolar bone resorption, and implant loss (Giannopoulou et al., 2012).

Osteoclastogenesis is coordinated by the interaction of three members of the tumor necrosis factor (TNF) superfamily: receptor activator of nuclear factor-kB (NF-kB) ligand (RANKL), RANK, and OPG. The RANK, RANKL, and OPG, known together as the RANK-RANKL-OPG system, effectively control the balance between osteoblasts and osteoclasts activity. RANKL is expressed by osteoblasts, stromal cells, fibroblasts, B cells, and T cells when stimulated by cytokines and bacterial lipopolysaccharides. The binding of RANK and RANKL on the surface of preosteoclast/osteoblast cells, activates the formation, maturation, and activation of osteoclasts, resulting in bone destruction. Conversely, OPG, produced by periodontal ligament cells, gingival fibroblasts, and epithelial cells, is a soluble circulating decoy receptor of RANK, blocks the activation of RANK by preferentially binding itself to RANKL, and thus protects bone against destruction. Therefore, RANKL and OPG regulate bone resorption by positive or negative stimulation of RANK on osteoclast cells (Giannopoulou et al., 2012). OPG is involved in the regulation of alveolar bone

destruction around dental implants through the regulation of osteoclast differentiation.

As follows from the results of our study, in patients of the age group <50 years OPG in PISF during the first 3 months of observation (1–3 months) increased compared to its level in GCF, but by the end of the sixth month returned to the initial level. In patients of the age group >50, the level of OPG in PISF did not statistically significantly change compared to its level in GCF during the entire follow-up period. Consequently, in the early stages of osteointegration in young patients, OPG protects alveolar bone destruction around dental implants and promotes osteointegration, while in older patients the effectiveness of this mechanism decreases.

In the regulation of inflammation in soft tissues around the implant, immunomodulation, antimicrobial defense, as well as anabolic reactions, and bone resorption process important role plays NO, a small-sized, highly reactive molecule, that is a secondary messenger in a living organism. During implantation, it is possible an increase in NO production as a result of the intensification of iNOS activity induced by proinflammatory cytokines, or a decrease in NO content related to its conversion into peroxynitrite in inflammation-induced oxidative stress conditions (Allaker et al., 2001). Mechanical stimulus, one of the factors involved in the bone remodeling process around implants, mediates osteoclast activity and also stimulates NO production (Baloul, 2016; Gokmenoglu et al., 2018). Therefore, NO metabolism is associated with the clinical state of peri-implant tissues, NO seems to have a biphasic effect on osteoblastic activity. *In vitro*, studies have shown that a small amount of NO constitutively produced by osteoblasts, or slowly released by donors, can act as a stimulator of osteoblast growth and differentiation, while high NO concentration has a potent inhibitory effect on osteoblastic growth and differentiation, and/or stimulates bone resorption, that may be partly due to its pro-apoptotic effect. In inflamed peri-implant tissues, the NO level was found to be higher than in healthy sites (Nascimento et al., 2020).

Our study results show that in patients with CIs and HIs of the age group <50 years, the mean values of NO_x concentration in PISF statistically insignificantly increased compared with the corresponding values in GCF on the sixth month of the implantation. In patients of the age group >50 years CIs induced a statistically significant increase of NO_x concentration in PISF, while in the case of HIs, it did not change statistically significantly compared to the corresponding values in GCF during the entire observation period.

It can be assumed that in patients <50 years there is a slight increase in NO_x concentration in PISF stimulates osteoblast growth and differentiation, and therefore, the osteointegration process, whereas the statistically significant increase of NO_x

concentration in PISF in >50 years old patients in the case of a CIs, may be related with the inflammatory reaction (which needs correction) or other factors (oxidative stress, mechanical stimulus, etc.) (Orjonikidze et al., 2020).

Conclusion

During the post-implantation period, the process of osteointegration is affected by age-related factors. Patients <50 years have higher levels of OPN, ALP, OC, and OPG, which result in lesser alveolar bone destruction around dental implants and a more intensive osteointegration process. Biological markers such as OPN, OC, ALP, PNG, and NO content in PISF can be used to monitor implant healing. The use of CIs leads to a more intensive process of osseointegration due to the higher mechanical loading produced by them.

Data availability statement

The raw data supporting the conclusion of this article will be made available by the authors, without undue reservation.

Ethics statement

The studies involving humans were approved by Tbilisi State medical University Ethics committee. The studies were conducted in accordance with the local legislation and institutional requirements. The participants provided their written informed consent to participate in this study.

DMED is a common complication of diabetes, for which new treatment methods are urgently required. Focused on DMED, the pharmacological mechanism of simvastatin (Sim) was probed. A model of DMED was made in rats with streptozotocin and orally medicated with Sim. Lentiviral vectors that interfere with miR-9-5p or PDCD4 were injected, and the erectile function, histopathology of cavernous tissue, and α-SMA expression were evaluated. Cavernous smooth muscle cells (CMSCs) obtained from DMED rats were treated with Sim and transfected with the plasmid vector that interferes with miR-9-5p or PDCD4 to observe cell viability and apoptosis. The binding relationship between miR-9-5p and PDCD4 was checked. After 8-week treatment with Sim, erectile function was improved and the corpus cavernosum injury was alleviated. Upregulating miR-9-5p or downregulating PDCD4 further improved erectile function and cavernous injury in rats. miR-9-5p targeted regulation of PDCD4. *In vitro* cell experiment results showed that Sim induced proliferation and reduced apoptosis of CSMCs by enhancing miR-9-5p-targeted regulating PDCD4 *in vitro*. Sim attenuates DMED in rats *via* miR-9-5p/PDCD4.

INTRODUCTION

Erectile dysfunction (ED) is defined as erection failure during sexual intercourse and is a common complication of diabetes (Che *et al.*, 2020). With lifestyle changes and population ages, the incidence rate of ED is increasing (He *et al.*, 2019). The incidence rate of ED in the normal population is 0.1–18%, while that in diabetic patients is nearly 3 times higher (Seftel, 2005). ED can affect physical, emotional, social, sexual, and interpersonal relationships, for which drug therapy is the main treatment, including PDE5 inhibitors, androgen therapy, and vasoactive drugs (Lau *et al.*, 2007). Compared with other treatments, such as intracavernous injection or intraurethral injection of alprostadil, drug treatment is less invasive (Talib *et al.*, 2021). However, the effect of oral medica-

tion on ED is significantly lower (Martínez-Salamanca*et al.*, 2014). Therefore, there is an urgent need to develop new drugs for the treatment of diabetes mellitus erectile dysfunction (DMED).

Statins are 3-hydroxy-3-methylglutaryl CoA reductase inhibitors, which are widely used to reduce cholesterol levels in patients with lipid metabolism disorders. Simvastatin (Sim) is one of the most widely used lipophilic statins (Aschenbrenner *et al.*, 2021) that has therapeutic value in human diseases, such as fracture healing (Hajializade *et al.*, 2020), tumorigenesis (Kopacz *et al.*, 2020), hydrocephalus (Chen *et al.*, 2017), Parkinson's disease (Carroll *et al.*, 2017). Sim can alleviate DMED by enhancing autophagy (Ding *et al.*, 2020), but other potential mechanisms of Sim action have not been fully studied.

MicroRNA (miRNA) involves in a variety of disease-related signaling pathways after transcription (Rupaimoole *et al.*, 2017). miR-126-engineered MDSCs can reconstruct blood vessels and repair rat cavernous injury, to reduce ED caused by rat cavernous injury (Zou *et al.*, 2021) and miR-205 is involved in the pathogenesis of DMED (Wen *et al.*, 2019). miR-9-5p has been widely studied in tumors, such as liver cancer (Wang *et al.*, 2020), prostate cancer (Wang *et al.*, 2021), and gastric cancer (Ba *et al.*, 2021). However, the role of miR-9-5p in DMED is not yet clear.

Our research aims to explore the potential mechanism of DMED by targeting miR-9-5p/PDCD4 and provide a new treatment for DMED.

MATERIALS AND METHODS

DMED rat model

The animal treatment complied with the "Experimental Animal Care and Guide" and was approved by the Experimental Animal Ethics Committee of Tongji Hospital, Tongji University School of Medicine, ShangHai (NO.T20116A301). Healthy male SD rats, aged 8 weeks old, were standard fed in a non-pathogenic environment, and blood glucose was tested a week later. After 24 h of fasting, 64 rats were injected with streptozotocin (STZ)-citrate buffer at 60 mg/kg, and the other 6 rats were with citric acid buffer. After that, rats were given normal feeding. At 24 h, 72 h, and 1-week post-injection, blood glucose was assessed and >16.67 mmol/L indicated the induction of diabetes. After 8 w of normal feeding, rats were subcutaneously injected with Apomorphine (APO) at 100 μg/kg in the neck and placed in the dark for 30 min during which the number of penis erections was re-

corded. A total of 54 DMED rats (rats without erection) were established, and the success rate was 84.4%.

Animal treatment

After modeling, rats were given oral medication with Sim (dissolved in DMSO and physiological saline, 2 mg/kg) or saline, once a day, for 8 days. Meanwhile, 48 DMED rats were intravenously injected with 7.6×10^7 IFU lentivirus (10 mg/kg), carrying miR-9-5p agomir, agomir NC, miR-9-5p antagomir, antagomir NC, si-PDCD4, si-NC, miR-9-5p agomir + oe-PDCD4, and miR-9-5p agomir + oe-NC, respectively. After the last injection, rats were fed ad libitum for 3 days, and body weight and blood glucose were measured. The rats were euthanized to harvest corpus cavernosum which was preserved in liquid nitrogen.

Construction and injection of lentivirus

Plasmid DNA (12.5 µg) and liposomes (9 µL) were diluted in 250 µL of serum-free RPMI1640 medium (R8758, Gibco, CA, USA), respectively, and mixed to form a plasmid-liposome complex which was then added into 293T cells (ATCC, VA, USA). After that, cells were incubated for 6–8 hours, and the whole culture medium was centrifuged at 716 g for 20 min to obtain lentivirus-enriched supernatant. Next, the supernatant was filtered through a 0.45 µm filter, stored at –80°C, and injected into the tail vein of DMED rats.

Evaluation of erectile function in vivo

Rats were anesthetized by intraperitoneal injection of 2% pentobarbital sodium (3 mg/kg). After the separation of the corpus cavernosum, the prostate was exposed and then the left common carotid artery was separated. Intracavernous pressure (ICP) and mean arterial pressure (MAP) to 50-s electrical stimulation were monitored (20 Hz, 5 V, 0.2 ms). The electrode stimulation interval lasted 15 min.

H&E staining

Penile tissue was routinely made into paraffin slices (about 4 µm) for staining with hematoxylin for 5 min and with eosin for 2 min. Afterward, the slices were dehydrated with ethanol, cleared with xylene, and sealed with neutral glue for microscopic observation.

Immunofluorescence

Sections were dewaxed, dehydrated in gradient ethanol, treated overnight with sodium citrate buffer solution (pH 6.0), permeabilized with 0.5% Triton X-100 and incubated at 5% bovine serum albumin. The slices were then treated with primary antibody α-SMA (1:200, millipore sigma) and the secondary antibody combined with Alexa fluor 488 or Alexa fluor 555 (1:200). Next, counter-staining with 4,6-diamidino-2-phenylindole was performed to capture the images under a fluorescence microscope (Olympus, ix83-fv3000, Tokyo, Japan) followed by quantification using ImageJ (v1.8.0, NIH, MD, USA).

TUNEL staining

Apoptosis in the paraffin section was detected by Apop Tag Plus In situ apoptosis Detection kit (Oncor Inc, Gaithersburg) and analyzed under an optical microscope (Nikon, Japan) (Hirfanoglu et al., 2019).

Cell culture

The euthanized DMED rats were sterilized in 75% alcohol, the penis was dissected along the inferior edge of the pubis, and the glans of the penis were collected. The albuginea vessels and urethra were stripped, and the corpus cavernosum was cut into 0.5–1 mm³ pieces and cultured for 5–7 days in a medium containing 20% fetal bovine serum. After 2-3 passages, cavernous smooth muscle cells (CMSCs) were treated with Sim (2 µM) for 24 h.

Cell transfection

CMSCs were transfected with miR-9-5p mimic, mimic NC, miR-9-5p inhibitor, inhibitor NC, sh-NC, sh-PDCD4, miR-9-5p mimic + pcDNA-PDCD4 and miR-9-5p mimic + pcDNA-NC using Lipofectamine 2000 (11668019, Invitrogen). The above plasmid was constructed by Sangon (Shanghai, China) with pEGFP-4.1N (Invitrogen) as the vector.

Cell viability assay

CMSCs proliferation was assessed at 24, 48, and 72 h using cell counting kit-8 (CK04, Dojindo, Kumamoto, Japan) by evaluating the optical density (OD) at 450 nm on a microplate reader.

Flow cytometry

CMSCs apoptosis was measured by annexin V-FITC apoptosis Kit (Abcam, Cambridge, UK) and detected on a flow cytometer (br168323; Luminex, Austin, TX, USA). Data were analyzed by Kaluza C analysis software (Beckman Coulter, CA, USA).

RNA extraction and analysis

Total RNA was extracted with RNeasy Mini Kit (Qiagen, CA, USA), and cDNA was generated with PrimeScript RT reagent Kit (RR047A, Takara, Japan) or miRNA first-strand cDNA synthesis Kit (Sangon). qPCR was performed using SYBR Premix Ex Taq™ II (Perfect Real Time) kit (DRR081, Takara, Japan) and ABI7500 Real-Time PCR system (ABI, Foster City, USA). Glycer-

GAPDH	F: CGGAGTCAACGGATTTGGTCGTAT
	R: AGCCTTCTCCATGGTGGTGAAGAC

Note: miR-9-5p, microRNA-9-5p; PDCD4, Programmed cell death 4; PCNA, Proliferating cell nuclear antigen; Bax, Bcl-2-associated X; GAPDH, glyceraldehyde 3-phosphate dehydrogenase

aldehyde-3-phosphate dehydrogenase (GAPDH) and U6 were considered internal controls. The primer sequences are shown in Table 1, miRNA negative primers and U6 upstream primers were provided by miRNA first-strand cDNA synthesis (Tailing Reaction) kit. Relative expression levels were calculated using the $2^{-\Delta\Delta Ct}$ method.

Western Blot

Proteins were extracted using RIPA lysis buffer (P0013C, Beyotime, China) and analyzed BCA protein detection kit (20201ES76, Yeasen, Shanghai, China). Proteins were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and then transferred to polyvinylidene fluoride membranes. After blocking with 5% skim milk, membranes were incubated with primary antibodies PDCD4 (1:1000, 9535, Cell Signaling Technology) and GAPDH (1:1000, ab8245, Abcam) and with goat anti-rabbit IgG (ab205718, Abcam) to analyze gray values using ImageJ 1.48u (NIH).

Dual-Luciferase Reporter Experiment

The 3'UTR fragment of PDCD4 and its mutation containing potential miR-9-5p binding site were inserted into the PGLO vector, namely PGLO-PDCD4 wild type (WT) and PGLO-PDCD4 mutant (MUT). The vectors were co-transfected with miR-9-5p mimic and mimic NC into 293T cells, respectively, thereby analyzing luciferase activity using a dual luciferase reporter gene detection system (e1910, Promega, WI, USA).

Data analysis

All data were statistically analyzed by SPSS 21.0 statistical software. Reported as mean ± standard deviation, the measurement data were compared by independent sample t-test if following normal distribution, otherwise by one-way ANOVA and Tukey's multiple comparison post hoc analysis. With $P<0.05$, the difference was considered to be statistically significant.

RESULTS

Sim can improve ED in DMED rats

Before intraperitoneal injection of STZ, rats showed no significant difference in body weight, blood glucose, or erectile function. Except for 8 rats that died due to STZ, the other 64 diabetic rats and 6 normal rats were subjected to the APO test. Among them, 1-3 erections happened in 10 diabetic rats in 30 min, and no erection in the other 54 diabetic rats. To verify the improvement effect of Sim on DMED rats, DMED rats took Sim orally. Diabetic rats had reduced body weight and increased blood glucose, which could be ameliorated by Sim (Fig. 1A, B). The ICP/MAP values were decreased in diabetic rats and could be restored by Sim (Fig. 1C). Then, we observed the pathological condition of the cavernous by HE staining, which showed that the capillaries of the cavernous sinus contained erythrocytes, which were intertwined in a network. A large number of capillaries were seen in the corpus cavernosum tissue of sham-operated rats while less in diabetic rats; after Sim treatment, the corpus cavernosum injury was relieved (Fig. 1D). Immunofluorescence analysis in the penile cavernous demonstrated that α-SMA expression was decreased in DMED rats; Sim increased α-SMA expression (Fig. 1E, F). In addition, RNA and protein expression analysis revealed that miR-9-5p expression was decreased and PDCD4 expression was increased in DMED rats; after Sim treatment, their expression trends were recovered (Fig. 1G).

miR-9-5p alleviates corpus cavernosum damage in DMED rats

For defining the impacts of miR-9-5p in DMED rats, Sim-treated DMED rats were injected with the lentiviral vector into the tail vein to interfere with miR-9-5p expression (Fig. 2A). Due to miR-9-5p overexpression,

(**A**) miR-9-5p expression; (**B–C**) Changes in body weight and blood glucose of rats; (**D**) Erectile function assessment *in vivo*; (**E**) HE staining; (**F–G**) immunohistochemical staining for α-SMA; values are expressed as mean ± standard deviation; *$P<0.05$ *vs.* agomir NC group; #$P<0.05$ *vs.* antagomir NC group.

rats gained weight, blood glucose decreased, and ICP/MAP values elevated (Fig. 2B-D), the corpus cavernosum damage was alleviated (Fig. 2E), and α-SMA expression was raised (Fig. 2F, G). While miR-9-5p inhibition counter-acted the ameliorating effect of Sim (Fig. 2B-G).

miR-9-5p targets PDCD4

The specific binding site between PDCD4 and miR-9-5p was identified through the bioinformatic website RNA22 (Fig. 3A). The binding of miR-9-5p to PDCD4 was verified by dual-luciferase reporter gene assay based on the experimental result that miR-9-5p mimic induced the impairment of PGLO-PDCD4-WT luciferase activity (Fig. 3B). Analysis of PDCD4 expression indicated that with the change in miR-9-5p expression, PDCD4 expression was altered in an opposite way (Fig. 3C).

Depleting PDCD4 attenuates ED in DMED rats

In Sim-treated DMED rats, a lentiviral vector carrying si-PDCD4 or miR-9-5p agomir + oe-PDCD4 was injected into the tail vein (Fig. 4A). It was verified that si-PDCD4

had the ameliorating effects as miR-9-5p agomir, however, oe-PDCD4 mitigated the protective role of miR-9-5p agomir in Sim-treated DMED rats (Fig. 4B-G).

Sim protects CSMCs *in vitro* by enhancing miR-9-5p and suppressing PDCD4 expression

The regulatory role of Sim through the miR-9-5p/PDCD4 axis was tested using CSMCs. CSMCs were treated with Sim and then transfected. Quantitative PCR detection (Fig. 5A) manifested that Sim treatment elevated miR-9-5p and restrained PDCD4 expression in CSMCs; miR-9-5p mimic and miR-9-5p inhibitor transfection could strengthen and impair Sim-mediated effects; sh-PDCD4 transfection promoted the inhibitory effect of Sim on PDCD4 expression; pcDNA-PDCD4 enhanced the level of PDCD4 that had been suppressed by miR-9-5p mimic. The regulatory effect of Sim on the biological characteristics of CSMCs was investigated, showing that Sim-mediated induction of proliferation and reduction of apoptosis could be further bolstered by overexpressing miR-9-5p or suppressing PDCD4 while impaired by inhibiting miR-9-5p; PDCD4 expression in-

(**A**) miR-9-5p and PDCD4 expression; (**B**) cell viability; (**C**) cell apoptosis; (**D–E**) PCNA and Bax mRNA expression; values are expressed as mean ± standard deviation; *$P<0.05$ *vs.* Control group; #$P<0.05$ *vs.* DMED group; &$P<0.05$ *vs.* mimic NC group; $$P<0.05$ *vs.* inhibitor NC group; ^$P<0.05$ *vs.* sh-NC group; %$P<0.05$ *vs.* miR-9-5p mimic + pcDNA-NC group.

duction served a blocker for miR-9-5p-mediated protection against anti-proliferation and apoptosis (Fig. 5B, C). As expected, mRNA expression of PCNA and Bax also confirmed the above results (Fig. 5D, E).

DISCUSSION

The number of diabetic patients is increasing every year and DMED affects more than half of men with diabetes (Huo *et al.*, 2020). The pathogenesis of DMED involves a contraction-relaxation imbalance of CSMCs. It has been reported that CSMCs can change their phenotype from a contractile state to a diastolic state under hyperglycemic conditions (Wei *et al.*, 2012). At present, oral drugs are often used in the clinical treatment of ED. Sim, a commonly used cholesterol-lowering drug, has been found to improve ED in patients over the age of 40 (Trivedi *et al.*, 2014). Particularly, our study suggested the therapeutic action of Sim in DMED by miR-9-5p/PDCD4 axis and further provided evidence to verify the therapeutic potential of Sim for DMED.

Bilateral cavernous nerve injury is a cause of ED, leading to profound changes in the penis and damage to CSMCs (Hannan *et al.*, 2014). It has been reported that a sufficient amount of relaxed smooth muscle is required for penile erection, and the lack of smooth muscle can lead to venous occlusive dysfunction that exacerbates the symptoms of ED (Rogers *et al.*, 2003). α-SMA, an important marker of smooth muscle, is downregulated during ED (Cho *et al.*, 2015). It is well known that Sim treatment upregulates α-SMA and enhances erectile function. Erectile function is generally assessed by measuring ICP/MAP and low ICP/MAP is detectable in ED rats (Wang *et al.*, 2019). We constructed an STZ-induced DMED rat model and evaluated it by APO. As the results presented, STZ treatment reduced body weight, ICP/MAP value, and α-SMA expression, increased blood glucose and corpus cavernosum damage, while Sim treatment attenuated the damage of STZ to DMED rats. Furthermore, we determined that Sim exerted its effects by targeting the regulation of the miR-9-5p/PDCD4 axis. To our knowledge, this is the first report that indicates that Sim regulates DMED by regulating miRNA expression.

Some miRNAs are abnormally expressed in the corpus cavernosum of ED rats, including miR-1, miR-200a, miR-203, and miR-206 (Pan *et al.*, 2014). In addition, miR-101a, miR-138, miR-338, and miR-142 are dysregulated in a rat model of bilateral cavernous nerve crush (Liu *et al.*, 2018). The abnormal expression of miR-9-5p is obvious in diabetes and controlling miR-9-5p confers a protection against pyroptosis in the illness (Roshanravan *et al.*, 2020). In addition, miR-9-5p has also been surveyed to affect the biological behavior of smooth muscle cells (Wang *et al.*, 2021). Our paper described for the first time that miR-9-5p was downregulated in DMED rats, and upregulating miR-9-5p could further enhance the ameliorating role of Sim in ED rats and CSMCs while downregulating miR-9-5p resulted in the opposite consequences.

PDCD4 was selected as a downstream target gene of miR-9-5p. PDCD4 is a pro-apoptotic gene that regulates many important cellular processes (Shuvalova *et al.*, 2021) and involves in the progression of ED (Huo *et al.*, 2020). Our research presented that PDCD4 expression was upregulated in DMED rats, and silencing PDCD4 protected DMED rats and CMSCs, but overexpressing PDCD4 mitigated the protection induced by miR-9-5p.

However, the study had limitations. First of all, the sample size of the study was small, and we hope to verify our research results with a larger sample size in the future. Secondly, we only explored the regulatory axis of Sim/miR-9-5p/PDCD4, and other possible regulatory mechanisms of Sim in DMED were not explored. For example, studies have shown that Sim can improve the endothelial function of retinal capillary endothelial cells under high glucose conditions by increasing the expression level of eNOS mRNA and NO production (Tun *et al.*, 2017). NOS is a kind of NO-generating enzyme with three isoforms: nNOS, iNOS, and eNOS (Suksawat *et al.*, 2018). Recently, an increasing number of studies have demonstrated that NO is a critical neurotransmitter in the corpus cavernosum for the mediation of penile erection (Coletto *et al.*, 2018; Li *et al.*, 2017). Evidence from previous studies indicates that OS-induced NO- mediated endothelial dysfunction is a key process in DMED (Castela *et al.*, 2016). Therefore, we hope to further explore NOS-related pathways in future studies and improve the molecular mechanism of simvastatin alleviating DMED.

CONCLUSION

Our study demonstrated that DMED was associated with apoptosis and Sim attenuated DMED by enhancing miR-9-5p-targeted regulation of PDCD4 expression to ameliorate cavernosal injury and apoptosis in CSMCs. Our results provide a reference for Sim as a therapeutic drug for DMED.

Effect of artemisinin combined with allicin on improving cardiac function, fibrosis and NF-κB signaling pathway in rats with diabetic cardiomyopathy

Lingjuan Kong✉, Xiaoqing Ji, Yan Liu and YingJie Du

Chengde Medical College, College of Traditional Chinese Medicine, Shuangqiao District, Chengde, Hebei, 067050 China

Myocardial fibrosis and inflammation cause cardiac hypertrophy, arrhythmias, and heart failure in diabetics, a leading cause of mortality. Since it's complicated, no drug treats diabetic cardiomyopathy. This research examined the effects of artemisinin and allicin on heart function, myocardial fibrosis, and the nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) signaling pathway in diabetic cardiomyopathy rats. A total of 50 rats were separated into 5 groups, 10 of which were the control group. 40 rats received 65 μg/g streptozotocin intraperitoneally. 37 of 40 animals fit the investigation. The artemisinin, allicin, and artemisinin/allicin groups each included nine animals. The artemisinin group received 75 mg/kg of artemisinin, the allicin group received 40 mg/kg of allicin, and the combination group received equal dosages of artemisinin and allicin gavage for four weeks. After the intervention, in each group cardiac functions, myocardial fibrosis, and NF-κB signaling pathway protein expression were assessed. All of the examined groups had greater levels of LVEDD, LVESD, LVEF, FS, E/A, and the NF-κB pathway proteins: NF-κB p65 and p-NF-κB p65 than the normal group, except for the combination group. Artemisinin and allicin did not vary statistically. Compared to the model group, the artemisinin, allicin, and combined groups showed various degrees of improvement from the pathological pattern, with more intact muscle fibers, neater arrangement, more normal cell morphology, artemisinin and allicin alleviated cardiac dysfunction and decreased myocardium fibrosis in diabetic cardiomyopathy rats by inactivating the NF-κB signaling cascade.

INTRODUCTION

Diabetic cardiomyopathy (DC) is a primary cause of mortality in people with diabetes mellitus (DM) and is characterized by myocardial fibrosis and myocardial inflammation, with cardiac hypertrophy, arrhythmias, and heart failure as the main manifestations (Dillmann, 2019). DC is complex and involves several factors, so there is no specific drug to treat this disease. Allicin, the active component of garlic (*Allium sativum*), has been clinically shown to have an anti-cardiac fibrosis effect, and it has been reported that allicin is effective in diabetic cardiomyopathy, but a single drug may not completely inhibit the progression of diabetic cardiomyopathy (Liu *et al.*, 2021). Artemisinin belongs to the extract of the Chinese herb *Artemisia annua*, which was found to attenuate myocardial fibrosis and ventricular remodeling *via* inhibition of the cascade of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-*κ*B (Gu *et al.*, 2012).

Artemisinin has recently been found to decrease inducible nitric oxide synthase (iNOS) generation and NF-*κ*B stimulation in human astrocytoma T67 cells. SM933, an artemisinin derivative, has been reported to suppress NF-*κ*B activity by blocking its breakdown through overexpression of its inhibitory protein kappa B alpha (I*κ*B-α) and MOG-reactive splenocytes (Zhang *et al.*, 2020). Combined, these findings suggest that artemisinin may have a role in immunological modulation and inflammation reduction. The effects of the anti-inflammatory properties of artemisinin on microglial activation are not clear (Kim *et al.*, 2019). The current study was carried out to assess the maximum extent of inhibition of diabetic cardiomyopathy development and the reduction of fibrosis and regulation of the NF-*κ*B cascade by a combination of allicin and artemisinin.

MATERIALS AND METHODS

Study area

The present study was carried out at the Chengde Medical College, College of Traditional Chinese Medicine from January to April 2022.

Main reagents

Streptozotocin (Beijing Ita Biotechnology Co., Ltd.), artemisinin (Nanjing Guangrun Biological Products Co., Ltd.), allicin (Zhengda Tianqing Group Co., Ltd.), NF-*κ*B p65, p-NF-*κ*B p65 antibody (primary) (Abcam, USA).

Animals study

In this study, 50 SPF pure standard Wistar male rats (6–8 weeks old, 220±20 g) were received from Hangzhou Qizhen Research Animal Technology Co., China. In this study, 7 days of acclimatization under constant temperature (22±2°C), humidity (55±5%), and artificial

12 hrs light and dark cycle. All were free to move, drink, and take food. Chengde Medical College, College of Traditional Chinese Medicine ethics committee gave its approval to carry out this investigation (approval number: FEH83456).

Modeling and intervention

In total, 50 animals (n=50, 16-week-old) were used in this study, of which 10 were chosen as the normal group. The remaining 40 animals were given a single injection of 65 g/kg streptozotocin intraperitoneally, and their blood glucose levels were evaluated one week later. If the blood glucose value was ≥ 16.7 mmol/L and there were polyuria, polydipsia, and polyphagia, then the modelling of diabetes was successful (Togashi *et al.*, 2016). Streptozotocin was administered to 40 animals, and these animals were successfully established as a model of diabetes. They were fed by standard fodder until 16 weeks, and 3 animals were detected by ultrasound as not having developed cardiomyopathy, and the remaining animals (n=37) were successfully established as diabetic cardiomyopathy models.

Experimental design

- Normal group: without treatment (n=10);
- Model group: saline treatment (10 μL) (n=10);
- Artemisinin group: 75 mg/kg of artemisinin (n=9);
- Allicin group: 40 mg/kg of allicin (n=9);
- Artemisinin and allicin groups: 75 mg/kg of artemisinin+ 40 mg/kg of allicin (n=9).

All of these groups were treated continuously for 4 weeks, and the changes in experimental indexes in each group were observed after 20 weeks.

Measurement of cardiac function

After the last pharmacological intervention, echocardiographic parameters were taken by using a 7.5-MHz transducer (Toshiba Co., Japan) in each group to determine changes in cardiac function, and left ventricular end-diastolic internal diameter (LVEDD), left ventricular end-systolic internal diameter (LVESD), left ventricular ejection fraction (LVEF), and short-axis shortening (FS) measurements were utilized to examine alteration in cardiac function, maximum mitral valve velocity in early dilatation (E), and maximum atrial systolic velocity (A) ratio. Echocardiographic measures were collected from grayscale M-mode images captured in the parasternal short-axis perspective at the mid-papillary level, as well as from B-mode images recorded in the parasternal long- and short-axis views. End-diastolic diameter (LVEDD), end-systolic diameter, anterior and posterior wall thicknesses, FS, wall thickening, fractional area change (FAC), end-systolic and end-diastolic volumes, EF, and LV mass were all traditional LV measures.

Observation of myocardial fibrosis

After the completion of cardiac function measurement, rapid sacrifice of rats, preparation of myocardial tissue, tissue sectioning and then Hematoxylin and Eosin (H&E) staining, Masson staining, and microscopic observation of myocardial fibrotic lesions were performed in each group. After soaking in 4% neutral formalin solution for 24 h, all tissues were promptly cut and stained with Masson's trichrome kit (Sigma-Aldrich, USA). On each slide, three sections were examined, and each region was divided into 100 squares. Collagen points (blue stains) were scored as 1 (existent) or 0 (absence). The findings are presented as a proportion of the total region covered by fibrosis.

NF-κB signaling cascade protein expression measurement

The expression of the NF-κB signaling pathway proteins NF-κB p65 and p-NF-κB p65 was determined using the Western blot technique. Myocardial tissue was obtained, 80 μL of lysis buffer was added, tissue protein was extracted, and 50 mg of the resulting protein were mixed with 2×SDS loading buffer. Following electrophoresis, 15% denaturing gels were prepared according to the method of Summer and others (Summer *et al.*, 2009). In this study, membrane transfer, and antisera binding, NF-κB p65 and p-NF-κB p65 primary antibodies diluted at a 1:1 000 ratio in TBST buffer were used, and the cells were maintained at 4°C. After 1 day, the TBST buffer was washed, an HRP-labeled secondary antibody was applied, and the membrane was rinsed. The diaminobenzidine technique was utilised for colour development, and GAPDH was employed as an internal reference to get the protein expression of NF-κB p65 and p-NF-κB p65.

Statistical analysis

The SPSS 22.0 statistical tool (V13.0; SPSS, Inc., USA) was employed to evaluate the data, and one-way ANOVA was utilised to examine variance between groups. For two-by-two comparisons among groups, the LSD-t test was utilized. After natural logarithm transformation and non-parametric test, the data did not adhere to normally distributed and were expressed as M (Qn) for data comparison. The threshold of significance was fixed at $p<0.05$.

RESULTS

Assessment of cardiac function in each group

The model group, artemisinin group, allicin group, and combined group had greater LVEDD, LVESD,

Table 1. Comparison of cardiac function in each group ($\overline{x} \pm s$)

Group	LVEDD (mm)	LVESD (mm)	LVEF (%)	FS (%)	E/A
Normal group (n=10)	5.70±0.11	2.20±0.08	78.75±2.31	57.54±2.10	2.23±0.12
Model group (n=10)	7.00±0.23*	4.65±0.10*	63.32±2.45*	36.55±1.04*	1.30±0.09*
Artemisinin group (n=9)	6.51±0.11*#	4.00±0.14*#	66.75±2.11*#	40.62±1.33*#	1.55±0.10*#
Allicin group (n=9)	6.48±0.11*#	4.03±0.16*#	66.98±2.09*#	40.55±1.54*#	1.58±0.11*#
Combined group (n=9)	6.00±0.10*#&Δ	2.98±0.09*#&Δ	73.42±2.76*#&Δ	53.39±2.13*#&Δ	2.07±0.13*#&Δ

Note: "*" indicates significant comparison with the normal group; "#" indicates significant comparison with the model group; "&" indicates significant comparison with the artemisinin group; "Δ" indicates meaningful comparison with the allicin group.

Figure 1. HE staining observation of myocardial tissue (×200)

LVEF, FS, E/A, etc. and cardiac function indexes than the normal control, and the variation was statistically relevant ($p<0.05$). The cardiac function indicators LVEDD, LVESD, LVEF, FS, and E/A were decreased in the artemisinin group, allicin group, and combined group compared to the model group, and the change was statistically significant ($p<0.05$). The cardiac performance parameters LVEDD, LVESD, LVEF, FS, and E/A were lower in the combination group compared to artemisinin and allicin groups, with significant variations ($p<0.05$). There was no discernible difference between the groups treated with artemisinin and allicin in terms of LVEDD, LVESD, LVEF, FS, E/A, and the cardiac function indices ($p>0.05$). For further details, see Table 1.

Myocardial fibrosis observation

Microscopic analysis of animal cardiac tissues revealed that myocardium cells in the normal group were in a healthy condition, but a minor quantity of collagen fibres and no pathological alterations were observed. The collagen fibres multiplied and structured themselves into a network in the model group, which led to many fibrous scar formations, cardiomyocyte enlargement, uneven staining, nucleus consolidation, fragmentation, and even disappearance. Myocardial fibrosis was dramatically reduced in each treatment group as compared to the model group, cell morphology was gradually recovered and staining was more uniform, and myofibers tended to be intact, in comparison to the artemisinin and allicin groups, pathological alterations were more clearly restored in the combination group (Figs 1 and 2).

Comparison of NF-κB signaling pathway protein expression among groups

The model group, artemisinin group, allicin group, and combined group had increased expression of NF-κB p65 and p- NF-κB p65, the NF-κB signaling pathway proteins, then the normal group, in which the variation was statistically relevant ($p<0.05$). The proteins of the NF-κB signaling pathway, NF-κB p65 and p-NF-κB p65, were expressed at lower levels in the artemisinin, allicin, and combination groups than in the model group, and the difference was statistically significant ($p<0.05$). The combined group had lower levels of NF-κB p65 and p-NF-κB p65, the NF-κB signaling pathway proteins, than the artemisinin and allicin groups, and

Table 2. Protein expression of the NF-κB signaling pathway in different groups

Group	NF-κB p65	p-NF-κB p65
Normal group (n=10)	0.35±0.04	0.56±0.07
Model group (n=10)	1.89±0.22*	1.93±0.24*
Artemisinin group (n=9)	1.03±0.15*#	1.12±0.15*#
Allicin group (n=9)	1.06±0.12*#	1.14±0.13*#
Combination group (n=9)	0.70±0.08*#&Δ	0.88±0.09*#&Δ

Note: "*" indicates significant comparison with the normal group; "#" indicates significant comparison with the model group; "&" indicates significant comparison with the artemisinin group; "Δ" indicates significant comparison with the allicin group.

the variation was statistically significant ($p<0.05$). There were no substantial changes in the expression of NF-κB, p65 and p-NF-κB, p65, the NF-κB signaling pathway proteins, between the artemisinin and allicin groups ($p>0.05$). More data was shown in Table 2.

DISCUSSION

Allicin causes cell death and limits cell growth in mammalian cell lines, including cancer cells, by reacting redox with thiol groups in glutathione and proteins, inhibiting bacterial and fungal proliferation or killing them completely in a dose-dependent manner. Allicin has a number of health-promoting qualities, including effects on cholesterol and blood pressure that are beneficial to the cardiovascular system. According to Kuo and others (Kuo *et al.*, 2013), allicin seems to prevent high-glucose-induced cardiomyocyte apoptosis *via* reducing NADPH oxidase-related ROS and its subsequent NK/NF-κB signaling, and may have therapeutic potential for diabetic cardiomyopathy.

Artemisinin belongs to the sesquiterpene lactones with peroxy bridges, which were first used in the treatment of malaria and have anticancer, antiviral, antiparasitic *in vitro* and *in vivo* anti-inflammatory properties, in addition

to their antimalarial effects (Ma *et al.*, 2020; Talman *et al.*, 2019). With extensive clinical studies on artemisinin, it has been found that it can alter fibrosis *via* several pathways, such as TGF, MAPK, Wnt/catenin, PI3K/AKT/mTOR, FRX and Notch, NF-*κ*B signaling pathways, as well as BMP-7 and cellular autophagy, which contribute to the anti-fibrotic process, as does its anti-inflammatory effect (Li *et al.*, 2019; Dolivo *et al.*, 2021).

The results of this paper showed that compared with artemisinin and allicin alone, the cardiac function of rats with the combined administration of both interventions improved more significantly. In HE and Masson staining, it was found that the myocardium of rats with diabetic cardiomyopathy showed obvious fibrosis, as well as the severity of cardiac fibrosis was relieved after the intervention of artemisinin and allicin, the myocardial fibers were more intact and neatly arranged, the cell morphology tended to be normal, and the staining was more homogeneous, but the improvement was more obvious with artemisinin combined with allicin, indicating that the myocardial damage was more serious in the occurrence of diabetic cardiomyopathy, and the cardiac function of rats with artemisinin and allicin administration improved significantly and the myocardial fibrosis was relieved.

The myocardial structure is altered when the animal cells are under prolonged hyperglycemia, and the NF-*κ*B signaling cascade is initiated during this process. NF-*κ*B is secreted by vascular endothelium, vascular smooth muscle cells, etc.; this is a nuclear transcription factor that degrades IB with the help of inflammatory mediators, turns on and activates NF-*κ*B, and when NF-*κ*B is activated it can increase the binding to nuclear DNA to some extent, which in turn acts on cardiomyocyte behavior and leads to apoptosis (Youssef *et al.*, 2021; Yao *et al.*, 2021; Tang *et al.*, 2018). In addition, NF-*κ*B activates inflammatory cytokines including interleukins and tumor necrosis factor and further circulates to activate NF-*κ*B itself, amplifying the local cascade response in this circulatory pattern and promoting the progression of myocardial injury (Yang *et al.*, 2018; Jin *et al.*, 2020; Ni *et al.*, 2020). The effects on the NF-*κ*B signaling pathway in diabetic cardiomyopathy rats were examined in this work. Transartemisinin combined with allicin reduced NF-*κ*B p65 expression and NF-*κ*B p65 phosphate activation level in diabetic cardiomyopathy rats, which inhibited over-activation of the NF-*κ*B signaling pathway, enhanced cardiac function, and reduced the degree of myocardial fibrosis, according to the findings. In summary, the present study found a rat model of diabetic cardiomyopathy and confirmed that artemisinin combined with allicin intervention improved cardiac function, myocardial fibrosis and NF-*κ*B signaling pathway in diabetic cardiomyopathy rats, implying that artemisinin conjunction with allicin intervention may perform a role in improving cardiac functions and inhibiting myocardial fibrosis via the NF-*κ*B signaling pathway, which has positive implications. However, this study also has its limitation in that the development of diabetic cardiomyopathy is associated with multiple factors and involves several mechanisms and further studies are needed regarding whether both act *via* other pathways.

CONCLUSION

Myocardial fibrosis and inflammation cause cardiac hypertrophy, arrhythmias, and heart failure in diabetics, a leading cause of mortality. Since it is complicated, no

drug treats diabetic cardiomyopathy. Therefore, there is a need to find a solution to this problem. This study was carried out to determine the effectiveness of artemisinin and allicin on heart function, myocardial fibrosis, and the nuclear factor kappa-light-chain-enhancer of activated B cells signaling pathway in diabetic cardiomyopathy rats. According to the findings of the study, artemisinin combined with allicin improved cardiac dysfunction and reduced myocardial fibrosis in rats with diabetic cardiomyopathy, and both may act *via* promoting the inactivation of NF-*κ*B signaling cascade.

Overexpression of long non-coding RNA GASL1 induces apoptosis and G_0/G_1 cell cycle arrest in human oral cancer cells

Rui Zhang[1], Wanjun Tao[2] and Lei Yu[1]✉

[1]Department of Pharmacy, West China Hospital, Sichuan University, Chengdu, 610041 China; [2]Department of Pharmacy, Chengdu Women's and Children's Central Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu 611731, China

Oral cancer is one of the commonly reported malignancies of the human oral cavity and pharynx. It accounts for a significant level of cancer-based mortality across the globe. Long non-coding RNAs (lncRNAs) are emerging as important study targets in cancer therapy. The present study aimed to characterize the role of lncRNA GASL1 in regulating the growth, migration, and invasion of human oral cancer cells. The qRT-PCR showed significant ($P<0.05$) upregulation of GASL1 in oral cancer cells. Overexpression of GASL1 led to the loss of viability of HN6 oral cancer cells by inducing apoptosis which was associated with upregulation of Bax and downregulation of Bcl-2. The apoptotic cell percentage increased from 2.81% in control to 25.89% upon GASL1 overexpression. Cell cycle analysis showed that overexpression of GASL1 increased the G_1 cells from 35.19% in control to 84.52% upon GASL1 overexpression indicative of G_0/G_1 cell cycle arrest. Cell cycle arrest was also accompanied by inhibition of cyclin D1 and CDK4 protein expression. Wound healing and transwell assays showed that overexpression of GASL1 significantly ($P<0.05$) inhibited the migration and invasion of HN6 oral cancer cells. The invasion of the HN6 oral cancer cells was found to be decreased by more than 70%. Finally, the results of *in vivo* study revealed that GASL1 overexpression inhibits the xenografted tumor growth *in vivo*. Thus, the results are thus suggestive of the tumor-suppressive molecular role of GASL1 in oral cancer cells.

Keywords: oral cancer, long non-coding RNA, GASL1, apoptosis, metastasis, prognosis

INTRODUCTION

Oral cancer is ranked among the most prevalent cancers of the human oral cavity and pharynx (Chaturvedi et al., 2022). This malignancy is responsible for a significant level of mortality and morbidity throughout the world (Dhanuthai et al., 2018). Among the different histological sub-types, oral squamous cell carcinoma (OSCC) is the most dominant type of oral cancer which is often detected at advanced stages and exhibits poor prognosis (Meng et al., 2021; Panarese et al., 2019). In addition, this neoplastic disorder is linked with lymph node metastasis (Panarese et al., 2019). OSCC is highly lethal owing to the invasion of cancer to distant body parts (Peng et al., 2020). The currently applied chemotherapy is often reported to exhibit less soothing clinical results. Moreover, it is linked with a number of side effects negatively affecting overall human health. Pertinent to this backdrop, there is vast scope for the development of efficient and reliable prognostic and therapeutic targets against oral cancer.

The non-coding RNAs (ncRNAs) have attained considerable research attention over the past years. Several studies have put forward that ncRNAs exhibit frequent involvement in tumorigenesis of different types of human cancers including oral cancer (Yi et al., 2019; Irimie et al., 2017). Long non-coding RNAs (lncRNAs), a subclass of single-stranded ncRNAs with an average size of more than 200 nucleotides, are known to regulate the key hallmarks of human cancer (Vafadar et al., 2019). There is growing support that lncRNAs play diverse roles in the human body by regulating the expression of several target genes at transcriptional, post-transcriptional/translational or epigenetic levels (Statello et al., 2021). The molecular dysregulations of lncRNAs have been shown to be associated with tumor development and progression (Sun et al., 2018). LncRNAs regulate the crucial aspects of cancer cells including proliferation, apoptosis, migration, and invasion (de Oliveira et al., 2019). They have been shown to be involved in the remodeling of the micro-environment and metastasis of human tumors (Lin et al., 2018). Furthermore, the lncRNAs are involved in maintaining the stemness of different types of human cancers (Ma et al., 2019). Considering the pivotal role of this group of regulatory RNAs, there is mounting evidence that lncRNA-based cancer therapeutics might soon change from a mere concept to reality, soon.

Consistently, the present study was designed to investigate the role of lncRNA GASL1 in regulating the growth and metastasis of human oral cancer cells.

MATERIALS AND METHODS

Cell lines

The oral cancer cell lines (SCC9, HN4, HN6 and Cal127) as well as the normal human epithelial ovarian cells (NCE) were bought from the ATCC, USA. The cell lines were cultured in Dulbecco's modified Eagle's medium (DMEM, Gibco, Gaithersburg, USA) supplemented

with 10% FBS and streptomycin-penicillin (100 U/ml). The cells were maintained using humidified incubated CO_2 incubator at 37°C with 5% CO_2.

Transfection

LncRNA GASL1 was amplified using cDNA prepared from the HN6 cell line and cloned into the pcDNA3.1 over-expression vector. Cell transfection was carried out in serum-free medium using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) following the manufacturer's protocol. 6 h post-transfection, fresh complete medium was used to incubate cells. About 48 h later, the cells were collected for detection. The pcNAD3.1 vector alone transfected cells were used to serve as the negative control cells.

qRT-PCR expression analysis

Trizol reagent and Revert Aid First Strand cDNA synthesis kit (both from Thermo Fisher Scientific) was used for total RNA isolation and reverse transcription of RNA, respectively as per the manufacturer guidelines. SYBR PCR master mix (Takara, Japan) was used to perform the qRT-PCR on QuantStudio 3.0 PCR system (Applied Biosystems). The cycling conditions were 95°C for 5 min, followed by 40 cycles of 95°C for 15 s, and 60°C for 60 s. GAPDH genes were used as an internal control in the expression study. The $2^{-\Delta\Delta Ct}$ method was used to calculate the relative expression levels of GASL1. The qRT-PCR primers used were: GASL1, 5'-CTGAG-GCCAAAGTTTCCAAC-3' (forward) and 5'-CAGC-CTGACTTTCCCTCTTCT-3' (reverse); GADPH, 5'-GTCCTCTGACTTCAACAGCG-3' (forward) and 5'-ACCACCCTGTTGCTGTAGCCAA-3' (reverse).

CCK-8 assay

Cell viability was determined with the help of a Cell Counting Kit-8 (Beyotime). In brief, 1×10^5 HN6 cells transfected with pcDNA-GASL1 or control vector (pcDNA3.1) were added per well of a 96-well plate and cultured for 24 h at 37°C. At this, the CCK-8 solution was added to each well and 37°C incubation was extended for 1 h. Next, the absorbance at 570 nm (OD_{570}) was determined for each well with the help of a microplate reader to analyze the cell viability.

EdU assay

The proliferation of HN6 cancer cells over-expressing GASL1 was studied with reference to negative control cells with the help of an EdU Apollo *in vitro* flow cytometry kit (RiboBio, Guangzhou, China) in accordance with the manufacturer's recommendations. Approximately, 1.5×10^6 transfected cells /well were cultured in 12 well plates for 24 h at 37°C. Afterwards, the cells were added with EdU solution at a concentration of 50 μmol/L and incubated for 2 h. The cells were then PBS washed, fixed with 4% paraformaldehyde, and stained using Apollo staining solution (San Francisco, CA) for 25 min. The cells were also counterstained with DAPI. The cells were visualized under a fluorescence microscope (Olympus, Japan) for nuclear fluorescence.

Annexin V/PI staining assay

To analyze the effect of GASL1 over-expression on HN6 cancer cell apoptosis, pcDNA-GASL1 transfected cells (1.5×10^6/well) as well as the negative control cells were initially cultured in DMEM for 24 h in a 12-well plate at 37°C. Next, the cells were harvested and washed three times with PBS. Annexin V-FITC/PI double staining was performed using an Annexin V-FITC Apoptosis Detection Kit (BD Biosciences, San Jose, CA) as per the manufacturer's instructions. The cells were examined using a BD FACSCantoII flow cytometer (BD Biosciences) and analyzed by FlowJo 6.0 software to determine the relative percentage of apoptotic cells.

Cell cycle analysis

Approximately, 1.5×10^6 HN6 cells/well transfected with NC and pcDNA-GASL1 were harvested 48 h after culture. Subsequently, the cells were PBS washed and fixed in 500 μl of 75% cold ethanol at 4°C overnight. The cells were then washed again with PBS, and stained by 100 μl propidium iodide (prepared in 3.8 nM sodium citrate, pH 7.0) containing RNase A (10 mg/ml) for 35 min in the dark at 37°C. The percentage of cells in different phases of the cell cycle was determined by flow cytometry (Beckman Coulter, Inc., Brea, CA, USA), and analyzed using ModiFit software.

Wound healing assay

For studying the migration of GASL1 over-expressing HN6 cancer cells with respect to the negative control cells, the wound-healing assay was performed. For the wound-healing assay, 5×10^5 transfected HN6 cells were placed into each well of a six-well plate. The cells were allowed to grow for 24 h. At this, the growth medium was removed, and the cell surface was scratched with a pipette tip to carve a uniform linear scratch which was photographed under a light microscope (Olympus). The plate was incubated at 37°C for 24 h and then the wound was again analyzed and photographed under a microscope.

Transwell assay

The transwell assay was performed to investigate the invasion of the transfected HN6 cancer cells. Here, the transwell chamber (8 μM, Corning Incorporated, Corning, NY) plated with Matrigel was used for invasion assay. 2.5 x10^4 cells suspended in 200 μl of serum-free medium were placed in the upper chamber while the lower chamber was added with serum-free medium alone. After 24 h of incubation at 37°C, the cells invading the lower chamber were fixed with 70% ethanol, stained with 0.2% crystal violet solution, and analyzed under a light microscope.

Western blotting

The RIPA lysis and extraction buffer (Thermo Fisher Scientific) was used to extract total proteins from the transfected HN6 cancer cells. Bradford's assay was performed to examine the concentration of proteins isolated. Exactly, 35 μg of protein samples were isolated using the sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). Resolved proteins were transferred onto the activated polyvinylidene difluoride membranes (PVDF; Millipore, Billerica, MA, USA). 5% skimmed milk powder was used to block the membranes for 1 h. Next, the PVDF membranes were incubated overnight 4°C with the primary antibodies like anti-Bax (Abcam, cat no. ab216494, 1:1000), anti-Bcl-2 (Abcam, cat no. A95253, 1:800), anti-Cyclin D1 (Abcam, cat no. ab226977, 1:600) anti-CDK4 (Bio-Rad, cat no. AHP2454, 1:1000) and β-actin (Santa Cruz, cat no. sc-47778, 1:1000). This was followed by the incubation of the membranes with peroxidase-conjugated anti-rabbit secondary antibody (Cell signaling technology,

cat no. 7074, 1:3000) for 1 h at room temperature. Finally, the protein bands were detected through chemiluminescence and analyzed with Image J software. β-actin served as the endogenous control.

In vivo study

Around 7-8 weeks old female SCID/NOD mice were maintained in well ventilated rooms under standard conditions on a 12-h light–dark cycle and given access to sterilized food and water. The study was approved by the animal research ethics committee of Sichuan University, Chengdu, China (SU/223/2021-23). HN6 cells at the density of 4×10^6 to induce tumor development. As the tumors reached 0.15–0.20 cm^3, the mice were randomly divided into 2 groups NC group and pcDNA-GASL1 group (n=10 for each group). Thereafter the mice were administered with intra-tumor injections (five in total, each after 3 days) carrying NC (empty vector) or pcDNA-GASL1 constructs. At the end of 3 weeks, the mice were sacrificed, and tumor weight (g) and volume (cm^3) were determined. The volume of tumors was calculated following this formula: 0.5×length×width^2 (mm^3).

Statistical analysis

The experiments were performed in triplicates and final values were given as the mean ± standard deviation. Student's *t*-test was performed using GraphPad Prism v6.0 (GraphPad Software, Inc.) to analyze the statistical difference between the two groups. The *p*-values less than 0.05 were considered to be representative of a statistically significant difference.

RESULTS

GASL1 is downregulated in oral cancer cells

In order to examine the expression levels of lncRNA GASL1 in different oral cancer cell lines (SCC9, HN4, HN6 and Cal127) with reference to normal oral epithelial cells (NCE), qRT-PCR was performed. The results showed that GASL1 expression is significantly down-regulated ($P<0.05$) in all the oral cancer cells (Fig. 1A). HN6 cancer cells were shown to express the least transcript levels of GASL1 and were thus chosen for further experimentation.

GASL1 inhibits proliferation and colony formation of oral cancer cells

GASL1 was over-expressed in HN6 oral cancer cells, and its upregulation was confirmed by qRT-PCR (Fig. 1B). Whether GASL1 has any bearing on the viability of oral cancer cells, a CCK-8 assay was performed to examine the effect of GASL1 over-expression on HN6 host cell proliferation. It was found that HN6 cancer cells over-expressing GASL1 showed a significant decline in their proliferation with reference to the corresponding negative control cells (Fig. 1C). In addition, over-expression of GASL1 was found to markedly decline the incorporation of EdU into HN6 cancer cells indicative of the loss of cell viability (Fig. 1D).

GASL1 induces apoptosis in oral cancer cells

To look for the possible mechanism mediating the anti-proliferative effects of GASL1 against oral cancer cells, the study of cell apoptosis was performed using Annexin V-FITC/PI staining method. It was shown that GASL1 over-expression in HN6 oral cancer cells significantly enhanced ($P<0.05$) the percentage of both early and late apoptotic host cells with reference to the negative control cancer cells (Fig. 2A). The apoptotic HN6 cell percentage increased from 2. 81% in control to 25.89% upon GASL1 overexpression. The western blotting study also showed that HN6 cancer cells up-regulating GASL1 exhibited significantly higher ($P<0.05$) expression of Bax protein while expression of Bcl-2 protein was markedly repressed with respect to the negative control cells (Fig. 2B).

GASL1 induces G0/G1 cell cycle arrest in oral cancer cells

To determine whether GASL1 overexpression affects cell cycle progression, cell cycle distribution was

Figure 3. Cell cycle analysis:
(**A, B**) Flow cytometry analysis showed that G0/G1 cells increased significantly (*P*<0.05) in HN6 cells upon GASL1 overexpression. (**C**) Western blots analysis for cyclin D1 and CDK4 expression. (**D**) Densitometry analysis of western blot. Three replicates were used for performing the experiments.

investigated by flow cytometry. The results showed that the proportions of G0/G1 cells increased significantly (*P*<0.05) in HN6 cells upon GASL1 overexpression indicative of G0/G1 arrest (Fig. 3A and 3B). To further evaluate the effect of GASL1 overexpression on cell cycle progression, cycle-related protein expression was determined by western blot analysis. It was found that GASL1 inhibited the expression of cyclin D and CDK4, consistent with a G0/G1 cell cycle arrest (Fig. 3C).

GASL1 inhibits the migration and invasion of oral cancer cells

The effect of GASL1 was also studied on the migration and invasion of oral cancer cells *in vitro*. Wound-healing assay showed that migration of HN6 cancer cells significantly decreased (*P*<0.05) by GASL1 overexpression (Fig. 4A). The percentage of cell migrationhas been

Three replicates were used for performing the experiment (**P*<0.05). Three replicates were used for performing the experiment (**P*<0.05).

Figure 5. Overexpression of GASL1 inhibits xenografted tumor growth *in vivo*.
(**A**) Effects of GASL1 on xenografted tumor growth *in vivo*. (**B, C**) Showed significant upregulation of GASL1 in pcDNA-GASL1 tumors. (**D**) Showed that the volume and tumor weight of pcDNA-GASL1 tumors was significantly lower than the NC tumors.

shown to be decreased by more than 70% in HN6 cells over-expressing GASL1 with respect to negative control cells. Similarly, the invasion of HN6 cancer cells was significantly reduced under GASL1 up-regulation (Fig. 4B). The HN6 oral cancer cells over-expressing GASL1 showed only one-fourth of the rate of invasion of the negative control cells.

GASL1 inhibits tumor growth *in vivo*

The effects of GASL1 were also investigated on xenografted tumor growth *in vivo* (Fig. 5A). To confirm the overexpression of GASL1 in xenografted tumors, expression analysis was carried out which showed significant upregulation of GASL1 in pcDNA-GASL1 tumors (Fig. 5B). Moreover, tumor volume and tumor weight of pcDNA-GASL1 tumors were significantly lower than the NC tumors (Fig. 5C). These findings indicate that overexpression of GASL1 inhibits xenografted tumor growth *in vivo*.

DISCUSSION

There is growing support that long non-coding RNAs (lncRNAs) affect the key biological, cellular, and physiological aspects of the human body (Statello *et al.*, 2021; Li & Chang, 2014). This group of RNAs is seen to lack the protein-coding capability however is crucial for homeostasis at molecular level (Ji *et al.*, 2020; Zhang *et al.*, 2019). The dysregulation of lncRNAs reportedly surfaces the development and progression of different human pathological conditions including cancer (Forrest and Khalil, 2017; Tan *et al.*, 2021). Several studies have implicated that lncRNAs play a key role in regulating the malignant behavior of human cancer cells (Suzuki *et al.*, 2016; Huo *et al.*, 2017; Acha-Sagredo *et al.*, 2020). They have also been shown to be involved in shaping the tumor microenvironment and affect the cellular dynamics related to cancer cell invasion and metastasis (Yuan *et al.*, 2014; Liu *et al.*, 2021; Wu *et al.*, 2015). In the present study, lncRNA GASL1 was studied for its possible involvement in the regulation of growth and metastasis of human oral cancer. As per recent studies, GASL1

exhibits significant down-regulation in human cancers like gastric cancer and esophageal cancer and acts as a tumor-suppressor to regulate cancer cell growth and proliferation (Liu *et al.*, 2020; Ren *et al.*, 2021). The results of the current study were reflective of GASL1 repression in oral cancer cells. The decline in cell viability by GASL1 overexpression signifies its anti-proliferative regulatory role in oral cancer. GASL1 inhibited oral cancer cell growth by inducing apoptosis and modulating the Bax/Bcl-2 protein ratio. Bax protein was upregulated while Bcl-2 was repressed in GASL1 up-regulating oral cancer cells. This sort of expressional modulation of Bax and Bcl-2 is known to favor the onset of cell apoptosis (Nazeri *et al.*, 2020; Wang *et al.*, 2016).

Metastasis is the process that promotes the development of secondary tumorigenesis at sites distant from the original tumor development (Fares *et al.*, 2020; Chang & Pauklin, 2021). The former is considered the major cause responsible for cancer-based mortality and failure of treatment procedures (Esposito *et al.*, 2021; Riggio *et al.*, 2021). Moreover, the process of cancer metastasis is poorly understood. It thus becomes interesting to study this important hallmark of human cancer and to identify the various regulators of cancer metastasis. Cancer cell migration and invasion to distant tissues are vital to the process of metastasis (Novikov *et al.*, 2021; Winkler *et al.*, 2020). The results of the current study indicated that oral cancer cells over-expressing GASL1 showed significantly lower rates of migration and invasion *in vitro*. This is in confirmation with a recent study wherein GASL1 has been shown to be involved in the regulation of esophageal squamous cell carcinoma (Ren *et al.*, 2021; Weidle & Birzele, 2022). The finding thus insights into the therapeutic utility of GASL1 against oral cancer. In sum, the study established the role of GASL1 in regulating growth and metastasis of human oral cancer cells however the same needs to be confirmed *in vivo* also.

Our findings imply that lncRNA GASL1 may serve as a new biomarker for the detection and management of oral cancer. Hence, a thorough understanding of the lncRNA GASL1 functioning mechanism will be beneficial for the detection and management of oral cancer. As master controllers of gene expression, lncRNAs are interesting candidates for targeted epigenetic pharmacological therapy. There are now tractable pharmacological methods that can either destroy excessive lncRNAs or competitively decrease their activity. For the first time, medicines that target particular lncRNAs may now be created, allowing for the epigenetic modulation of particular metabolic pathways. If this is the case, lncRNA medicines will significantly improve upon the relatively low specificity of currently available medications that serve as epigenetic regulators.

CONCLUSION

Taken together, oral cancer cells exhibit significant downregulation of lncRNA GASL1. GASL1 overexpression inhibited the cancer cell proliferation by inducing apoptosis. Interestingly, the oral cancer cell migration and invasion was significantly declined by GASL1 upregulation. The study thus confirmed the tumor-suppressive action of GASL1 in oral cancer however the findings need to be verified further.

Vitamin D supplementation improves the therapeutic effect of mometasone on allergic rhinitis

Minfei Guo✉

Respiratory Department, Huichang People's Hospital, Ganzhou, China

This study aimed to investigate the efficacy and safety of vitamin D supplementation in the treatment of allergic rhinitis (AR) using mometasone. A total of 140 patients with moderate and severe AR treated at our hospital between January 2017 and August 2020 were recruited as subjects for this study. The patients were randomly divided into control and experimental groups, with 70 patients in each group. Mometasone nasal spray was used in both groups, and vitamin D was administered to the experimental group for four weeks. The total nasal symptom scores (TNSS) and rhinoconjunctivitis quality of life questionnaire (RQLQ) were used to assess the efficacy of treatment. T lymphocyte subsets (CD3+, CD4+ and CD8+) and serum anti-inflammatory and proinflammatory cytokines such as interleukin-10 (IL-10), tumor necrosis factor-α (TNF-α), and interferon-γ (IFN-γ) were analyzed. The incidence of adverse reactions was recorded. Serum vitamin D levels were lower in patients with AR. After 4 weeks of treatment, total TNSS scores, T lymphocyte subsets (CD3+, CD4+), CD4+/CD8+ ratio, TNF-α, and total RQLQ scores were significantly reduced compared to the initial testing (P<0.05) in the two groups; CD8+, IFN-γ, and IL-10 levels as well as serum vitamin D were significantly increased compared to the initial test (P<0.05). The improvement in these parameters in the experimental group was significantly greater than that in the control group (P<0.05), except for sneezing and eye symptoms in the TNSS and RQLQ scores. It was concluded that vitamin D supplementation improves the therapeutic effect of mometasone nasal spray on AR and is thus recommended as an adjuvant therapy for moderate and severe AR.

INTRODUCTION

Allergic rhinitis (AR), although a non-life-threatening disease, is a common disorder that frequently occurs in children and adolescents after exposure to allergens in a highly prevalent environment (Meng *et al.*, 2019). It is often associated with other allergic diseases such as asthma and has adverse effects on sleep, school performance, quality of life, and important short-term and long-term health consequences (Foresi, 2000; Schuler & Montejo, 2019). AR patients develop specific immunoglobulin E (IgE) antibody responses to allergens, resulting in repeated sneezing, rhinorrhea, nasal congestion, itching, ocular redness, tearing, and itching (Bernstein *et al.*, 2016). Epidemiological studies have shown that the prevalence of this disease among adults and children has increased in recent years (Kakli & Riley, 2016; Khan, 2014). The etiology of AR is complex and is affected by many factors, including heredity, environment, and immune function (Eifan & Durham, 2016; Khan, 2014). Several pharmacotherapy guidelines have been developed to treat the disease, and routine therapy options consist of the use of antihistamines, intranasal corticosteroids, and decongestant drugs such as cetirizine, montelukast, mometasone, and desloratadine (Bousquet *et al.*, 2020; Okubo *et al.*, 2020). Although these drugs have demonstrated efficacy in AR, they require a long treatment time and have poor patient compliance (Khare & Martin, 1995). Furthermore, despite recent epidemiologic data showing that the incidence of AR is increasing worldwide, less than 12% of AR patients seek medical recommendations, resulting in the disease being frequently under-recognized, misdiagnosed, and ineffectively treated (Berger, 2003; Dennis *et al.*, 2012).

Vitamin D is an important human nutrient and functions as an immunomodulatory hormone. In recent years, studies have shown that vitamin D has an immune regulatory effect and can be used as a supplement to treat asthma and other immune-related diseases, including AR, with satisfactory results (Charoenngam & Holick, 2020; Forno *et al.*, 2020; Yepes-Nunez *et al.*, 2018). Vitamin D plays an important role in regulating the immune system and has been demonstrated to have therapeutic benefits in the treatment of various diseases, such as melanoma, inflammatory bowel diseases, rheumatoid arthritis, tuberculosis, sepsis, and respiratory infection (Battistini *et al.*, 2020; Charoenngam & Holick, 2020; Sun *et al.*, 2021). It may alleviate AR symptoms by reducing IgE, cytokines, interleukin (IL)-4, IL-5, and interferon (IFN) to suppress inflammation (Cho *et al.*, 2019; Yu *et al.*, 2017). However, the therapeutic effect of vitamin D on AR remains controversial (Bhardwaj & Singh, 2021; Liu *et al.*, 2020; Luo *et al.*, 2022) and the effect of vitamin D on AR treated with corticosteroids has not been fully explored. In the present study, the impact of vitamin D supplementation was assessed in patients with moderate-to-severe seasonal pollen AR.

MATERIALS AND METHODS

Trial design and study population

We conducted a randomized, assessor/statistician-blinded, single-center trial with two parallel groups to investigate the effects of vitamin D on AR. Patients

treated at our hospital between January 2017 and January 2022 were enrolled in this study. Patients were included if they met the diagnostic criteria of the Guidelines for Diagnosis and Treatment of Allergic Rhinitis (Subspecialty Group of Rhinology *et al.*, 2016), confirmed by allergen tests, had moderate-to-severe AR (symptoms (nasal congestion, runny nose, itchy nose, or sneezing) occurring ≥4 days per week for consecutive 4 weeks and were severe enough to affect quality of life) according to the disease severity classification based on the above guidelines, did not receive any AR-related treatment within two weeks of diagnosis, were aged between 16 and 60 years, and had good drug compliance. Patients were excluded if they had non-allergic rhinitis, severe organ dysfunction, malignant tumor, other respiratory diseases, and nasal cavity abnormalities such as sinusitis and nasal polyps. Pregnant and lactating women were excluded from the study. The sample size was determined using the formula N (each group) = (r+1) $(Z\alpha/2 + Z1-\beta)^2 \, \sigma^2 / \, rd^2$ (Suresh & Chandrashekara, 2012). In a pilot study, the minimal detectable difference means (d) of the two group as 0.62 scores on the total nasal symptom scale (TNSS) and 1.21 the standard deviation (σ), respectively. Therefore, the minimum sample size for each group required to detect the mean difference between the two means was 37 persons/group. Considering a dropout rate of 10%, 45 patients were required for each treatment group. This study was approved by the Ethics Committee of the Huichang People's Hospital, Ganzhou, China. Informed consent was obtained from all the patients.

Randomization and blinding

After baseline evaluations and routine laboratory tests, the patients were randomly allocated 1:1 to the control and experimental groups. The assignment was made according to a computer-generated randomization table created by a biostatistician. The treatments were labelled A and B to ensure blinding of the biostatistician. A physician from another department was tasked with using a randomization list to allocate patients. All assessors were blinded to group allocation, treatment details, and patient information.

Treatment

Patients in both groups were administered 200 µg mometasone nasal spray (Xianju Pharmaceutical, Zhejiang, China) 2 puffs BD for four weeks. In addition, two oral vitamin D capsules (400 IU vitamin D per capsule, Shuangjing Pharmaceuticals, Qingdao, China) were given BD in the experimental group for 4 weeks.

Biochemical assessments

Peripheral venous blood samples were collected before and one month after treatment. Lymphocytes and T lymphocyte subsets ($CD3^+$, $CD4^+$, and $CD8^+$) were measured on a flow cytometer (Accuri C6 plus cell analyzer, BD, US) using monoclonal four-color antibody CD3/CD4/CD8/CD45 (cat. no. 561707), monoclonal antibodies to CD3 (cat. no. 30062), CD4 (cat. no. 100538), and CD8 (cat. no. 561644) (produced by BD, USA). The contents of interleukin-10 (IL-10, IL-10 Human ProcartaPlex™ Simplex Kit, cat. no. EPX01A-10215-90), tumor necrosis factor (TNF-α, TNF alpha Human ProQuantum Immunoassay Kit, cat. no. A35601), and interferon-γ (IFN-γ, IFN gamma Human ProQuantum Immunoassay Kit, cat. no. A35576) were assessed by enzyme-linked immunosorbent assay (ELISA) using kits purchased from Thermo Fisher Scientific, USA, according to the manufacturer's instructions. Vitamin D levels were assessed using ELISA kit (cat. no. EY-01H1295) was obtained from Yiyan Biotech (Shanghai, China). All assays were performed in triplicate.

Clinical efficacy evaluation

The TNSS and rhinoconjunctivitis quality of life questionnaire (RQLQ) were used to assess the efficacy. The TNSS is a subjective evaluation tool used to measure the severity of the main symptoms of patients with AR (Downie *et al.*, 2004). Four symptoms, runny nose, itchy nose, nasal congestion, and sneezing, were assessed in all patients using a score of 4 (0 = no symptoms and 3 = severe symptoms), with lower scores indicating less severe symptoms.

Patients were also assessed for improvement in their quality of life after treatment using the RQLQ. The

Statistical analysis: repeated measured ANOVA, *denotes significant difference from before treatment within group (*P*<0.05), *t* value of independent two-sample Student's *t*-test.

RQLQ has 28 questions in 7 sections (activity limitation, sleep disturbances, nose symptoms, eye symptoms, non-nose/eye symptoms, practical problems, and emotional function). Patients responded to the questions on a 7-point scale (0 = not impaired at all, 6 = severely impaired), with higher scores indicating worse quality-of-life (Juniper & Guyatt, 1991).

Safety evaluation

Adverse reactions, including nausea, diarrhea, nasal dryness and bleeding, and throat irritation in the two groups were recorded to assess the safety of the treatment.

Statistical analysis

All statistical analyses were performed using the SPSS19.0 statistical software. Quantitative data were described as mean ± standard deviation (S.D.), and the independent t-test or Mann Whitney U test was used to compare the mean values between the two groups. Qualitative data are described as [n (%)], and compared using the χ 2 test or Fisher's exact test. A *P*-value of <0.05 was considered to indicate statistical significance.

RESULTS

Baseline characteristics

A total of 140 patients were enrolled and randomized to two groups, and 128 patients completed the study after 5 and 7 patients were lost during the treatments. There were 46 males and 19 females with an average age of 31.4±12.7 years in the control group and 43 males and 20 females with an average age of 30.9±10.7 years in the experimental group (Fig. 1). The numbers of patients with moderate and severe AR were 45 and 20 in the control group and 42 and 21 in the experimental group, respectively. The mean courses of disease were 4.2 and 4.0 years, respectively, in the two group. Statistical analysis showed that there was no difference in sex, age, disease severity, or course of disease between the two groups (Table 1; *P*>0.05).

Vitamin D improves AR symptoms and quality-of-life

After 4-week treatment, the TNSS scores in both groups were assessed and compared (Table 2). The results showed that the total TNSS scores were significantly reduced compared with those before treatment in both groups for all four main symptoms assessed: itching, runny nose, nasal congestion, and sneezing (*P*<0.05). The improvements with vitamin D supplementation were significantly greater than those of the control group in the symptoms assessed, except for sneezing (Table 2, *P*<0.05).

At the end of the 4-week treatment, we assessed the quality-of-life of the participating AR patients using the RQLQ. The results showed that the scores in both groups were significantly lower after the therapy than before the therapy in all aspects (*P*<0.05), and the improvements with vitamin D supplementation were significantly greater than those in the control group, except for eye symptoms, which were improved, but the differ-

ence was not statistically significant as compared to the control ($P<0.05$, Table 3).

Vitamin D alters T lymphocyte subsets

We also compared the levels of T lymphocyte subsets before and after the therapy. The results showed that while the percentage of CD3+ in the lymphocytes remained unchanged, the percentages of CD4+ and CD4+/CD8+ ratios were reduced, and the percentages of CD8+ were increased in the two groups after the therapy compared to before the therapy ($P<0.05$). Furthermore, compared to the control group, vitamin D supplementation resulted in greater changes in the subsets (Table 4).

Vitamin D changes serum levels of pro-inflammatory anti-inflammatory cytokines

To further assess the impact of vitamin D on AR-associated inflammation, we profiled the serum levels of pro-inflammatory and anti-inflammatory cytokines before and after therapy. The data showed that TNF-α levels

were significantly decreased, and IFN-γ and IL-10 levels were significantly increased in the two groups after the therapy compared to before the therapy ($P<0.05$, Table 5). These changes were significantly greater in the experimental group than in the control group ($P<0.01$, Table 5).

Vitamin D is reduced in patients with AR and increased after treatment

To elucidate the role of vitamin D in AR, we analyzed serum vitamin D levels in patients with AR before and after treatment. The results showed that compared to healthy participants, patients with AR had significantly lower serum vitamin D levels, which were significantly increased after vitamin D supplementation (Table 6).

Adverse reactions

No serious adverse reactions were observed in either of the groups. In the experimental group, one patient

DISCUSSION

In this study, we investigated the effect of vitamin D as a supplementary therapeutic to mometasone in moderate-to-severe AR. Our results showed that vitamin D effectively improved the therapeutic efficacy of mometasone. It moderates T lymphocyte subsets and pro-inflammatory and anti-inflammatory cytokine levels, leading to significantly better quality-of-life with AR.

As a common disease that seriously affects the physical and mental health and quality of life of patients. Currently, there is no cure for RA, but active treatment can effectively control the pathological symptoms of patients to reduce pain and stop or slow further damage (Bullock *et al.*, 2018). Therefore, it is important to develop better treatment plans with fewer complications, better patient compliance, and lower costs. Nasal glucocorticoids and antihistamines are the first-line clinical drugs for AR with excellent efficacy for persistent moderate-to-severe AR, and the combination of intranasal antihistamines and corticosteroids is conducive to the rapid control of symptoms and reduction of TNSS (Wheatley & Togias, 2015), there are various adverse effects, including osteoporosis, dyslipidemia, body fat redistribution, insulin resistance, glucose intolerance, and even diabetes associated with glucocorticoid drugs (Sundahl *et al.*, 2015). Recent studies have shown that vitamin D deficiency is common in AR patients whose serum contains less vitamin D than in healthy individuals (Chen *et al.*, 2016). Vitamin D, as an important human nutrient, does not cause any adverse reactions if taken at the dose recommended by the physician. Vitamin D has been demonstrated to have various immunomodulatory effects and to protect against a number of autoimmune diseases, including multiple sclerosis and inflammatory bowel disease (Christakos *et al.*, 2016; Holick, 2007). However, the benefits of vitamin D in AR treatment with corticosteroids have not yet been fully explored.

The corticosteroid drug mometasone has been demonstrated to be effective and safe for treating inflammatory diseases of the nose and paranasal sinuses including AR (Yarom *et al.*, 1982). As expected, treatment with nasal spray for one month, resulted in significant control of all AR-related symptoms as well as better quality of life in our cohort with moderate-to-severe AR, as assessed using the TNSS and RQLQ, both of which are well-recognized tools that assess the primary outcome in clinical trials on AR. Furthermore, the assessments showed that Vitamin D supplementation further improved the control of AR and quality-of-life of AR patients in all assessed items except sneezing and eye symptoms. These data demonstrate that vitamin D supplementation improves the overall therapeutic effect of corticosteroid drugs, to a certain extent.

In the present study, the vitamin D dose prescribed were 1600 IU per day based on the manufacture's recommendation to minimize potential adverse effect. Previously, various doses have been used from 100 IU per day for patients with refractory allergic rhinitis (Chen *et al.*, 2016), 2000 IU over 2 months in children (Tiazhka & Selska, 2020) to 42000 IU per day via nasal dropping (Liu *et al.*, 2018) and 50 000 IU/week of vitamin D for 8 weeks along with antihistamines (Bakhshaee *et al.*, 2019). It is likely that the optimal dose is depending on the formulations (chew pill, soft gel and capsule) and patient populations and need to be defined further.

To better understand the mechanisms underlying the improved therapeutic effect of vitamin D supplementation, we compared the changes in T lymphocyte subsets following the therapies. The results showed that the levels of CD4+, CD8+, and CD4+/CD8+ in the experimental groups were changed compared to those in the control group, suggesting that vitamin D might modulate cellular immune function by lowering the levels of CD4+ and increasing the level of CD8+. Vitamin D receptor (VDR) is produced in respiratory epithelial cells, where Vitamin D binds to vitamin D receptor (VDR) to enhance both innate and acquired immunity *via* various immune cells, including dendritic cells, monocytes, megaphagocytes, T lymphocytes, and B lymphocytes (Bakdash *et al.*, 2014; Mailhot & White, 2020). It inhibits the proliferation of T lymphocytes and promotes the differentiation of Foxp3+ regulatory T cells (Barragan *et al.*, 2015; Hewison, 2011). Therefore, at least part of the enhanced therapeutic effect of vitamin D is likely due to the modulation of immune function in patients with AP.

Vitamin D also exerts regulatory effects on many cytokines involved in inflammation. For example, it downregulates the production of IL-12, TNF-α, and IL-2 and upregulates the synthesis of IL-4 and IL-10 (Barragan et al., 2015; Hewison, 2011), which are secreted by immune cells to regulate their proliferation and differentiation of immune cells. Our data showed that pro-inflammatory cytokine TNF-α levels were significantly reduced and anti-inflammatory cytokine IFN-γ and IL-10 levels were significantly increased after vitamin D supplementation, suggesting that vitamin D may improve the therapeutic effect by modulating cytokine production to inhibit inflammation. IL-10 and IFN-γ can not only inhibit the T cell response but also inhibit the production of immunoglobulin E, which plays a negative role in regulating AR pathological symptoms. TNF-α mediates various inflammatory reactions, and a reduction in TNF-α levels may lead to the inhibition of AR-related inflammation.

In addition, vitamin D supplementation may attenuate vitamin D deficiency in patients with AR and modulate immune function to strengthen its anti-inflammatory effect. In this study, the serum level of vitamin D was found to be lower in AR patients, and this vitamin D deficiency was partially alleviated after vitamin D supplementation. These results are consistent with those of previous studies on children and women (Aryan et al., 2017; Srimani et al., 2017).

This study had several limitations. Although this trial was blinded to the assessors, the patients were aware of their treatment because of the absence of placebo indistinguishable from patients, resulting in potential bias in treatment outcomes. In addition, physiologic measures, including peak nasal inspiratory flow and nasal airflow, were not used to measure the outcomes, yielding potential bias in the results. A single dose of vitamin D was applied in the therapy; patients were not classified based on the AR etiologies, such as seasonal allergic rhinitis or perennial allergic rhinitis, for better treatment and explanation of the therapeutic outcome. For example, patients with seasonal allergic rhinitis pass the onset season and recover spontaneously. Since this was a single-center, short-term, and small-scale study, more extensive multicenter work is needed to address the limitations and to validate our conclusion.

CONCLUSIONS

Vitamin D supplementation of mometasone nasal spray is effective and safe for improving AR symptoms and quality of life. These improvements were partially due to the modulation of cellular immunity and inhibition of inflammation. Therefore, vitamin D adjuvant therapy is highly recommended for patients with moderate or severe seasonal AR.

Silencing circCAMSAP1 suppresses malignant behavior of endometrial cancer by targeting microRNA-370-3p/MAPK1

Hai Feng Zhang[1], Cheng Cheng Cao[1], Cui Cui Nie[2] and Ting Zhang[2]✉

[1]Department of Gynecology, Affiliated Hospital of Weifang Medical College, Weifang City, Shandong Province, 261000, China; [2]Department of Gynecology and Obstetrics, Sunshine Union Hospital, Weifang City, Shandong Province, 250131, China

The study was conducted to figure out the function and mechanism of circular RNA circCAMSAP1 in repressing malignant behavior of endometrial carcinoma (EC) by targeting microRNA (miR)-370-3p /MAPK1. Tumor tissues and normal adjacent tissues of EC patients were harvested, and circCAMSAP1 and MAPK1 were elevated but miR-370-3p was reduced in tissues and cells of EC patients. Functional test results clarified transfection of si-circCAMSAP1 or miR-370-3p-mimic refrained cancer cell proliferation, migration and invasion, but motivated cancer cell apoptosis. Meanwhile, the amount of E-cadherin elevated and the amount of N-cadherin elevated or reduced. After co-transfection with si-circCAMSAP1 and miR-370-3p-inhibitor, miR-370-3p-inhibitor blocked si-circCAMSAP1's therapeutic impact. Furthermore, after co-transfection of pcDNA-circCAMSAP1 and si-MAPK1, si-MAPK1 turned around the malignant effect of pcD-NA-circCAMSAP1. It was testified that miR-370-3p was circCAMSAP1's target, and inversely controlled *via* circ-CAMSAP1. Meanwhile, enhancing miR-370-3p led to repressive MAPK1, which was recognized as miR-370-3p's downstream target. All in all, the results of this study convey silencing circCAMSAP1 refrains the malignant behavior of EC by controlling miR-370-3p /MAPK1 axis.

Abbreviations: circRNA, Circular RNA; EC, Endometrial cancer; hEEC, endometrial endothelial cells

INTRODUCTION

Endometrial cancer (EC) is an extremely familiar cancer in women, with over 380 000 new pathologies diagnosed globally every year. Recently, EC's presence has been increasing, especially in developed countries. EC ranks second among female genital cancers in China, with a mortality rate of 2.7 per 100 000 (Wilczynski *et al.*, 2020). ECs' recently new molecular classification is on grounds of the research of the Cancer Genome Atlas Research Network and assignation of them into 4 molecular subgroups is conducted. Among them, endometrioid ECs are present in all subgroups (Cancer Genome Atlas Research *et al.*, 2013), and their molecular diversity may cause more aggressive tumors in many women with type I EC. The treatment options for EC largely relie on the stage of the disease, and surgery is still the major method of early treatment, covering but not limited to pelvic lymph node cesarean section, bilateral salpingo-oophorectomy, etc. (Sonoda, 2012). Several molecular targeted therapies for EC are currently under study, like epidermal growth factor inhibitors, phosphatidylinositol 3-kinase (PI3K)/AKT inhibitors, etc. (Leslie *et al.*, 2012; Oza *et al.*, 2015). Targeted molecular identification has facilitated the diagnosis and cure of EC.

Circular RNA (circRNA) is a kind of covalent body, which is dorsally linked to the precursor mRNA and is in the form of a closed single strand (Ebbesen *et al.*, 2017). CircRNAs are not easily degraded by RNase R due to their absence of 5'-3' ends and polyadenylated tails, so they are more stable vs. linear RNAs (Suzuki *et al.*, 2014). Circ-CAMSAP1, a circular RNA, also known as circ_0004338, is linked with the regulation of the occurrence and development of diversified cancers (Chen *et al.*, 2021). For instance, circCAMSAP1 can motivate the biological function of hepatocellular carcinoma *in vitro* and *in vivo via* the miR-1294/GRAMD1A molecular axis (Luo *et al.*, 2021); Circ-CAMSAP1 can be employed as a latent therapeutic target and a biomarker for diagnosis and prognosis of colon cancer (Zhou *et al.*, 2020). However, circCAMSAP1's role and regulatory mechanism in EC remains uncertain.

By targeting and combining with mRNA in the 3' untranslated region, microRNA (miRNA) can control gene expression, cause messenger RNA (mRNA) cleavage, or lead to translational repression of target genes. Therefore, miRNA takes a momentous function in cell growth, apoptosis, migration, etc. (Bueno *et al.*, 2008). Numerous studies have clarified miRNAs can control the specificity of diversified cancers, for example, miR-411-5p can restrain the growth and metastasis of bladder cancer, and target the transport of ZnT1 protein (Finnson *et al.*, 2012); MiR-153-3p can target CFL2 to control the carcinogenesis process of breast cancer cells (Zhang *et al.*, 2021) and so on. Some researchers find miR-370-3p can down-regulate EDN1 in endometrial stromal cells, thereby depressing endometriosis' development (Zhou *et al.*, 2021); MiR-370-3p represses the cell proliferation of endometrium by regulating steroid synthesis factors (Hu *et al.*, 2019). However, the regulatory mechanism of miR-370-3p on EC is unknown.

In this paper, circCAMSAP1 was chosen as the research object to deeply figure out and study the regulatory mechanism and impacts of the circCAMSAP1/miR-370-3p/MAPK1 molecular axis on EC, offering new therapeutic targets and ideas for EC.

MATERIAL AND METHODS

Experimental subjects

Fifty EC tissue specimens and adjacent normal tissues (≥ 4 cm) were harvested from patients with primary EC

confirmed by surgery and pathology in Affiliated Hospital of Weifang Medical College from July 2014 to July 2018. The mean age of the patients was 45.1±7.2 years. In the light of the surgical and pathological staging of endometrial cancer, 8 cases of stage I, 12 cases of stage II, 15 cases of stage III, and 15 cases of stage IV were presented. Tissues were Stored in liquid nitrogen and transferring to -80°C until total RNA or protein extraction. All patients signed signature of the informed letter, and this study was reviewed and approved by the Ethics Committee of Affiliated Hospital of Weifang Medical College (No: 201302WF353L).

Cell culture and transfection

EC cell lines (HEC-1A, HEC-1B, KLE) and endometrial endothelial cells (hEEC) (Thermo Scientific, USA) were cultured in high glucose [Dulbecco's phosphate buffer modified Eagle culture medium (Hyclone, USA) and replenishment of 10% FBS (Gibco, USA), 110 U/mL penicillin and 110 mg/mL streptomycin (Hyclone, USA)] at 37°C with 5% CO_2, selection for were conducted. Cells were sub-cultured before transfection and cells in logarithmic growth phase was selected for cell transfection. Si-circCAMSAP1, si-NC, pcDNA-circ-CAMSAP1, pcDNA3.1, si-MAPK1, miR-370-3p-inhibitoribitor, miR-370-3p-mimic, and mimic/inhibitor-NC were produced and validated by GeneStar (Shanghai, China). The above plasmids or oligonucleotides were transfected into HEC-1A cells using Lipofectamine 2000 (Thermofisher, USA) according to the manufacturer's instructions. The transfection efficiency was verified by RT-QPCR, and the cells were obtained for subsequent experiments.

Cell counting kit (CCK)-8 and EdU assay

The proliferation ability of EC cells was detected via CCK-8 kit and EdU kit (Enzyme-Linked Bio, Shanghai, China) in the light of the manufacturer's instructions. In the CCK-8 experiment, transfected HEC-1A cells ($2×10^4$ cells/well) was seeded in 96-well plates. Adding 10 μL CCK-8 solution at 24, 48, 72 and 96 h while incubation was conducted. The absorbance at 450 nm was measured with a microplate reader and the curve was drawn. In the EdU experiment, transfected HEC-1A cells ($2×10^4$ cells/well) was added to EdU medium, and fluorescence staining solution was added after incubation. The DNA replication activity of the fluorescently labeled mixture at 350 nm was tested applying a fluorescence microscope (Troth & Kyle, 2021).

Transwell assay

Transfected HEC-1A cells ($2×10^4$ cells/well) were seeded on transwell plates. The upper chamber covered serum-free DMEM (Gibco, USA), and the lower chamber covered 600 μL DMEM and 10%. FBS The upper cavity was incubated, fixed with 95% ethanol and stained. The number of cells in 5 fields was calculated randomly to analyze the migration ability of cells.. Matrigel was flattened on each transwell plate and placed. After the basement membrane gel was solidified, hydration of the basement membrane was with serum-free DMEM to analyze the cell invasion ability (Huang & Li, 2021).

Flow cytometry detection

Cells were stained with fluorescein isothiocyanate (FITC) kit (ThermoFisher, USA) according to the manufacturer's instructions. The adherent cells were harvested by trypsin; The supernatant was taken by centrifugation for the second time and mixed with the binding solution, V-FITC and propidium iodide in the kit for incubation. Part of the sample solution was added into the buffer to take effect, and then flow cytometry was performed (Zong *et al.,* 2020).

Reverse transcription quantitative polymerase chain reaction (RT-qPCR)

Total RNA from BMSC cells was extracted via Trizol reagent (Invitrogen, Carlsbad, CA, USA). Assessment of the quantity and quality of RNA was via adopting a NaoDrop spectrophotometer (Thermo, USA). Then, reverse transcription of the RNA was into cDNA employing PrimeScript RT Master Mix (Takara, Dalian, China). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and U6 were applied as the loading controls for mRNA and miRNA separately. Primer sequences were manifested in Table 1. PCR detection was performed in the light of the instructions of Hieff® qPCR SYBR® Green Master Mix (Yisheng Bio, Shanghai, China), and the $2^{-\Delta\Delta Ct}$ method was put into effect to calculate circCAM-SAP1, miR-370-3p and MAPK1 in EC cells (Huang *et al.,* 2020).

Western blot detection

Cells were lysed by Radio-Immunoprecipitation assay-covering lysis buffer (Beyotime, Shanghai, China), and the supernatant was harvested after high-speed centrifugation (12 000 rpm/min, 15 min) at 4°C. The protein concentration's detection was by bicinchoninic acid kit (Enzyme-Linked Biology, China). Isolation of proteins was by Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (120 V, 1.5 h) and electrically transferring to polyvinylidene fluoride membrane was conducted (300 mA, 1.5 h). Incubation of membranes was with primary antibody MAPK1, anti-E-Cadherin antibody, anti-N-Cadherin antibody and anti-GAPDH antibody (all 1:1000) overnight at 4°C, add horseradish peroxidase-labeled goat anti-rabbit secondary antibody (1:5000) for 1 h. Antibodies were bought from Abbott (Shanghai, China). After incubation, electrogenerated chemiluminescence luminescent solution (Yisheng Bio, Shanghai, China) was used to obtain bands and calculation of protein expression were conducted (Yang *et al.,* 2021).

Table 1. Primer sequence

Genes		Primer sequence
MiR-370-3p	F	GCCGAGGCCTGCTGGGGTGG
	R	GCAGGGTCCGAGGTATTC
U6	F	GCTTCGGCAGCACATATACTAAAAT
	R	CGCTTCACGAATTTGCGTGTCAT

	R	GCTGGACAGGAGAAGCTTGA
MAPK1	F	TGGATTCCCTGGTTCTCTCTAAAG
	R	GGGTCTGTTTTCCGAGGATGA
GAPDH	F	CGCTCTCTGCTCCTCCTGTTC
	R	ATCCGTTGACTCCGACCTTCAC

The luciferase activity assay

HEC-1A cells were seeded in 24-well plates to reach 65% confluence. circCAMSAP1 or MAPK1 3'UTR WT and MUT (Zima Pharmaceuticals, Shanghai, China) were cloned into empty plasmids (Miaoling Bio, Wuhan, China). Lipofectamine 2000 (Thermofisher, USA) was employed for co-transfecting luciferase reporter plasmids into cells with miR-370-3p-mimic and miR-370-3p-NC. Then measurement of the luciferase activity of the samples was conducted applying a dual luciferase reporter gene analysis system (Promega, Shanghai, China).

RNA immunoprecipitation (RIP) assay

EZ-Magna RIP kit (Millipore, USA) was applied for RIP determination. Cells were lysed in RIP lysis buffers and then incubated in RIP buffers covered with magnetic beads coupled with negative controls (normal mouse IgG) or human anti-Argonaute 2 (Ago2, Millipore). Then, conducting Isolation, purification, and final detection by RT-qPCR of the co-precipitated RNA (Wang & Yang, 2021).

Statistical analysis

Data were analyzed employing PSS 24.0 software and presented as mean ± standard deviation (S.D.). A t-test was used for the comparison between the two groups with normal distributions, a nonparametric test was used for the comparison between the two groups with abnormal distributions. Repeating all functional tests in the research was for three times. GraphPad Prism 7.0 software was applied to draw the result pictures, and evaluation of the correlation between the expression levels and cells was by the linear correlation coefficient r. $P<0.05$ clarified statistical significance.

RESULTS

CircCAMSAP1 is elevated in EC cell lines and tissues

In contrast with adjacent normal tissues, circCAMSAP1 was clearly enhanced in EC tissues ($P<0.05$) (Fig. 1A). Compared with hEEC, circCAMSAP1 was also elevated in HEC-1A, HEC-1B and KLE cells ($P<0.05$). Among them, HEC-1A cells had the highest expression ($P<0.01$), followed by the lowest expression of KLE, and HEC-1B (Fig. 1B). Since circCAMSAP1 had the highest expression in HEC-1A cells, HEC-1A cells were chosen for subsequent experiments. These data suggested circCAMSAP1 might participate in the EC disease process.

The effect of knockdown circCAMSAP1 on the biological function of EC cells

After transfection of si-circCAMSAP1, circCAMSAP1 in cells was clearly reduced ($P<0.05$) (Fig. 2A). Cell progression results showed knocking down circCAMSAP1 reduced cell proliferation ($P<0.05$) (Fig. 2B), and EdU positive cells declined ($P<0.05$) (Fig. 2C). Meanwhile, the amount of N-cadherin declined in HEC-1A cells (both $P<0.05$) (Fig. 2D–E); Cell migration and invasion ability were descended (both $P<0.05$) (Fig. 2F–G). Moreover, the apoptosis rate was enhanced after knockdown circCAMSAP1 ($P<0.05$) (Fig. 2H). These data conveyed silencing circCAMSAP1 could refrain EC cells' advancement.

Figure 1. CircCAMSAP1 is elevated in EC cell lines and tissues (**A, B**) CircCAMSAP1 in EC tissues and cell lines; Measurement data were clarified as mean ± S.D.; *$P<0.05$, **$P<0.01$.

CircCAMSAP1 targets miR-370-3p

Plentiful studies have clarified circRNA takes on a role in controlling diseases via competitive adsorption of downstream miRNAs (Tu et al., 2021). The target genes of circCAMSAP1 were forecast employing the bioinformatics database, and miR-370-3p was found to be a candidate target gene of circCAMSAP1 (Fig. 3A). The results of luciferase activity assay illustrated the luciferase activity of HEC-1A cells were declined after co-transfection of miR-370-3p-mimic and circCAMSAP1 WT, while the co-transfection of miR-370-3p-mimic and circCAMSAP1 MUT had no clear impact on luciferase activity ($P<0.05$) (Fig. 3B). After transfection of si-circCAMSAP1, miR-370-3p in HEC-1A cells was clearly enhanced ($P<0.05$) (Fig. 3C). Meanwhile, it was also confirmed that circCAMSAP1 and miR-370-3p were abundant in the anti-Ago group (both $P<0.05$) (Fig. 3D). Moreover, miR-370-3p in EC tissues and cell lines was clearly reduced vs. adjacent normal tissues and hEEC cells (both $P<0.05$) (Fig. 3E-F); MiR-370-3p was opposite to that of circCAMSAP1 (r = –0.7929, $P<0.0001$) (Fig. 3G). The above results proved miR-370-3p was circCAMSAP1's target gene, and the expression patterns of the two were inversely associated.

Elevation of miR-370-3p can depress EC cell evil behavior

MiR-370-3p's biological role in EC was examined by functional acquisition experiments. After introduction of miR-370-3p-inhibitorbitor, miR-370-3p-mimic and mimic/inhibitor-NC into HEC-1A cells, miR-370-3p was measured. It turned out transfection of miR-370-3p-mimic/inhibitor elevated but reduced miR-370-3p respectively ($P<0.05$) (Fig. 4A). The results of functional experiments clarified miR-370-3p-mimic refrained the proliferation ability of HEC-1A cells, and fewer EdU positive cells exhibited (both $P<0.05$) (Fig. 4B–C). Meanwhile, the amount of E-cadherin was elevated but the amount of N-cadherin was declined (both $P<0.05$) (Fig. 4D-E), cell migration and invasion abilities were descended, but apoptosis rate was enhanced (both $P<0.05$) (Fig. 4F–H). The opposite results were gained after transfection of miR-370-3p-inhibitoribitor. These experimental results exhibited elevation of miR-370-3p could refrain EC cell biological function.

Depressive miR-370-3p blocks the therapeutic effect of silencing circCAMSAP1

Transfection or co-transfection of si-circCAMSAP1 and miR-370-3p-inhibitor was to study their effects and regulation on the malignant behavior of EC cells. After transfection with si-circCAMSAP1, miR-370-3p in HEC-1A cells were elevated, while after co-transfection with

Figure 2. The effect of knockdown circCAMSAP1 on the biological function of EC cells
(**A**) RT-qPCR to test circCAMSAP1; (**B–C**) CCK-8 and EdU experiments to evaluate the effect of circCAMSAP1 down-regulation on EC cell proliferation; (**D–E**) Western blot to examine the amount of E-cadherin and N-cadherin after repressing circCAMSAP1; (**F–G**) Transwell assay to evaluate the effect of circCAMSAP1 down-regulation on EC cell migration and invasion; (**H**) EC cell apoptosis rate after circCAM-SAP1 down-regulation was detected by flow cytometry; *$P<0.05$.

Figure 3. CircCAMSAP1 targets miR-370-3p
(**A**) Binding region of miR-370-3p and circCAMSAP1; (**B**) The luciferase activity assay to detect circCAMSAP1 and miR-370-3p's targeting; (**C**) MiR-370-3p after silencing circCAMSAP1; (**D**) CircCAMSAP1 and miR-370-3p were enriched in anti-Ago2 group; (**E–F**) MiR-370-3p in EC tissues and cells; (**G**) Correlation between circCAMSAP1 and miR-370-3p expression pattern; *$P<0.05$.

Figure 4. Elevation of miR-370-3p can depress EC cells' biological behaviors
MiR-370-3p in EC cells was regulated by transfection of miR-370-3P-mimic /inhibitior. (**A**) RT-qPCR to test miR-370-3p; (**B–C**) CCK-8 and EdU experiments to examine cell proliferation; (**D–E**) Western blot to examine the amount of E-cadherin and N-cadherin; (**F–G**) Transwell assay to check cell migration and invasion; (**H**) EC cell apoptosis was detected by flow cytometry; *P<0.05.

si-circCAMSAP1 and miR-370-3P-inhibitor, miR-370-3p in HEC-1A cells were declined (both P<0.05) (Fig. 5A). After circCAMSAP1 was silenced, the proliferation ability of HEC-1A cells (both P <0.05) (Fig. 5B), and the number of EDU-positive cells were declined (Fig. 5C), the amount of E-cadherin was elevated but the amount of N-cadherin was declined (both P<0.05) (Fig. 5D–E); The migration and invasion abilities were repressed (both P<0.05) (Fig. 5F–G), but the apoptosis rate was enhanced (P<0.05) (Fig. 5H). These effects were blocked by transfection of miR-370-3p-inhibitor. These data suggested silencing circCAMSAP1 downregulated EC and blocked the malignant behavior of miR-370-3p-inhibitor in EC cells.

MiR-370-3p targeted MAPK1

MiRNAs frequently combines with the 3 untranslated regions of mRNA and are transcribed to control miRNA expression (Jiang et al., 2021). Therefore, it was predicted the target mRNA of miR-370-3p by StarBase and discovered a latent binding site between MAPK1 and miR-370-3p (Fig. 6A). It came out MAPK1 was elevated in EC tissues and cells (both P < 0.05) (Fig. 6B–C). In the light of the validation results of the bidirectional luciferase activity assay, transfection of miR-370-3p-mimic clearly restrained the reporter activity of MAPK1-WT, while miR-370-3p-inhibitorbitor elevated the reporter activity of MAPK1-WT. The reporter activity of MAPK1-MUT was almost unchanged (P<0.05) (Fig. 6D). Meanwhile, it came out miR-370-3p and MAPK1 were also abundant in the anti-Ago2 group (both P < 0.05) (Fig. 6E). Furthermore, miR-370-3p-mimic downregulated MAPK1, whereas miR-370-3p-inhibitororibitor did the opposite (both P<0.05) (Fig. 6 F–G). These results clarified miR-370-3p inversely controlled MAPK1 in EC cells. Linear analysis exhibited MAPK1 was negatively linked with miR-370-3p (r = −0.7086, P<0.0001) (Fig. 6H). The above experimental results conveyed circCAMSAP1 could target MAPK1 through miR-370-3p.

Si-MAPK1 turns around the malignant effect of pcDNA-circCAMSAP1

Functional rescue experiments were conducted to figure out the mechanism by which circCAMSAP1 controls EC development through the miR-370-3p/MAPK1 molecular axis. The experimental results manifested after transfection of pcDNA-circCAMSAP1, miR-370-3p in HEC-1A cells was reduced but MAPK1 was elevated. After co-transfection of pcDNA-circCAMSAP1 and si-MAPK1, miR-370-3p was enhanced but MAPK1 was

Figure 5. Depressive miR-370-3p blocks the therapeutic effect of silencing circCAMSAP1
Si-circCAMSAP1 was blocked by transfection with miR-370-3p-inhibitor. (**A**) RT-qPCR to test miR-372-3p; (**B–C**) CCK-8 and EdU experiments to examine cell proliferation; (**D–E**) Western blot to examine the amount of E-cadherin and N-cadherin; (**F–G**) Transwell assay to check cell migration and invasion; (**H**) EC cell apoptosis was detected by flow cytometry; *$P<0.05$.

decreased in HEC-1A cells (both $P<0.05$) (Fig. 7A). Results of functional experiments confirmed the proliferation ability of HEC-1A cells was enhanced after elevation of circCAMSAP1 ($P<0.05$) (Fig. 7B), and the number of EDU-positive cells was elevated ($P<0.05$) (Fig. 7C). Meanwhile, the amount of E-cadherin was reduced but the amount of N-cadherin was elevated (Fig. 7D–E), cell migration and invasion ability were strengthened (both $P<0.05$) (Fig. 7F–G), but apoptosis rate was declined ($P<0.05$) (Fig. 7H). These effects were blocked by transfection of si-MAPK1. The experimental results showed elevation of circCAMSAP1 up-regulated MAPK1 by depressing miR-370-3p.

DISCUSSION

Targeted therapy can impact tumor cell growth, apoptosis, signaling, receptor activation, etc., and is considered as a breakthrough in human cancer therapy (Padma *et al.,* 2015). Noncoding RNAs are increasingly momentous in this field as they are implicated in clinical and functional cancer development (Wang *et al.,* 2019). Although patients with early-stage EC have a relevant high survival rate, patients with advanced or recurrent disease still have poor prognosis and limited treatment options

(Mitamura *et al.,* 2019). This study contrasted circCAMSAP1 in EC tissue samples and cells with normal paracancerous tissues and cells for the fist time, and found that circCAMSAP1 was elevated in EC tissues and cells, suggesting that circCAMSAP1 might have adverse effects on EC development.

CircRNAs, highly conserved and stable non-coding RNAs, have received extensive attention owing to their great potential in cancer therapy (Barrett & Salzman, 2016). They have diversified miRNAs binding sites, which can mediate the activity of targeted miRNAs and competitively combine them, thereby depressing the transcription of downstream target genes (Mitra *et al.,* 2018). For instance, circ_0001073 targeting miR-626 can depress the occurrence and development of lung cancer (Liu *et al.,* 2021a); Circ_0004507 targeting miR-873 can upregulate drug resistance proteins, thereby motivating the development of laryngeal cancer (Yi *et al.,* 2021). In former studies, it is found that CAMSAP1 is a gene encoding mammalian astroglial cytoskeleton and neuron-associated cytoskeleton-linked proteins (Yamamoto *et al.,* 2009). Meanwhile, CAMSAP1 is expressed on mature astrocytes in the adult brain and is also considered a novel marker of cells of the astrocyte lineage (Yoshioka *et al.,* 2012). Circ_0001900 derived from exons 2 to 3 of the CAMSAP1 gene, also known as circCAMSAP1,

Figure 6. MiR-370-3p targeted MAPK1
(**A**) Binding region of miR-370-3p and MAPK1; (**B, C**) MAPK1 in EC tissues and cells; (**D**) The luciferase activity assay to detect miR-370-3p and MAPK1's targeting; (**E**) MiR-370-3p and MAPK1 were abundant in anti-Ago2 group; (**F–G**) RT-qPCR and western blot examination of miR-370-3p and MAPK1's targeting; (**H**) Correlation between MAPK1 and miR-370-3p; *$P<0.05$.

which has been clarified to have a momentous role in colorectal cancer. Circ_0004338 (circCAMSAP1 in the research) is derived from exons 1 to 7 of the CAMSAP1 gene and is spliced to form a single-stranded continuous loop structure network by connecting the 3' and 5' ends. These features convey circCAMSAP1 is formed by "direct splicing" and is stably expressed in different cell lines and tissues (Jeck *et al.,* 2014). Although circCAMSAP1 has been well studied in plentiful cancers, it has been less studied in EC. This study is the first to propose and demonstrate that circCAMSAP1 was elevated in EC, and its expression is significant. In the light of the experimental results, knockout of circCAMSAP1 can reduce the proliferation, migration, and invasion of EC cells, but motivate cancer cell apoptosis.

Recently, studies have found circRNAs can combine with miRNAs, thereby exerting tumor-promoting or tumor-suppressing effects (Han *et al.,* 2017). Using Starbase database, circCAMSAP1 and miR-370-3p were found to have binding sites. Subsequent analysis showedcirc-CAMSAP1 refrained miR-370-3p in EC cells. The role of miR-370 as a tumor-promoting or tumor-suppressor gene in different human tumors is controversial. For instance, miR-370 is a latent oncogene in melanoma (Wei *et al.,* 2017); up-regulation of miR-370 suppresses the tumor suppressor FOXO1 in prostate and gastric cancers and motivates cancer cell proliferation (Fan *et al.,* 2013). In contrast, miR-370 has been testified to perform as a tumor suppressor in colon and liver cancer by depressing cell proliferation and accelerating apoptosis (Shen *et al.,* 2018; Sun *et al.,* 2016). In this study, the correlation of miR-370-3p with EC was figured out for the first time, and it was found to be reduced in EC cells. Meanwhile, the results of luciferase activity assay confirmed miR-

370-3p had a binding site with circCAMSAP1, and circ-CAMSAP1 could target miR-370-3p. The experimental results clarified elevation of miR-370-3p could depress the proliferation, migration and invasion of EC cells but accelerate apoptosis, and restraining miR-370-3p blocked the therapeutic effect of silencing circCAMSAP1. These data demonstrated miR-370-3p could downregulate EC and accelerate cancer cell apoptosis.

The MAPK signaling cascade is an intracellular series of serine/threonine protein kinases that take on key roles in diversified cellular functions (Xiong *et al.,* 2021). Studies have shown the p38-MAPK signaling pathway participates in signal transduction, and is initiated by extracellular signals to initiate cascade transduction. Phospho-p38-MAPK forms double phosphorylation through threonine and tyrosine binding sites, and is transferred to the nucleus. Depending on the corresponding target, this can motivate hepatic stellate cell activation (Yang *et al.,* 2021). Meanwhile, MAPK can also control various cellular activities, such as proliferation, differentiation, apoptosis, etc. (Yi *et al.,* 2021). Some studies have suggested MAPK signaling is a promising target for cancer therapeutic intervention (Zhang *et al.,* 2021). As a member of the MAPK family, MAPK1 is a extensively used oncogene that can be activated or expressed, and is elevated in various types of human cancers (Zhao *et al.,* 2021). At present, MAPK1 has been confirmed to combine with diversified miRNAs to regulate downstream signals to achieve cell biological functions (Liu *et al.,* 2021b). This study originally demonstrated miR-370-3p could bind MAPK1 to regulate EC. In the light of the target gene prediction and the results of the bidirectional luciferase activity assay, this study confirmed MAPK1 was miR-370-3p's target gene, and miR-370-3p could

Figure 7. Si-MAPK1 turns around the malignant effect of pcDNA-circCAMSAP1
PcDNA 3.1-circCAMSAP1 was reversed by transfection of si-MAPK1. (**A**) RT-qPCR to test miR-370-3p (**a**) and MAPK1 (**b**); (**B–C**) CCK-8 and EdU experiments to examine cell proliferation; (**D–E**) Western blot to examine the amount of E-cadherin and N-cadherin; (**F–G**) Transwell assay to check cell migration and invasion; (**H**) EC cell apoptosis was detected by flow cytometry; *$P<0.05$.

negatively regulate MAPK1. MAPK1 was elevated. The present study also found silencing MAPK1 could reverse the malignant effects of overexpressing circCAMSAP1 on cells. These experimental results suggested MAPK1 could regulate EC and upregulate disease.

CONCLUSION

In summary, silencing circCAMSAP1 can restrain EC cells' biological functions by targeting the miR-370-3p/MAPK1 molecular axis. The circCAMSAP1/miR-370-3p/MAPK1 axis can become a new marker for EC diagnosis and treatment, and offer a theoretical basis for more research later. However, the research still takes on several limitations. In the research, it was only figured out the circCAMSAP1/miR-370-3p/MAPK1 signaling pathway, more mechanistic signaling pathways, and the possibility of targeting miR-370-3p or MAPK1 to treat EC require to be explored, and further investigation and research are needed.

To investigate the function and possible mechanism of miR-92a in malignant behaviors such as paclitaxel resistance in ovarian cancer (OC) cells. The miR-92a and PTEN expression were detected by real-time PCR (RT-PCR). The cell viability and apoptosis were detected by MTT, colony formation and flow cytometry assay, respectively. Dual-luciferase reporter assay was adopted to verify the targeting relationship between miR-92a and PTEN. Besides, we measured the relative protein levels of PTEN and p-AKT/AKT by Western blot. MiR-92a was significantly highly expressed in OC cells, and its high expression could notably enhance paclitaxel resistance, cell proliferation and colony formation, as well as inhibit apoptosis in SKOV3-Tax cells. Further luciferase reporter assay and expression detection showed that miR-92a could target and regulate PTEN and that there was a targeted relationship between them. In addition, further exploration of the mechanism revealed that miR-92a regulated PTEN/Akt signaling pathway. MiR-92a not only promotes the proliferation, colony formation and paclitaxel resistance of SKOV3-Tax cells in OC, but also inhibits apoptosis, and it may be related to the regulation of the PTEN/Akt signaling pathway. MiR-92a serves as a potential biomarker for the malignant biological behavior of OC cells.

INTRODUCTION

Ovarian cancer (OC), a common gynecological malignancy in the world, is the fifth leading cause of cancer death (Kossai *et al.*, 2018; Funston *et al.*, 2020). Due to inconspicuous early symptoms, most patients with OC are diagnosed at an advanced stage, and thus their 5-year survival rate is approximately 30% (Sehouli Grabowski, 2019; Rooth, 2013). Chemotherapy and immunotherapy are currently the first-line clinical treatments for OC patients. However, most patients develop resistance after a period of treatment (Narod, 2016; Kurnit *et al.*, 2021; Shang *et al.*, 2019). The main treatment for OC is surgi-

cal resection of the visible tumor followed by chemotherapy adjuvant with drugs such as paclitaxel (Mueller *et al.*, 2016). Most patients with OC develop resistance to paclitaxel leading to recurrence. Nevertheless, the molecular mechanisms of paclitaxel resistance are not yet fully understood. Therefore, exploring effective clinical therapeutic targets and clarifying their mechanism will be conducive to the treatment of OC.

MicroRNAs (miRNAs) are small non-coding RNAs of approximately 18–25 nucleotides in length. As important epigenetic regulators, miRNAs are widespread in the biological community and considered highly conservative (Filipowicz *et al.*, 2008). Much research has demonstrated that miRNAs are involved in the evolution of tumors and play a vital role. For example, miRNAs not only participate in the development of tumors by acting as tumor suppressor genes (Gai *et al.*, 2018) or proto-oncogenes (Huang *et al.*, 2019) but also regulate the proliferation, migration and invasion of tumor cells *via* serving as significant biological molecules. In addition, increasing evidence manifested that aberrantly expressed miRNAs exerted an essential effect on drug resistance or drug sensitivity in chemotherapy (Du Pertsemlidis, 2012; De Cecco *et al.*, 2017). As a known carcinogenic miRNA, miR-92a in most cases enhances the development of tumors such as lung cancer (Zhou *et al.*, 2015), cervical cancer (Lin *et al.*, 2013), and pancreatic cancer (Ohyagi-Hara *et al.*, 2013) by regulating the expression of tumor-related genes. In recent years, the biological characteristics and function of miR-92a have been preliminarily understood, but its effect and mechanism in the proliferation, apoptosis and paclitaxel resistance of OC are still unclear. Therefore, we probed into the role of miR-92a in OC by knocking down and overexpressing miR-92a in SKOV3-Tax cells, and its possible molecular regulatory mechanism by bioinformatics prediction and molecular biology experiments. And we believed that with the continuous deepening of the study of miR-92a-related downstream target genes, there would be a scientific basis and clues provided for the diagnosis, treatment and prognosis analysis of OC.

MATERIALS AND METHODS

Cell culture and transfection

Human normal ovarian epithelial cells IOSE80 and OC cell line SKOV3 were purchased from the National Collection of Authenticated Cell Cultures. All cells were cultured in RPMI-1640 medium (Gibco, USA) contain-

ing 10% FBS (Gibco, USA) and 1% penicillin-strepto-mycin (Gibco, USA) in an incubator at 37°C with 5% CO_2 and 95% humidity. Paclitaxel (Tax)-resistant model cells of SKOV3 (SKOV3-Tax) were constructed using induction of concentration gradient.

NC mimics and miR-92a mimics, NC inhibitor and miR-92a inhibitor were purchased from GenePharma Co., Ltd. (China). SKOV3-Tax cells in the logarithmic growth phase were collected and seeded in a 6-well plate. Transfection was performed when the cells were cultured to about 80% confluence. Subsequently, the above plasmids were transferred into SKOV3-Tax cells according to the instructions of Lipofectamine 2000, and were named NC mimics group, miR-92a mimics group, NC inhibitor group and miR-92a inhibitor group, respectively. The plate was placed in the cell incubator for 48-h culture and then the cells were collected.

Real-time PCR (qRT-PCR)

Total cellular RNA was extracted with Trizol reagent (Invitrogen), and the quality and concentration of extracted RNA were determined by Nanodrop. The cDNA was synthesized by reverse transcription according to the instructions of the reverse transcription-PCR kit (Takara, Japan). The PTEN expression level and miR-92a were tested based on the instructions of the SYBR Green PCR Master Mix kit, with GAPDH and U6 as their internal control genes, respectively. The primer sequences were seen in Table 1. And the data analysis was performed by the $2^{-\Delta\Delta Ct}$ method (Zhu *et al.*, 2019).

Table 1. Primer Sequences

MTT

The transfected SKOV3-Tax cells were collected and seeded in a 96-well plate at 5×10^3 cells/well, and then cultured in a cell incubator until the cell adhesion was presented. Next, the cell proliferation was determined at 0 h- and 24 h- adherence as referring to the instructions of MTT kit (Beyotime, China). And then 20 μl MTT solution (5 mg/ml) was added to each well for 4-h culture. After removal of the supernatant, 150 μl DMSO was added to each well, and they were mixed well at ambient temperature for 5 min to dissolve the formazan crystals. The absorbance value at 490 nm was determined by a microplate reader. Finally, different concentrations (0, 1, 2, 3, 4, and 5 logs [Tax] nM) of paclitaxel (Tax) were added for 24-h co-culture after cell adhesion presented in the paclitaxel resistance assay, and then cell survival rate was tested by MTT.

Cell colony formation assay

The transfected SKOV3-Tax cells were collected and seeded in a 6-well plate at 800 cells/well, and then cultured in a cell incubator for 10–14 days. After they formed macroscopic clones, the culture medium was discarded. Afterwards, the cultured cells were fixed with 4% paraformaldehyde (Beyotime, China) for 15 min, and later stained with a crystal violet staining solution (Beyotime, China). The excess staining solution was washed off with PBS and eventually the cells were dried and photographed.

Flow cytometry

Annexin V-FITC/propidium iodide (PI) apoptosis detection kit (BD Pharmingen, USA) was applied to detect SKOV3-Tax in apoptosis. The cells were collected and washed twice with cold PBS buffer, and 500 μl of 1× Binding Buffer was adopted to prepare 1×10^6 cells/ml cell suspension. With the addition of 5 μl of Annexin V-FITC solution, the treated cells were incubated in the dark for 15 min, followed by 10 μl of PI solution at ambient temperature (20–25°C) for another incubation in the dark for 5 min. Lastly, the early and late apoptosis rates of the cells were measured by a flow cytometry system (Becton Coulter, USA) within 1 h.

Dual-luciferase reporter assay

When reaching 80~90% confluence, 293T cells were co-transfected with constructed wild-type (PTEN WT) or mutant-type (PTEN MUT) dual-luciferase reporter vectors of PTEN and miR-92a mimics or NC mimics. Subsequently, the transfected cells were incubated for 48 h and then collected to be lysed at ambient temperature for 20 min. After that, the cell centrifugation was performed, and then the supernatant was collected and stored at −20°C. Subsequently, luciferase substrate was directly added to the supernatant and the luciferase activity was measured by luminescence. The relative firefly luciferase activity was calculated with Renilla luciferase activity as an internal control (Zou *et al.*, 2019).

Western blot

RIPA lysate was added to the cells in each group and cells were lysed on ice for 20 min and centrifuged at 10 000 rpm, 4°C for 20 min to obtain the protein supernatant. Afterwards, the protein concentration was detected by the BCA kit (Solarbio, China). There was 20 μl of total protein separated using SDS PAGE (sodium dodecyl sulfate-polyacrylamide gel electrophoresis). Next, the protein was transferred to PVDF membranes, blocked with 3% BSA blocking solution for 1 h at ambient temperature, and then incubated overnight at 4°C in diluted primary antibodies (anti-PTEN, ab32199, Abcam; anti-p-Akt, #9271, CST; anti-Akt, #9272, CST; anti-GAPDH, ab8245, Abcam; USA). Later, the membranes were washed twice with TBST, and then a diluted secondary antibody (ZSGB-Bio Co., Ltd., China) was added for 1-h incubation at ambient temperature. After that, the membranes were washed three times with TBST, and then ECL luminescence solution was added to the membranes. And then, the membranes were exposed to

the gel imaging system for photography. Finally, the gray values of the protein bands were analyzed by Image pro plus software, and then the relative expression level of the proteins was analyzed with GAPDH as an internal control.

Statistical analysis

All results were expressed as mean ± standard deviation (S.D.) and GraphPad Prism 9.0 was utilized to plot. Statistical analysis was performed with GraphPad Prism 9.0 and SPSS 24.0 software. *T*-test was adopted to compare the two groups, and a one-way analysis of variance was employed for comparison among multiple groups.

$P<0.05$ was considered a statistically significant difference.

RESULTS

MiR-92a promotes SKOV3-Tax cell proliferation, colony formation and improves paclitaxel resistance of cells

Examination of miR-92a expression in normal ovarian epithelial cells IOSE80 and OC cells SKOV3 revealed that miR-92a expression was notably higher in SKOV3 than in IOSE80 ($P<0.01$, Fig. 1A). To clarify the role

Figure 2. MiR-92a inhibits apoptosis of SKOV3-Tax cells.

Figure 3. MiR-92a targets PTEN.
(**A**) TargetScan to predict the targeting sequences between miR-92a and PTEN; (**B**) dual-luciferase reporter assay to validate the targeting relationship between miR-92a and PTEN; C, qRT-PCR to detect the PTEN expression level in IOSE80 and SKOV3 cells, **$P<0.01$ vs., IOSE80; (**D/E**) Western blot to detect PTEN protein expression level in IOSE80 and SKOV3 cells, **$P<0.01$ vs., IOSE80; F, qRT-PCR to detect PTEN expression level in SKOV3-inhibitor cells after knockdown or overexpression of miR-92a, **$P<0.01$ vs., NC mimics, ##$P<0.01$ vs., NC inhibitor.

of miR-92a in OC, we induced SKOV3-Tax, a cell line with apparent resistance to paclitaxel, by concentration gradient (Fig. 1B). Then miR-92a was knocked down and overexpressed respectively in SKOV3-Tax cells by transfection, and the efficiencies of knockdown and overexpression were shown in Fig. 1C. Compared with NC mimics, miR-92a mimics remarkably increased miR-92a expression in SKOV3-Tax cells; compared with NC inhibitor, miR-92a inhibitor markedly inhibited miR-92a expression in SKOV3-Tax cells ($P<0.01$). Meanwhile, the results of MTT and colony formation assays revealed a noticeable climb in proliferation, colony formation and cell activity under different concentrations of Tax treatment of SKOV3-Tax cells in the miR-92a mimics group, compared with the NC mimics group; while in the miR-92a inhibitor group, the above items exhibited an evident reduction compared with the NC inhibitor group (Fig. 1D/E). These results suggested that miR-92a promoted SKOV3-Tax cell proliferation, colony formation as well as resistance to Tax.

MiR-92a inhibits apoptosis of SKOV3-Tax cells

Subsequently, the effect of miR-92a on the apoptosis of SKOV3-Tax cells was further explored. As results shown, compared with the NC mimics group, the apoptosis rate of SKOV3-Tax cells in the miR-92a mimics group was greatly reduced, and the expression level of pro-apoptotic gene Bax in the cells was considerably lowered, while the level of anti-apoptotic gene Bcl-2 was evidently increased ($P<0.01$). By contrast, the opposite results were shown after inhibiting miR-92a in SKOV3-Tax cells by miR-92a inhibitor: The apoptosis level of the cells and the Bax expression level were significantly increased, whereas the Bcl-2 expression was markedly decreased ($P<0.01$) (Fig. 2A–D), indicating that overexpression of miR-92a inhibited apoptosis of SKOV3-Tax cells, while knockdown of miR-92a enhanced apoptosis of SKOV3-Tax cells.

MiR-92a targets PTEN

MicroRNAs mediate the expression of target genes mainly by directly targeting the 3'-untranslated region (3'-UTR) of mRNAs, thereby regulating the behavior of a variety of malignancies (Shi *et al.*, 2021). And we predicted the downstream target gene of miR-92a on the online website TargetScan (https://www.targetscan.org/vert_72/). The outcomes reported that miR-92a was

able to target and regulate PTEN and their targeting sequences were displayed in Fig. 3A. The results of subsequent dual-luciferase reporter assay also manifested that co-transfection of miR-92a mimics notably suppressed the luciferase activity of cells in the PTEN-WT group, but the luciferase activity of the PTEN-MUT group was not obviously changed (Fig. 3B). And the above confirmed that there was a targeting relationship between PTEN and miR-92a. The mRNA and protein expression level of PTEN in SKOV3 cells was significantly lower than those in IOSE80 cells ($P<0.01$, Fig. 3C–E). In addition, the PTEN expression in the cells was remarkably declined after the overexpression of miR-92a in SKOV3-Tax cells, while the opposite was true after the knockdown of miR-92a (Fig. 3F). From the above, it was suggested that miR-92a could target and regulate PTEN expression.

MiR-92a regulates PTEN/Akt signaling pathway in SKOV3-Tax cells

Several studies have demonstrated that through the PTEN/Akt signaling pathway, miR-92a promotes the malignant behavior of tumors such as prostate cancer, nasopharyngeal carcinoma as well as osteosarcoma (Yanshen *et al.*, 2021; Zhang *et al.*, 2016; Xiao *et al.*, 2017). To clarify miR-92a function in OC to promote proliferation, inhibit apoptosis and improve chemoresistance to Tax whether, through the PTEN/Akt signaling pathway, we analyzed the expression of PTEN/Akt signaling pathway by Western blot. And a noticeable decrease was revealed by the results in the PTEN expression level ($P<0.01$), while a marked climb in both the phosphorylation level of Akt and the ratio of p-Akt/Akt ($P<0.01$) in SKOV3-Tax cells in the miR-92a mimics group when compared with the NC mimics group. Besides, in SKOV3-Tax cells in the miR-92a inhibitor group, the PTEN expression level remarkably rose ($P<0.01$), while the phosphorylation level of Akt and the ratio of p-Akt/Akt notably reduced ($P<0.01$) compared with the NC inhibitor group ($P<0.01$) (Fig. 4A/B). All these indicated that miR-92a was able to regulate the PTEN/Akt signaling pathway in SKOV3-Tax cells.

DISCUSSION

Despite the progress at the social medical level, the incidence of malignant tumors is still growing year by year,

Figure 4. MiR-92a regulates PTEN/Akt signaling pathway in SKOV3-Tax cells.
(**A/B**) Western blot to detect the protein level of PTEN, p-Akt and Akt in SKOV3-Tax cells of each group and grayscale analysis was performed for the relative expression level of PTEN and p-Akt/Akt, **$P<0.01$ *vs.*, NC mimics, ##$P<0.01$ *vs.*, NC inhibitor.

and the age of onset of malignant tumors is increasingly younger. Therefore, how to improve the overall health of mankind is a concern and attention in the world today (Vasan *et al.*, 2019). As an important component of cell signaling pathways, miRNAs have been suggested by increasing evidence that are major regulators of many life activities, such as cell proliferation, differentiation, apoptosis, stress response, and angiogenesis. These activities function by binding the 3'UTR region of multiple target genes (Ji *et al.*, 2017). It has been revealed that miRNAs can act as suppressor genes and oncogenes to regulate the development of tumors (Schwarzenbach *et al.*, 2014). In addition, several researchers have reported that miRNAs also play a crucial role in the migration, differentiation, apoptosis, and other processes of OC (Li *et al.*, 2019; Ye *et al.*, 2019). MiR-92a, a novel miRNA discovered in recent years, is highly expressed and exerts a cancer-promoting effect in a variety of tumors (Zhou *et al.*, 2015; Lin *et al.*, 2013; Ohyagi-Hara *et al.*, 2013). In this study, miR-92a was remarkably highly expressed in OC cells *via* a series of in vitro cell experiments. Furthermore, high miR-92a expression promoted OC cell proliferation, colony formation, and paclitaxel resistance, while inhibiting apoptosis.

Peptidyl-prolyl cis/trans isomerase (NIMA-interacting 1, PTEN) is a tumor suppressor gene with bispecific phosphohydrolase function and a high mutation rate in various human cancers (Li *et al.*, 1997). The PTEN gene is located on the short arm of chromosome 10 (10q23.3), with a complex encoded protein structure and a variety of physiological functions. PTEN gene can act not only on the nucleus to regulate the cell cycle, but also on the cell membrane to participate in cell-cell interaction and adhesion functions (Leslie den Hertog, 2014). Studies have manifested that PTEN presents low expression in some human tumors (Yeh Means, 2007). For example, PTEN was down-regulated in various tumors such as lung cancer (Malaney *et al.*, 2018), liver cancer (Liu *et al.*, 2018) and breast cancer (Ngeow *et al.*, 2017). Loss of PTEN function has been demonstrated to stimulate cell growth and survival by excessively activating the PI3K/AKT signaling pathway (Salmena *et al.*, 2008; Hollander *et al.*, 2011; Xie *et al.*, 2021). In this study, PTEN was found to be a downstream target gene of miR-92a through a miRNA-mRNA interaction database. Additionally, luciferase reporter assay and expression analysis revealed that miR-92a could target and regulate the PTEN expression, and down-regulation of miR-92a expression greatly promoted the PTEN expression. More importantly, we discovered that overexpression of miR-

92a notably increased the p-Akt level and the ratio of p-Akt/Akt in OC cells; however, inhibition of miR-92a expression considerably lowered the p-Akt level and the ratio of p-Akt/Akt in OC cells. The above is consistent with the results of previous studies that miR-92a promotes the malignant behavior of tumors such as prostate cancer, nasopharyngeal carcinoma and osteosarcoma through the PTEN/Akt signaling pathway (Zhang *et al.*, 2016; Xiao *et al.*, 2017; Yanshen *et al.*, 2021).

The present study experimentally demonstrated that miR-93a promoted the proliferation, colony formation and paclitaxel resistance of OC cells, and inhibited apoptosis. However, only one OC cell line was tested in this study without mutual confirmation of multiple cell lines. Moreover, this study was an experimental exploration only in cells and did not validate whether miR-92a exerts the same function *in vivo*. Besides, only PTEN/Akt signaling pathway has been investigated in mechanism exploration, and it is not certain whether miR-92a also acts through other pathways. The above issues need to be further experimentally validated and explored.

CONCLUSIONS

In summary, miR-92a was up-regulated in OC cell line SKOV3, and high miR-92a expression not only promoted the proliferation, colony formation and resistance to paclitaxel chemotherapy of SKOV3-Tax cells, but also inhibited apoptosis. Additionally, miR-92a may play a cancer-promoting role by regulating the PTEN/Akt signaling pathway. And miR-92a/PTEN/Akt signaling is possibly a potential therapeutic target for OC patients in the future.

Promoting action of long non-coding RNA small nucleolar RNA host gene 4 in ovarian cancer

Chao Liu[1], Shu Zhao[2], Zhi Xiang Lv[3] and Xiao Juan Zhao[2]✉

[1]Department of Obstetrics and Gynecology, Maternal and Child Health Hospital of Ningyang County, Tai'an City, Shandong Province, 271499, China; [2]Department of Obstetrics, Qingdao Central Hospital, Qingdao City, Shandong Province, 266042, China; [3]Department of Vascular Surgery, Qingdao Central Hospital, Qingdao City, Shandong Province, 266042, China

Objective: Long non-coding RNA (LncRNA) small nucleolar RNA host gene 4 (SNHG4) has been shown to be aberrantly expressed in a variety of cancers and involved in cancer development, but its role in ovarian cancer (OC) is unclear. The purpose of this study was to explore the biological function of SNHG4 in OC and reveal its potential downstream molecular targets. **Methods:** OC tumor tissue and normal tissue were collected; normal human ovarian epithelial cell line (IOSE80) and human ovarian cancer cell line (A2780, SKOV-3, OV-90 and CAOV3) were selected. RT-qPCR was used to detect SNHG4, miR-98-5p, and TMED5, while western blot was used to detect the protein expression levels of TMED5, Ki67, MMP-9, Bcl-2, Bax, Gsk3β, Wnt3a, and β-catenin. The subcellular localization of SNHG4 was assessed by nucleocytoplasmic separation assay. CCK-8, colony formation assay, flow cytometry, and Transwell were used to assess the biological behavior of OC cells. The targeting relationship between SNHG4, miR-98-5p and TMED5 was verified by dual luciferase reporter assay and RIP assay. **Results:** In OC, SNHG4 and TMED5 were highly expressed, and miR-98-5p was underexpressed. Knockdown of SNHG4 inhibited OC cell proliferation, migration and invasion, promoted apoptosis, and prevented Wnt/β-catenin pathway activation. The effect of knockdown of SNHG4 was reversed by knockdown of miR-98-5p or overexpression of TMED5. Mechanistically, SNHG4 competitively adsorbed miR-98-5p to mediate TMED5 expression, thereby activating the Wnt/β-catenin pathway. **Conclusion:** SNHG4 accelerates OC development *via* mediating the miR-98-5p/TMED5 axis and activating the Wnt/β-Catenin pathway. SNHG4 gene silencing might be a novel option for OC treatment.

INTRODUCTION

Ovarian cancer (OC) is an extremely lethal gynecological tumor in women, taking up about 14,000 deaths per annum, which severely threatens women's health and safety around the world (Elsayed *et al.*, 2021). OC's cause remains elusive, and presently, genetic and endocrine factors are regarded as the crucial reason (Gao *et al.*, 2021). Presently, surgery, chemotherapy and radiotherapy are the crucial cure strategies for treating OC (Redondo *et al.*, 2021). These methods have achieved a tremendous breakthroughs, the 5-year survival rate of OC patients is still inferior owing to the lack of elevated specificity of long-term imperative treatment and easy recurrence after recovery (Zhu *et al.*, 2021; Opławski *et al.*, 2021). Consequently, to improve OC patients' quality of life has been a hot topic to explore the molecular mechanism of OC occurrence and development and hunt for brand-new therapeutic targets.

Long non-coding RNA (LncRNAs), a group of ncRNA composed of more than 200 nucleotides transcribed *via* RNA polymerase II, have been testified in multiple cancer occurrence and development (Zhang *et al.*, 2021). Accumulated evidence has illuminated that lncRNAs exert the regulatory role in OC biological functions *via* modulating genes, genomic stability, a competitive endogenous RNA (ceRNA) mechanism and epigenetics after transcription (Xu *et al.*, 2021; Xie *et al.*, 2021). For instance, it has been reported that LINC02323 boosts OC cell growth *via* targeting miR-1343-3p to stimulate TGF-β receptor 1 (Li *et al.*, 2021). Yu and others (Yu *et al.*, 2018) also maintain that lncRNA LUCAT1 accelerates OC malignant tumors *via* modulating the miR-612/HOXA13 pathway. LncRNA small nucleolar RNA host gene 4 (SNHG4) has been identified as a novel target for multiple cancers covering osteosarcoma (OS) (Xu *et al*, 2018), non-small cell lung cancer (NSCLC) (Li *et al.*, 2021), liver cancer (LC) (Jiao *et al.*, 2020), and cervical cancer (CC) (Ji *et al.*, 2019) and a novel target in human diseases (Chu *et al.*, 2021). Nevertheless, the role of SNHG4 in ovarian cancer is unclear.

In terms of mechanism, LncRNA-mediated ceRNA network is frequently explored (Xu *et al.*, 2021). LncRNA prevents mRNA degradation *via* interacting with microRNA (miRNA) (Braga *et al.*, 2020). Consequently, SNHG4-associated miRNA (miR-98-5p) and miRNA (TMED5) were studied. Studies have manifested that miR-98-5p is implicated in OC (Dong et *al.*, 2020). Additionally, reports have clarified that miR-G-1 boosts CC cell nuclear autophagy and malignant behaviors by targeting LMNB1 and TMED5 in CC (Yang *et al.*, 2019).

This research hypothesized that SNHG4 might be involved in the occurrence and development of OC. Through loss-of-function and gain-of-function experiments, the role of SNHG4 was identified as a tumor-promoting factor in OC. Through functional rescue experiments, it was confirmed that SNHG4 affects the biological behavior of OC by regulating the miR-98-5p/TMED5 axis.

MATERIALS AND METHODS

Clinical specimens

A total of 40 pairs of ovarian tumor tissues and adjacent normal tissues were collected from patients undergoing oophorectomy at Maternal and Child Health Hospital of Ningyang County from January 2017 to December 2018. Tissue specimens were histopathologically and clinically diagnosed by a pathologist and stored at −80°C. This study was approved by the Ethics Committee of Maternal and Child Health Hospital of Ningyang County (approval number: 20160811ER), and written informed consent was obtained from all participants. Clinical studies were conducted following the guidelines of the Declaration of Helsinki, and subjects were anonymized during data analysis.

Cell culture and transfection

Normal human ovarian epithelial cell line (IOSE80) and human OC cell line (A2780, SKOV-3, OV-90 and CAOV3) were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China) and identified by STR. Cell culture was done using Roswell Park Memorial Institute-1640 medium (Gibco) covering 10% fetal bovine serum, 2% sodium pyruvate and 1% streptomyces penicillin (Gibco) (Qiao *et al.*, 2021).

Cells were harvested when SKOV-3 cells were subcultured for 3-4 passages and were 70–80% confluent. SKOV-3 cells were divided into 6 groups: si-negative control (NC), si-SNHG4, si-SNHG4 + in-NC, si-SNHG4 + in-miR-98-5p, si-SNHG4 + pcDNA3.1, si-SNHG4 + pcDNA-TMED5. Human TMED5 (Accession: NM_001167830.2) coding sequence (lack of 3'untranslated region (UTR)) was combined with BamH I and EcoR V sites. The recombined control sequences were synthesized by BGI (Shenzhen, China) and inserted into the pcDNA3.1 vector (Invitrogen). TMED5 overexpression plasmid (pcDNA-TMED5) and negative control (pcDNA) were generated with the BamH I and EcoR V sites opened (Zou, Chen, Liu, & Gan, 2021). SNHG4 small interfering RNA (siRNA) and control siRNA were generated (Invitrogen). miR-98-5p mimic (miR-98-5p), miR-98-5p inhibitor (in-miR-98-5p), NC mimic (miR-NC), and NC inhibitor (in-NC) were obtained (RIBOBIO, Guangzhou, China). Then transfection or co-transfection was implemented using Lipofectamine 2000 transfection reagent (Invitrogen). Wnt/β-catenin signal inhibitorX-AV939 was purchased (Selleck Chemicals, Shanghai, China) (L. N. Gao *et al.*, 2021). The transfection efficiency was verified by reverse transcription quantitative polymerase chain reaction (RT-qPCR) after 48 h.

Subcellular localization analysis

Cytoplasmic RNA and nuclear RNA of SKOV-3 cells were isolated using PARIS Kit (Ambion, Austin, TX, United States). SNHG4 expression was tested by RT-qPCR, taking U6 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as nuclear and cytoplasmic control, respectively.

RT-qPCR

Extraction of total RNA was done using Trizol reagent (Invitrogen). Reverse transcription for lncRNA/mRNA and miRNA was implemented *via* lnRcute lncRNA cDNA kit and Rcute Plus miRNA cDNA kit (TIANGEN, China), respectively. RT-qPCR was done

Table 1. Primer sequences

using SYBR Green kit (Thermo Fisher Scientific) and Mx3005P QPCR system (Agilent Technologies, Santa Clara, CA, USA). U6 and GAPDH were loading controls for miRNA and mRNA/lncRNA, respectively. The primer sequence was manifested in Table 1. All primers were designed and validated through the primer-BLAST website.

Western blot

Total protein extraction was done with 500 µL Radio-Immunoprecipitation assay lysis buffer (Beyotime, China). Protein (20 µg) was loaded onto 8% sulfate polyacrylamide gel electro-pheresis gel (Solarbio), electroblotted onto a polyvinylidene fluoride membrane (Invitrogen), and blocked with 5% skim milk. Then incubation with primary antibodies and horseradish peroxidase conjugating with goat anti-rabbit secondary antibody Immunoglobulin G (IgG) (1:1000, ab181236, Abcam) was conducted. The signals were visualized using an enhanced chemiluminescence kit (34080, Thermo Fisher Scientific, Waltham, Massachusetts, USA). Density analysis was done with ImageJ software. Primary antibodies were TMED5, Ki67, MMP-9, Bcl-2, Bax, Gsk3β, Wnt3a, and β-catenin (TMED5 and Gsk3β were from Millipore-Sigma; Others were from Cell Signaling Technology, Beverly, MA, USA, and the dilution was 1:1000) (T. Liu *et al.*, 2021).

Cell Counting Kit-8 (CCK-8) detection

SKOV-3 cells (1×10^3 cells/well) were seeded on 96-well plates and added with 10 µL CCK-8 reagent (Dojindo, Kumamoto, Japan) at the designated time points (0, 24, 48 and 72 h). Ultimately, the absorbance was determined with a SPECTROstar nano spectrophotometer (Germany) at a wavelength of 450 nm.

Colony formation assay

SKOV-3 cells (1×10^3 cells/well) were seeded in a 6-well plate for 1 week. After, the cells were fixed with 4% formaldehyde and GIMSA staining was performed. Ultimately, colonies (≥100 µm) were counted with a microscope (Olympus, Tokyo, Japan).

Flow Cytometry

After transfection, SKOV-3 cells were detached with 0.25% trypsin, and mixed with 100 µL binding buffer to

prepare 1×10^6 cells/mL suspension. Then 5 μL Annexin V-fluorescein isothiocyanate and propidium iodide were added in sequence, and cells were loaded on a CytoFLE S flow cytometer for data analysis (Xu *et al.*, 2021).

Transwell analysis

SKOV-3 cell invasion and migration were assessed by Transwell chamber (8 μm well, Corning Inc. Corning, NY, USA). The upper chamber was covered with 6×10^3 cells in 0.1 mL serum-free medium, and the lower chamber with a medium covering 20% fetal calf serum. Matrigel (356234, Millipore, Burlington, MA, USA) was coated only for invasion. After 12 h, 1% crystal violet staining (Sigma-Aldrich, St. Louis, MO, USA) was performed on the cells in the lower chamber, followed by cell counting under a light microscope (Yu *et al.*, 2021).

The luciferase activity assay

SNHG4 and TMED5 wild-type sequences (SNHG4/TMED5-WT) and corresponding mutant sequences (SNHG4/TMED5-MUT) containing the miR-98-5p binding site were synthesized by RiboBio. These sequences were inserted into the psiCHECK2 reporter vector (Promega, WI, USA). The SNHG4-WT/MUT reporter vector was co-transfected with in-miR-98-5p or in-NC into

SKOV-3 cells. After transfection of 48 h, an assessment of the luciferase activity was done using the luciferase reporter test kit (Promega) (Xing, An, & Chen, 2021).

RNA immunoprecipitation (RIP) detection

RIP was implemented using Magna RIP kit (Millipore). The cells were lysed with complete RIP lysis buffer and combined with magnetic beads. Subsequently, the magnetic beads were combined with human anti-ago2 or normal mouse immunoglobulin G (Millipore). After digestion with proteinase K, immunoprecipitated RNA was analyzed by RT-qPCR (Liu *et al.*, 2021).

Statistical analysis

The data were analyzed by SPSS 21.0 (SPSS, Inc, Chicago, IL, USA) statistical software. After Kolmogorov-Smirnov test, the data were normally distributed, and the results were manifested in the form of mean ± standard deviation (S.D.). Two-group comparison was done using *t*-test and multiple-group comparison was performed with one-way analysis of variance (ANOVA) and Fisher's least significant difference *t*-test. *P* was a two-sided test, and $P<0.05$ was accepted as indicative of distinct differences.

RESULTS

SNHG4 is elevated in OC and associated with adverse clinical characteristics

SNHG4 has been shown to be highly expressed in various cancers. The expression of SNHG4 was assessed in OC. As presented in Fig. 1A, SNHG4 expression in OC tissues was higher than that in normal tissues. Clinical analysis indicated that SNHG4 expression was linked with tumor size, lymph node metastasis and tumor node metastasis (TNM) staging, but had no link with age, distant metastasis and pathological type (Table 2). Additionally, survival analysis (Kaplan-Meier) elaborated that OC patients with high expression of SNHG4 had poor overall survival (OS) rates (Fig. 1B). SNHG4 expression in all human OC cell lines (A2780, SKOV-3, OV-90 and CAOV3) was higher in the normal human ovarian epithelial cell line (IOSE80) (Fig. 1C). Nucleocytoplasmic separation experiments also confirmed that SNHG4 was mainly expressed in the cytoplasm of SKOV-3 cells (Fig. 1D).

To sum up, SNHG4 was elevated in OC and might be implicated in OC progression.

Silenced SNHG4 gene is available to restrain OC's deterioration

Since SNHG4 has the highest expression level in SKOV-3 cells, the SKOV-3 cell line was selected for subsequent functional experiments. To explore the function of SNHG4 in ovarian cancer, an SNHG4 knockdown cell model was constructed. The transfection efficiency was affirmed by RT-qPCR, as manifested in Fig. 2A, si-SNHG4 restrained SNHG4 expression in SKOV-3 cells. Silenced SNHG4 constrained the SKOV-3 cell proliferation (Fig. 2B–C). After restraining SNHG4, SKOV-3 cell apoptosis was promoted and migration and invasion were suppressed (Fig. 2D, E). Meanwhile, knockdown of SNHG4 suppressed the expression of Ki67, MMP-9, Bcl-2 proteins and increased

Figure 5. MiR-98-5p immediately targets TMED5
(**A**) The bioinformatics website predicted the binding site of TMED5 with miR-98-5p; (**B–C**) The luciferase activity assay and RIP experiment evaluation of the interaction of TMED5 with miR-98-5p; (**D–E**) RT-qPCR and Western blot test of TMED5 in OC tumor tissues; (**F–G**) Pearson association analysis of TMED5 with miR-98-5p and SNHG4; (**H–I**) RT-qPCR and Western blot detection of TMED5 in SKOV-3. Measurement data were in the form of mean ± S.D.; #vs. the Normal Tissue, n=40, P<0.05; &vs. the miR-NC, &&vs. the Anti-IgG, *vs. the si-NC, N=3, P<0.05.

the expression of Bax protein (Fig. 2F). These data suggest that knockdown of SNHG4 suppresses the biological behaviors of OC.

SNHG4 performs like a sponge for miR-98-5p

To investigate the novel mechanism by which SNHG4 regulates OC progression, the bioinformatics website https://starbase.sysu.edu.cn was utilized to predict potential miRNAs of SNHG4. miR-98-5p was found to have a potential binding site for SNHG4 (Fig. 3A). The interaction between miR-98-5p and SNHG4 was verified by dual-luciferase reporter gene assay. As shown in Fig. 3B, overexpression of miR-98-5p significantly inhibited the luciferase activity of SNHG4-WT, but not SNHG4-MUT. RIP assay also further confirmed that both SNHG4 and miR-98-5p were enriched in Ago2 magnetic beads (Fig. 3C). Additionally, miR-98-5p expression was downregulated in OC tumor tissues (Fig. 3D) and was negatively linked with SNHG4 expression (Fig.3E). RT-qPCR data showed that inhibition of SNHG4 promoted the expression of miR-98-5p in SKOV-3 cells (JIP 3F). In short, SNHG4 targeted miR-98-5p.

SNHG4 impacts OC cell progression via targeting miR-98-5p

To explore whether miR-98-5p is involved in the regulation of SNHG4 in OC, a functional rescue experiment was performed. si-SNHG4 and miR-98-5p

inhibitor were co-transfected into SKOV-3 cells. RT-qPCR showed that knockdown of SNHG4 promoted the expression of miR-98-5p, which was reversed by miR-98-5p inhibitor (Fig. 4A). Functional experiments showed that knockdown of SNHG4 inhibited cell proliferation, invasion and migration, and promoted apoptosis, but these effects were reversed by knockdown of miR-98-5p (Fig. 4B–F). In brief, SNHG4 impacts OC cell progression via targeting miR-98-5p.

MiR-98-5p immediately targets TMED5

Subsequently, potential downstream mRNAs of miR-98-5p were explored. First, miR-98-5p was found to have potential binding sites with TMED5 by star-Base prediction (Fig. 5A). Meanwhile, dual-luciferase reporter assays revealed that miR-98-5p overexpression could attenuate the luciferase activity of TMED5-WT, while the luciferase activity of TMED5-MUT was not significantly changed (Fig. 5B). Additionally, SNHG4, miR-98-5p and TMED5 are all enriched in RNA-induced silencing complexes immunoprecipitated by Ago2 antibody (Fig. 5C). TMED5 expression in OC tumor tissues was higher than in normal tissues (Fig. 5D–E) and positively associated with SNHG4 while negatively linked with miR-98-5p (Fig. 5F–G). Additionally, in SKOV-3 cells depleted of SNHG4 or restored of miR-98-5p, TMED5 expression was suppressed (Fig. 5H–I). In general, TMED5 was a downstream gene of miR-98-5p.

Figure 6. SNHG4 modulates OC's advancement *via* targeting miR-98-5p/TMED5 axis
(**A–B**) RT-qPCR and western blot test of transfection efficiency in SKOV-3 cells; (**C–D**) CCK-8 and plate cloning experiments detection of cell proliferation ability; (**E**) Flow cytometry examination of cell apoptosis; (**F**) Transwell detection of cell migration and invasion; (**G**) Western blot examination of Ki67 (proliferation marker), MMP-9 (invasion marker), Bcl-2 (anti-apoptotic molecule) and Bax (pro-apoptotic molecule). Measurement data were in the form of mean ± S.D.; &&&&*vs.* the pcDNA3.1, ****vs.* the si-SNHG4 + pcDNA-3.1, N=3, $P<0.05$.

SNHG4 modulates OC progression *via* targeting the miR-98-5p/TMED5 axis

To assess whether SNHG4 is involved in ovarian cancer progression through miR-98-5p-regulated TMED5, a functional rescue assay was performed. In SKOV-3 cells, transfection of pcDNA-TMED5 elevated TMED5 expression, while TMED5 expression was partially upregulated after pcDNA-TMED5 blocked si-SNHG4 (Fig. 6A–B). As manifested in Fig. 6C–E, upregulation of TMED5 reversed the proliferation-inhibiting and apoptosis-promoting effects of SNHG4 silencing on SKOV-3 cells. At the same time, transfection with overexpressing TMED5 plasmid also reversed the inhibitory effect of si-SNHG4-induced migration and invasion of SKOV-3 cells (Fig. 6F). Additionally, Ki67, MMP-9 and Bcl-2 protein expression were augmented, while Bax protein expression was inhibited after pcDNA-TMED5 blocked si-SNHG4 (Fig. 6G). In brief, SNHG4 modulates OC progression *via* targeting the miR-98-5p/TMED5 axis.

Wnt/β-Catenin pathway participates in SNHG4/miR-98-5p/TMED5 axis-mediated OC cell growth

Wnt/β-Catenin pathway may lead to uncontrolled cell growth. Therefore, we further investigated whether SNHG4 regulates the downstream target of miR-98-5p, TMED5, to alter the Wnt/β-catenin signaling pathway in OC cells. Western blot results showed that the expression of Gsk3β was decreased, while the expressions of Wnt3a and β-catenin were upregulated in SKOV-3 cells transfected with pcDNA-TMED5 (Fig. 7A).

To determine whether the Wnt/β-catenin signaling pathway is involved in SNHG4-induced OC progression, the Wnt/β-catenin-specific inhibitor XAV939 (10 µM) was added to pcDNA-TMED5-treated SKOV-3 cells. XAV939 treatment increased Gsk3β expression in pcDNA-TMED5-treated SKOV-3 cells, while Wnt3a and β-catenin protein expression decreased (Fig. 7B). In addition, XAV939 also inhibited the effect of pcDNA-TMED5 on the promotion of proliferation and inhibition of apoptosis in SKOV-3 cells (Fig. 7C/D/E). Similarly, XAV939 inhibited the promoting effect of pcDNA-TMED5 on SKOV-3 cell migration and invasion (Fig. 7F). More importantly, Western blot results showed that the expression of Ki67, MMP-9, and Bcl-2 proteins decreased, while the expression of Bax protein increased (Fig. 7G). In short, SNHG4 activated the Wnt/β-Catenin pathway by targeting the miR-98-5p/TMED5 axis.

DISCUSSION

Some factors like late diagnosis, chemotherapy resistance rate and easy recurrence lead to unpleasing prognosis and high mortality rate in OC patients (Wu *et al.*, 2021). Novel evidence has illuminated that targeting aberrantly-expressed lncRNAs in OC may be latent biomarkers and curative targets for OC (Guo *et al.*, 2021). Additionally, the lncRNA-microRNA-mRNA regulatory

Figure 7. Wnt/β-Catenin pathway implicates in the SNHG4/miR-98-5p/TMED5 axis-mediated OC cells' deterioration

network offers novel perspective for brand-new therapy strategies for OC (Lin *et al.*, 2021).

As reported, SNHG4 is elevated in OS (Xu *et al.*, 2018), NSCLC (Li *et al.*, 2021), LC (Jiao *et al.*, 2020), CC (Ji *et al.*, 2019). SNHG4 has been considered a biomarker for cancer prognosis or diagnosis. Likewise, our work found the upregulated SNHG4 in OC tissues was associated with patients' pathological characteristics and prognosis. Accumulated evidence has elaborated that SNHG4 exerts a regulatory role in cancer cells with multiple biological functions like chemotherapy resistance (Chu *et al.*, 2021). For instance, in colorectal cancer (CRC), suppression of SNHG4 constrains CRC cell growth with immune escape (Zhou *et al.*, 2021). In CC, silenced SNHG4 distinctly restrains CC cell progression (Li *et al.*, 2019). As expected, in this study, suppressing SNHG4 was available to constrain OC cell development (HeLa), clarifying that SNHG4 performed as an oncogene in OC.

In terms of mechanism, lncRNAs, as ceRNAs, elevate mRNA expression *via* interacting with miRNAs (Xu *et al.*, 2021; Xie *et al.*, 2021). It is speculated that SNHG4 may act as a ceRNA to regulate genes, thereby promoting the malignant phenotype of OC cells. In this research, miR-98-5p was confirmed as SNHG4's downstream miRNA in OC. As reported, miR-98-5p is negatively mediated by SNHG4 in LC (Tang *et al.*, 2019). Additionally, a report has illuminated that miR-98-5p expression is reduced in OC, and its silencing is available to alle*via*te OC cell development with cisplatin resistance (Guo *et al.*, 2021).

Likewise, in this research, miR-98-5p was downregulated in OC tissues, and SNHG4 combined with miR-98-5p in OC cells. Besides, silencing miR-98-5p rescued the effects of silenced SNHG4 on OC cells.

In this research, miR-98-5p immediately targeted TMED5's 3'UTR in OC, leading to degradation of TMED5 and repression of its transcription. TMED5, appertaining to the TMED protein family, is implicated in vesicular transport of proteins. As reported, TMED5 expression is elevated in CC and boosts CC cell malignant behaviors (Zou *et al.*, 2021). In this research, TMED5 was augmented in OC tissues, while SNHG4 was available to positively modulate TMED5 *via* miR-98-5p. Additionally, elevated TMED5 rescued silenced SNHG4-mediated repression on OC cell development.

Wnt/β-Catenin, the crucial oncogenic pathway, exerts in multiple cancer progression covering OC and OS (Gao *et al.*, 2021; Guo *et al.*, 2021). Numerous studies have clarified that the Wnt/β-Catenin pathway is linked with OC development with chemotherapy resistance (Vallée *et al.*, 2021). For instance, it has been reported that miR-217 constrains the Wnt/β-Catenin pathway activation, thereby suppressing OC cell progression with drug resistance (Liu & Zhao, 2021). LncRNA HCP5 stimulates OC cell development with epithelial-mesenchymal transition (EMT) *via* the miR-525-5p/PRC1/Wnt/β-Catenin axis (Wang *et al.*, 2020). TMED5 is available to activate the Wnt/β-Catenin pathway in CC (Yang *et al.*, 2019). As expected, in this study, TMED5 declined Gsk3β expression, while enhanced Wnt3a and β-catenin

expression, illuminating that TMED5 activated the Wnt/β-Catenin pathway in OC. Additionally, SNHG4 activated the Wnt/β-Catenin pathway *via* targeting the miR-98-5p/TMED5 axis, thereby boosting OC cell development. We speculate that SNHG4/miR-98-5p/ TMED5 may also be involved in the chemoresistance of OC, which may affect the drug resistance of OC by regulating the Wnt/β-catenin pathway. Notably, although we demonstrated *in vitro* that SNHG4 can regulate the biological behavior of the SKOV-3 cell line, more cell lines are needed to validate the role of SNHG4 in OC. In addition, it is unclear whether SNHG4 has similar effects in animal models of OC, which needs to be explored in follow-up studies. SNHG4 may target a variety of molecules in OC, including miRNA and mRNA, and it is necessary to further refine the regulatory network of SNHG4 in the future.

In conclusion, this work demonstrates for the first time that SNHG4 is highly expressed in OC and reveals the role of SNHG4 as a tumor-promoting factor in OC by regulating the miR-98-5p/TMED5 axis. The SNHG4/miR-98-5p/TMED5 axis may serve as a potential therapeutic target for OC in the future.

Marine natural products: potential agents for depression treatment

Xunqiang Wang†, Cece Yang†, Xing Zhang, Caiping Ye, Wenping Liu and Chengmin Wang*

Department of Psychiatry, Shenzhen Longgang Center for Chronic Disease Control, Shenzhen, China

Depression is a common psychiatric disorder. Due to the disadvantages of current clinical drugs, including poor efficacy and unnecessary side effects, research has shifted to novel natural products with minimal or no adverse effects as therapeutic alternatives. The ocean is a vast ecological home, with a wide variety of organisms that can produce a large number of natural products with unique structures, some of which have neuroprotective effects and are a valuable source for the development of new drugs for depression. In this review, we analyzed preclinical and clinical studies of natural products derived from marine organisms with antidepressant potential, including the effects on the pathophysiology of depression, and the underlying mechanisms of these effects. It is expected to provide a reference for the development of new antidepressant drugs.

Introduction

As one of the most common mental illnesses, there are currently at least 50 million patients with depression in China (Huang et al., 2019). The incidence of depression is increasing year by year, and it is expected to become one of the major causes of disease burden in China by 2030 (Huang et al., 2019). Depression imposes a heavy burden on individuals, families and society due to its high incidence, high disability rate and high suicide rate (Cipriani et al., 2018). Selective serotonin reuptake inhibitors (SSRIs), norepinephrine reuptake inhibitors (NRIs), and dopamine reuptake inhibitors (DRIs) are the main first-line antidepressants used in clinical practice today (Harmer et al., 2017; Moragrega and Ríos, 2021). These medications either work on the neurotransmitter systems of serotonin (5-HT), Norepinephrine (NE), and dopamine (DA) or they suppress the action of the enzyme monoamine oxidase (MAO) to produce antidepressant effects (Harmer et al., 2017). However, even after adequate and sufficient antidepressant treatment, about one-third of patients still do not have a significant therapeutic effect. Patients often experience side effects such as gastrointestinal discomfort and loss of libido, in addition to poor treatment compliance. Therefore, it is of great significance to find more effective and safer antidepressant compounds from a wide range of natural

FIGURE 1
The pathogenesis of depression.

products, and it can also provide new ideas for the development of antidepressant products.

The living environment of marine organisms is complex, resulting in a large number of marine natural products (MNPs). Studies have shown that MNPs have significant pharmacological activities, and the toxicity and side effects are significantly lower than those of synthetic compounds (Corona, 2018). These marine-derived active substances have played an important role in the prevention and treatment of many diseases, and their pharmacodynamic mechanisms are constantly being elucidated. In recent years, with the relentless exploration of researchers, the bioactive substances derived from MNPs have increased. The metabolites isolated from marine organisms have diverse chemical structures, including polyketides, terpenoids, alkaloids, macrolides, cyclic peptides, quinones, polyethers, sterols, polysaccharides, unsaturated fatty acids, and a wide range of pharmacological activities, including antibacterial, antiparasitic, enzyme inhibitor, antioxidant, cytotoxic activity, etc. The majority of marine drug research and development is focused on anti-tumor, anti-cardiovascular disease, and antibacterial agents (Russo et al., 2015; Lima and Medeiros, 2022). Many marine compounds have received clinical approval for use, including the analgesic ziconotide and the anti-cancer drug cytarabine (Jimenez et al., 2020; Yang et al., 2021). MNPs and compounds generated from MNPs are becoming more and more valuable due to their biological activities. Numerous studies have recently revealed that MNPs have antidepressant properties and may slow the course of depression (Subermaniam et al., 2021a). MNPs may be a useful resource for the development of brand-new

antidepressant alternatives. This article examines preclinical and clinical studies on the antidepressant effects of MNPs and research on the neuroscience of depression.

Subsections relevant to the subject

Pathogenesis of depression

The pathogenesis of depression is complex and the biological mechanism is not fully understood (Jesulola et al., 2018). Currently, the widely accepted pathogenic hypotheses include the Monoamine hypothesis, the Neural plasticity hypothesis, the Neuroinflammatory hypothesis, and the Hypothalamic-pituitary-adrenal (HPA) axis (Figure 1) (Subermaniam et al., 2021a; Borbély et al., 2022). It should be mentioned that depression has a complex etiology and may be brought on by a confluence of various pathogenic variables. The search for drugs with multiple targets is thus a crucial area of research for the development of antidepressants.

Monoamine hypothesis

One of the primary causes of depression has been determined to be decreased levels and functional deficiencies of 5-HT, DA, and NE, which are typically present in the brains of depressed patients (Matraszek-Gawron et al., 2019; Wang et al., 2022). The monoamine hypothesis is strongly supported by the fact that 5-HT or NERI can alleviate depression (Locher et al., 2017; Rana et al., 2021). By improving neurotransmission in the central nervous system and increasing the amount of related monoamine neurotransmitters in the synaptic cleft, this class of medications reduces the symptoms of depression (Locher et al., 2017; Yohn et al., 2017).

Neural plasticity hypothesis

The pathogenesis of depression is significantly influenced by neuroplasticity and remodeling failure (Wang et al., 2021a). The neurotrophic family includes brain-derived neurotrophic factor (BDNF), which regulates neuronal plasticity (Castrén and Monteggia, 2021). On the one hand, it might have an impact on the development of synaptic structures, such as axons and dendrites, and their growth and remodeling. On the other hand, it might enhance the long-term synaptic transmission function of the hippocampus through pre- and post-synaptic pathways (Wardle and Poo, 2003). Decreased levels of BDNF have been found in brain samples from depressed patients (Chen et al., 2001; Dwivedi, 2009; Dwivedi et al., 2009; Carlino et al., 2013). In contrast, antidepressant treatment increases the expression of BDNF in the brains of depressed patients (Chen et al., 2001). Therefore, it shows great potential in the treatment of depression as it increases BDNF levels.

TABLE 1 Antidepressant Natural Products of Marine animal Origin.

Natural products	Model establishment	Behavioral outcome	Mechanism	Ref.
Tilapia skin peptides	CP	FST, TST, OFT	Decreased Iba-1, TNF-α, and IL-1β levels	Zhao et al. (2022a)
			Increased Keap1, SOD, and GSH-Px levels via the Nrf2/HO-1 pathway	
			Increased Bcl-2, Bax, and caspase-3 levels via the BDNF/TrkB/CREB pathway	
Bryostatin-1	CUMS	Open water swimming	N.A.	Alkon et al. (2017)
EPA and DHA	CUMS	SPT, TST, OFT	Decreased IL-1β, IL-6, TNF-α, and CD11b levels	Peng et al. (2020)
			Increased BDNF, GDNF and NGF levels	
Resolvin D1	myocardial infarction	FST	Anti-inflammation	Gilbert et al. (2014)
Krill oil	CLET	FST	Increased BDNF levels	Wibrand et al. (2013)
5,6-Br-DMT	FST	FST, TST	N.A.	Zhang et al. (2023)
Astaxanthin	LPS	FST, TST	Decreased TNF-α, IL-1β, IL-6, iNOS, nNOS and COX-2 levels via the NF-κB pathway	Jiang et al. (2016), Jiang et al. (2017)

EPA, eicosapentaenoic acid; DHA, docosahexaenoic acid; 5,6-Br-DMT, 5,6-dibromo-N, N-dimethyltryptamine; CP, cyclophosphamide; CUMS, chronic unpredictable mild stress; CLET, conditioned light extinction test; LPS, lipopolysaccharides; FST, forced swim test; TST, tail suspension test; OFT, open field test; N.A., not applicable.

Neuroinflammatory hypothesis

Glial cells and cytokines play a role in the immune response known as neuroinflammation that occurs in the central nervous system (Zhou et al., 2022). Depression is an inflammation-related disease that worsens as inflammation increases and progresses (Yirmiya et al., 2015; Wang et al., 2021b). According to research, aberrant glial cell activation in the brains of depressed patients results in the release of pro-inflammatory cytokines such as interleukin-6 (IL-6), interleukin 1 beta (IL-1β), and tumor necrosis factor-alpha (TNF-α), which can lead to neuroinflammation and neuronal death (Matraszek-Gawron et al., 2019). In addition, glial cells produce nitric oxide synthase (NOS), and cyclooxygenase-2 (COX-2) could also induce neuroinflammation by promoting oxidative stress levels. Neuroinflammation has emerged as a novel target for the treatment of depression (Wang et al., 2021b; Zhou et al., 2022).

Hypothalamic-pituitary-adrenal (HPA) axis

The hypothalamus, pituitary, and adrenal glands work together as part of the HPA axis to govern the body's reaction to physiological or psychological stimuli (Herman et al., 2016; Lew et al., 2020). Patients with depression have been discovered to have HPA dysfunction, resulting in high glucocorticoid (GC) levels, which in turn cause neuronal dysfunction and structural changes in the hippocampus (Dean and Keshavan, 2017). Clinical trials have established the antidepressant properties of glucocorticoid receptor (GR) antagonists and the viability of targeting HPA regulation in the treatment of depression (Dean and Keshavan, 2017).

MNPs have anti-depressant potential

A significant number of MNPs are produced by the complex living environment of marine animals, and a novel entity structure and enormous diversity are provided by the chemical structure with strong biological activity (Zhao et al., 2022a). Some MNPs have participated in antidepressant preclinical or clinical trials and have proven to be great sources for novel and effective antidepressants (Tables 1, 2). The marine environment is a rich source of novel pharmaceuticals, many of the substances found there can regulate brain activity, reduce anxiety, and have potential therapeutic applications for disorders associated with anxiety and depression (Zhao et al., 2022a). At present, with the interaction between academia and the pharmaceutical sector, a large number of MNPs have been discovered and tested using current analytical methods.

Antidepressant natural products of marine animal origin

Tilapia skin peptides (TSP)

Tilapia skin peptides (TSP), derived from tilapia (*Oreochromis mossambicus*) scraps (Zhao et al., 2022a), have

TABLE 2 Antidepressant compounds derived from marine plants.

Natural products	Model establishment	Behavioral outcome	Mechanism	Ref.
Spirulina	FST	FST	Increased serum BUN and LDH levels	Kim et al. (2008)
Neoechinulin A	LPS	FST	N.A.	Sasaki-Hamada et al. (2016)
Zeaxanthin	diabetic rats	OFT, FST	Decreased IL-6, IL-1β and TNF-α levels	Peng et al. (2020)
Fucoxanthin	LPS	FST, TST	Decreased TNF-α, IL-1β, IL-6, iNOS, and COX-2 level via the AMPK/NF-κB pathway	Gilbert et al. (2014)
Lutein	corticosterone	TST, OFT	Decreased corticosterone levels	Wibrand et al. (2013)
β-Carotene	FST	FST	Decreased TNF-α and IL-6 levels	Kim et al. (2016)
			Increased DNF and p-ERK levels	
Total Sterols and β-sitosterol	FST and TST	FST, TST	Increased NE, 5-HT, and the metabolite 5-HIAA	Zhao et al. (2016)
Fucoidan	LPS and CRS	FST, TST	Inhibited caspase-1 levels	Li et al. (2020)
			Increased BDNF levels	
Fucosterol	FST and TST	FST, TST	Increased NE and 5-HT levels	Zhen et al. (2015)
Alternanthera philoxeroides	ovariectomized	FST, TST	Inhibited MAO-A and MAO-B with IC50 values of 252.9 and 90.69 μg/mL, respectively	Khamphukdee et al. (2018)
Botryococcus braunii	FST	FST	Increased BDNF, TH, and PC levels	Sasaki et al. (2017)
Padina australis	corticosterone	N.A.	Decreased corticosterone levels	Subermaniam et al. (2020)
Ulva species	FST	FST	N.A.	Violle et al. (2018)
Chlorella vulgaris	patients	N.A.	N.A.	Jiang et al. (2016), Jiang et al. (2017)
				Panahi et al. (2015)

LPS, lipopolysaccharides; CRS, chronic restraint stress; FST, forced swim test; OFT, open field test; TST, tail suspension test; N.A., not applicable.

biological actions that are antioxidant, anti-inflammatory, anti-apoptotic and hypotensive (Ling et al., 2018; Zhao et al., 2022b; Song et al., 2022). Hippocampal neurons in mice that received an intraperitoneal infusion of cyclophosphamide (CP) experienced oxidative stress, neuroinflammation, and neuronal death (Iqubal et al., 2019). TSP [1,000 mg/kg/d, intragastrically (*i.g.*)] could improve CP-induced depressive-like behaviors such as Sucrose Preference Test (SPT), Forced Swim Test (FST), Tail Suspension Test (TST) and Open Field Test (OFT) in mice (Zhao et al., 2022a). Mechanistically, TSP may reduce CP-induced neuroinflammation by decreasing the expression of ionized calcium-binding adaptor molecule 1 (Iba-1), TNF-α, and IL-1β in the hippocampus of mice. TSP also attenuated CP-induced oxidative stress by increasing the Nrf2/HO-1 signaling pathway and increasing the levels of kelch-like ECH-associated protein 1 (Keap1), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and malondialdehyde (MDA). In addition, TSP could also reduce neuronal apoptosis by increasing Bcl-2/Bax/Caspase-3 through the BDNF/TrkB/CREB signaling pathway. In conclusion, the antidepressant effect of the TSP may be

involved in the regulation of synaptic plasticity and anti-inflammatory activity (Zhao et al., 2022a).

Bryostatin-1

Bugula neritina-derived bryostatin-1 can increase the expression of protein kinase C (PKC), induce PKC membrane translocation, and enhance synaptic plasticity (Nelson et al., 2017). PKC activity was reduced in the brains of depressed individuals (Pandey et al., 2021). In the rat model of depression generated by chronic unpredictable mild stress (CUMS), PKC expression was markedly reduced (Han et al., 2015). According to these investigations, PKC levels and the development of depression may be related. Furthermore, PKC has the ability to significantly alter synaptic transmission (Wierda et al., 2007; Shen et al., 2021). Bryostatin-1 [100 nmol/kg, intravenous (*i.v.*)] shortened the immobility time in the FST in rats. This antidepressant effect of Bryostatin-1 is largely abolished by 1-(5-isoquinolinylsulfonyl)-2-methylpiperazine (H-7), a PKC inhibitor, which suggests that Bryostatin-1 may have an

antidepressant effect by enhancing synaptic plasticity through activation of PKC action (Alkon et al., 2017).

Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)

Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are mainly derived from the Omega-3 long-chain polyunsaturated fatty acids (n-3 PUFA) of deep-sea fish and shrimp, which play a key role in brain development (Andraka et al., 2020). Continuous oral administration (*p.o.*) of EPA or DHA for 45 days reduced the weight loss and depressive-like behavior caused by CUMS in SPT/OFT/FST. Mechanistically, EPA and DHA effectively reduced CUMS-induced expression of IL-1β, IL-6, TNF-α, microglial marker α M Integrin alpha M (CD11b), and increased expression of astrocyte marker glial fibrillary acidic protein (GFAP) by regulating the NF-κB/ p38 signaling pathway (Peng et al., 2020). Additionally, EPA and DHA modulated the BDNF/TrkB signaling pathway to upregulate the production of BDNF, glial cell-derived neurotrophic factor (GDNF), nerve growth factor (NGF), and Bcl-2 and reduce the expression of Bax, reversing the effects of CUMS-induced neurotrophic factor deficiency and apoptosis (Peng et al., 2020). Moreover, EPA and DHA can also reduce the serum total cholesterol (STC) contents of serum total cholesterol and corticosterone (a glucocorticoid), and induce 5-HT and NE deficiency in the hippocampus, suggesting that EPA and DHA exert antidepressant activity by regulating HPA (Peng et al., 2020). Notably, EPA was more effective than DHA in reducing depressive-like behavior, which was also confirmed in clinical studies. Lipopolysaccharide (LPS) activates BV2 microglia, and docosapentaenoic acid (DPA, a PUFA) balances microglial M1 and M2 polarization, inhibiting NF-κB and p38 while activating neuronal BDNF/TrkB-PI3K/AKT pathways to protect neurons from neuroinflammatory damage (Liu et al., 2021). By increasing the expression of DA, decreasing the expression of NE and gamma-aminobutyric acid (GABA), and reducing the turnover rate of 5-HT in the mouse hippocampus, PUFAs may also enhance CUMS-induced depressive-like behaviors in the SPT, OFT, and FST (Yang et al., 2019). More importantly, a previous clinical trial has been carried out as a result of the positive safety and antidepressant characteristics of EPA and DHA (Su et al., 2014). Nobody left the study during the 2 weeks due to adverse events and, as determined by the investigators, the incidence of Interferon-alpha (IFN-α)-induced depression in patients with hepatitis C virus infection was significantly lower in those treated with EPA but not in those treated with DHA (Su et al., 2014). In a population-based study to prevent the risk of *postpartum* depression in Brazilian pregnant women, a daily intake of 1.8 g of PUFAs (1.08 g of EPA and 0.72 g of DHA) for 16 weeks starting at 22–24 weeks of gestation had no significant effect on early depressive symptoms during pregnancy or *postpartum* (Vaz et al., 2017). However, the

Edinburgh Postnatal Depression Scale (EPDS) scores of women in the EPA/DHA group with a history of depression showed a greater decrease from the second trimester to the *postpartum* period. Additionally, there were no changes between the EPA/DHA groups and control groups in terms of gestational duration or birth weight (Vaz et al., 2017). According to a recent meta-analysis, both EPA and DHA have antidepressant effects, although EPA's are more potent (Sublette et al., 2011).

Resolvin D1

Resolvin D1, a PUFA metabolite mostly found in deep-sea fish and shrimp, is effective in reducing inflammation by activating Akt and binding to 2 G-protein-coupled receptors (ALX and GPR32) (Serhan and Chiang, 2008; Nelson et al., 2014). Resolvin D1 reduces the depressive-like behavior seen in experimental models of myocardial infarction when administered before ischemia or 5 minutes after reperfusion (Gilbert et al., 2014). In the FST, there was a statistically significant relationship between infarct size, and immobility time (Gilbert et al., 2014). After myocardial infarction, inflammation is indeed well-documented, especially in the first hours of reperfusion (Sharma and Das, 1997; Nah and Rhee, 2009). Therefore, the anti-inflammatory effect may be the reason for its antidepressant-like function.

Krill oil

Antarctic krill (*Euphausia superba*), a zooplankton that resembles shrimp and is rich in EPA, DHA, and astaxanthin, is used to produce krill oil (Wibrand et al., 2013). The conditioned Light Extinction Test (CLET) - induced depressive-like behavior in the FST was reduced in rats after 7 weeks of krill oil administration. Additionally, krill oil reduced depressive-like behaviors by modifying the expression levels of synaptic plasticity-related genes in the prefrontal cortex and hippocampus (Wibrand et al., 2013). Moreover, krill oil supplementation in mice ameliorated chronic unpredictable mild stress (CUMS)-induced depressive-like behaviors by prompting the metabolism of glycerophospholipids and sphingolipids through regulation of differentially expressed genes mainly enriched in the membrane structures and neuroactive ligand-receptor interaction pathway (Zhang et al., 2023). Additionally, Krill oil facilitated fear extinction and reduced depressive-like behaviors by increasing hippocampal calcineurin A levels in mice (Alvarez-Ricartes et al., 2018).

5,6-dibromo-N, N-dimethyltryptamine (5,6-Br-DMT)

5,6-dibromo-N, N-dimethyltryptamine (5,6-Br-DMT) was isolated as a pale light yellow crystal. The precise mechanism underlying how 5,6-Br-DMT [20 mg/kg, intraperitoneally, (*i.p.*)] ameliorated depressive-like behaviors in the FST and TST in mice has not been determined. Indole alkaloids related to 5,6-Br-

DMT have been found to have a strong affinity for $5\text{-}HT_2$ receptors, indicating that their antidepressant effects may be caused by inhibition of 5-HT reuptake (Hu et al., 2002).

Astaxanthin

The red carotenoid pigment astaxanthin is abundant in microalgae, salmon, trout, and marine invertebrates (Ávila-Román et al., 2021). It has numerous pharmacological properties, such as anti-inflammatory and antioxidant activities (Wu et al., 2015; Balietti et al., 2016). Trans-astaxanthin (20–80 mg/kg, *p.o.*) for 7 days prevented mice from displaying depressive-like symptoms after being exposed to LPS (Jiang et al., 2016). Neurochemical analysis showed that trans-astaxanthin could also reverse LPS-induced overexpression of IL-1β, IL-6, and TNF-α, and reduce the expression of inducible nitric oxide synthase (iNOS), neuronal nitric oxide synthase (nNOS), and COX-2 by modulating the NF-κB pathway (Jiang et al., 2016). In conclusion, trans-astaxanthin may produce antidepressant effects through its potent anti-inflammatory properties (Jiang et al., 2016). Similarly, administration of astaxanthin (20–80 mg/kg, *i.g.*) to mice improved their depressive-like behavior and reduced immobility time during the FST and TST (Jiang et al., 2017). Pretreatment with para-chlorophenylalanine (PCPA) (a 5-HT synthesis inhibitor) abolished the anti-immobility effect of Astaxanthin in FST and TST, suggesting that the mechanism of the antidepressant-like effects of Astaxanthin may involve the 5-HT system (Jiang et al., 2017). More importantly, a clinical trial investigated the effects of Astaxanthin on 28 adults diagnosed with depression and fatigue. The study also recruited healthy, active, and non-depressed adults. Subjects who received 12 mg of Astaxanthin daily for 8 weeks significantly reduced depression and fatigue, compared to the group who received a matching placebo (Talbott et al., 2019).

Natural antidepressants derived from marine plants

Spirulina

Spirulina is a kind of true filamentous spiral cyanobacteria protoplasm that has the biological activities of enhancing immunity, antioxidation, reducing cholesterol levels, and relieving hyperlipidemia (Kim et al., 2008; Subermaniam et al., 2021b). Hydrolyzed Spirulina by malted barley reduces immobility time on FST in mice and increases serum blood urea nitrogen (BUN) and LDH levels (Kim et al., 2008). Moreover, Spirulina improved adolescent stress-induced anxiety and depressive-like symptoms via oxidative stress and alterations in prefrontal cortex BDNF and 5HT-3 receptors in female rats (Moradi-Kor et al., 2020). The specific mechanism needs to be further explored.

Neoechinulin A

Aspergillus amstelodami yielded Neoechinulin A, an isoprenyl indole alkaloid with antioxidant, anti-tumor, and anti-apoptotic properties from Aspergillus fumigatus MR2012 from the Red Sea. Neoechinulin A [300 ng/kg, Intracerebroventricularly, (*i.c.v.*)] significantly ameliorated memory decline caused by LPS and restored immobility time in the FST in mice. This effect may be due to modulation of the 5-HT system by direct or indirect action on the $5\text{-}HT_{1A}$ receptor (Sasaki-Hamada et al., 2016).

Zeaxanthin

Zeaxanthin, a yellow-orange xanthophyll, has been extracted from the *cyanobacteria Synechocystis sp.* and *Microcystis aeruginosa and* the microalgae *Nannochloropsis oculate* (Lee et al., 2006; Wojtasiewicz and Stoń-Egiert, 2016). Daily oral zeaxanthin administration from weeks 6–19 could reduce depressive-like behaviors in the OFT and FST of diabetic rats. Zeaxanthin administration could also reduce IL-6, IL-1, and TNF-α overproduction, indicating that it has anti-inflammatory characteristics that help minimize depressive-like behaviors in diabetic rats (Zhou et al., 2018a).

Fucoxanthin

Fucoxanthin, a natural carotenoid, is abundant in edible brown seaweed and has been shown to have excellent antioxidant, anti-inflammatory, and anti-diabetic effects (Méresse et al., 2020; Bustamam et al., 2021). In the FST and TST of mice, fucoxanthin (200 mg/kg, *i.g.*) significantly reversed LPS-induced depressive-like behaviors (Jiang et al., 2019). Biochemical analysis showed that Fucoxanthin could inhibit LPS-induced overexpression of IL-1β, IL-6, TNF-α, iNOS, and COX-2 in the hippocampus, frontal cortex, and hypothalamus by regulating the AMPK-NF-κB signaling pathway (Jiang et al., 2019).

Lutein

Lutein, orange-yellow, is mainly found in microalgae and *Chlorella vulgaris* (Jalali Jivan and Abbasi, 2019; Wang et al., 2020), and has neuroprotective effects (Stringham et al., 2019). In the TST, OFT, and Splash test (ST), lutein (10 mg/kg, *p.o.*) administered once daily for 7 or 21 days significantly reversed corticosterone-induced depressive-like behaviors. This suggests that Lutein may regulate the HPA to exert neuroprotective effects by reducing the level of glucocorticoids (Zeni et al., 2019).

β-Carotene

β-Carotene has been extracted mainly from the microalga *Dunaliella salina* (Han et al., 2019). β-Carotene has also been shown to be a potent inhibitor of oxidative stress and inflammation (Zhou et al., 2018b). Oral administration of β-carotene once daily for 28 days significantly reduced immobility time during the FST in mice (Kim et al., 2016). When compared

to the control group, β-Carotene significantly reduced the levels of TNF-α and IL-6, and increased the levels of BDNF and pERK (Kim et al., 2016).

Total sterols and β-sitosterol

Total Sterols and β-sitosterol have been extracted from *Sargassum horneri*, a brown seaweed found in the Northwestern Pacific Ocean and adjacent seas of Korea, Japan, and China (Zhao et al., 2016). Total steroids and β-sitosterol have been used to treat scrofula, gall, goiter, and edema (Shao et al., 2014; Shao et al., 2015). In both the FST and TST, mice who received total sterols (100–200 mg/kg, *p.o.*) and β-sitosterol (10–30 mg/kg, *i.p.*) had significantly shorter immobility times. Additionally, NE, 5-HT, and the metabolite of 5-Hydroxyindoleacetic acid (5-HIAA) were all considerably elevated by total sterols and β-sitosterol in the mouse brain, suggesting that these neurotransmitters may be involved in mediating the antidepressant-like function (Zhao et al., 2016).

Fucoidan

Fucoidan is a bioactive sulfated polysaccharide abundant in brown seaweed with anti-inflammatory activity (Li et al., 2017). Fucoidan (50–100 mg/kg, *p.o.*) significantly attenuated LPS and chronic restraint stress (CRS) induced depressive-like behaviors in the TST and FST in mice (Li et al., 2020). Fucoidan also reduced the downregulation of BDNF-dependent synaptic plasticity in the mouse hippocampus and decreased caspase-1-mediated inflammation (Li et al., 2020). Furthermore, blocking BDNF abolished the antidepressant-like effects of fucoidan in mice, indicating that fucoidan ameliorates depression by inhibiting inflammation and modulating synaptic plasticity (Li et al., 2020).

Fucosterol

Fucosterol is a bioactive compound belonging to the sterol group that can be isolated from algae, seaweed and diatoms (Meinita et al., 2021). Fucosterol exhibits various biological activities including anticancer, anti-inflammatory, anti-neurological, and antioxidant characteristics (Lee et al., 2003; Jung et al., 2013; Gan et al., 2019). Fucosterol (10–40 mg/kg, *i.p.*) significantly shortened the immobility time in the FST and TST of mice. The expression of NE and 5-HT was strongly upregulated by fucosterol in the mouse brain, suggesting that fucosterol may act via these neurotransmitters (Zhen et al., 2015).

Alternanthera philoxeroides

Alternanthera philoxeroides is a true puree of filamentous, spiral-shaped, blue-green freshwater microalgae (Kim et al., 2008). The crude ethanolic extract of *A. philoxeroides* (250–500 mg/kg, *p.o.* once daily for 8 weeks) significantly ameliorated antidepressant-like behaviors in the FST and TST of ovariectomized mice (Khamphukdee et al., 2018). Additionally, it was discovered that the crude extract

controlled the levels of BDNF in the frontal cortex and hippocampus. In addition, the crude ethanol extract of *A. philoxeroides* was found to inhibit both MAO-A and MAO-B with IC$_{50}$ values of 252.9 and 90.69 μg/mL, respectively. These findings suggest that the antidepressant effect of the *A. philoxeroides* extract may be involved in regulating synaptic plasticity and inhibiting MAO activity (Khamphukdee et al., 2018).

Botryococcus braunii

Botryococcus braunii is a pyramid-shaped green colonial microalga that contains triterpenes (Cheng et al., 2019). Daily administration of *B. braunii* ethanol extract (100 mg/kg, for 14 days, *p.o.*) ameliorated depressive-like behaviors with decreased immobility in the FST (Sasaki et al., 2017). The administration of *B. braunii* ethanol extract induced upregulation of gene expression associated with energy metabolism (polyribonucleotide nucleotidyltransferase 1/PNPT1), dopamine production (arginine/serine-rich coiled-coil 1/SRC1), and neurogenesis (short stature homeobox 2/SHOX2, paired-like homeodomain transcription factor 2/PITX2, teashirt zinc finger family member 1/TSHZ1, LIM homeobox 9/LHX9). In addition, the expression of BDNF, tyrosine 3-monooxygenase (TH), and pyruvate carboxylase (PC) was also upregulated (Sasaki et al., 2017). The antidepressant effect of *B. braunii* in animal models of depression is mediated by enhancing energy promotion, neurogenesis, and dopamine synthesis in the brain.

Padina australis

Padina australis is a species of brown macroalgae belonging to the class Phaeophyceae (Subermaniam et al., 2021a). *P. australis* has been reported to possess numerous biological activities including antioxidant, anti-neuroinflammatory, and anti-acetylcholinesterase properties (Gany et al., 2014). pretreatment with *P. australis* (0.25 mg/mL) attenuated high-dose corticosterone-mediated oxidative damage in a PC12 cell model mimicking depression (Subermaniam et al., 2020). *P. australis* reversed the effects of corticosterone, which decreased cell viability, glutathione levels, aconitase activity, and mitochondrial membrane potential while increasing the release of lactate dehydrogenase. This finding indicates that *P. australis* could be developed as a mitochondria-targeted antioxidant to mitigate antidepressant-like effects (Subermaniam et al., 2020).

Ulva species

Ulva species are green macroalgae found in marine, fresh, and brackish waters. *U. species* are widely distributed throughout the world with 18 species identified in Japan (Shimada et al., 2008). Acute and subchronic oral toxicity studies showed that 10–40 mg/kg body weight/day of hydrophilic extract of *U. species* for 14 days significantly reduced the immobility time

in the FST in rats (Violle et al., 2018). *U. species* have the potential to be a useful supplement or replacement for currently prescribed antidepressants. Further studies are necessary to confirm the mechanism of action of MSP and its modulation of brain function (Violle et al., 2018).

Chlorella vulgaris

Chlorella vulgaris is a unicellular green microalgae with many pharmacological properties that include antioxidant, anti-inflammatory, antihypertensive, detoxifying, and anti-atherosclerotic effects (Panahi et al., 2012a; Panahi et al., 2012b). A clinical trial investigated the effects of *C. vulgaris Beijerinck* on 92 patients with major depression. 42 patients were assigned to adjuvant therapy with *C. vulgaris*, while 50 patients received standard antidepressant therapy. Participants in the *C. vulgaris* intervention group received six 300 mg tablets per day for 6 weeks, and the intervention group showed improvements in somatic and cognitive symptoms of depression and anxiety (Panahi et al., 2015).

Current regulatory situation and commercialization of MNPs

MNPs are the source of modern marine pharmaceuticals. The study of MNPs, which originated in the 1930 s, can be regarded as the starting point of modern marine drug research. So far, about 33,200 new MNPs have been reported. Based on these new MNPs, the FDA has approved eight marine drugs, i.e., Cefalotin, Alexan, Zikonotide, Omega-3 fatty acid ethyl ester, Ericline mesylate, Brentuximab vedotin, and Trabectedin. Research on MNPs in China began in the 1970 s. In China, the first Marine Pharmaceutical Symposium was held in 1979. In 1982, the journal "Chinese Marine Drugs" was founded. In 1985, the first marine polysaccharide new drug, alginate diester sodium (for cardiovascular disease), was successfully developed and approved for marketing in China in 1990. In view of the unique structure and significant activity of MNPs, the Ministry of Science and Technology launched the Marine "863" Science and Technology Project ("863" Marine Biotechnology Research Program) in 1996. The National Natural Science Foundation of China also separated marine drugs from medicinal chemistry and funded them separately in 2008. These initiatives have greatly promoted the development of marine natural products in China and trained a group of excellent marine drug researchers. So far, about 6,700 new MNPs have been found in China, accounting for approximately 20% of the world's new MNPs.

Discussion

With the continuous development of modern society, the incidence of depression is increasing, but the existing antidepressant drugs are not effective enough to meet the clinical needs. Therefore, the need for novel, effective antidepressant treatments is critical. In total, 95% of biodiversity and 71% of the Earth's surface are in the oceans (Haefner, 2003; Sagar et al., 2010). The physical and chemical conditions of the ocean provide marine organisms with unique active compounds that offer new possibilities for the development of new drugs. The data presented in this review shows the great value of MNPs and their derivatives in the prevention and treatment of depression, demonstrating the potential of MNPs as a promising source of antidepressant drugs. Through a variety of processes, such as the modulation of neurotransmitter systems, synaptic plasticity, anti-inflammatory qualities, and the modulation of HPA function, these MNPs exhibit antidepressant properties. However, most of the current efficacy of MNPs and derivatives in the treatment of depression is based on data from *in vitro* and *in vivo* studies, and a large number of clinical studies are still needed to prove their safety and efficacy, which will help to develop promising new medicines. With the in-depth exploration of marine organisms by mankind, an increasing number of new compounds will be continuously extracted and isolated from marine organisms, which will bring new impetus to the treatment of depression, a disease that plagues the world.

Mutation in the *VEGF* gene disturbs the production of chondrocytes and angiogenesis which are essential for cartilage health. Cytokines and chemokines produced by auto-activation of B-cells degrade cartilage. Bruton's Tyrosine Kinase (BTK) plays a crucial role in the activation of these B-cells. VEGF has a central part in angiogenesis, in the recruitment of endothelial cells, and is involved in mechanisms that result in tumour formation. The objective of this research is to investigate the potential role of *VEGF* polymorphism in the development of Rheumatoid Arthritis (RA) and the screening of potential natural, synthetic BTK inhibitor compounds as possible *in-silico* chemotherapeutic agents to control auto-activation of B-cells and cartilage degrading cytokines. In this study, it had been shown that allele A frequency was significantly higher than that of allele C in RA-positive patients as compared to controls. Hence it depicts that allele A of *VEGF* (rs699947) can increase the risk of RA while allele C has a protective role. The phytochemicals which showed maximum binding affinity at the inhibitory site of BTK include beta boswellic acid, tanshinone, and baicalin. These phytochemicals as BTK inhibitor give insights to use them as anti-arthritic compounds by nanoparticle drug delivery mechanism.

Keywords: angiogenesis, phytochemicals, Bruton's tyrosine kinase, Rheumatoid Arthritis, *VEGF* gene

Abbreviations: BTK, Bruton's Tyrosine Kinase; RA, Rheumatoid Arthritis

INTRODUCTION

Rheumatoid Arthritis is an inflammatory auto-immune disorder of joints (van Delft & Huizinga, 2020). The inflammatory process enhances as new blood vessels originate and supply different growth factors, oxygen,and cytokines to the cells which leads to the development of irregular fibrous tissues and ultimately causesthe destruction of joints (Nakkala *et al.*, 2021). A ratio of 1:3 between male and female susceptibility can be seen in previous studies. The worldwide prevalence of RA is 0.5–1% depending on geographical changes. The stud-ies conducted in Pakistan and India represent the RA prevalence as 0.5% and 0.2–1% respectively (Bahari *et al.*, 2021). Population diversity is responsible for the higher prevalence of RA in India (Otón & Carmona, 2019). There are some influential factors of RA that play a significant role in the susceptibility of RA like genetic factors and environmental factors. Almost 60% of the susceptibility is caused due to genetic factors. Although further studies are required to explain the role of environmental factors in the onset of RA, however, it is reported that smoking, dietary contents, micro-organisms, and silica exposure have a detrimental effect and they can also exacerbate the condition of RA patients (Ganesan *et al.*, 2020). Dietary contents may also have a role in the severity of the disease. The majority of patients claimed that eating foods like dairy, red meat, green leafy vegetables, etc. made their medical state worse. Red meat contains high amounts of protein and fats whichenhance the pro-inflammatory process resulting in increasedseverity of the disease in patients with RA (Karami *et al.*, 2019).

There are evidence and studies which support that many autoimmune ailments like rheumatoid arthritis along with systemic lupus erythematosus (SLE) and multiple sclerosis are linked with the *VEGF* gene (Martins & Fonseca, 2019). *VEGF* gene has eight exons with alternate splicing, and it is present on chromosome 6p 12. During embryonic developmental stages, the multiplication and migration of endothelial cells are induced by VEGF, and have crucial involvement in tumour development, angiogenesis, and wound healing (Jutley *et al.*, 2017). In the synovial fluid of obstructed joints of RA patient, enhanced expression of VEGF is observed. The enhanced expression also results in inflammation, changes in joints, and different pathological conditions in patients along with angiogenesis. The severity of the disorder or disease can be determined by the VEGF level in the serum of patients. An elevated level of VEGF has been recorded in patients suffering from RA as compared to controls (healthy individuals) and osteoarthritis patients (Philippou *et al.*, 2021). SNPs that are known and also illustrate a significant role in the expression of VEGF proteins are VEGF-2578 A/C (rs 699947), +405 G/C, –460 C/T +936 C/T (Aterido *et al.*, 2017). According to a study in Korea, an association is seen between VEGF SNPs and RA (Qindeel *et al.*, 2020).

Although VEGF is very significant to proliferate cartilage and bone cells but in RA auto-activation of B-cells produces chemicals that damage these cells so, this auto-activity of the B-cells must be controlled (Goswami *et al.*, 2022). Their activation is mediated by a regulatory protein Burton's Tyrosine Kinase. This protein stimulates B-cells to produce cytokines and chemokines. In a healthy individual, synoviocytes produce lubrication and nutrition for the surrounding cartilage tissue, and the synovium has a minimal number of cellular infiltrates. In RA, B-cells infiltrate the synovium and release cytokines, chemokines, and enzymes that promote joint deterioration and inflammation (Wang *et al.*, 2021). It causes the synovium to enlarge, causing synoviocyte production and inflammatory cell penetration to form a pannus that eventually invades the nearby bone and cartilage. B-cell receptor-dependent cell proliferation is inhibited by BTK inhibition, which ultimately results in a decrease in inflammatory cytokines. Targeting the BTK's activity may therefore result in the loss of B cell signaling, which in turn may open up a treatment option for RA. The cytoplasmic, non-receptor tyrosine kinase BTK transmits signals via numerous cell surface molecules. All hematopoietic cell types, except for T, NK, and plasma cells, express it (Miao *et al.*, 2020). BTK communicates with chemokine receptors, Fc receptors, Toll-like receptors, B cells receptors, CD40, and B cells receptors. These activated proteins damage tissues, especially joints. A high level of BTK causes autoimmunity while a low level of BTK helps in improving autoimmune diseases like RA (De Vries *et al.*, 2019). The abnormal activity of BTK might be ceased via various inhibitor synthetic as well as natural bioactive compounds. The core aim of this study was to find out VEGF SNP in the Pakistani population and possible chemotherapeutic drugs.

METHODOLOGY

Sampling

Samples of blood from 100 healthy individuals (controls) and 100 RA patients who were positive for Rheumatoid Factor were collected from two major cities of Pakistan. These blood samples were collected from D.H.Q Hospital Toba Tek Singh, Sheikh Zaid Hospital, Lahore, and Fatima Memorial Hospital Lahore. The participant's approval was taken on an informed consent form and their disease history was recorded on a Performa (covered all aspects related to disease and the risk factors associated with RA). Afterwards the experimental work was carried out at the Institute of Microbiology and Molecular Genetics of the University of the Punjab, Lahore-Pakistan.

IRB approval

The ethical approval for this research study was granted by Departmental Research Ethics and Biosafety Committee under the issuance certificate D/2302/MMG, dated 6-12-2019.

DNA Isolation and Amplification

The fast DNA extraction method makes it simpler to extract DNA from blood and produces a significant volume of non-degraded DNA. The application of triton X-100 prevents DNA degradation (Shahraki *et al.*, 2022). $MgCl_2$ acts as a buffering agent in the red blood cell lysis buffer, whereas EDTA acts as a chelating agent,

stops DNA deterioration, and concentrates DNA. Nuclear lysis buffer and red cell lysis buffer both lysed red blood cells, break the nuclear wall and release the nuclear material inside. SDS was added to the lysis buffer to solubilize proteins and lipids, and chloroform was used to breakdown proteins and purify DNA. Chloroform was used to separate the organic phase from the aqueous phase while maintaining DNA protection in the latter. The precipitation of DNA was accomplished using ethanol. The first procedure involved transferring 500 µl of blood into an Eppendorf tube and then adding 1000 µl of RBC lysis buffer. The Eppendorf was centrifuged for 2 minutes at 7000 rpm(revolutions per minute) after being lightly inverted or gently shaken. After that, the supernatant was removed, and the Eppendorf tube containing the pellet received another 1000 µl addition of RBCs lysis buffer. Once more, the particle was centrifuged at 7000 rpm for 2 minutes, three to four times, until the haemoglobin was eliminated. After RBC lysis buffer was added, the tube was vortexed to break up the pellet and remove the haemoglobin, revealing that the particle exclusively contained WBCs. The tube was then positioned downward on the tissue paper for a brief period of time. The Eppendorf tube was then filled with 600 µl of chloroform (kept at 4°C), 400 µl of nucleic lysis buffer, 100 µl of NaCl, and 400 µl of lysis buffer (kept at 4°C). After that, centrifugation took place for two minutes at 7000 rpm. The result was two phases, an organic phase and an aqueous phase, separated by a layer. Then, 800 µl of 100% ethanol (pre-chilled and maintained at –20ºC) was added to the Eppendorf tube containing the supernatant after 400 µl of the supernatant had been emptied into another Eppendorf tube. After the vortex, the DNA manifested itself in the aqueous phase as a white thread-like structure. The tube was centrifuged at 12000 rpm for one minute, the supernatant was removed, and the tube was dried at room temperature (on tissue paper). After adding 100 µl of T.E. buffer, the tube was vortexed. The DNA-filled Eppendorf tube was then kept at –20°C. The stock solution for the primers was created using a 1:10 ratio.

- Forward inner primer (A allele) "GCCAGCTGTAGGC-CAGACCCTGGT"
- Reverse inner primer (C allele) "TCAGTCTGATTATC-CACCCAGACCG"
- Forward outer primer "GTGCACGAATGATGGAAAGG-GAGG"
- Reverse outer primer "CCCCATCCCATTCTTGCAT-ATAGG"

50 µl were used to conduct the PCR reaction. Forward and reverse primers, genomic DNA, 10 µl of nuclease-free water, and 25 µl of the master mix were all added. The DNA strand was first denaturized at 95°C for 5 minutes, and then it was finally denaturized at 95°C for 30 seconds. For rs699947, the DNA strand was annealed at 67.3°C for 30 seconds, extended at 72°C for 1 minute, and finally extended for 5 minutes at 72°C. The PCR was run for 30 cycles. The PCR products had lengths of 183 bp and 299 bp for rs 699947 and were kept at a temperature of 4ºC. On electrophoresis on 1.3% agarose gel, the amplified products were seen. The size of the PCR products was measured using Thermo Scientific's quick ruler low-range DNA ladder (SM1103).

In-Silico Screening of BTK Inhibitor Chemicals

Plants have a variety of bioactive compounds that can block the activity of BTK to control the auto-activation

Table 1. The laboratory parameters and disease activity in association with VEGF

Parameters	AA		CA + CC		P

*$P<0.05$, Significant; $P>0.05$, non-Significant

of the B-cell, chemokines, and cytokines. Screening of these phytochemicals has been done by using computational tools and online databases. To avoid a huge number of resources, funding, and wastage of time to sort out a particular chemical as a BTK inhibitor, in-silico screening is the best approach to screen out target bioactive chemicals. The target protein BTK was found in PDB to have a 3D structure (ID-6J6M). Using Py-Mol (version 2.5.2), water molecules and already-bound ligands were removed (Hari, 2017). Target ligand information was gathered from a variety of sources, and 3D ligand structures were acquired in SDF format from online chemical databases like Zinc 15, PubChem, and CHEMBL database. Then, using Swiss ADME and Lipinski's Rule of Five, the ligands' drug resemblance was evaluated. Online SMILES Translator (nih.gov) was used to convert the SDF format of the ligands to the PDB format, and Auto Dock Vina (version 1.5.7) was used to convert the PDB to the PDBQT format and then docking by using the command prompt (Samdani & Vetrivel, 2018).

RESULTS

Patients were diagnosed according to the criteria defined AmericanCollege of Rheumatology (ACR) in 2010. Among those 100 patients, males were only 33% while females constitute a major proportion (67%) of the study. The common symptoms in RA patients, whose blood samples were used, found morning stiffness (82%), tenderness in the joints (78%), fatigue (25%), severe pain in joints (85%), fever (20%), and joint Swelling (63%) (Fig. 1) (Ganesan et al., 2020). The risk factors associated with RA were genetic disorder (9%), smoking (7%), diet (33%), hormonal changes (17%), other infectious diseases (6%), and no response (28%) (Fig. 2).

Single Nucleotide Polymorphism in DNA due to extrinsic or intrinsic factors has both deleterious and beneficial effects depending on its nature. In this study, a base change in the VEGF gene in different populations showed significant results in the progression of rheumatoid arthritis. In Table 1, a possible linkage between VEGF polymorphism with RA disease activity was analyzed based on the demographic and clinical condition of the patients. The alleles of the VEGF gene were correlated with disease duration, rheumatoid factor, age of patients and C-reactive protein level.

The appearance of 183bp DNA bands on agarose gel electrophoresis indicated A allele (Fig. 3) and 299bp DNA bands represented C allele (Fig. 4), and the DNA ladder used was Fermantas SM1103. In VEGF, C allele functions as a major allele and A allele as a minor allele. The frequencies of genotype and allele were considerably different in patients and controls. The percentage of AA genotype in RA patients and in controls was 71% and 39% respectively. However, the percentage of CC

Figure 1. Symptoms reported by Rheumatoid Arthritis

Figure 2. Risk factors involved in progression in RA patients

Figure 3. Amplified DNA band of our interest (183bp) shown under the UV Illuminator

Figure 4. Amplified DNA band of our interest (299bp) shown under the UV Illuminator

genotype in RA patients and control was 23% and 52% respectively.

Moreover, in heterogeneous conditions where both alleles (A and C) were present, the percentage of AC genetic constitution in patients and controls was 06% and 09% respectively. Hence, the above data endorsed that VEGF A/C polymorphism hasa role in association with the risk of rheumatoid arthritis. Table 2 and Table 3 revealed different frequencies of genotypes and frequencies of alleles in controls and patients. Our findings suggested that the AA genotype of VEGF was observed considerably higher in RA patients but lower

in healthy individuals that depicted the role of SNPs in the severity of RA.

The chi-square test was done by keeping a degree of freedom (df) value 2, the *p*-value was 0.034 which is less than 0.05, and the regression value was 0.461. All these values showed that the VEGF gene SNP has a significant influence on rheumatoid arthritis progression.

Bioactive Compounds to Inhibit BTK Activity

Plants have a variety of bioactive compounds capable of curing rheumatoid arthritis. These compounds can be screened out in-silico by using different computational tools. The results of docked compounds have been given in Tables 4 and 5 showing binding affinities to block BTK. Protein-ligands docking was done by targeting THR 474, GLU 475, MET 477, and CYS 481 residues of BTK. The results were observed in PyMol (Version: 2.5.2) and noted binding affinities in KJ/mol shown in Fig. 5. The Pleckstrin homology (PH) domain, the Tec homology (TH) domain, the Src homology (SH3) domain, the SH2 domain, and the C-terminal region containing kinase activity are the five sections that make up BTK, according to its structures. BTK inhibitors can be divided into two categories based on how they bind to BTK and how their chemical scaffold structures and mechanisms of action. The amino acid residue CYS 481 in the ATP-binding region of BTK is a covalently bonded target for irreversible BTK inhibitors (Wang *et al.*, 2021). The other class of BTK inhibitors are reversible inhibitors, which bind to an inactive form of the kinase by accessing the particular SH3 pocket of BTK. In order to treat RA, phytochemicals are delivered as drugs via nanoparticles, acting as a BTK inhibitor (Fig. 6).

DISCUSSION

The VEGF gene has a prominent role in the onset of many other autoimmune diseases. There are almost thirteen studies that depict the evidence that *VEGF* was higher in RA patients in contrast to healthy individuals, and hence are in favour of an association between RA and the *VEGF* gene. But contrary to that there are also many studies that deny this and report no association among *VEGF* and the risk of RA like + 936 T/C, *VEGF*-634 C/G, -1154 A/G and −2578 A/C polymorphisms have no relation with RA. In another study, a significant association was observed between *VEGF* (rs 699947) SNPs and RA (Paradowska-Gorycka *et al.*, 2016). The studies show a relationship between the *VEGF* gene and RA in terms of severity along with overlap-

Table 2. Genotypes and Allele frequencies of VEGF C/A polymorphism

Gene mutation	Genotypes	Genotype frequency cases (n=100)	Genotype frequency controls (n=100)	Alleles	Allele frequency cases (n=100)	Allele frequency controls (n=100)

ping of various other disease parameters i.e., activity of disease, functional disability, and joint damage. The main objective behind this work was to access the risk of single nucleotide polymorphism of the *VEGF* gene in RA patients. Two alleles A and C were studied, and their frequency was determined. It had been shown that allele A frequency was significantly higher than that of allele C in RA-positive patients. On the other hand, controls have more frequency of allele C as compared to allele A. Hence it depicts that allele C plays a minor role in the

risk or severity of the RA disease. Recent studies also indicated that allele A of *VEGF* (rs699947) can increase the risk of RA; however, only a protective role is seen in the case of allele C (Saravani *et al.*, 2019). A low level of VEGF is due to allele A and its genotype AA can be its risk factor. While in the case of atherosclerosis, allele C has a protective effect. A relationship has been observed between low serum level and the AA genotype of VEGF in RA patients, as illustrated by a cohort study of 419 patients (Laurindo *et al.*, 2022). Similarly, another

Figure 5. BTK inhibition interactions with different chemicals; (**A**) BETA-BOSWELLIC ACID, (**B**) TANSHINONE, (**C**) BAICALIN, (**D**) BERBERASTINE, (**E**) RN-486, (**F**) QUERCETIN

Figure 6. Phytochemicals used *via* nanoparticle drug delivery as BTK inhibitor to cure RA

research study elucidates that functional polymorphism of VEGF (A/C) may increase the risk of RA in older and Anti-Citrullinated Peptide Antibody negative patients (Arleevskaya *et al.*, 2021). There are some other factors that may be involved in the progression of RA like auto-activation of BTK protein, age, and CRP (Alam *et al.*, 2017).

Rheumatoid arthritis is a multifactorial joint disorder, and VEGF SNP is one of those factors at a genetic level and abnormally activated BTK protein is another one. Only we found that mutation in this gene causes disturbance in angiogenesis proliferation and cartilage repair which is the major possible effect of a mutated VEGF gene. On the other hand, targeting the BTK protein is a phenotypic therapeutic approach which is involved in the destruction of joint lining. So, it is better to cease the damaging effects of this abnormally activated BTK protein to protect the remaining joints' assets. The effect of SNP on the VEGF product protein is the formation of abnormal heparin-binding protein which does not involve in repairing the cartilage and in the proliferation of new blood vessels (Huang and Wang, 2020).

Tanshinone showed binding affinity -8.3 (kJ/mol) at MET 477 (CO-OH,3.0), and ALA 478 (CO-OH,3.4). This chemical is extracted from red sage or commonly known as behmansurkh which is a root of *Salvia miltiorrhiza* and belongs to the Labiatae family of plant kingdom native to China and Japan (Li *et al.*, 2021). For 2000 years ago in China, it is also being used to treat cardiovascular and cerebrovascular disorders, functions of blood flowing into the heart and liver by removing blood stasis according to Traditional Chinese Medicine (TCM) (Deng *et al.*, 2019).

Baicalin showed binding energy of -8.2 (kJ/mol) at CYS 481 (CN-OH,2.9), ASN 479 (CN-OH,2.3), ASN 484 (CN-OH,3.1) residues. It is a flavonoid phytochemical obtained from the root of *Scutellaria baicalensis* belonging to the mint family of flowering plants. This plant is commonly known as Chinese Skullcap or Huangqin. It has powerful antioxidant properties greater than ascor-

bic acid which can scavenge toxic free radicals like superoxide ion, hydroxyl ion, hydroquinone, and polycyclic aromatic compounds (Shakya *et al.*, 2023). It has anti-inflammatory, anti-allergic, anti-bacterial, anti-hypertensive, and food condiment (Ma *et al.*, 2021). Berberastine showed binding energy of –8.1 (KJ/mol) at MET 477 (CN-OH,3.2). It is a phytochemical obtained from the rhizome of *Hydrastis canadensis* belonging to the Ranunculaceae family of angiosperm plants. It is utilized as a yellow dye, astringent, and insect repellent. Goldenseal contains various alkaloids like hydrastine, berberine, canadine, tetrahydroberberastine and berberastine which have great pharmaceutical importance (Brullo *et al.*, 2021).

RN-486 is a synthetic chemical under development which showed binding energy of –7.9 (kJ/mol) at CYS 481 (CN-CO,3.0), LYS 430 (CN-OH,3.1), and ASN 479 (CO-OH,3.2). It binds directly to CYS 481 amino acid to inhibit the enzyme, Bruton's Tyrosine Kinase. RN-486 inhibits inflammation of joints and other systemic inflammation alone or along with methotrexate. It potentially inhibits BTK as small molecule disease-modifying drugs to treat rheumatoid arthritis and other auto-immune disorders (Sakthivel and Habeeb, 2018). It is a potent reversible BTK inhibitor. It also blocks the signals of BCR to inhibit phosphorylation of both BTK and PLC-2 in B-cells. RN-486 shows similar activities in both human and rodent models to prevent type I and type III hypersensitivity responses effectively (Arneson *et al.*, 2021). Ibrutinib is a commercially available synthetic drug, but it has some side effects like diarrhea, upper respiratory tract infection, bleeding, fatigue and cardiac side effects. But RN-486 is a synthetic and under development chemical which has only in-silico trials as compared to phytochemicals which showed more binding affinity than RN-486 to inhibit BTK. Moreover, synthetic drugs take more time and expense, but phytochemicals are ready-made with less or no side effects at the very cheapest cost and can be extracted from plants (Aziz *et al.*, 2023a; Naveed *et al.*, 2023a; Naveed *et al.*, 2023b; Naveed *et al.*, 2023c; Naveed *et al.*, 2022a; Naveed *et al.*, 2022b).

CONCLUSIONS

From this study, it is concluded that AA and CC were the most common genotypes. The allele A of *VEGF* (rs699947) can increase the risk of RA; however, only a protective role is seen in the case of allele C. There are some possible chemotherapeutic drugs in plants like beta boswellic acid, tanshinone, baicalin etc. that can be used *via* nanoparticle drug delivery to cure RA by inhibiting BTK, auto-activation of B-cells and cytokines that damage cartilage. There are some limitations of this study in that the genetic variability cannot be accessed entirely by

the polymorphism on a functional basis because RA is an autoimmune and multifactorial disease, and the genome of the Pakistani population is relatively homogenous because of the cousin marriages.

Circ-POLA2-mediated miR-138-5p/SEMA4C axis affects colon cancer cell activities

YanDong Huang[1#], QingYang Bai[1#], HongBo Yu[2], YanRu Li[1], Hao Lu[1], HuiMin Kang[1], XueWei Shi[1] and Kai Feng[1✉]

[1]Department of Oncology, The First Affiliated Hospital of Baotou Medical College, Inner Mongolia University of Science and Technology, Baotou City, Inner Mongolia Autonomous Region, 014017, China; [2]Practical Teaching Skills Center, Baotou Medical College, Inner Mongolia University of Science and Technology, Baotou City, Inner Mongolia Autonomous Region, 014017, China

This study aimed to investigate the mechanism of circ-POLA2 in colon cancer (CC). Circ-POLA2, miR-138-5p, and SEMA4C levels in CC tissues and cells were recorded. The influences mediated by circ-POLA2, miR-138-5p or SEMA4C on cell proliferation, migration, invasion, and apoptosis were determined. The feedback loop of circ-POLA2/miR-138-5p/SEMA4C was surveyed. As measured, circ-POLA2 and SEMA4C were highly expressed, while miR-138-5p was poorly expressed. Meanwhile, circ-POLA2 could mediate SEMA4C through miR-138-5p targeting. Circ-POLA2 knockdown caused the blockade for cell activities, but this effect was alleviated by miR-138-5p inhibition or SEMA4C overexpression. Overall, circ-POLA2 is tumorigenic for CC through miR-138-5p/SEMA4C axis, which may provide a promising molecular target for CC therapy.

INTRODUCTION

More than 1,090,000 new cases of colon cancer (CC) are diagnosed annually, of which approximately 50% die due to the high rate of metastasis (Siegel *et al.*, 2017; Bray *et al.*, 2018). With changes in people's lifestyle and diet, new cases of CC and young patients are increasing year by year (Zheng *et al.*, 2017). Today, the mainstay of treatment for CC is segmental or total colectomy followed by anastomosis, possibly with the introduction of adjuvant chemotherapy if necessary (Benson *et al.*, 2017; Sun *et al.*, 2020). However, high recurrence/metastasis rates after surgery have not been effectively solved, which is a future direction for CC management.

Circular RNAs (circRNAs) take part in the occurrence, development, metastasis and invasion of CC, and confer diagnostic and prognostic values (Zhao *et al.*, 2019; Han *et al.*, 2021). Indeed, circRNAs are newly discovered in a variety of cells (Wang *et al.*, 2022). Currently, the interaction between circRNAs and miRNAs has been a study focus (Lux & Bullinger, 2018). miRNAs primarily act on target mRNA 3'UTR and are key regulatory roles in CC (Wang *et al.*, 2022; Siciliano *et al.*, 2013; Hollis *et al.*, 2015). Circ-POLA2, a cancer-associated circRNA, has been clarified to express abnormally in endometrial cancer (Fang *et al.*, 2021), acute myeloid leukemia (Li *et al.*, 2021), cervical squamous cell carcinoma (Cao *et al.*, 2020) and lung cancer (Fan *et al.*, 2020). But its relationship with CC has not been reported. Through multiple bioinformatics tools, miRNA (miR-138-5p) and mRNA (SEMA4C) of circ-POLA2 were predicted. miR-138-5p has been confirmed to have decreased expression in colorectal cancer (CRC) and have anti-tumor effects (Wei *et al.*, 2021) and SEMA4C has been illustrated to promote CC progression (Hung *et al.*, 2022). Based on this, circ-POLA2 is likely to competitively upregulate SEMA4C by sponging miR-138-5p, thereby participating CC. Here, circ-POLA2/miR-138-5p/SEMA4C axis-related function and mechanisms were explored, finding new insights into CC treatment.

METHODS

Clinical samples

Following Declaration of Helsinki, the study procedures proceeded with approval of the Ethics Committee of The First Affiliated Hospital of Baotou Medical College, Inner Mongolia University of Science and Technology. All patients has informed of the study and signed written informed consent. CC tumor tissues and adjacent tissues were operationally collected from 40 patients (19 males and 21 females) and immediately frozen in liquid nitrogen. None of patients received preoperative chemotherapy or radiotherapy. Patients with other intestinal diseases, primary cancers, or organ failure were excluded.

Cell lines and culture

SW480, SW620, HT29, and HCT116 were human CC cell lines purchased from ATCC, and NCM460 was normal human colonic mucosal epithelial cell line provided by INCELL Corporation LLC. In a Dulbecco's modified Eagle's medium made of 10% fetal bovine serum (Thermo Fisher Scientific, USA), 100 IU/mL penicillin (SigmaAldrich, USA), and 100 µg/mL streptomycin (Sigma-Aldrich), the cell lines were maintained.

Cell transfection

Short hairpin RNA (shRNA) stably against circ-POLA2 (sh-POLA2), circ-POLA2 overexpression (oe-POLA2), miR-138-5p mimic, miR-138-5p inhibitor, pcDNA-SEMA4C, and corresponding controls were obtained from RiboBio (Guangzhou, China). After Lipo-

fectamine 2000 (Invitrogen)-guided transient transfection, cells were amasses after 24 h.

CCK-8

On the 96-well plates, each well was covered with 5×10^3 SW480 cells and added with 10 μL of CCK-8 solution (Beyotime) after 72 h. The absorbance at 450 nm was recorded on a microplate reader (Tecan Sunrise, Mannedorf, Switzerland) after 4 h.

Clone formation

On the 6-well plates, each well was filled with 1×10^3 SW480 cells for 14 d until staining with 1% crystal violet (Corning). The stained colonies were counted using a microplate reader (Tecan Sunrise).

Transwell

SW480 cells (2×10^5) were seeded into upper chambers (Corning) containing serum-free medium. Matrigel (BD Biosciences, USA) was only coated for testing invasion. Fresh medium containing 10% FBS (Thermo Fisher Scientific) in the lower chamber aimed to attract cell movement. The transmembrane cells during 24 h were conditioned to crystal violet dyeing (0.1%) and microscopical counting.

Flow cytometry

On 1×10^6 SW480 cells, apoptosis was detected by the AnnexinV-fluorescein isothiocyanate/propidium iodide kit (BD Pharmingen, USA) and the apoptosis rate was measured by a BD FACS Aria (BD Biosciences).

RT-qPCR

All tissues and cells were processed for extracting total RNA using Trizol® reagent (Thermo Fisher Scientific). After determination of RNA quality and concentration by NanoDrop 2000 (Thermo Fisher Scientific), reverse transcription was done with SuperScript IV VILO kit (Invitrogen) and All-in-One First-Strand cDNA Synthesis kit (GeneCopoeia, Guangzhou, China). With ABI SYBR Green Master Mix (Invitrogen), PCR was carried out to measure gene expression according to the calculation method 2-ΔΔCT. The primer sequences are shown in Table 1.

Immunoblotting

Sample lysates collected by RIPA lysis buffer (Pierce, USA) were measured by BCA assay kit (Beyotime, China). Proteins were separated by 10-12% sodium dodecyl sulfate polyacrylamide gel electrophoresis (Beyotime), loaded onto a polyvinylidene fluoride membrane (Millipore), after which 5% nonfat dry milk was added, and primary antibodies SEMA4C (1:10000; sc-136445; Santa Cruz Biotechnology) and GAPDH (1:1000; ab8245; Abcam), and horseradish peroxidase-conjugated secondary antibody (1:5000; sc-2054; Santa Cruz Biotechnology) were supplemented. Protein levels were detected by Bio-Rad Gel Imaging System using enhanced chemiluminescence (Thermo Fisher Scientific).

Dual-luciferase reporter gene assay

pmiR-GLO (Promega) was inserted with the amplified wild-type or mutant sequences (POLA2-WT, SEMA4C-WT, POLA2-MUT, SEMA4C-MUT) and co-transfected with miR-138-5p or miR-NC into SW480 cells with Lipofectamine 2000 (Thermo Fisher Scientific), and the

luciferase activity was detected using a dual-luciferase reporter gene detection system (Genomeditech, Shanghai, China).

RNA pull-down

Pierce Magnetic RNA-Protein Pull-Down Kit (Thermo Fisher Scientific) was used. SW480 cells (1×10^7) were lysed in RIP lysis buffer (Thermo Fisher Scientific), followed by interaction with circ-POLA2 probe-coated C-1 magnetic beads. The final results were obtained by RT-qPCR.

Statistical analysis

SPSS 21.0 software and GraphPad Primer 6.0 were employed to perform statistical analysis. All data presented as mean ± standard deviation were analyzed by Student's t-test and one-way ANOVA. The Kaplan-Meier method was utilized to assess survival and analyzed by the Log rank test while Pearson analysis was to analyze the gene correlation. $P<0.05$ was considered statistically significant.

RESULTS

circ-POLA2 is associated with CC progression

High circ-POLA2 was expressed in CC patients' tumor tissues (Fig. 1A), and circ-POLA2 expression was further increased in CC patients' tumor tissues in TNM stage III and with lymph node metastasis (Fig. 1B, C). CC patients were divided into high or low circ-POLA2 expression groups defined by circ-POLA2 median value, and Kaplan-Meier analysis evaluated that patients with high circ-POLA2 expression had lower overall survival (Fig. 1D). These findings suggest that circ-POLA2 is upregulated in tumor tissues of patients with CC and is associated with poor prognosis.

Circ-POLA2 knockdown inhibits activities of CC cells

Circ-POLA2 in CC cells and normal colon epithelial cells was detected by RT-qPCR. The results showed that circ-POLA2 expression was increased in CC cell lines (SW480, SW620, HT29 and HCT116), and circ-

Figure 1. Upregulation of circ-POLA2 is associated with CC progression
(**A**) circ-POLA2 in tumor tissues of CC patients was detected by RT-qPCR. (**B**) circ-POLA2 in tumor tissues of CC patients with TNM stage III was detected by RT-qPCR. (**C**) circ-POLA2 in tumor tissues of CC patients with lymph node metastasis was detected by RT-qPCR. (**D**) Kaplan-Meier analysis of overall survival of CC patients; values are expressed as mean ± standard deviation.

POLA2 expression was most significantly increased in SW480 cells (Fig. 2A). Therefore, SW480 cells were analyzed for subsequent experiments. After transfection of sh-POLA2 or oe-POLA2, circ-POLA2 in SW480 cells decreased or increased accordingly (Fig.

2B), indicating that the cells were successfully transfected. CCK-8 assay, colony formation assay, Transwell assay, and flow cytometry were then performed to explore the role of circ-POLA2 in CC cells. CCK-8 results showed that circ-POLA2 knockdown inhibited SW480 cell activity (Fig. 2C). Meanwhile, colony formation experiments determined that circ-POLA2 knockdown inhibited the proliferation of SW480 cells (Fig. 2D, E). Transwell analysis presented that circ-POLA2 knockdown inhibited SW480 cell migration and invasion (Fig. 2F, G). In addition, flow cytometry suggested that circ-POLA2 knockdown promoted apoptosis of SW480 cells (Fig. 2H, I). However, the effect of circ-POLA2 overexpression on CC cells was opposite to that of circ-POLA2 knockdown (Fig. 2C–I). In conclusion, circ-POLA2 plays a carcinogenic role by promoting proliferation, migration, and invasion of CC cells and inhibiting cell apoptosis.

Circ-POLA2 confers mediation of miR-138-5p

miR-138-5p was cross-screened on bioinformatics websites (CircBank, starBase, miRanda, and RNAhybrid) to be the potential miRNA of circ-POLA2 (Fig. 3A). Measurements of luciferase activity demonstrated that miR-138-5p inhibited the luciferase activity of POLA2-WT (Fig. 3B) and RNA pull-down test discovered that circ-POLA2 significantly increased miR-138-5p enrichment (Fig. 3C). Actually, miR-138-5p expression kept lowly in CCpatients' tumor tissues (Fig. 3D), which was in an inverse correlation with circ-POLA2 expression (Fig. 3E). Likewise, miR-138-

(**B–C**) The binding relationship between circ-POLA2 and miR-138-5p was verified by dual luciferase reporter assay and RNA Pull-Down assay. (**D**) miR-138-5p in tumor tissues of CC patients was detected by RT-qPCR. (**E**) The correlation between circ-POLA2 and miR-138-5p expression in CC tissues was evaluated by Pearson correlation coefficient. (**F**) miR-138-5p in CC cell lines was detected by RT-qPCR. G: miR-138-5p was detected by RT-qPCR after circ-POLA2 expression intervention; values are expressed as mean ± standard deviation. *$P<0.05$ vs. sh-NC group; #$P<0.05$ vs. oe-NC.

5p expression was downregulated in CC cells lines (SW480, SW620, HT29, and HCT116) (Fig. 3F). While miR-138-5p was up-regulated in SW480 cells intervened with sh-POLA2 and down-regulated in those transfected with oe-POLA2 (Fig. 3G). In conclusion, circ-POLA2 acts as a molecular sponge for miR-138-5p to inhibit miR-138-5p expression.

miR-138-5p prevents the aggressive activities of CC cells

After transfection with miR-138-5p mimic or inhibitor, miR-138-5p in SW480 cells increased or decreased accordingly (Fig. 4A). CCK-8 detection results showed that upregulating miR-138-5p inhibited the activity of SW480 cells (Fig. 4B). Colony formation assay found that upregulating miR-138-5p inhibited the proliferation

(**A**) Bioinformation sites predicted the binding sites of miR-138-5p and SEMA4C. (**B**) The binding relationship between miR-138-5p and SEMA4C was verified by dual luciferase reporter assay. (**C**) SEMA4C in tumor tissues of CC patients was detected by RT-qPCR. (**D**) The correlation between miR-138-5p and SEMA4C expression in CC tissues was evaluated by Pearson correlation coefficient. (**E**) SEMA4C in CC cell lines was detected by RT-qPCR. (**F**) SEMA4C was detected by RT-qPCR and Western blot after miR-138-5p expression intervention; values are expressed as mean ± standard deviation. *$P<0.05$ *vs.* sh-NC group; #$P<0.05$ *vs.* oe-NC.

of SW480 cells (Fig. 4C, D). Transwell analysis showed that overexpressing miR-138-5p inhibited the migration and invasion of SW480 cells (Fig. 4E, F). Flow cytometry showed that upregulating miR-138-5p promoted apoptosis of SW480 cells (Fig. 4G, H). Down-regulation of miR-138-5p had opposite effects on CC cells compared with upregulation of miR-138-5p (Fig. 4B–H). These data indicate that miR-138-5p plays an antitumor function by inhibiting cell proliferation, migration, and invasion and promoting cell apoptosis.

miR-138-5p has a modificatory action on SEMA4C expression

On the bioinformatics website starBase, miR-138-5p had a targeted binding site with SEMA4C (Fig. 5A). Further detection results revealed that the luciferase activity of the SEMA4C-WT was inhibited by miR-138-5p transfection (Fig. 5B). High SEMA4C expression was measured in CC patients' tumor tissues (Fig. 5C) in a negative correlation with miR-138-5p expression (Fig. 5D). The upregulation of SEMA4C was also seen in CC cells lines (SW480, SW620, HT29, and HCT116) (Fig. 5E) and cellular SEMA4C levels could be negatively modified by miR-138-5p (Fig. 5F). These results suggest that SEMA4C expression is negatively regulated by miR-138-5p.

miR-138-5p/SEMA4C axis can intervene the influences of circ-POLA2 on CC

miR-138-5p or SEMA4C expression was intervened in sh-POLA2-modified SW480 cells and the successful transfection was verified, as evidenced by miR-138-5p inhibitor-induced decline of miR-138-5p and SEMA4C-induced elevation of SEMA4C expression (Fig. 6A). CCK-8 assay showed that the sh-POLA2-mediated decrease in SW480 cell viability was reversed by anti-miR-138-5p or SEMA4C (Fig. 6B). Meanwhile, colony for-

mation assay showed that anti-miR-138-5p or SEMA4C could attenuate sh-POLA2-induced proliferation inhibition in SW480 cells (Fig. 6C, D). Furthermore, anti-miR-138-5p or SEMA4C mitigated Sh-PolA2-mediated decrease in SW480 cell migration and invasion (Fig. 6E, F). In addition, anti-miR-138-5p or SEMA4C mitigated an increase in sh-POLA2-mediated apoptosis in SW480 cells (Fig. 6G, H). In conclusion, circ-POLA2 can promote proliferation, migration, and invasion of CC cells and inhibit cell apoptosis by regulating miR-138-5p/SEMA4C axis.

DISCUSSION

Accumulating evidence suggests that circRNAs can act as tumor biomarkers and regulate CC progression (Chen and Shen 2020). Ju and others (Ju *et al.,* 2019) analyzed 667 cases of stage II/III CC with R0 resection and found that circRNA could predict postoperative recurrence of stage II/III CC. Abnormal expression of circRNAs is indicative of patients' prognosis in CC (Hsiao *et al.,* 2017; Zhou *et al.,* 2020; Zheng *et al.,* 2019). In CC patients' tumor, circ-POLA2 was upregulated, having an association with TNM stage III, lymph node metastasis, as well as low overall survival rate. Furthermore, our findings suggest that circ-POLA2 exerts oncogenic effects via miR-138-5p/SEMA4C axis.

The up-regulated expression and stability of circ-POLA2 make it a potential biomarker and diagnostic and therapeutic target for human cancer (Fang *et al.,* 2021; Li *et al.,* 2021; Cao *et al.,* 2020; Fan *et al.,* 2020). Furthermore, circ-POLA2 can sponge different miRNAs, including miR-31, miR-34a, miR-326 and miR-34a, to intercede tumor progression. Similarly, this study clarified a competitive binding of circ-POLA2 to miR-138-5p.

miR-138-5p is a cancer-related miRNA in gastric cancer (Zhang *et al.,* 2020), prostate cancer (Huang *et al.,*

Figure 6. miR-138-5p/SEMA4C axis can intervene the influences of circ-POLA2 on CC
(**A**) The transfection efficacy of sh-POLA2 + anti-miR-138-5p, sh-POLA2 + anti-NC, sh-POLA2 + SEMA4C, or sh-POLA2 + Vector was verified by RT-qPCR and Western blot. (**B**) Cell viability was detected by CCK-8. (**C–D**) Cell proliferation was detected by colony formation assay. (**E–F**) Cell migration and invasion were analyzed by Transwell. (**G–H**) Apoptosis was analyzed by flow cytometry; values are expressed as mean ± standard deviation. *$P < 0.05$ *vs.* sh-POLA2+ anti-NC; #$P < 0.05$ *vs.* sh-POLA2 + Vector.

2020), and cervical cancer. Notably, it is known that miR-138-5p is decreased in CRC and that miR-138-5p serves to disrupt the aggressive activities of CRC cells (Wei *et al.,* 2021). Here, miR-138-5p expression was reduced in CC and was anti-tumorigenic achieved by impeding cell malignancy.

SEMA4C, a member of the semaphorin family originally named M-SemaF, can mediate directional growth of axons and the development of myotubes (Yang *et al.,* 2020). As miRNAs target, SEMA4C is associated with various tumors. For example, SEMA4C mediates chemoresistance in cervical cancer (Jing *et al.,* 2019), induces tumor progression in pancreatic cancer (Fei *et al.,* 2020), and is considered an epigenetic regulator involved in CC progression (Hung *et al.,* 2022). Here, SEMA4C was upregulated in CC, and involved in circ-POLA2/miR-138-5p axis-regulated progression of CC. In detail, miR-138-5p downregulation or SEMA4C upregulation could attenuate the reduction of cell activities mediated by circ-POLA2 knockdown.

Although this study found that circ-POLA2/miR-138-5p/SEMA4C axis promotes CC progression in vitro, it has not been further validated *in vivo*. Circ-POLA2 expression in serum of CC patients should also be detected in the future to verify whether circ-POLA2 is of feasibility for blood biopsy of CC patients. Furthermore, circRNAs may encode proteins or peptides to participate in tumor progression (Qian *et al.,* 2018; Peng *et al.,* 2021; Wang *et al.,* 2021; Wu *et al.,* 2021). However, this research did not investigate the coding ability of circ-POLA2.

CONCLUSION

Circ-POLA2 has potent oncogenic activity in CC and an association with patients' poor prognosis. Furthermore, circ-POLA2 upregulates SEMA4C expression by miR-138-5p, thereby promoting cancer development. This study extends the understanding of circRNA function in CC pathogenesis and proposes a novel circRNA as a therapeutic target for CC.

Hsa_circ_0023826 protects against glaucoma by regulating miR-188-3p/MDM4 axis

Bin Qu[1], Jing Wang[1], Yan Li[1], XiaoWei Wu[1] and MingYing Zhang[2]✉

[1]Department of Ophthalmology, Muping District Hospital of Traditional Chinese Medicine, Yantai City, Shandong Province, 253400, China; [2]Department of Ophthalmology, Ningjin County People's Hospital, Dezhou City, Shandong Province, 253400, China

Objective: Circular RNAs (circRNAs) are characterized as a class of covalently closed circRNA transcripts and are associated with various cellular processes and neurological diseases by sponging microRNAs. The most common feature of glaucoma, a form of retinal neuropathy, is the loss of retinal ganglion cells. Although the pathogenesis of glaucoma is not fully understood, elevated intraocular pressure is undoubtedly the only proven modifiable factor in the classic glaucoma model. This study investigated the role of circ_0023826 in glaucoma-induced retinal neurodegeneration by modifying the miR-188-3p/mouse double minute 4 (MDM4) axis. **Methods:** The expression pattern of circ_0023826 was analyzed during retinal neurodegeneration. The effect of circ_0023826, miR-188-3p, and MDM4 on retinal neurodegeneration *in vivo* was assessed by visual behavioral testing and H&E staining in glaucoma rats, while that on *in vitro* retinal ganglion cells (RGCs) was evaluated by MTT assay, flow cytometry, Western blot, and ELISA. Bioinformatics analysis, RNA pull-down assay, luciferase reporter assay were performed to reveal the regulatory mechanism of circ_0023826-mediated retinal neurodegeneration. **Results:** Circ_0023826 expression was downregulated during retinal neurodegeneration. Upregulating circ_0023826 attenuated the visual impairment in rats and promoted the survival of RGCs *in vitro*. Circ_0023826 acted as a sponge of miR-188-3p sponge, resulting in increased expression of MDM4. MDM4 silencing or miR-188-3p upregulation reversed the protective effect of upregulated circ_0023826 on glaucoma-induced neuroretinal degeneration *in vitro* and *in vivo*. **Conclusion:** Overall, circ_0023826 protects against glaucoma by regulating the miR-188-3p/MDM4 axis, and targeted intervention of circ_0023826 expression is a promising therapeutic strategy for the treatment of retinal neurodegeneration.

INTRODUCTION

Glaucoma, a retinal neurodegenerative disease characterized by progressive and irreversible degeneration of retinal ganglion cells (RGCs) and optic nerve, is the second leading cause of blindness (Quigley *et al.*, 2006). Elevated intraocular pressure (IOP) is a risk factor and RGC apoptosis is the core cause of glaucoma (Geva *et*

al., 2021). At present, the treatment methods of glaucoma mainly include surgery and drugs (Hooshmand *et al.*, 2022). Despite effective medical and surgical treatment to lower IOP, many patients will continue to lose vision due to the death of RGCs and degeneration of the optic nerve. Therefore, further elucidation of the pathogenesis of glaucoma is still required.

CircRNAs are a new class of non-coding RNAs characterized by closed-loop structures (Ebbesen *et al.*, 2017). With bioinformatics analysis and high-throughput sequencing, circRNA may participate in the pathogenesis and progression of various eye diseases, including glaucoma, diabetic retinopathy, and retinoblastoma (Guo *et al.*, 2019). Therefore, an in-depth understanding of circRNAs involved in glaucoma will help to open up new avenues for early diagnosis and clinical treatment.

CircRNAs serve as gene modulators of microRNAs (miRNAs) (Yang *et al.*, 2021), thereby participating in the progression of glaucoma. have found that circ_0023826 is upregulated in glaucoma-related retinal neurodegeneration, and is capable of regulating neurodegeneration by acting as a miR-615 sponge (Wang *et al.*, 2018). In another report, circZRANB1 directly regulates Müller cell function and RGC function through miR-217 (Wang *et al.*, 2018). TENM4-encoded circ_0023826 has been identified as a diagnostic biomarker for glaucoma (Chen *et al.*, 2020), but rare studies have reported its action in glaucoma.

The present paper hypothesized that circ_0023826 protects against retinal neurodegeneration by regulating the miR-188-3p/MDM4 axis. First, we constructed a glaucoma model by chamber injection of microbeads and isolated RGCs to study the expression patterns of circ_0023826 in glaucoma-induced retinal neurodegeneration. Then, we confirmed the downstream miRNA (miR-188-3p) and target gene (MDM4) to elucidate the regulation of circ_0023826/miR-188-3p/MDM4 in glaucoma, targeting to develop a new theoretical basis for glaucoma therapy.

MATERIALS AND METHODS

Collection of patient tissues

From January 2017 to March 2018, 12 pairs of human fascia tissue and normal human fascia tissue (3 mm from the conjunctival edge) from glaucoma patients were collected at Muping District Hospital of Traditional Chinese Medicine. Tissue samples were frozen in liquid nitrogen and then stored at -80°C. All procedures were performed under the review of the Ethics Committee of

Muping District Hospital of Traditional Chinese Medicine. All patients provided written consent.

Establishment of a glaucoma model

All animal experiments were performed with the approval of the Animal Ethics Committee of Muping District Hospital of Traditional Chinese Medicine. Forty-eight Sprague Dawley (SD) rats (male, 200–250 g) were purchased from Hunan SJA Laboratory Animal Co., Ltd. After one week of adaptive feeding, 42 rats were randomly selected to construct a glaucoma model by intra-chamber injection of microbeads. In short, anesthetized by intraperitoneal injection of a mixture of xylazine (10 mg/kg) and ketamine (75 mg/kg), the rats were injected with sterile microbeads into one eye and dropped with 0.5% moxifloxacin hydrochloride in each eye. IOP was measured after 24 h. At 4 weeks post-injection, the second injection of microbeads was performed. IOP was measured every 4 days using a digital tonometer. An equal volume of phosphate-buffered saline (PBS) served as a sham operation procedure.

Lentiviral intervention

The glaucoma rats were randomly divided into 7 groups: Glaucoma group, sh-NC group, sh-circ_0023826 group, Lenti-NC group, Lenti-circ_0023826 group, Lenti-circ_0023826 + Lenti-miR-188-3p group, Lenti-circ_0023826 + sh-MDM4 group. Except for the Glaucoma group, the other rats were additionally injected with a single injection of shRNA lentiviral vector or lentiviral overexpression vector targeting circ_0023826/miR-188-3p/MDM4. After 3 weeks, the rats were subjected to visual behavioral testing and subsequently euthanized by inhalation of excess CO_2 and the eyeball tissue was collected. The above lentiviral vectors were prepared by GenePharma.

Visual behavior test

An infrared light-illuminated black room (0.3 m×0.5 m×0.5 m) and a larger infrared light-illuminated white room (0.5 m×0.5 m×0.5 m) were used for visual behavior testing. There is a 10 cm×12 cm hole between the two rooms, allowing rats to freely shuttle from one room to another. The activity of the rats was recorded by a camera and the time spent by the rats in the dark room was calculated using Nordx ethovision XT 8.0 software (Li et al., 2018).

Hematoxylin-eosin (H&E) staining

Rats' eyeballs were fixed with 4% paraformaldehyde (Solarbio). The cornea was incised along the sclera, the iris and lens were obtained, and the retinas were frozen in 30% sucrose and sectioned into 5 μm. Frozen tissues were stained with H&E solution (Solarbio) routinely and observed under an optical microscope (BX-51, Olympus, Tokyo, Japan) in 5 fields. The thickness of the ganglion cell layer (GCL) and the inner plexiform layer (IPL) was measured with SE IPS image analyzer Each group selected 3 slices from 5 rats for measurement (Nie et al., 2018).

Isolation and culture of RGCs

The retinas were isolated from 10 normal rats under a dissecting microscope, digested with 0.125% trypsin, and centrifuged at 179×g. The retinal pellet was centrifuged with 0.25% trypsin inhibitor (Sigma Aldrich), rinsed with Kreb solution containing magnesium and 1% bovine serum albumin (BSA), and made into a single-cell suspension. The cell suspension ($1×10^6$ cells) was treated with 0.1 mg/ml poly-L-ornithine (Sigma Aldrich) and 1 g/ml laminin (Sigma Aldrich), cultured in basal medium Eagle (BME) medium (Nanjing SenBeiJia Biological Technology) containing 10% FBS, 25 mol/l glutamine and 0.1 mg/ml gentamicin.

Retinal single-cell suspension was incubated with goat anti-mouse IgG antibody (ab-6785; 1:1,000; Abcam) and rat anti-mouse Thy-1.1 antibody (ab-44898; 1:1,000; Abcam). The adherent cells were digested with 0.125% trypsin, centrifuged at 1000 rpm, and cultured with polylysine. Every three days, half of the medium was renewed (Xu et al., 2021). The isolated RGCs were immunocytochemically stained for Thy-1 (Kong et al., 2014). Briefly, antigen retrieval treatments were performed in citrate buffer in the microwave on medium heat for 5 min and then cooled to room temperature. After washing 3 times with PBS buffer, the slides were sealed with goat serum (ZSGB Bio, Beijing, China) for 30 min and incubated with anti-Thy-1 (Abcam, ab92574) overnight at 4°C. After 30 min incubation with HRP-conjugated secondary antibody solution (PV-6001, ZSGB Bio) at room temperature, staining was performed using DAB (ZSGB Bio). RGCs specific markers Brn3a (Abcam, ab245230, 1/1000), Thy-1 (Abcam, ab92574, 1/1500) and NF-L (Abcam, ab223343, 1/1000) were all analyzed by Western blot.

To establish an in vitro glaucoma model, RGCs were treated with N-methyl-D-aspartic acid (NMDA, 100 μmol/L) and glycine (10 μmol/L) for one hour. PBS-treated RGCs served as a negative control.

Lentiviral transfection

NMDA- and glycine-treated RGCs were collected. Transfection was performed when cells reached 70-80% confluence. shRNA targeting circ_0023826/MDM4 lentiviral vector (sh-circ_0023826/sh-MDM4), lentiviral vector overexpressing circ_0023826/miR-188-3p (Lenti-circ_0023826/Lenti-miR-188-3p), sh-NC and Lenti-NC were from GenePharma. RGCs were transfected using Lipofectamine 2000 reagent (Invitrogen). The medium was changed 24 h after transfection (Shen et al., 2020).

Subcellular localization analysis

Cytoplasmic and nuclear RNAs of cells were isolated using the PARIS Kit (Invitrogen) and allowed to quantitatively analyze circ_0023826 expression.

RT-qPCR

Based on the Trizol reagent (Invitrogen), total RNA was extracted for reverse transcription of circRNA/mRNA and miRNA using PrimeScript RT reagent kit (Takara, Tokyo, Japan) and miRNA First Strand Synthesis kit (Takara), respectively. SYBR Green kit (Thermo Fisher Scientific, Waltham, MA, USA) in combination with the Mx3005P QPCR system (Agilent Technologies, CA, USA) was employed for PCR. U6 and GAPDH were used as internal controls. The primer sequences are shown in Table 1.

Western blot

Total protein was extracted with RIPA lysis buffer (Beyotime, China), loaded on 8% SDS-PAGE gels (Solarbio), transferred to PVDF membranes (Invitrogen), and blocked with 5% skim milk. It was incubated with primary antibodies MDM4 (ab39470, Abcam), Bax (ab32503, Abcam), Bcl-2 (ab196495, Abcam), cleaved caspase-3 (ab2302, Abcam), GAPDH (ab8245, Abcam) and with the HRP-conjugated goat anti-rabbit IgG secondary antibody (Beyotime, China). Developed by ECL kit (34080, Thermo Fisher Scientific), signals were analyzed using ImageJ software (Li *et al.*, 2022).

Cell viability assay

After 24 h of different treatments, transfected or untransfected RGCs (1×10^5 cells/well) were added with 1 mL of MTT solution (Beyotime) for 2 h, and with 1 mL DMSO for 10 min. Finally, optical density$_{570\ nm}$ values were recorded with a microplate reader (PerkinElmer) (Zhang *et al.*, 2021).

Flow cytometry

RGCs were centrifuged at $1000\times g$, resuspended in 195 µL Annexin V-FITC binding buffer, and added with 5 µL Annexin V-FITC and 10 µL propidium io-

dide. The apoptosis of RGCs was detected by a FACS-Calibur flow cytometer (BD Biosciences).

ELISA

ELISA kits TNF-α (Abcam, ab181421), IL-6 (Abcam, ab178013) and IL-1β (Sigma-Aldrich, RAB0273) were employed to measure inflammation in the culture supernatants (Gao *et al.*, 2020).

Dual-luciferase reporter assay

Potential binding sites for hsa_circ_0023826 and miR-188-3p were predicted by https://circinteractome.nia.nih.gov, while those for miR-188-3p and MDM4 were predicted by https://cm.jefferson.edu/rna22/. Based on the above wild-type sequence of hsa_circ_0023826 containing the miR-188-3p binding site, a mutant sequence was designed. RGCs were transfected with PGL4 containing hsa_circ_0023826/MDM4 wild-type sequence (hsa_circ_0023826/MDM4-WT) or hsa_circ_0023826/MDM4 mutant sequence (hsa_circ_0023826/MDM4-mut) together with miR-188-3p mimic or miR-NC. A dual-luciferase reporter assay system (Promega, Madison, WI, USA) was implicated to measure luciferase activity (Sui *et al.*, 2020).

RNA pull-down experiment

A biotin-labeled RNA (Roche, Shanghai, China) was used. After RGCs were lysed using RIPA lysis buffer (Beyotime, China), biotin miR-188-3p-labeled streptavidin magnetic beads were added for 1-h incubation. After elution, the RNA levels were analyzed (Wei *et al.*, 2021).

Statistical analysis

SPSS 21.0 statistical software was used to analyze the data, and the Kolmogorov-Smirnov test showed that the data were normally distributed, and the results were expressed as mean ± standard deviation (S.D.). One/Two-

way ANOVA analysis of variance and the least significant difference t test were suitable for comparing data. P was a two-sided test, and $P<0.05$ was considered statistically significant.

RESULTS

Hsa_circ_0023826 is downregulated during glaucoma

A previous study showed that circ_0023826 was downregulated in chronic glaucoma rats. It was speculated that circ_0023826 may have an important relationship with the development of glaucoma. Circ_0023826 expression was assessed in glaucoma patients. As shown in Fig. 1A, circ_0023826 expression in the eye fascia of glaucoma patients was lower than that of normal human eye fascia. Then, a rat model of glaucoma was constructed and the IOP was tested before and after modeling. The results showed that the IOP of the glaucoma rats began to increase after the microbead injection, and the IOP was higher than that of the rats in the Sham group until the end of the modeling (Fig. 1B). The visual behavior test manifested that the rats treated with microbead surgery stayed longer in the dark room than the rats in the sham-operated group (Fig. 1C), indicating that the increase of IOP caused by the injection of microbeads impairs the visual function of rats. These results indicated that a rat model of glaucoma was successfully constructed.

Circ_0023826 expression pattern in retinal tissue was checked by RT-qPCR, manifesting a decline in glaucoma rats (Fig. 1D). Subsequently, RGCs were isolated from rat eyeball tissues. The isolated cells were confirmed to be positive for Thy-1 expression by IHC staining (Fig. 1E). In addition, the expression of RGCs markers (Brn3a, Thy-1, and NF-L) in the isolated cells was higher than that in the rat eyeball tissue (Fig. 1F). This indicates that the collected cells were high-purity RGCs. Subsequently, an *in vitro* model of glaucoma was established by NMDA induction. As shown in Fig. 1G, the expression of circ_0023826 in the NMDA-treated RGCs was significantly higher than that in the PBS-treated RGCs. Subcellular isolation test further confirmed that circ_0023826 was a cytoplasmic RNA (Fig. 1H). All the above data suggest that circ_0023826 may be involved in the development of glaucoma at the cellular post-transcriptional translational level.

Hsa_circ_0023826 improves glaucoma symptoms and survival of RGCs

To explore the role of circ_0023826 in glaucoma, circ_0023826 was upregulated and downregulated in glaucoma rats (Fig. 2A). Visual behavioral test showed that knockdown of circ_0023826 increased the dark room dwell time of rats, while overexpression of circ_0023826 decreased the dark room dwell time of rats (Fig. 2B). H&E staining observed the morphological changes of the retinas, showing that IPL and GCL

Figur 3. circ_0023826 is a sponge for miR-188-3p.
(**A**) The binding site (https://circinteractome.nia.nih.gov/) between circ_0023826 and miR-188-3p. (**B–C**) Dual-luciferase reporter assay and RNA pull-down assay to evaluate the interaction between circ_0023826 and miR-188-3p. (**D**) Changes of miR-188-3p in RGCs after MNDA induction (**E**) miR-188-3p expression after downregulating circ_0023826 in isolated RGCs. Data are presented as mean ± S.D. (n=3). **p<0.01, ***p<0.001.

were reduced in the Glaucoma group, while knockdown of circ_0023826 resulted in further reduction of IPL and GCL, but overexpression of circ_0023826 restored the levels of IPL and GCL (Fig. 2C). In addition, the number of RGCs in glaucoma rats was significantly reduced, knockdown of circ_0023826 further reduced the number of RGCs, while overexpression of circ_0023826 was able to restore the number of RGCs (Fig. 2D). Subsequently, the effect of circ_0023826 on the biological behavior of RGCs was examined. As shown in Fig. 2E, MNDA reduced the viability of RGCs, while knockdown of circ_0023826 resulted in a further decrease in the cell viability of RGCs, but overexpression of circ_0023826 restored the cell viability of RGCs. In addition, MNDA promoted the apoptosis rate of RGCs and increased the expression of apoptosis-related proteins Bax and cleaved caspase-3, which was further enhanced by knockdown

of circ_0023826, but attenuated by overexpression of circ_0023826 (Fig. 2F, G). These data suggest that overexpression of circ_0023826 improves glaucoma by promoting the cell viability of RGCs.

Circ_0023826 is a sponge for miR-188-3p

To reveal the underlying mechanism by which circ_0023826 works, a bioinformatics website was used to predict the downstream miRNAs of circ_0023826. miR-188-3p was found to have a targeted binding site of circ_0023826 (Fig. 3A). Next, their interaction was verified by dual-luciferase reporter assay and the results revealed that the luciferase activity decreased after co-transfection of miR-188-3p-mimic and circ_0023826-WT, but did not change after co-transfection with circ_0023826-MUT (Fig. 3B). Meanwhile, RNA pull-down assay showed that Bio-miR-188-3p was able to

Figur 4. miR-188-3p directly targets MDM4.

pull down circ_0023826 (Fig. 3C). Furthermore, MNDA promoted the expression of miR-188-3p in RGCs (Fig. 3D); knockdown of circ_0023826 increased the expression of miR-188-3p (Fig. 3E). The above data indicated that miR-188-3p was the target gene of circ_0023826.

MiR-188-3p directly targets MDM4

There are multiple complementary binding sites in miR-188-3p and MDM4 based on bioinformatics analysis (Fig. 4A). The results of dual-luciferase reporter gene assay confirmed that co-transfection of miR-188-3p-mimic with MDM4-WT reduced luciferase activity, while co-transfection with MDM4-MUT had no effect on luciferase activity (Fig. 4B). Meanwhile, the results of RNA pull-down experiment detected that Bio-miR-188-3p enriched MDM4 (Fig. 4C). Furthermore, MNDA treatment decreased MDM4 expression in RGCs (Fig. 4D, E). Knockdown of circ_0023826 or overexpression of miR-188-3p also inhibited the expression of MDM4 (Fig. 4F, G). The above data indicate that MDM4 is a downstream target gene of miR-188-3p.

Circ_0023826 alleviates glaucoma and the survival of RGCs by miR-188-3p targeting MDM4

To investigate the effect of circ_0023826 on glaucoma via the miR-188-3p/MDM4 axis, Lenti-NC, Lenti-circ_0023826, Lenti-circ_0023826 + Lenti-miR-188-3p, Lenti-circ_0023826 + sh-MDM4 were injected into the eyes of rats, respectively. As shown in Fig. 5A, over-expression of circ_0023826 promoted the expression of MDM4, but this effect was reversed by overexpression of miR-188-3p or knockdown of MDM4 (Fig.

5A). The results of visual behavioral test showed that up-regulation of circ_0023826 could improve visual function in rats, while up-regulation of miR-188-3p or down-regulation of MDM4 could reverse the improvement of visual function in rats by circ_0023826 addition (Fig. 5B). H&E staining found that Lenti-circ_0023826 significantly protected the reduction of GCL and IPL, and significantly increased the number of RGCs. However, Lenti-miR-188-3p or sh-MDM4 could reverse the effects of Lenti-circ_0023826 (Fig. 5C, D). As shown in Fig. 5E–G, Lenti-circ_0023826 can increase the cell viability and inhibit apoptosis of RGCs. However, Lenti-miR-188-3p or sh-MDM4 could reverse the effects of Lenti-circ_0023826. Taken together, circ_0023826 ameliorates glaucoma symptoms and promotes the survival of RGCs by regulating the miR-188-3p/MDM4 axis.

DISCUSSION

Glaucoma is a major cause of irreversible vision loss and is characterized by retinal neurodegeneration (Van *et al.*, 2022). Directly or indirectly promoting the survival of RGCs can delay or prevent the progression of glaucoma. Here, we reported that circ_0023826 was downregulated during glaucoma and demonstrated that circ_0023826 alleviated visual impairment in glaucoma rats and promoted the survival of RGCs. Mechanistically, circ_0023826 worked through sponge-absorbing miR-188-3p, which affected its downstream gene MDM4. Regarding study novelty, we reported for the first time that circ_0023826 was involved in the pathogenesis of glaucoma through the downstream miR-188-3p/MDM4 axis.

CircRNAs are abundant in the eukaryotic transcriptome (Jeck *et al.*, 2013) and significantly enriched in human brain and retinal tissues (Akhter *et al.*, 2018). It has been reported that circRNAs may drive changes that lead to glaucoma progression through one or more of these pathophysiological processes and lead to RGC death (Rong *et al.*, 2021). Studies have revealed the significance of circRNAs in glaucoma, including circZNF609 and circZRANB1. circ_0023826 suggests a diagnostic value in glaucoma. We first studied circ_0023826's biological function in glaucoma. Apoptosis and inflammation of RGCs are important pathological features of eye diseases such as glaucoma (Ou *et al.*, 2021). We found that circ_0023826 in glaucoma-induced rats could alleviate the visual impairment, increase the number of RGCs, and inhibit the apoptosis of RGCs.

It has been demonstrated that circRNAs can act as miRNA sponges to regulate targeted downstream gene expression. Therefore, we predicted the targeted miRNA (miR-188-3p) of circ_0023826. miRNAs are important regulators of the complex biological progression of various neurodegenerative diseases (Mead *et al.*, 2022). Recently, miRNAs have been widely reported to be involved in the regulation of cell growth, differentiation, metabolism and apoptosis in the biological progression of glaucoma (Greene *et al.*, 2022). MiR-126 promotes retinal ganglion cell apoptosis in glaucoma rats (Wang *et al.*, 2020) and miR-223 induces retinal ganglion cell apoptosis. miR-188-3p has been reported to be associated with various diseases, such as cancer (Luo *et al.*, 2021), cardiovascular disease (Mi *et al.*, 2020), and diabetic nephropathy (Jin *et al.*, 2021) miR-188-3p has been reported to disrupt gemmarone-mediated podocyte protection in a mouse model of type 1 diabetic nephropathy by triggering mitochondrial damage (Wang *et al.*, 2021). Despite accumulating evidence that miR-188-3p exerts antiapoptotic roles in several cell types, its function in retinal ganglion cell apoptosis and glaucoma progression is unclear. We first found that miR-188-3p was upregulated in RGCs isolated from retinal tissue of glaucoma rats and confirmed that circ_0023826's effect on the survival of RGCs could be reversed by overexpressing miR-188-3p.

Subsequently, we further predicted downstream factors of miR-188-3p and found that MDM4 was downregulated during glaucoma. MDM4 protein, also known as MDMX, was first discovered in 1996 by screening for p53-binding proteins (Shvarts *et al.*, 1996). It has been reported that MDMX is often amplified and highly expressed in human cancers, promoting cancer cell growth, and inhibiting apoptosis (Yu *et al.*, 2020). However, the function of MDMX in retinal ganglion cell apoptosis and glaucoma progression is currently unclear. To further verify the regulatory effect of circ_0023826/miR-188-3p/MDM4 axis on NSCLC, we performed rescue assays and confirmed that downregulating MDM4 or upregulating miR-188-3p could reverse the therapeutic effect of circ_0023826 on glaucoma progression.

Taken together, our study confirmed our hypothesis that circ_0023826 protected against glaucoma by targeting the miR-188-3p/MDM4 axis. Nonetheless, we focused on retinal ganglion cells, other retinal cell types may also be affected by circ_0023826; because our findings are based on cell culture investigations and experimental animal studies, they cannot be directly generalized to patients. In the future, we will conduct more experiments to further verify the molecular mechanism of circ_0023826 protecting glaucoma *in vitro* and *in vivo*.

CONCLUSION

Our study reports the protective effect of circ_0023826 in glaucoma-induced neuroretinal degeneration. It was confirmed that upregulating circ_0023826 expression in glaucoma-induced rats can alleviate the damage to visual function in rats, increase the number of RGCs, and inhibit the apoptosis of RGCs. Mechanistically, our results suggest that circ_0023826 acts in glaucoma-induced neuroretinal degeneration by regulating the miR-188-3p/MDM4 axis and defines circ_0023826 as a new target for neuroprotective therapy of glaucoma.

Prognostic value of serum albumin level in patients with diffuse large B cell lymphoma

Liyan Chen[1], Lili Pan[2] and Tingbo Liu[3]✉

[1]Department of Breast Surgery, Zhuhai Maternity and Child Health Hospital, Zhuhai, China; Fujian Medical University Union Hospital, Fujian, China; [2]Pediatric Hematology Department, Fujian Medical University Union Hospital, Fujian, China; [3]Hematology Department, Fujian Medical University Union Hospital, Fujian, China

Objective: To investigate the prognostic value of serum albumin (SA) levels before chemotherapy in patients with diffuse large B-cell lymphoma (DLBCL) after receiving chemotherapy. **Methods:** This is a retrospective study, and 127 patients with DLBCL including 71 males (55.9%) and 56 females (44.1%) were included. Patients' gender, age, Ann Arbor staging, eastern cooperative oncology group (ECOG) score, treatment options, international prognostic index, response rate, overall survival (OS), and progression-free survival (PFS) were obtained for statistical analysis. **Results:** Univariate analysis showed that SA≤34 g/L, Ann Arbor III-IV, B symptoms, ECOG≥2, and bone marrow involvement suggest a poor prognosis in patients with DLBCL. Patients with persistent SA>34 g/L had significantly longer OS than patients with persistent SA≤34 g/L (P=0.020). Multivariate analysis showed that SA≤34 g/L (HR=0.48, 95% CI=0.26-0.90, P=0.022) and R-CHOP-like treatment regimen (HR=0.43, 95% CI=0.24-0.76, P=0.004) are independent factors that could affect the prognosis of patients with DLBCL. **Conclusion:** SA can be used as an indicator of prognosis in patients with DLBCL before the first chemotherapy. DLBCL patients with SA≤34 g/L are associated with short OS and poor prognosis, which may potentially provide guidance for the clinician to pay more attention to this population before the first chemotherapy.

Keywords: diffuse large B-cell lymphoma, serum albumin, chemotherapy, prognosis, IPI

INTRODUCTION

Diffuse large B-cell lymphoma (DLBCL) is the most common pathological subtype of non-Hodgkin's lymphoma (NHL), and its incidence rate is 6.3% with an estimated more than 25 thousand new cases in the United States in 2016 (Li *et al.*, 2018). The heterogeneities of DLBCL in clinical manifestations and histomorphology lead to differences in treatment response and prognosis.

The international prognostic index (IPI) is currently the common risk stratification criteria for lymphoma, which includes age, Ann Arbor disease stage, serum lactate dehydrogenase (LDH) level, extranodal involvement and eastern cooperative oncology group (ECOG) score (Ziepert *et al.*, 2010). Afterwards, the age-adjusted international prognostic (aaIPI) can be used to assess the long-term prognosis of patients aged ≤60 years (Sehn *et al.*, 2007).

The National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) followed the five clinical features of IPI, and the LDH and age factors were more subdivided, and their evaluation was better than IPI (1993). The R-CHOP regimen is effective in the treatment of patients with DLBCL, and its overall survival (OS) and event-free survival (EFS) are superior to the CHOP-like regimen (Coiffier *et al.*, 2002; Coiffier *et al.*, 2010; Pfreundschuh *et al.*, 2006)

BCL-2, MYC, and BCL-6 molecular biological indicators have made significant progress in assessing prognosis (Miyaoka *et al.*, 2018), though the examination is expensive. Serum albumin (SA) results show that patients with low SA have lower OS (Dalia *et al.*, 2014), and SA can predict the prognosis of patients with DLBCL (Eatrides *et al.*, 2015), but it is excluded from the IPI prognosis approach due to insufficient data (1993). In this study, we aimed to investigate the prognostic value of SA levels before chemotherapy in patients with DLBCL after receiving chemotherapy. After determining the optimal threshold of SA level in DLBCL patients, the patients were divided into high and low cut-off SA groups. The OS and progression-free survival (PFS) were analyzed to assess the effectiveness of NCCN-IPI in DLBCL patients, especially those under 60 years of age. This retrospective analysis of DLBCL patients with different SA levels might provide more clinically relevant guidance for clinicians to assess the prognostic outcomes of patients before the first chemotherapy.

OBJECTIVES AND METHODS

Object selection

This retrospective study was approved by the Ethics Committee of Fujian Medical University Union Hospital (the approval number: 2019KY029) in Fuzhou City, Fujian Province, China in 2019. A total of 127 patients with DLBCL admitted to the Union Hospital of Fujian Medi-

cal University from January 1, 2010 to December 31, 2014 were consecutively enrolled. Inclusion criteria were as follows: 1) initial treatment and age ≥18 years; 2) initial diagnosis of DLBCL; 3) pathological tissues were diagnosed according to WHO lymphoma typing (Fmedsci & Frs, 2015); 4) no severe heart, lung, liver, and kidney dysfunction; 5) patients were treated with rituximab and CHOP (R-CHOP) like regimen or CHOP-like regimen. Exclusion criteria were as follows: 1) initial treatment and age <18 years; 2) no chemotherapy in our hospital or incomplete data; 3) patients with history of heart, lung, liver, or kidney dysfunction; 4) patients were diagnosed with primary central nervous system diffuse large B-cell lymphoma, primary diffuse large B-cell lymphoma, primary mediastinal diffuse large B-cell lymphoma, original bone marrow diffuse large B-cell lymphoma, or Epstein-Barr virus (EBV)-positive elderly diffuse large B-cell lymphoma. The clinical data, including gender, age, germinal center B cell-like (GCB) subtypes (by the Hans algorithm (Hans *et al.*, 2004)), Ann Arbor staging (Sehn *et al.*, 2005), B symptoms, ECOG, extranodal involvement, LDH, SA, treatment regimen, and NCCN-IPI, were analyzed in this study. All patient details were de-identified and the identity of patients could not be ascertained from this study. Meanwhile, the reporting of this study conforms to the STROBE statement (von Elm *et al.*, 2007).

Treatment

The patients' consent to treatment was obtained in this study. All patients received an R-CHOP-like regimen (rituximab (R) 375 mg/m^2 once, cyclophosphamide (CTX) 750 mg/m^2 once, vincristine (VCR) 1.4 mg/m^2 or vindesine (VDS) once, doxorubicin (Adriamycin, ADM) 50 mg/m^2 once and epirubicin (EPI) or prednisone (Pred) 40 mg/m^2 for 5 continuous days) repeated at 14-day intervals for 1-6 cycles, or CHOP-like regimen (CTX, VCR or VDS, ADM, EPI or Pred) for 1-6 cycles (Lamy *et al.*, 2018).

AUC = 0.68 ± 0.51
95% CI = 0.52-0.72
P = 0.02

DLBCL, diffuse large B-cell lymphoma; ECOG, eastern cooperative oncology group; LDH, lactate dehydrogenase; GCB, germinal center B cell-like; IPI, international prognostic index; aaIPI, age-adjusted international prognostic index; NCCN-IPI, the national comprehensive cancer network international prognostic index.

Prognostic assessment method

Patients were assessed by IPI, aaIPI and NCCN-IPI (Table 1A, B and C). NCCN-IPI assessment includes patients' age, ECOG score, serum lactate dehydrogenase level (LDH), extranodal involvement (involved distinct sites, such as bone marrow, CNS, gastrointestinal tract, liver or lung), and Ann Arbor stage. By using this assessment method, patients were divided into low-risk group (NCCN-IPI=0–1), low-intermediate risk group (NCCN-IPI=2–3), high-intermediate risk group (NCCN-IPI=4–5) and high-risk group (NCCN-IPI ≥6) (Table 1C).

SA grouping

The cut-off value of SA was obtained by analyzing the SA level- receiver operating characteristic (ROC) curve. Following this approach, the cut-off value of SA was 34 g/L. Therefore, in this study, the DLBCL patients were divided into low SA≤34 g/L and high SA>34 g/L groups (Fig. 1).

Efficacy criteria

The short-term efficacy evaluation was based on the Response Criteria for Malignant Lymphoma (Cheson et al., 2007) by using CT or PET-CT imaging techniques after the first chemotherapy. Generally, the short-term efficacy was divided into four groups: complete remission (CR, defined as disappearance of all evidence of disease), partial remission (PR, defined as regression of measurable disease and no new sites), stable disease (SD, defined as failure to attain the CR/PR), Progressive disease (PD, defined as any new lesion or increase by 50% of previously involved sites from nadir). OS and PFS are followed up by inpatient medical records or by telephone. The deadline is the study endpoint December 31, 2017, to obtain 3-year and 3-year of OS and PFS data. OS: The primary endpoint was OS with 3 years (3-year OS), defined as the time from diagnosis to death from any cause, following the IPI criteria. PFS was defined as the time from DLBCL diagnosis until the disease recurrence, death-from-any-cause, or censoring (Cheson et al., 2007).

Data processing method

All data were analyzed using SPSS 20.0. ROC curve analysis was performed to obtain the cut-off SA value. OS and PFS were assessed by using the Kaplan-Meier estimator. Univariate and multivariate analyses were performed using the Cox regression model, and short-term efficacy analysis was performed by using the chi-square test. P<0.05 was statistically significant.

RESULT

General clinical characteristics of patients with DLBCL

A total of 156 cases of DLBCL were diagnosed by pathology in our hospital from January 1, 2010 to December 31, 2014, while 26 cases were not treated with chemotherapy and 3 cases were combined with other tumors. Therefore, 127 patients were finally collected, including 71 males (55.9%) and 56 females (44.1%). Generally, the median age of patients was 56 (18–86) years, while 45 patients (35.4%) were aged >60 years. The ECOG<2 points were reported in 105 cases (82.7%), while ECOG≥2 points were reported in 22 cases (17.3%). There were 82 cases (64.6%) who had no

B symptoms, and 45 cases (35.4%) were with B symptoms. The patients with normal LDH levels were found in 60 cases (47.2%), while 67 cases (52.8%) were shown with high LDH. The low SA (≤34 g/L) was observed in 70 cases (55.1%) and high SA (>34 g/L) was in 54 cases (42.5%). The other clinical characteristics of these patients are shown in Table 2.

Pathologically diagnosed with germinal center B cell-like (GCB) was found in 45 cases (35.4%) and non-GCB was in 81 cases (63.8%). Meanwhile, 41 cases (32.3%) were diagnosed with Ann Arbor staging I-II, while 86 cases (67.7%) were Ann Arbor staging III-IV. In addition, 58 cases (45.7%) were not found with extranodal involvement, while 69 cases (54.3%) were shown with extranodal involvement. According to the NCCN-IPI assessment, there were 23 cases (18.1%) in the low-risk group, 64 cases (50.4%) in the low-intermediate risk group, 32 cases (25.2%) in the high-intermediate risk group, and 8 cases (6.3%) in the high-risk group, with 3-year OS of 76.5%, 73.8%, 32.5%, 37.5 %, respectively. Meanwhile, 54 patients (42.5%) received CHOP-like regimens, 69 patients (54.3%) received R-CHOP-like regimens, and the other 4 patients received other chemotherapy (Table 2).

Survival and prognosis analysis

Up to the last follow-up date, the rate of loss to follow-up was 15.7%, while the mortality rate was 35.4%. The median follow-up time was 25 (0–66) months. The OS of 1 year, 3 years and 5 years were 70.3%, 61.0% and 50.5%, respectively. The PFS rates of 1 year, 3 years and 5 years were 56.7%, 41.2% and 32.0%, respectively (Fig. 2A and B).

Cox regression analysis of factors in association with OS of patients with DLBCL

By using univariate Cox analysis, it showed that Ann Arbor staging (P=0.008), B symptoms (P=0.008), ECOG score (P=0.004), bone marrow involvement (P=0.017), LDH levels (P=0.063), SA levels (P=0.002), and treatment regimens (P=0.003) were significantly associated with 3-year OS in patients with DLBCL (Table 3). However, when using the multivariate Cox regression model, it showed that Ann Arbor staging, B symptoms, ECOG score, bone marrow involvement, and LDH levels had no significant correlation with the prognostic values of DLBCL patients. On the contrary, SA levels (P=0.022) and treatment regimens (P=0.004) were an independent prognostic factor for patients with DLBCL (Table 4).

Figure 2. The 3-year overall survival of the low-risk group, the low-intermediate-risk group, the high-intermediate-risk group and the high-risk group of the IPI/aaIPI (A) and the NCCN-IPI (B).

Table 3. Results of univariate Cox regression model

Index	3-year OS		
	HR	95% CI	P
Sex (Male *vs* Female)	1.045	0.788-1.385	0.762
Age (≤60 years *vs* >60 years)	0.945	0.528-1.691	0.849
Ann Arbor staging (I-II *vs* III-IV)	2.689	1.302-5.553	0.008
B symptoms (Yes *vs* No)	0.469	0.267-0.823	0.008
ECOG Score (<2 *vs* ≥2)	2.55*	1.348-4.824	0.004
Extranodal involvement (Yes *vs* No)	0.972	0.732-1.290	0.842
Bone marrow involvement (Yes *vs* No)	0.701	0.524-0.938	0.017
LDH (Normal *vs* > Normal)	0.761	0.571-1.015	0.063
Low SA *vs* High SA	1.629	1.193-2.224	0.002
GCB *vs* non-GCB	1.151	0.647-2.045	0.633
CHOP- like *vs* R-CHOP-like	1.571	1.208-2.044	0.003
IPI	1.571	1.208-2.044	0.001
NCCN-IPI	2.131	1.522-2.984	0.000

*Example in this analysis: HR is obtained from the exponential regression coefficient, and gives the effect size of the predictors. In our example, the ECOG variable had an HR =2.55, meaning that the hazard (year OS) in patients with ECOG ≥2 is about 2.55 times higher than in the patients with ECOG <2. ECOG, Eastern Cooperative Oncology Group; LDH, Lactate Dehydrogenase; GCB, germinal center B cell-like; IPI, International Prognostic Index; SA, serum albumin; NCCN-IPI, the National Comprehensive Cancer Network International Prognostic Index; OS, overall survival; HR, hazard ratio; CI, confidence interval.

The association of SA concentration with short-term efficacy

In the SA of ≤34 g/L population (n=70), the overall response rate (ORR) was 58.6%, with 28 complete remission (CR) patients and 13 partial remission (PR) patients, while the non-remission rate (NRR) was 41.4%. In the SA>34 g/L population (n=54), the ORR was 90.7% (n=49), while the NRR was 9.3% (n=5). The short-term efficacy of patients with DLBCL between these two groups was statistically significant (P=0.033), indicating the low SH patient has a low CR rate after receiving chemotherapy (Table 5). In addition, the 3-year OS and PFS in the high SA group were 57.4% and 32.8%, which was significantly better than that in the low SA group (P=0.002 and P=0.022) (Fig. 3 and Table 6).

Prognostic value of SA level in association with other factors of patients with DLBCL

The 3-year OS in patients with a sustained SA of >34 g/L was significantly longer than those with a continuous SA of ≤34 g/L (P=0.02), whereas there was no significant difference in terms of PFS, suggesting that patients with SA>34 g/L before the initial chemotherapy have longer OS than that of patients with SA≤34 g/L, while the level of SA did not affect on PFS of patients with DLBCL (Fig. 4). The 3-year OS of high SA patients with NCCN-IPI stratified low-intermediate risk group was significantly higher than the 3-year OS of low SA (P=0.029), while there was no significant difference in 3-year OS between high and low SA levels in low-risk/high-intermediate group (P>0.05) (Fig. 5). The 3-year OS of patients with high SA with ECOG score of 0-1 was significantly higher than that of pa-

Table 4. Results of multivariate Cox regression model

Index	3-year OS		
	HR	95.0% CI	P
Ann Arbor staging (I-II *vs* III-IV)	1.67	0.74-3.79	0.219
B symptoms (Yes *vs* No)	0.73	0.37-1.42	0.350
ECOG score (2 *vs* ≥2)	1.58*	0.77-3.25	0.212
Bone marrow involvement (Yes *vs* No)	0.78	0.4-1.48	0.451
LDH (Normal *vs* > Normal)	1.14	0.60-2.18	0.685

CHOP-like *vs* R-CHOP -like	0.43	0.24-0.76	0.004

*Example in this analysis: HR is obtained from the exponential of regression coefficient, and gives the effect size of the predictors. In our example, the ECOG variable had an HR=1.58, meaning that the hazard (3-year OS) in patients with ECOG ≥2 is about 1.58 times higher than in the patients with ECOG <2. ECOG, Eastern Cooperative Oncology Group; LDH, Lactate Dehydrogenase; OS, overall survival; HR, hazard ratio; CI, confidence interval.

Table 5. Comparison of serum albumin levels and short-term efficacy

Serum albumin (g/L)	CR (%)	NRR (%)	ORR (%)
≤34 g/L (n=70)	28 (40)	29 (41.4)	41 (58.6)*
>34 g/L (n=54)	32 (59.3)	5 (9.3)	49 (90.7)*

*P=0.033; CR: complete remission; NRR, non-remission rate; ORR, overall response rate.

Table 6. Analysis of Serum albumin levels and 3-year OS/PFS by univariate Cox regression model

%	HR	95% CI	P
3-year OS ratio: low SA (43.6%) *vs* high SA (57.4%)	1.629	1.193-2.224	0.002
3-year PFS ratio: low SA (20%) *vs* high SA (32.8%)	0.607	0.392-0.938	0.022

OS, overall survival; PFS, progression-free survival; SA, serum albumin; HR, hazard ratio; CI, confidence interval.

Figure 3. Analysis of 3-year OS (A) and PFS (B) in the low and high SA patients.

tients with low SA with ECOG score of 0-1 (HR=0.439, 95% CI=0.232–0.831, P=0.011) (Table 7). In the non-GCB group, the low SA patients survived for 47.9% in 3 years, and the 3-year survival rate of high SA patients was 78.3 %, which was statistically significant (P=0.004, Table 8). The 3-year OS of low SA patients in group III-IV was 33.2 %, which was significantly lower than 72 % in high SA patients (P=0.018) (Fig. 6 and Table 9).

Analysis of 3-year OS of treatment regime grouped SA group by univariate Cox regression model

The Kaplan–Meier test showed that in the CHOP-like treatment group, the 3-year OS ratio of patients in the high SA group was higher than that in the low SA group (62% *vs* 38%) (P=0.087, Fig. 7A). In the R-CHOP like treatment group, the 3-year OS ratio of patients in the high SA group was higher than that in the low SA group (87% *vs* 61% (P=0.101, Fig. 7B). Univariate Cox regression analysis showed that there were significantly different in the 3-year OS between low and high SA among the CHOP like (P=0.035) and R-CHOP like groups (P=0.04) (Table 10).

DISCUSSION

In this study, we retrospectively analyzed the 127 patients with DLBCL and found that the cut-off SA value of 34 g/L could be used as a prognostic predictor for DLBCL patients in the clinic. Similarly, Wei and others (Wei *et al.*, 2021) reported that the best cutoff value of SA for survival analysis of patients with DLBCL was 39.2 g/L, and also concluded that hypoalbuminemia can act as a simple and effective adverse prognostic factor in

3-years OS (**A**) and 3-year PFS (**B**) in patients with two SAs>34 g/L and two SAs ≤ 34 g/L before the first two chemotherapy. 3 years OS (**C**) and 3-year PFS (**D**) in patients with two SAs≤34 g/L and initial SA 34 g/L, second SA>34 g/L before the first two chemotherapy. 3-year OS (**E**) and 3-year PFS (**F**) in patients with two SAs>34 g/L and initial SA>34 g/L, second SA≤34 g/L before the first two chemotherapy.

these patients. In addition, Eatrides and others (Eatrides *et al.*, 2015) showed that SA <37g/L in patients treated with R-CHOP like had a lower OS and PFS. However, in this study, we divided the DLBCL patients into >34 g/L and SA≤34 g/L groups, and compared the prognostic outcomes of these patients in different subgroups, including NCCN-IPI risk grouping, before and after

chemotherapy, Ann Arbor staging, ECOG score, treatment options, respectively. By evaluating SA concentration predictive efficacy in these subgroups, it showed that SA may serve as the prognostic predictor in DLBCL patients with specific clinical characteristics.

IPI/aaIPI/NCCN – IPI assessment

IPI/aaIPI has been used as a prognostic indicator for DLBCL. In this study, univariate Cox regression model analysis IPI/aaIPI showed significant differences in OS of different risk stratification, indicating that IPI/aaIPI may effectively assess the prognosis of patients. Ziepert et al reported that rituximab increases OS in patients with DLBCL, and IPI can effectively assess patient prognosis in both CHOP-like and R-CHOP like regimens (Ziepert *et al.*, 2010). In this study, patients with DLBCL who received an R-CHOP regimen had

longer OS than patients with DLBCL who received a CHOP-like regimen, which is consistent with other studies. IPI was able to assess the prognosis of patients with DLBCL treated with the R-CHOP-like regimen but was unable to completely distinguish the four risk stratifications and the effectiveness of IPI in assessing the prognosis of such patients was limited (Salles *et al.*, 2011). Multivariate analysis showed that age ≥60 years, elevated LDH levels, low SA and Ann Arbor staging were independent prognostic risk factors (Ngo *et al.*, 2008). Zhou and others (Zhou *et al.*, 2014) studied patient data from seven clinical centers and proposed an NCCN-IPI prognostic assessment model to assess the prognosis of patients with DLBCL treated with the R-CHOP-like regimen.

NCCN-IPI is effective in assessing OS in patients treated with CHOP-like and R-CHOP-like regimens, and

Figure 5. 3-year overall survival of patients with SA≤34 g/L and with SA>34 g/L in NCCN-IPI risk stratification grouping.
(**A**) low-risk group; (**B**) low-intermediate risk group, (**C**) high-intermediate risk group; (**D**) high-risk group.

Figure 6. Comparison of OS between SA>34 g/L and SA≤34 g/L patients.
(**A**) Ann Arbor staging I-II group; (**B**) Ann Arbor staging III-IV group.

is more effective than IPI/aaIPI, in patients treated by R-CHOP-like (Salles *et al.*, 2011; Ngo *et al.*, 2008; Zhou *et al.*, 2014). However, Melchardt and others (Melchardt *et al.*, 2015) believe that the effectiveness of NCCN-IPI in evaluating the prognosis of patients treated with an R-CHOP-like regimen is still insufficient. Our study was stratified by age and the results showed that NCCN-IPI was able to effectively assess risk stratification in patients >60 years old and ≤60 years old.

SA levels

As an independent prognostic risk factor, SA has been confirmed in other hematological malignancies, including Hodgkin's lymphoma, myelodysplastic syndrome, acute myeloid leukemia, primary cutaneous T-cell lymphoma, spleen marginal lymphoma, and Primary mediastinal DLBCL (Huang *et al.*, 2015; Chihara *et al.*, 2009; Watanabe *et al.*, 2010; Zhu *et al.*, 2011; Arcaini *et al.*, 2006; Kharfan-Dabaja *et al.*, 2011; Komrokji *et al.*, 2012). The SA detection cycle is short, and the cost is

Figure 7. Comparison of 3-year OS between SA>34 g/L and SA≤34 g/L patients.
(**A**) CHOP-like treatment group; (**B**) R-CHOP like treatment group.

low, which can cover the population in remote areas. At the same time, SA is also a stable biomarker. A previous study showed that the 3-year OS in patients with SA levels >34g/L before chemotherapy was significantly higher than low SA (Eatrides *et al.*, 2015), which was consistent with our current finding. SA levels before chemotherapy are an independent prognostic risk factor for DLBCL. After chemotherapy, patients with low SA had shorter OS. CHOP like and R-CHOP-like treated patients with low SA had shorter OS than patients with high SA.

Evaluation of SA concentration predictive efficacy

The chi-square test showed a difference in CR between the two groups of SA that the short-term efficacy of low SA was poor. The long-term efficacy evaluation of COX regression showed that patients with low SA had significantly shorter PFS/OS than high SA patients. Patients with SA sustained >34 g/L before the second chemotherapy had longer OS than patients with SA sustained ≤ 34 g/L. Before the initial chemotherapy, patients with SA >34 g/L had higher OS than patients with SA≤34 g/L and were not affected by SA changes before the second chemotherapy.

Limitations

There were some limitations in this study. Firstly, this is a retrospective clinical analysis and should eliminate mutual interference between effective factors by using multivariate analysis. Secondly, as a limited case number was involved in this study, a comparsion of chemotherapy courses was not performed among these patients. Thirdly, the patients with the CHOP regimen had a very high population in this study, while the current chemotherapy is commonly applied with the R-CHOP regimen. Therefore, further investigations among DLBCL patients who received R-CHOP should be required to provide the guidance for the current clinical settings. Last but not least, as this is a single-center retrospective study, further studies with multi-center with larger sample size can help reinforce our current findings.

CONCLUSION

Before the initial chemotherapy, high SA patients had a longer 3-year OS than the low SA group. Pre-chemotherapy SA is an independent prognostic risk

factor for patients with DLBCL. This study indicates that the CR and NRR of SA≤34 g/L patients will be significantly lower than that of SA>34 g/L patients. In addition, the R-CHOP-like regimen may help improve low and high SA patients 3-year OS.

Review

Imiquimod-induced psoriasis model: induction protocols, model characterization and factors adversely affecting the model

Manahel Mahmood Alsabbagh✉

College of Medicine and Medical Sciences, Arabian Gulf University, Manama 329, Kingdom of Bahrain

Imiquimod-induced psoriasis is widely-employed to study disease pathogenesis and to screen drugs. While the original protocol was published more than a decade ago and has been rigorously used in research since then, a modified protocol was described recently with several advantages including milder systemic manifestations although the disease morphology is highly conserved. Being a toll-like receptor 7 and 8 agonist, IL-23/IL-17 axis predominates in imiquimod-induced psoriasis. In addition, different immunocytes were described to aggravate or supress the disease. This article aims to review the currently available protocols of imiquimod-induced psoriasis *in vivo*, to characterize the model as described in literature and to define the five important independent factors adversely influencing the model which researchers should pay attention to.

INTRODUCTION

Animal models of psoriasis are categorized into four categories: the first category represents models resulting from spontaneous mutations, such as homozygous asebia (Scd1^{ab}/Scd1^{ab}) and flaky skin (Ttc^{fsn}/Ttc^{fsn}) mice where the latter model shares with human psoriasis acanthosis, parakeratosis, and corneal neutrophils infiltration. The second category represents genetically-engineered models where epidermal proteins like keratins and/or cytokines are modified to produce features resembling psoriasis. The third category includes humanized models or models generated by xenotransplantation where lesional skin biopsy or skin equivalent is transplanted to mice. A recently-described but frequently used model is the directly induced model, where imiquimod is used to produce an immunological reaction resembling the one seen in psoriasis, largely mediated by IL-23/IL-17 axis and TNF-α (Guerrero-Aspizua *et al.*, 2020; Jean & Pouliot, 2010; Jeong & Lee, 2018).

This article aims to review the model of imiquimod-induced psoriasis, highlighting the currently published two induction protocols and characterizing the model in terms of dominant cytokines and cellular infiltrate. It also tackles the five factors that may influence disease modelization.

THE ORIGINAL AND MODIFIED PROTOCOLS OF IMIQUIMOD-INDUCED PSORIASIS

Imiquimod was first described in the mid-1990s as an immunomodulatory agent that augments the innate and adaptive immune systems. It is a toll-like receptor-7 and 8 agonist. It obtained the US Food and Drug Administration approval to treat anogenital warts, facial actinic keratoses and superficial basal cell carcinoma (Hanna *et al.*, 2016). Topical application of imiquimod may induce psoriasis (Wu & Strutton, 2004).

Van der Fits and others (van der Fits *et al.*, 2009) were the first to employ imiquimod to modelize psoriasis *in vivo*. They applied 62.5 mg of imiquimod 5% cream (Aldara) daily, equivalent to 3.125 mg of active ingredient, on the shaved back and right ear of BALB/c and C57BL/6 mice for five or six consecutive days and they assessed the severity of psoriasis using modified Psoriasis Area and Severity Index (PASI). Signs of psoriasis start to appear within the first three days and severity steadily increases till the end of the experiment. Authors reported lack of difference between the two strains of mice. Imiquimod-treated skin shows the cardinal histopathological features of psoriasis such as acanthosis (Singh *et al.*, 2019), parakeratosis and hypogranulosis. Immunohistochemical staining shows infiltration of dendrocytes, neutrophils and CD4$^+$ cells. Imiquimod also induces IL-23 and augments IL-17A, IL-17F and IL-22 production (van der Fits *et al.*, 2009).

Horvath and others (Horvath *et al.*, 2019) further modified the original protocol. They applied 25 mg of imiquimod 5% cream in Finn chambers on the back of C57BL/6 mice daily. This protocol results in erythema after the second application and scaling and skin thickening after the third application. The modified protocol was reported to be comparable to the original one. On histological examination, features of psoriasis such as parakeratosis, acanthosis, Munro microabscesses and dilated blood vessels in the dermal papillae were observed among both groups. Consistently, immunohistochemical examination reveals overexpression of Ki-67 in both. However, the modified protocol minimizes systemic manifestations and allows for prolonged imiquimod treatments.

Imiquimod-induced psoriasis model is largely used to study disease pathogenesis and to screen drugs. The model was employed for drug screening in more than 100 publications. In the majority of studies, the experimental drug of interest was administered concurrently on the same day of psoriasis induction. In a limited number of studies, it was started a few days before (1–21 days) or after induction. Regarding the protocol of induction, majority of studies complied with the original duration described as five or six consecutive days; few, howev-

er, applied the cream for shorter (three to four days) or longer periods (vast majority for seven days, up to 15 days). Prolonged daily application of imiquimod cream results in tachyphylaxis where Ki-67 expression diminishes in alignment with spontaneous attenuation and disappearance of erythema and scaling at three to four weeks despite continuous application of the cream (Kataoka et al., 2018).

Some studies lack a positive control; but where a positive control was used, it is a topical or systemic preparation that matches the route of administration of the experimental agent. Topical control preparations include betamethasone, calcipotriol, clobetasol, dexamethasone, dithranol, methotrexate and tacrolimus. Systemic control preparations include cyclosporine orally, dexamethasone orally and intraperitoneally, etanercept, methotrexate orally and intraperitoneally and tacrolimus.

CHARACTERIZATION OF IMIQUIMOD-INDUCED PSORIASIS MODEL

Jabeen and others (Jabeen et al., 2020) characterized the model of imiquimod-induced psoriasis where they applied 62.5 mg of imiquimod 5% cream for eight days. Cutaneous concentration of imiquimod approaches 100 µg/g on day 2 and it doubles by six folds on day 8 corresponding with a pronounced worsening of redness, thickness, scaling and total modified PASI. Acanthosis is evident on day 8 compared with day 2, explaining the clinically apparent thickness. Dermal hypervascularity is also marked, explaining the progressive redness. In terms of cytokine profile, elevation of IL-1β, IL-6 and IL-17A was observed in skin and TNF-α and IL-17A in serum. Disease progression associates with elongation of spleen, enlargement of total area of lymph nodes, and loss of weight independently of food intake (Zhang et al., 2020).

Macrophages and dendrocytes were investigated in the current model of psoriasis. While plasmacytoid dendrocytes are absent in imiquimod-induced lesions, the model shows a biphasic cellular behaviour. During the early phase, neutrophils infiltrate the epidermis and monocytes predominate in the dermis. Whereas in the late phase, Langerhans cells are pronounced in the epidermis and macrophages in the dermis. Depletion of Langerhans cells results in massive neutrophil infiltrate during the late phase, suggesting a potential anti-inflammatory role of Langerhans cells (Terhorst et al., 2015). On the contrary (Xiao et al., 2017) concluded that Langerhans cell depletion attenuates psoriasis and downregulates psoriasis-associated cytokine gene expression. (Lee et al., 2018) found that resident and monocyte-derived Langerhans cells secrete IL-23. Depletion of these cells inhibits IL-22 and IL-17A secretion (Lee et al., 2018), diminishes gamma-delta T-cell infiltration (Lee, 2016) and ultimately, attenuates psoriasis (Lee et al., 2018). Parallelly (Yoshiki et al., 2014) found IL-23-secreating Langerhans cells to induce IL-17A-producing gamma-delta T-cells. Depletion of Langerhans cells decreases Th-17-related cytokines and ameliorates psoriasis. In contrast, Kusuba and others (Kusuba et al., 2016) found that depletion of neutrophils early during psoriasis induction inhibits the infiltration of dermal monocytes, whereas depletion of both, neutrophils and monocytes, significantly attenuates psoriasis (Kusuba et al., 2016).

While IL-17 receptor is expressed on different cells, including T-cells and keratinocytes, its importance is cell-specific. For instance, deletion of keratinocyte's IL-17 receptor reduces neutrophil infiltration and abolishes

psoriasis; yet, this is not the case with T-cell-expressed receptor, emphasizing on keratinocytes' role in neutrophil chemoattraction (Moos et al., 2019). Likewise, IL-17 abrogation inhibits imiquimod-induced psoriasis (Ha et al., 2013). On the contrary (El Malki et al., 2013) found that in IL-17A receptor-knockout mice, imiquimod may still induce psoriasis independently of IL-17 pathway. The C-X-C motif chemokine receptor type-2 is involved in neutrophil chemoattraction as well. It promotes neutrophil-produced leukotriene-B$_4$ and augments neutrophil chemotaxis and infiltration (Sumida et al., 2014). Likewise, kallikrein-related peptidase-8 is elevated in psoriasis. If knocked out, the severity of imiquimod-induced psoriasis is comparable to wildtype, however, lesions lack neutrophil microabscesses (Iinuma et al., 2015).

IL-1 and IL-36α chemoattract neutrophils. Both molecules mediate human generalized pustular psoriasis which is accompanied by systemic symptoms such as fever and malaise. In the current model of psoriasis, mice also display systemic symptoms such as weight loss and generalized malaise, suggesting the contribution of IL-1 and IL-36α to model development. Deficiency of IL-1 receptor-1 or IL-36α variably attenuates psoriasis; however, deficiency of both absolutely abolishes the disease (Alvarez & Jensen, 2016). IL-36 role is further verified in IL-36 receptor-knockout mice where these are resistant to imiquimod (Goldstein et al., 2019).

Imiquimod-treated mice exhibit antihistamine-resistant itching that is largely driven by µ-opioid receptor located in the epidermis, the dorsal root ganglia, and the spinal cord. In alignment, naloxone, a µ-opioid antagonist successfully inhibits itching in imiquimod-treated mice (Takahashi et al., 2017). Itching is also mediated by sphingosine 1-phosphate receptor-3, which if knocked out, scratching behaviour improves (Hill et al., 2020). In addition, Oishi and others (Oishi et al., 2019) found imiquimod treatment to associate with expansion of mastocytes and overexpression of the nerve growth factor, the neurotrophic factor neurotrophin 3 and enkephalin precursor preproenkephalin (Oishi et al., 2019).

REGULATION OF IMIQUIMOD-INDUCED PSORIASIS

Imiquimod-induced psoriasis is negatively regulated by B-cells (Yanaba et al., 2013), regulatory T-cells (Choi et al., 2020; Oka et al., 2017), matrix remodelling associated-7 (Ning et al., 2018), indoleamine 2, 3-dioxygenase 2 (Elizei et al., 2018; Fujii et al., 2020), IFN regulatory factor-2 (Kawaguchi et al., 2018), IFN regulatory factor-5 (Nakao et al., 2020), dermokine β/γ (Tokuriki et al., 2016), IL-10 (Jin et al., 2018), IL-27 (Chen et al., 2017; Shibata et al., 2013), poly(ADP-ribose) polymerase-1 (Kiss et al., 2020), endogenous n-3 polyunsaturated fatty acids (Qin et al., 2014), L-selectin and ICAM-1 (Mitsui et al., 2015).

The regulatory role of B-cells, regulatory T-cells and IL-10 is evident in different studies. In a model of CD19$^{-/-}$ mice, exacerbation of psoriasis is attributed to the loss of IL-10-secreting regulatory B-cell subset (Yanaba et al., 2013). Likewise, depletion of regulatory T-cells disturbs the closely regulated gamma-delta T-cells, augments TNF-α and IL-17A secretion and aggravates the disease (Choi et al., 2020). Neutralization of IL-10 in imiquimod-induced psoriasis promotes epidermal thickening, increases neutrophil infiltration and accentuates IL-23/IL-17 axis (Xu et al., 2018). Likewise, knocking out IL-10 aggravates psoriasis macroscopically and mi-

croscopically, emphasising on its anti-inflammatory role in the disease (Jin *et al.*, 2018).

FACTORS INFLUENCING IMIQUIMOD-INDUCED PSORIASIS

Five factors adversely modify the model of imiquimod-induced psoriasis: the brand of imiquimod 5% cream, mouse strain, mouse sex, stress and obesity.

The brand of the commercially available imiquimod 5% cream may interfere with the model. While (Singh *et al.*, 2019) claimed generic formulations of imiquimod to produce a psoriasiform inflammation that is comparable to Aldara, Luo and others (Luo *et al.*, 2016) found that in comparison with Aldara, Likejie creams mediates a milder form of psoriasis with a modified PASI of 3.25±1.56 (compared with 9.81±0.84 in Aldara), a less pronounced acanthosis with a Backer's score of 2.93±1.07 (compared with 6.47±1.50 in Aldara) and an epidermal thickness of 49.79±14.16 µm (compared with 85.62±17.55 µm in Aldara), concluding that different brands may adversely affect the successful establishment of the model (Luo *et al.*, 2016).

In terms of the employed strain of mice, although van der Fits and others (van der Fits *et al.*, 2009) described their protocol in two different strains, (Swindell *et al.*, 2017) reported variation in modelization across six different strains of mice using a five-day course of 62.5 mg imiquimod 5% cream (Aldara). Microarray showed gene expression of imiquimod-induced psoriasis to largely overlap with that of human psoriasis. C57BL/6 mice, in particular, show the highest consistency, in contrast to MOLF/EiJ and 129X1/Sv mice where gene expression is opposite to human psoriasis. In terms of IL-17 gene expression, C57BL/6 mice highly express IL-17A, IL-17B, IL-17C and IL-17F. D'Souza and others (D'Souza *et al.*, 2020) examined the psoriatic changes induced by imiquimod in two different strains: BALB/c and the Swiss mice and concluded that imiquimod induces psoriatic changes macroscopically and microscopically among both strains, although these are more pronounced in the Swiss mice.

In terms of sex differences, and compared with male mice, female mice develop severe psoriasis in response to imiquimod, resulting in a greater weight loss, significant distress and unexpected early death. Inductions in females may also mandate euthanization (Alvarez & Jensen, 2016). In contrast, the influence of patient's sex on the severity of psoriasis is controversial. While female patients were found to significantly display milder psoriasis than male patients in two studies conducted in Swaziland and Sweden (Guillet *et al.*, 2022; Hagg *et al.*, 2017), this was contradicted by a third study (Goldburg *et al.*, 2022).

Wang and others (Wang *et al.*, 2020) investigated the effect of stress on imiquimod-induced psoriasis in a model of mice with emotional stress. In comparison with a control group with psoriasis kept off stress, stress was found to prolong the disease, to upregulate IL-1β, IL-17 and IL-22 gene expression and to increase IL-1β, IL-12, IL-17 and IL-22 secretion. This should further explain the role of stress in human psoriasis. For instance, stressful events were found to proceed psoriasis onset and were reported to trigger the disease in 31-88% of patients. Stress was also observed to aggravate psoriasis where daily stressors may expand the disease and worsens pruritus (Rigas *et al.*, 2019; Rousset & Halioua, 2018). This is evident in pediatrics as well, where childhood trauma is commoner in patients with psoriasis, and likewise, children with psoriasis score higher in anxiety scores (Wintermann *et al.*, 2022).

Obesity is known to exacerbate psoriasis in humans. This is also evident in imiquimod-induced psoriasis model where obese mice display thicker psoriatic lesions compared with non-obese subjects. Diet restriction partially improves psoriasis and cytokine profile (Hong *et al.*, 2019; Kanemaru *et al.*, 2015) and consistently, leptin deficiency attenuates the disease (Stjernholm *et al.*, 2017). The relationship between human psoriasis and obesity was vigorously studied. A metanalysis found the odd ratio of obesity in psoriasis is 1.66, and it can approach 2.23 in patients with severe disease (Armstrong *et al.*, 2012). A systematic review did also conclude that seven out of nine studies found a statistically significant association between increased psoriasis severity and increased body mass index (Fleming *et al.*, 2015). Such an association is attributed to a shared mechanism involving inflammatory mediators and adipokines (Jensen & Skov, 2016).

CONCLUSIONS

Imiquimod-induced psoriasis serves as an acceptable model to study IL-23/IL-17 axis and to screen pharmaceutical agents in psoriasis. While the model could be induced using two protocols, the original protocol described by van der Fits and others (van der Fits *et al.*, 2009) is widely employed in different studies. To ensure consistency of results, researchers should take into account that variation in the brand of imiquimod 5% cream, strain of mice, sex of mice, exposure to stress and obesity may adversely modify the course of disease.

MicroRNA-508-3p regulates the proliferation of human lung cancer cells by targeting G1 to S phase transition 1 (GSPT1) protein

Xingyou Chen[1], Chen Feng[2], Jiliang Zha[2], Zihao Shen[2] and Wei Ji[3]✉

[1]School of Medicine, Nantong University, Nantong, Jiangsu, 226007, China; [2]Department of Thoracic Surgery, The Affiliated Hospital of Nantong University, Medical School of Nantong University, Nantong, Jiangsu, 226001, China; [3]Department of Thoracic Surgery, Rudong People's Hospital, Nantong, Jiangsu, 226499, China

Purpose: Due to its crucial cancer regulatory role, microRNA-508-3p has been reported as a potential therapeutic anticancer molecular target. The present work encompassed the molecular characterization of microRNA-508-3p in lung cancer emphasizing on understanding the possible mechanism of its regulatory action. **Methods:** qRT-PCR was performed to estimate the relative gene expression of microRNA-508-p in the tissue samples. The proliferation of cancer cells was determined by cell counting kit-8. The colony formation from cancer cells was analyzed by clonogenic assay. Mitotic phase distribution was understood by employing the flow cytometric technique. Edu-Hoechst staining was used for the assessment of cell viability. *In silico* analysis and dual-luciferase assay were used for target identification of microRNA-508-3p in lung cancer. Immunofluorescence and western blotting studies were carried out for relative protein expression. The rat models were used for performing the *in vivo* experimental procedures. **Results:** The study showed the significant down-regulation of microRNA-508-3p in lung cancer. The lower expression levels of microRNA-508-3p were shown to be associated with poor survival of lung cancer patients. The over-expression of microRNA-508-3p was found to decline the proliferation and viability of cancer cells together with the induction of mitotic cell cycle arrest at G1 by targeting G1 to S phase transition 1 (GSPT1) protein. MicroRNA-508-3p up-regulation inhibited the in vivo tumor growth in rat models. **Conclusion:** Our study identifies miR-508-3p as a pivotal regulator of lung cancer cell proliferation by targeting the GSPT1 protein. This highlights its potential as a tumor suppressor and a therapeutic target for lung cancer. Our findings offer mechanistic insights into miRNA-mediated cancer progression, prompting further research in this intricate regulatory network.

INTRODUCTION

Lung cancer is the most commonly diagnosed human cancer worldwide and accounts for the highest mortality rate among both sexes of the human population at the global level (Thandra *et al.*, 2021; Malhotra *et al.*, 2016). On average, about 1.2 million new lung cancer cases are reported annually, worldwide (Cheng *et al.*, 2016). In 2018, more than 2 million lung cancer cases were diagnosed and the total number of deaths from lung cancer was 1.76 million (Bray *et al.*, 2018). Lung cancer has a very poor prognosis and the 5-year survival rates range between 10–20% making it a very destructive disorder (Hirsch *et al.*, 2017). In recent times, scientists have suggested an in-depth understanding of the molecular mechanics of lung cancer primarily aiming at the exploration of various genetic alterations to develop better prognostic and therapeutic measures against the severity of this dominant malignancy (Rong & Yang, 2018). In this regard, the research investigations apart from focusing on the protein-coding genes have laid considerable stress on the characterization of non-coding RNAs including micro-RNAs (miRNAs) for their cancer regulatory role (Bhan *et al.*, 2017).

The miRNAs include the class of very short, single-stranded and non-coding RNAs which typically regulate the gene expression in eukaryotes at post-transcriptional/translational level through mRNA degradation or by restraining the translation of eukaryotic genes through direct interaction with their 3'-untranslated region (3'-UTR; O'Brien *et al.*, 2018). The miRNAs have been reported to regulate the vital aspects of human physiology and have an important role in disease development. The miRNAs exhibit altered expression in many human cancers suggesting their possible role in cancer growth and proliferation (D'Angelo *et al.*, 2016). Several miRNAs were found to be dysregulated in lung cancer and these were proposed to act as prognostic biomarkers against lung cancer (Wu *et al.*, 2019). MicroRNA-508-3p (miRNA-508-3p) has been shown to regulate the tumor growth and proliferation of many human cancers like gastric and liver cancers (Shang *et al.*, 2016; Wu *et al.*, 2017). miR-508-3p exhibits reduced expression in cancer cells displaying resistance to treatment, which correlates with unfavorable survival outcomes (Zhao *et al.*, 2019). Additionally, diminished levels of miR-508-3p in breast cancer are linked to the occurrence of distant and lymph node metastases. Furthermore, within the same cluster of miRNAs, including miR-508-3p, miR-509-3p, miR-509-3-5p, and miR-514a-3p, there is a frequent downregulation in advanced and recurrent ovarian carcinoma (Bagnoli *et al.*, 2011), implying their coordinated regulation and co-expression. Various studies have also highlighted the prognostic relevance of these miRNAs in diverse cancer types (Hiramoto *et al.*, 2017; Shang *et al.*, 2014), although

exceptions exist. For instance, in esophageal squamous cell carcinoma (SCC), elevated miR-508-3p expression is paradoxically associated with shorter disease-free and overall survival. The growth regulatory role of microRNA-508-3p in lung cancer tumorigenesis has not been worked out.

The G1 to S phase transition 1 (GSPT1) protein is pivotal in orchestrating cell cycle progression, making it a significant player in cancer biology (Dang *et al.*, 2017). Its involvement in cancer pathogenesis has garnered attention across various cancer types, with an emerging focus on its implications within lung cancer. GSPT1's essential role lies in mediating the transition of cells from the growth-arrested G1 phase to the proliferative S phase of the cell cycle (Nishiguchi *et al.*, 2021). By regulating the translation termination process, GSPT1 controls gene expression, impacting fundamental cellular functions such as DNA replication and cell division. Its role extends beyond its involvement in the cell cycle, as GSPT1 has been implicated in cellular stress responses, mRNA quality control, and RNA metabolism.

In the context of cancer, GSPT1's dysregulation contributes to tumorigenesis through various mechanisms. Elevated GSPT1 expression has been associated with increased proliferation rates, reduced apoptosis, and altered gene expression patterns, all hallmark cancer cell features (Long *et al.*, 2021). Additionally, GSPT1's potential involvement in angiogenesis and metastasis underscores its multifaceted contributions to cancer progression (Tian *et al.*, 2018). Specifically, in lung cancer, GSPT1's perturbation has garnered attention due to its potential role in disease pathogenesis. Altered GSPT1 expression has been reported in lung cancer tissues, and its over-expression has been correlated with unfavorable clinical outcomes (Cheng *et al.*, 2021). GSPT1's regulatory influence over cellular processes in lung cancer aligns with its broader roles in other cancer types.

Understanding GSPT1's intricate role in cancer development and progression opens up avenues for therapeutic exploration. Targeting GSPT1 holds promise as a strategy to curtail uncontrolled proliferation and enhance the efficacy of cancer treatments. The intricate interplay of GSPT1 within cellular pathways underscores its potential as a druggable target. The primary objective of this study is to delve into the pivotal role played by miRNA-508-3p in governing the proliferation of human lung cancer cells. This investigation centers on the specific mechanism through which miRNA-508-3p exerts its influence, by targeting the GSPT1.

MATERIALS AND METHODS

Human clinical samples and cell lines

Sixty-five (65) paired specimens of lung cancer and normal adjacent tissues (taken from tumor margins and representing pathologically normal lung tissues) were collected from lung cancer patients after surgery at The Affiliated Hospital of Nantong University from 2014 to 2018. The patients didn't receive chemo or radiotherapy during tissue collection. The patients were informed about the study in advance and tissues were collected only after consent. The tissues were frozen immediately after collection in liquid nitrogen and then stored at -80ºC till experimental use. The study was approved by the institutional ethical guidelines committee. The study has been approved by the ethics committee of The Affiliated Hospital of Nantong University (No: AADEX124).

Four lung cancer cell lines (A427, A549, SK-LU-1 and HCC827) and the normal lung cell line (MRC5) were purchased from the American Type Culture Collection and their propagation was performed at 37°C with 5% CO_2. Dulbecco's Modified Eagle's Medium (DMEM, Gibco BRL) containing 10% FBS (v/v, Hyclone) was used as the cell culturing medium.

For transfection purposes, lung cancer cell lines (2×10^5 per well) were seeded in 6-well plates and allowed to attach for at least 18 h. miR-508 mimics (100 pmol), si-GSPT1 (100 pmol) together with their negative controls (100 pmol; designed and synthesized by RiboBio, Guangzhou, China) were transfected into cells using Lipofectamine 2000 reagent (Thermo Fisher Scientific) according to manufacturer guidelines. Over-expression of GSPT1 was achieved using the over-expression vector pcDNA3.1 (4 μg). The transfections were performed at 37°C for 48 h. Total RNA and protein were collected 48 hours post-transfection.

RNA isolation and qRT-PCR

Total cellular RNA from tissues and cell lines was extracted using the Trizol method (Thermo Fisher Scientific) which was reverse transcribed to cDNA with Reverse Transcription Kit (Takara). The following thermal cycling conditions were applied: 16°C for 30 min, 42°C for 30 min and 85°C for 5 min. The gene expression analysis was performed through qRT-PCR with the help of SYBR Green PCR Master Mix (Thermo Fisher Scientific). The qRT-PCR procedure was executed according to the following temperature protocol: an initial step at 50°C for 2 minutes, followed by denaturation at 95°C for 10 minutes. Subsequently, 40 cycles were performed, involving denaturation at 95°C for 15 seconds, followed by an annealing/extension step at 60°C for 60 seconds. Relative expression levels were estimated by the $2^{-\Delta\Delta CT}$ method. U6 was used as the internal expression control. The primer sequences used were as follows: miR-508-3p forward, 5'-TTCAAGAGACATGAGTGAC-3' and reverse, 5'-TCTCTTGAACATGAGTGACG-3'; U6 forward, 5'-TGCGGGTGCTCGCTTCGGCAGC-3' and reverse, 5'-CCAGTGCAGGGTCCGAGGT-3.

Proliferation and clonogenic assays

The proliferation of stably transfected lung cancer cells was analyzed through an MTT assay. The transfected cells were incubated in 96-well plates at 37ºC for 0 h, 20 h, 40 h, 60 h, 80 h or 100 h prior to the addition of MTT reagent (0.5% final concentration) to wells. The plate for incubated for 4 h again after adding MTT. Then the culture medium was replaced with 250 μl DMSO to dissolve the formazan crystals. Using a microplate reader (ELx808™, Agilent, USA), the optical density (OD) values were recorded at 570 nm for each well. These values were used for analyzing the relative cell proliferation using the formula: Cell viability (%) = (Absorbance of treated samples/Absorbance of control samples) ×100.

After their stable transfection for 48 hours, the cells at a cellular density of 500 cells per well were propagated for 14 days at 37°C. The colonies were then fixed with methanol for 20 min and stained with 1.0% crystal violet. The relative colony number was estimated by manually counting the colonies in 10 random fields under a microscope.

Cell cycle analysis

The stably transfected cancer cells were cultured in the 12-well plates at 37°C for 48 h using an initial cellular concentration of 1.6×10^6 cells/well. The cells were harvested and fixed with 70% ethanol at 4°C overnight. Staining of cells with 50 μg/ml propidium iodide (Thermo Fisher Scientific) followed by flow cytometric analysis was carried out for studying the cancer cell mitosis. The fluorescence-activated cell sorting (FACS) Calibur and Cell Quest software were used for estimating the cell cycle phase distribution of cancer cells.

Edu-Hoechst staining

Approximately 0.5×10^5 transfected cells were seeded per well of the 96-well plate. Each well was added to the EdU-medium for 2.5 h. The cells were then washed with PBS and ethanol fixed. The EdU assay kit (RiboBio) was used for viability assessments. The cells were also incubated with Hoechst solution for whole sample staining.

In vivo experiments

The nude rat xenografts were obtained using five- to six-week-old BALB/c nude male rats. The rats were distributed into 2 groups (10 rats per group). The rats were maintained using the institute's central animal house facility. The animal flanks were subcutaneously injected with 5×10^6 matrigel suspended A549 cancer cells to obtain the xenograft models. After tumor induction, the rats were treated with intra-tumor injections carrying miR-508-3p mimics or its negative control on alternate days. The intra-tumor injections were given for a varied number of days. On the 25th day after tumor induction, the rats were sacrificed and rat tumors were rescued. The size and weight of tumors were determined and used for calculating the tumor volume. The protein levels of PCNA and Cyclin D1 in rat tumors were analyzed through immune-histochemical staining.

Western blotting

Total cellular proteins were extracted by treating the cells with RIPA lysis and extraction buffer (Thermo Fisher Scientific). The protein expression was determined through chemiluminescence after PAGE and protein blotting using specifically designed primary antibodies like anti-GSPT1 (Novus Biologicals, NBP2-16754, 1;1000) and anti-actin (Sigma Aldrich, A2066, 1:1000). After overnight incubation, followed by proper washing, blots were incubated with HRP-linked secondary antibody (Cell Signaling Technology, 7074, 1:2000). Human actin protein served as the internal reference in western blotting study.

Bioinformatics and dual luciferase assay

To predict the molecular targets of miRNA-508, online miRNA target prediction software like Starbase (http://starbase.sysu.edu.cn) and TargetScan (http://www.targetscan.org/) were used. The latter also predicted the microRNA-508-3p binding site in the 3'-UTR of GSPT1. The prediction was assessed by luciferase assay using a dual luciferase reporter assay system (Promega). The 3'-UTR binding site (in native, WT or mutated, MUT state) bearing stretch of GSPT1 was cloned into the pGL3 vector for generating the reporter construct. The latter was co-transfected with miR-508-3p mimics or miR-NC into A549 cancer cells. The luciferase activity measurements were performed as per the manufacturer's protocol.

Statistical analysis

The experiments carried three replicates and the final data represented mean± S.D. Student's t-test and one-way ANOVA were performed using SPSS software (SPSS 22.0, Chicago, IL, USA) to analyze the statistical difference between the two values performed. The p-values <0.05 were deemed to represent a statistically significant difference between the two values.

RESULTS

Decreased microRNA-508-3p correlates with poor survival of lung cancer patients

The gene expression of microRNA-508-3p was determined from 65 of each lung cancer tissue samples and normal adjacent tissues through qRT-PCR. It was found that microRNA-508-3p has significantly lower expression in lung cancer tissues in comparison to normal lung tissues (Fig. 1A). The analysis of microRNA-508-3p expression from the paired cancerous and normal adjacent samples also revealed a similar inference (Fig. 1B). Interestingly, the 5-year study on the survival period of the patients from the month of detection of lung cancer receiving the similar therapy procedures was analyzed with the expression level of miRNA-508. It was found that the expression of microRNA-508-3p positively correlated with the period of patient's survival (months), i.e., the higher the expression of miRNA-508, the longer the survival period (Fig. 1C). Further, when the expression of miR-508 was determined in four lung cancer cell lines (A427, A549, SK-LU-1 and HCC827) and compared with its expression in a normal lung cell line (MRC5);

Figure 1. Decreased microRNA-508-3p correlates with poor survival of lung cancer patients.
(**A**) Lower microRNA-508-3p expression in lung cancer tissues in comparison to the normal lung tissues. (**B**) microRNA-508-3p expression from the paired cancerous and normal adjacent samples revealed a similar inference. (**C**) microRNA-508-3p expression positively correlated with the period of patient's survival (months), i.e., the higher the expression of miRNA-508, the higher the survival period. (**D**) qRT-PCR expression analysis revealing significant down regulation of microRNA-508-3p in lung cancer cell lines (A427, A549, SK-LU-1 and HCC827) in comparison to normal lung cell line (MRC5). Experiments were carried out in three replicates. (*) represents statistical significance at $p<0.05$ *vs* normal control.

it was seen that the panel of lung cancer cell lines exhibited significantly lower microRNA-508-3p expression in comparison to the normal lung cell line (Fig. 1D). The cancer cell lines, A427 and A549 were seen to exhibit the least expression among the four cancer cell lines used and were thus used for further characterization of miRNA-508. The results thus reveal significant repression of microRNA-508-3p in lung cancer and its decreased expression negatively correlating with lung cancer patient survival.

MicroRNA-508-3p overexpression declined the cancer cell growth and colony formation

To infer whether the lowered expression level of microRNA-508-3p has any doing with the lung cancer cell growth, microRNA-508-3p was over-expressed in A549 and A427 cancer cell lines and its over-expression was confirmed by RT-PCR (Fig. 2A). Both the cell lines over-expressing microRNA-508-3p showed significantly lower proliferation in comparison to the respective negative control cells (Fig. 2B). Again, the colony formation was markedly reduced by microRNA-508-3p over-expression (Fig. 2C). Both A549 and A427 cancer cell lines exhibited almost 50 % lower colony formation when microRNA-508-3p was over-expressed in them (Fig. 2D). The results suggest that microRNA-508-3p negatively regulates the growth of lung cancer cells and higher proliferation of cancer cells might be achieved through low-ered microRNA-508-3p down-regulation among other regulatory factors.

The cell cycle was arrested at the G1 phase in cancer cells over-expressing miRNA-508

The flow cytometric analysis of A427 and A549 cancer cells over-expressing microRNA-508-3p was performed to study the mitotic phase distribution which was compared with the negative control cells. A significantly higher percentage of cancer cells was shown to depict the Go/G1 cell cycle phase for the cancer cells over-expressing microRNA-508-3p while the percentage of cells was significantly lower exhibiting S and G2/M when compared with the phase distribution of negative control cells (Fig. 3A). To further validate the finding, the cancer cells over-expressing microRNA-508-3p in comparison with negative control cells were stained with EdU fluorescent stain to detect the relative number of cells which had undergone DNA synthesis. The number of EdU-stained cells was significantly lower under microRNA-508-3p overexpression in comparison to negative control cells (Fig. 3B). The percent number of EdU-positive cells was as low as 10% for both A549 and A427 cancer cell lines over-expressing microRNA-508-3p when compared with the respective negative control cells (Fig. 3C). Together, the results indicated that microRNA-508-3p overexpression induced lung cancer cells with cell cycle arrest at the G1 stage and thus reduced their *in vitro* proliferation.

Figure 2. MicroRNA-508-3p over-expression declined the cancer cell growth and colony formation.
(**A**) A549 and A427 cells transfected with microRNA-508-3p mimics showing significant up-regulation of microRNA-508-3p in comparison to respective miR-NC transfected cells. (**B**) A549 and A427 cells overexpressing microRNA-508-3p exhibit limited growth *in vitro* than the respective miR-NC transfected cells. (**C**) A549 and A427 cells over expressing microRNA-508-3p exhibit significantly lower colony formation than the respective miR-NC transfected cells (magnification ×100). Experiments were carried out in three replicates. (*) represents statistical significance at *p*<0.05 *vs* miR-NC.

Figure 3. Cell cycle was arrested at the G1 phase in cancer cells overexpressing miRNA-508.
(**A**) Flow cytometry analysis of A549 and A427 cells showed that overexpression of microRNA-508-3p produces a significantly higher percentage of cancer cells in the Go/G1 cell cycle phase while s significantly lower percentage of cancer cells in S and G2/M compared with the phase distribution of negative control cells. (**B**) A549 and A427 cells overexpressing microRNA-508-3p showed a lower number of EdU stained cells (10%) than the respective miR-NC transfected cells (magnification ×200). Experiments were carried out in three replicates. (*) represents statistical significance at *p*<0.05 *vs* miR-NC.

Figure 4. MicroRNA-508-3p up-regulation inhibited in vivo rat tumorigenesis.
(**A**) Morphological comparison of the rat tumors rescued from the animals overexpressing miR-NC and microRNA-508-3p mimic. (**B**) *In vivo* rat tumor volume was significantly decreased under microRNA-508-3p over-expression than the respective miR-NC. (**C**) Tumor weight was significantly decreased under microRNA-508-3p over-expression than the respective miR-NC. (**D, E**) The IHC staining of PCNA revealed that tumors exhibited significantly lower PCNA protein expression under microRNA-508-3p over-expression and a similar observation was made about the expression level of cyclin D1 (magnification ×20). Experiments were carried out in three replicates. (*) represents statistical significance at $p<0.05$ *vs* miR-NC.

MicroRNA-508-3p up-regulation inhibited *in vivo* rat tumorogenesis

During the *in vivo* study, the intra-tumor overexpression was achieved in the rat models. The morphological comparison of the rat tumors rescued from the animals after their sacrifice revealed that the rat tumor size was significantly lower under microRNA-508-3p over-expression when compared with that of the negative control rats (Fig. 4A). Similarly, the *in vivo* rat tumor volume was significantly decreased under microRNA-508-3p over-expression (Fig. 4B). Tumor weight also showed a similar trend (Fig. 4C). The immune-histochemical staining of proliferating cell nuclear antigen (PCNA) revealed that rat tumors exhibited significantly lower PCNA protein expression under microRNA-508-3p overexpression and a similar observation was made about the expression level of cyclin D1, both of which are used are the proliferation markers (Fig. 4D and 4E). Hence, the results suggest that up-regulation of microRNA-508-3p inhibited the growth and proliferation of *in vivo* rat tumors indicating its tumor-suppressive role in lung cancer.

MicroRNA-508-3p exercised its effects by targeting GSPT1 in lung cancer

To look for the possible regulatory mechanism of action of microRNA-508-3p in lung cancer, online bioinformatics was performed. MicroRNA-508-3p was predicted to be targeting G1 to S phase transition 1 (GSPT1) protein (Fig. 5A). MicroRNA-508-3p was shown to specifically bind with the 3'-UTR of GSPT1 in sequence-specific fashion (Fig. 5B). The dual luciferase reporter assay was performed to confirm this prediction. The significant reduction in the luciferase activity when the overexpression construct of microRNA-508-3p was co-transfected with the native (WT) reporter construct

Figure 5. MicroRNA-508-3p exercised its effects by targeting GSPT1 in lung cancer.
(**A**) TargetScan software predicted that microRNA-508-3p targets the GSPT1 protein. (**B**) *In silico* analysis predicted a specific microRNA-508-3p binding site in 3'-UTR of GSPT1. (**C**) The significant reduction in the luciferase activity when the overexpression construct of microRNA-508-3p was co-transfected with the native (WT) reporter construct of GSPT1 in A549 cancer cells showed that microRNA-508-3p interacted with 3'-UTR of GSPT1. (**D**) Expression of GSPT1 in normal and lung cancer tissues. (**E**) GSPT1 expression from the paired cancerous and normal adjacent samples revealed a similar inference. (**F**) Expression analysis of GSPT1 in lung cancer cell lines in comparison to normal liver epithelial cell line. (**G**) Over-expression of microRNA-508-3p in A549 cancer cells negatively affected the protein level of GSPT1 suggesting post-transcriptional/translational targeting of the latter by microRNA-508-3p in lung cancer. Experiments were carried out in three replicates. (*) represents statistical significance at $p<0.05$ *vs* miR-NC.

of GSPT1 in A549 cancer cells showed that microRNA-508-3p interacted with 3'-UTR of GSPT1 (Fig. 5C). Further support was attained from the expression study of the GSPT1 gene from lung cancer tissues and cancer cell lines in comparison to normal tissues and cell line. GSPT1 was found to have significantly higher expression in cancer tissues and cell lines corresponding to lower microRNA-508-3p expression (Fig. 5D, 5E and 5F). Further, the over-expression of microRNA-508-3p in A549 cancer cells negatively affected the protein level of GSPT1 suggesting post-transcriptional/translational targeting of the latter by microRNA-508-3p in lung cancer (Fig. 5G).

MicroRNA-508-3p directly binds to GSPT1 in lung cancer

To explore whether the observed effects of microRNA-508-3p against lung cancer were modulated through GSPT1 targeting, RNA interference-mediated silencing of GSPT1 was performed in A549 cancer cells and repression was confirmed by qRT-PCR (Fig. 6A). The cancer cells exhibited significantly lower proliferation under GSPT1 silencing (Fig. 6B). GSPT1 silencing was seen to induce G0/G1 phase cell cycle arrest (Fig. 6C). Similar to microRNA-508-3p over-expression, the down-regulation of GSPT1 reduced the proliferative viability of lung cancer cells (Fig. 6D). Confirming the execution of microRNA-508-3p role in lung cancer through GSPT1, the over-expression of GSPT1 in A549 cancer cells minimized the antiproliferative effects of microRNA-508-3p up-regulation (Fig. 6E). Summing up, the results are suggestive of direct binding of microRNA-508-3p with GSPT1 to down-regulate the expression of latter translationally in lung cancer and exertion of mi-

Figure 6. MicroRNA-508-3p directly binds to GSPT1 in lung cancer.
(**A**) Relative expression of GSPT1 in A549 cancer cells after silencing of GSPT compared to si-NC. (**B**) A549 cancer cells exhibited significantly lower proliferation under GSPT1 silencing compared to cells transfected with si-NC. Experiments were carried out in three replicates. (*) represents statistical significance at $p<0.05$ vs si-NC.

croRNA-508-3p tumorogenesis regulatory role through miRNA-508/GSPT1 molecular axis which further insights into the therapeutic value of miRNA-508/GSPT1 axis against the deadliest cancer, the human lung cancer.

DISCUSSION

Lung cancer is by far the deadliest human cancer with high incidence and mortality rates worldwide (Busch et al., 2016). The disease is reportedly induced through genetic alterations and external environmental factors (Samet, 2013). A thorough understanding of lung cancer progression is essential for formulating effective treatment measures against this lethal menace. At the molecular level, the studies have focused on exploring different regulatory molecules regulating the growth and propagation of lung cancer including the non-coding RNAs (Lin & Yang, 2018). Falling in the category of non-coding RNAs, the micro-RNAs (miRNAs) were shown to profoundly affect the tumorogenesis of many human cancers (Vannini et al., 2018). Many miRNAs have been shown to exercise a key developmental role in human lung cancer (Kabekkodu et al., 2020). Although

microRNA-508-3p has been found to exhibit active involvement in a number of cancer types, but its in-depth role has not been explored in lung cancer. The current study revealed a significant transcriptional down-regulation of microRNA-508-3p in lung cancer. microRNA-508-3p has also been elucidated to exhibit transcriptional repression in human cancers like gastric cancer, and colon cancer (Wang & Jin, 2019). Additionally, the level of microRNA-508-3p down-regulation negatively correlated with the survival of lung cancer patients. This indicated that microRNA-508-3p functions as a tumor suppressor in lung cancer and other human cancers, as reported by earlier studies (Huang et al., 2016). The microRNA-508-3p over-expression declined lung cancer growth both in vitro and in vivo. The anti-cancer effects of microRNA-508-3p up-regulation were also evidenced as the arrest of lung cancer cell cycle at the G1 subphase of mitotic interphase, which suggests that microRNA-508-3p negatively regulates lung cancer cell growth as has been supported by previous studies (Bao et al., 2016). Importantly, the current study showed that G1 to S phase transition 1 (GSPT1) protein is functionally targeted by microRNA-508-3p in lung cancer. The role of microRNA-508-3p was found to be attenuated via GSPT1. The GSPT1 is a protein-coding gene that regulates the translational termination in eukaryotes associated with eukaryotic release factor 1 (eRF1; Zhouravleva et al., 2006). It is involved in cell cycle regulation and cell apoptosis. In the present study, the GSPT1 over-expression resulted from microRNA-508-3p repression and the former was proved to considerably affect the molecular level progression of lung cancer. The up-regulation of GSPT1 was also reported to be linked with the growth and development of gastric and breast cancer (Tian et al., 2018). In another report, the expression of GSPT1 was shown to be significantly higher in non-small lung cancer cells and negatively correlated with miRNA-27b-3p expression (Sun et al., 2019). The miRNA/GSPT1 axes have been suggested to act as potential therapeutic targets against human cancers including lung cancer (Li et al., 2020). Concluding with a similar inference, the miRNA-508/GSPT1 was unravelled as a vital growth regulatory link in lung cancer. The results of the present study support its therapeutic utility against human lung cancer.

The functional analyses conducted in this study provide mechanistic insights into how microRNA-508-3p exerts its tumor-suppressive effects in lung cancer. The inhibition of cancer cell proliferation and viability following microRNA-508-3p overexpression aligns with the notion that this microRNA acts as a negative regulator of tumor growth. The induction of cell cycle arrest at the G1 phase, as evidenced by the down-regulation of the GSPT1 protein, suggests that microRNA-508-3p exerts its antiproliferative effects by interfering with key cell cycle regulatory pathways. These findings offer a clearer picture of the molecular events modulated by microRNA-508-3p that contribute to its tumor-suppressive functions.

The in vivo experiments using rat models provide a relevant and translational dimension to the study. The observed inhibition of tumor growth in response to microRNA-508-3p up-regulation underscores the potential therapeutic application of this microRNA in lung cancer treatment. These results add to the growing body of evidence supporting microRNA-based therapies as promising avenues for cancer intervention.

It is worth noting that the findings of this study resonate with the broader understanding of microRNA dysregulation in cancer and reinforce the idea that targeting

specific microRNAs could hold immense therapeutic potential. However, further investigations are warranted to delve deeper into the exact mechanisms through which miRNA-508-3p modulates its target gene(s), potentially involving intricate regulatory networks that influence cancer progression.

The current study significantly contributes to our understanding of the role of microRNA-508-3p in lung cancer. The comprehensive molecular characterization, functional analyses, and in vivo experiments underscore the potential of microRNA-508-3p as a promising therapeutic target for lung cancer treatment. By elucidating its regulatory mechanisms and demonstrating its impact on tumor growth, this research opens up avenues for developing innovative therapeutic strategies to improve patient outcomes in lung cancer management.

CONCLUSIONS

The current study showed that microRNA-508-3p experiences a key regulatory role in the growth and proliferation of lung cancer, and the lowered expression levels of microRNA-508-3p account for poor disease survival. The results were conclusive of the prognostic and therapeutic role of microRNA-508-3p against lung cancer, which might be utilized as a novel and alternative anticancer therapy for the treatment of lung cancer.

Circular RNA METTL15/miR-374a-5p/ESCO2 axis induces colorectal cancer development

Feng Guo, Yang Luo, GuangYao Ye and WeiJun Tang✉

Department of Gastrointestinal Surgery, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai City, 200127, China

This study investigated the biological role and mechanism of circMETTL15 in colorectal cancer (CRC). Cancer tissues and matched adjacent normal tissues were collected. CircMETTL15, miR-374a-5p, and ESCO2 levels were detected by RT-qPCR and Western Blot. LoVo cells were selected for loss- and gain-of-function assays and rescue assays. Cell proliferation was detected by CCK-8 and colony formation tests, cell apoptosis and cell cycle were detected by flow cytometry, cell migration and invasion were detected by Transwell assay, and protein expression of ki-67, E-cadherin, N-cadherin, and cleaved caspase-3 was detected by Western blot. Through bioinformatics analysis and verification assays, the targeting relationship between circMETTL15, miR-374a-5p, and ESCO2 was studied. The results suggest that circMETTL15 was a stable circRNA that was highly expressed in CRC tissues and cells and was associated with tumor size, higher TNM staging, and lymph node metastasis in CRC patients. Functionally, knocking down circMETTL15 inhibited the proliferation, migration, invasion, and EMT of LoVo cells, and induced apoptosis. Overexpression of circMETTL15 showed the opposite effect. The effects of knockdown or overexpression of circMETTL15 on the biological behavior of LoVo cells were reversed by knockdown of miR-374a-5p or knockdown of ESCO2, respectively. Mechanistically, circMETTL15 acts as a ceRNA for miR-374a-5p to regulate ESCO2 expression, thereby promoting the biological behavior of LoVo cells. In conclusion, the results of this study reveal the role of circMETTL15 in CRC and the underlying molecular mechanism, which provides potential data support for the development of future CRC drugs.

INTRODUCTION

Colorectal cancer (CRC) remains one of the leading causes of cancer deaths worldwide (Ameli-Mojarad *et al.*, 2021). So far, surgery, chemotherapy, and radiotherapy have been the main treatment strategies for CRC (Shao *et al.*, 2021). Most patients are diagnosed in an intermediate or late stage because of the hidden early symptoms (Simon, 2016). In addition, limited efficacy, postoperative recurrence, and long-term metastasis lead to poor prognosis for CRC patients (Díaz-Tasende, 2018). Accumulating studies have shown that changes at the genetic and epigenetic levels of oncogenes and tumor suppressor genes are involved in the development and progression of CRC and act as potential therapeutic targets for CRC (Tsai *et al.*, 2021; Slattery *et al.*, 2017). Therefore, identifying these regulatory genes will offer new insights into the development of molecularly targeted therapies for CRC.

Circular RNA (circRNA) has been widely confirmed to be involved in cancer development (Zhang *et al.*, 2021) and is associated with drug resistance, differentiation, metastasis, angiogenesis, proliferation, migration, and apoptosis (Ameli-Mojarad *et al.*, 2021). For example, circPCLE1 promotes CRC epithelial-mesenchymal transition (EMT), glycolysis, and tumor-associated macrophage polarization (Yi *et al.*, 2022) and N-methyladenosine modification of circALG1 promotes CRC migration, invasion, and metastasis (Lin *et al.*, 2022). It can be seen that the regulation of circRNA has a profound impact on the occurrence and progression of CRC. As a member of circRNA, methyltransferase-like 15 (circMETTL15) is involved in the proliferation, metastasis, immune escape, and apoptosis of lung cancer (Zhang *et al.*, 2022). Based on this, we speculate that circMETTL15 may be involved in the regulation of CRC.

In recent years, the competing endogenous RNA (ceRNA) hypothesis has been widely proposed (Salmena *et al.*, 2011). We predicted circMETTL15-related miRNAs (miR-374a-5p) and miRNA target genes (The establishment of sister chromatid cohesion N-acetyltransferase 2, ESCO2). As a short non-coding RNA, miR-374a-5p negatively regulates gene expression and regulates various biological processes (Lin *et al.*, 2020; Guo *et al.*, 2021). miR-374a-5p abnormal expression has been tested in CRC indicating a correlation with patients' survival rates (Slattery *et al.*, 2015; Slattery *et al.*, 2017). ESCO2 is an evolutionarily conserved cohesion acetyltransferase (Zhu *et al.*, 2021) that can suppress the development of CRC (Guo *et al.*, 2018).

This study aimed to investigate the effect of circMETTL15 on the biological function of CRC cells and to discover the molecular mechanism of circMETTL15 with miR-374a-5p and ESCO2 in CRC.

MATERIALS AND METHODS

Clinical samples

Between 2016 and 2019, 78 cancer tissues and matched adjacent normal tissues (≥ 3 cm from cancer tissue) were surgically resected from CRC patients (excluding those receiving radiotherapy or chemotherapy) at Renji Hospital, Shanghai Jiaotong University School of Medicine. All tissues were kept at –80°C. All clinical and pathological diagnoses were validated by two independent pathologists according to the AJCC and UICC guidelines. This study was approved by the Ethics Committee of Renji Hospital, Shanghai Jiaotong University School of Medicine. Each patient was informed about the content.

Cell culture

LoVo, Caco-2, SW620, SW480, and NCM460 cells were maintained in DMEM, HT-29 and HCT-116 were in DMEM/F12 medium, while DLD-1 was in RPMI-1640 medium. All the media (Gibco, CA, USA) were added with 10% fetal bovine serum, 1% penicillin, and streptomycin, and all cell lines were offered by the Chinese Academy of Sciences Culture Collection (Shanghai, China) and grown in a 5% CO_2 humidified incubator at 37°C.

RNA analysis

With Trizol reagent (Takara, Japan), circRNA, mRNA, and miRNA were extracted from tissues and cells for reverse transcription after detection on Nanodrop 2000 (Thermo Fisher Scientific). In the reverse transcription system, PrimeScript RT master mix (Takara) was utilized for mRNA and circRNA, while for miRNA, Bulge-Loop™ miRNA Quantitative Real-Time Polymerase Reaction Starter Kit (RIBOBIO, China) was applied. cDNA amplification was implemented in the ABI Prism 7500 Sequence Detection System with TB Green Premix Ex Taq II (Takara). The PCR cycling parameters are as follows: 95°C for 30 s followed by 40 cycles at 95°C for 5 s and 60°C for 30 s. mRNA and circRNA were normalized to GAPDH, while miRNA was to U6. The calculation of relative expression was dependent on the $2^{-\Delta\Delta CT}$ method. Primers are listed in Table 1.

Table 1. Primer sequences

Genes	Primers
circMETTL15	F: 5'- GCCAGCATCGTTGCAGATTT-3'
	R: 5'- GCTGTTGGGTCTCTGTCCAA-3'
miR-374a-5p	F: 5'- CGCGCGTTATAATACAACCTGA -3'
	R: 5'- GCAGGGTCCGAGGTATTC -3'
GAPDH	F: 5'-CACCCACTCCTCCACCTTTG-3'
	R: 5'-CCACCACCCTGTTGCTGTAG-3'

Note: F, forward; R, reverse; circMETTL15, circular RNA METTL15; miR-374a-5p, microRNA-374a-5p; GAPDH, glyceraldehyde-3phosphate dehydrogenase

Nucleic acid electrophoresis

Agarose gel electrophoresis (2%) was performed using 45 mmol/L Tris-boronic acid and 1 mmol/L EDTA (TBE). DNA was separated by electrophoresis at 120 V for 30 min, taking marker L (50-500 bp) as the DNA marker (Beyotime, China). UV irradiation was used to examine the bands.

Actinomycin D and RNase R

RNase R (3 U/g, Epicenter) was used to treat RNA (10 μg) from LoVo cells. After incubation at 37°C for 30 min, circRNA and linear mRNA were detected using reverse transcription and RT-qPCR.

Actinomycin D (2 μg/mL, Sigma) was adopted to treat LoVo cells for 4, 8, 12, and 24 h, followed by checking the stability of linear mRNA and circRNA by RT-qPCR.

Cell transfection

siRNA or pcDNA 3.1 overexpression vectors targeting circMETTL15 and ESCO2, and miR-374a-5p mimic/inhibitor were constructed and provided by Genepharma (Shanghai, China). The oligonucleotides and plasmids were transiently transfected into LoVo cells using Lipofectamine 3000 (Invitrogen) and gene expression was analyzed by RT-qPCR and western blot after 48 h.

CCK-8 assay

LoVo cells (2000 cells/well) were plated in 96-well plates and added with 10 μL of CCK-8 reagent (Sangon Biotech, Shanghai, China) at the indicated time points (24, 48, and 72 h). Absorbance at 450 nm was measured using an iMark microplate reader (Bio-Rad) after 2 h.

Colony formation test

LoVo cells were grown at 1000 cells/well in 6-well plates to allow colony formation at 37°C. The colonies were observed every 3 days, and after 2 weeks, the colonies fixed with paraformaldehyde were counted under a microscope (Olympus) after 0.1% crystal violet staining.

Flow cytometry

Cells were fixed overnight at –20°C in 75% alcohol, washed 3 times, and detected by a cell cycle analysis kit (Beyotime). Cells were digested by trypsin, washed in cold PBS, and analyzed by an Annexin V-FITC/PI kit (Vazyme, Nanjing, China) to assess cell apoptosis. Cell cycle distribution and apoptosis rate were determined on the BD FACSCanto II (BD Biosciences).

Transwell assays

LoVo cells were suspended in a fresh medium (100 μL) and added to the upper Transwell chamber (BD Bioscience). Matrigel coating (BD Bioscience) was required for the invasion test but not the migration test. After 24-h induction, cells appearing in the lower chamber were fixed with paraformaldehyde and stained with 0.1% crystal violet for microscopic observations (× 100, Olympus).

Protein analysis

Protein samples collected by RIPA buffer were separated by 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis after quantification using a BCA kit (Beyotime). Next, the samples were transferred to polyvinylidene fluoride membranes and blocked with 5% nonfat milk for 2 h. After reaction with the primary antibody overnight at 4°C, the membranes were incubated with the secondary antibody (1:5000, CST, MA, USA) for 2

h. The protein blots which were visualized by Omni-ECL chemiluminescent reagent (EpiZyme, China) were then analyzed by Image Lab. Primary antibodies: ESCO2 (ab86003, Abcam), E-cadherin (610181, BD Biosciences), N-cadherin (22018-1-AP, Proteintech), cleaved caspase-3 (ab2302, Abcam), Ki-67 (ab15580, Abcam).

Dual-luciferase reporter assay

Genepharma constructed PGL4 luciferase reporters (Promega) containing circMETTL15 wild-type sequence or mutant sequence (with or without miR-374a-5p binding site), namely circMETTL15-WT and circMETTL15-MUT, respectively. Likewise, ESCO2 3'UTR-WT and ESCO2 3'UTR-MUT were also constructed. The luciferase reporter vector was co-transfected with miR-374a-5p mimic or mimic NC into LoVo cells using Lipofectamine 3000 (Invitrogen) and its luciferase activity was determined in the Dual Luciferase Assay System (Promega) after 48 h.

RIP experiment

Under the guidance of the Magna RIP kit (Millipore), LoVo cells were lysed and mixed with Ago2 antibody-conjugated or IgG antibody-conjugated magnetic beads. RNA complexes on magnetic beads were eluted to isolate total RNA for calculation of RNA expression by RT-qPCR.

Observation of tumor formation

Animal experiments were approved by the Animal Ethics Committee of Renji Hospital, Shanghai Jiaotong University School of Medicine (Approval number: 201511F760). LoVo cells (1×10^6, 100 μL) stably transfected with si-circMETTL15 or si-NC were injected subcutaneously into the axilla of 5-week-old male BALB/c nude mice (n=5/group). After 1 week, the tumor volume (length×width^2/^{2}) was calculated and recorded once a week. Five weeks later, mice were euthanized to resect tumors for IHC analysis (Zhou *et al.*, 2021).

Data analysis

At least 3 biological replicates were run for each experiment. All statistical analyses were performed using GraphPad Prism 9.0 software (La Jolla, CA, USA). Bilateral comparisons were run by Student's *t*-test, while multiple comparisons were by one-way ANOVA. The correlation between circMETTL15 expression and clinicopathological data was assessed by Chi-square test, while that between circMETTL15 expression and overall survival was by Log-rank (Mantel-Cox) test. $P<0.05$ was considered as significant difference.

RESULTS

circMETTL15 is abnormally highly expressed in CRC

To investigate whether circMETTL15 participates in CRC, its expression was analyzed in 78 cancer tissues and matched adjacent normal tissues by RT-qPCR. CircMETTL15 was abnormally highly expressed in the tumor samples compared with paired normal tissues (Fig. 1A). Also, circMETTL15 expression was analyzed in CRC cell lines, and elevated circMETTL15 was demonstrated in CRC cell lines than in NCM460 cell line

Figure 1. circMETTL15 is abnormally highly expressed in colon cancer

(**B**) RT-qPCR to detect circMETTL15 in human colorectal cancer cell lines and human colon epithelial mucosa cell line (NCM460). (**C**) Correlation analysis between circMETTL15 and survival rate of CRC patients. (**D**) Genetic information of circMETTL15. (**E**) Agarose gel electrophoresis confirmed the amplification of circMETTL15 by diverging primers in cDNA but not in gDNA. (**F**) RNase R experiment verified the ring structure of circMETTL15. (**G**) Actinomycin D experiment verified the ring structure of circMETTL15; data are expressed as mean ± S.D. (N=3).

Table 2. Relationship between circMETTL15 and clinicopathological features of CRC patients

Characteristic	Cases	The expression of circMETTL15		P
	n=78	Low (n=39)	High (n=39)	
Gender				
Male	48	23	25	0.6416
Female	30	16	14	
Age (year)				
≤ 60	14	5	9	0.2379
> 60	64	34	30	
Tumor size				
< 3 cm	52	33	19	0.0008
≥ 3 cm	26	6	20	
TNM staging				
I/II	19	14	5	0.0176
II/IV	59	25	34	
Lymph node metastasis				
Positive	34	12	22	0.0224
Negative	44	27	17	
Distant metastasis				
Positive	29	13	16	0.4821
Negative	49	26	23	

(Fig. 1B). Next, the relationship between circMETTL15 levels and clinicopathological characteristics of CRC patients was explored, and the data emphasized that the abundance of circMETTL15 was positively associated with tumor size, TNM stage, and lymph node metastasis

(Table 2). "Log-rank (Mantel-Cox) test" survival analysis showed that CRC patients with high circMETTL15 had poorer overall survival (Fig. 1C). Subsequently, the genetic information of circMETTL15 was determined from the bioinformatics website circbase. circMETTL15 was generated from exon 1 to exon 4 of the METTL15 gene with a full length of 862 bp (Fig. 1D). Agarose gel electrophoresis indicated that circMETTL15 was successfully detected by convergent primers for gDNA and cDNA, but it could only be generated from cDNA by different primers in LoVo cells (Fig. 1E). To further verify the stability of circMETTL15, RNase R and actinomycin D were used. CircMETTL15 was resistant to digestion by RNase R and had a longer half-life compared with linear mRNA (Fig. 1F, G).

circMETTL15 inhibition blocks CRC cell proliferation, invasion, migration, and EMT and promotes apoptosis

Subsequently, the effects of circMETTL15 on the biological behavior of CRC cells were investigated by loss of function assay. si-circMETTL15 was transfected into LoVo cells to downregulate circMETTL15 (Fig. 2A). CCK-8 and colony formation assays were utilized to evaluate cell proliferation ability. It was observed that knockdown of circMETTL15 reduced LoVo cell proliferation rate (Fig. 2B) and colony formation capacity (Fig. 2C). Then, cell cycle was detected by flow cytometry. As shown in Fig. 2D, knockdown of circMETTL15 increased the proportion of cells in G0/G1 phase and decreased the proportion of cells in G2/M phase. To investigate the effect of circMETTL15 on apoptosis, Annexin V-FITC/PI kit was used to evaluate apoptosis rates. As shown in Fig. 2E, circMETTL15 knockdown resulted in an increased apoptosis rate. In addition, the invasion and migration ability of LoVo cells was examined by Transwell assay. The results showed that circMETTL15 knockdown reduced the number of cells that invaded and migrated (Fig. 2F). At last, the changes of apoptosis, proliferation, and EMT-related proteins were observed by Western blot. As shown in Fig. 2G, after circMETTL15 downregulation, N-cadherin and Ki-67 expression decreased but cleaved caspase-3 and E-cadherin expression increased in LoVo cells. These data suggest that circMETTL15 knockdown inhibits LoVo cell proliferation, invasion, migration, and EMT, pro-

motes apoptosis, and increases the proportion of G0/G1 phase cells.

circMETTL15 binds to miR-374a-5p

Given that circRNAs primarily act as miRNA sponges in the cytoplasm, online databases (https://starbase.sysu.edu.cn and https://circinteractome.nia.nih.gov) predicted the possible miRNAs that bind to circMETTL15, and screened 8 kinds of overlapping of miRNAs (Fig. 3A). RIP experiments confirmed that three of the eight miRNAs were enriched with circMETTL15 (Fig. 3B), but only miR-374a-5p was downregulated in LoVo cells (Fig. 3C). Therefore, miR-374a-5p might be a downstream miRNA of circMETTL15. With their predicted potential binding sites (Fig. 3D), circMETTL15-WT and circMETTL15-MUT reporters were constructed, and their luciferase activity was observed by dual luciferase reporter assay. The results were consistent with the prediction, that is, circMETTL15 targets miR-374a-5p (Fig. 3E). RT-qPCR analyzed miR-374a-5p expression in patients' tissues and found its downregulation in CRC tissues (Fig. 3F). CircMETTL15 knockdown effectively increased miR-374a-5p expression in LoVo cells (Fig. 3G).

The effects of circMETTL15 on CRC cell proliferation, invasion, migration, apoptosis, cell cycle, and EMT are reversed by the silencing of miR-374a-5p

To explore whether miR-374a-5p is involved in the process of circMETTL15 regulating the biological behavior of LoVo cells, a functional rescue experiment was performed. Firstly, the expression changes of miR-374a-5p were evaluated by RT-qPCR. As shown in Fig. 4A, miR-374a-5p mimic and si-circMETTL15 both promoted miR-374a-5p expression, but miR-374a-5p inhibitor re-

Figure 4. The effects of circMETTL15 on CRC cell proliferation, invasion, migration, apoptosis, cell cycle, and EMT are reversed by the silencing of miR-374a-5p
miR-374a-5p mimic/inhibitor and si-circMETTL15 were transfected into LoVo cells. (**A**) RT-qPCR to detect miR-374a-5p. (**B**) CCK-8 to detect cell proliferation rate. (**C**) Colony formation assay to detect cell proliferation. (**D**) Flow cytometry to detect cell cycle. (**E**) Flow cytometry to detect apoptosis. (**F**) Transwell assays to detect cell invasion and migration. (**G**) Western blot to evaluate Ki-67, E-cadherin, N-cadherin, and cleaved caspase-3 expression; data are expressed as mean ± S.D. (N=3).

Figure 5. miR-374a-5p serves as a regulator of ESCO2 expression
(**A**) Potential downstream mRNA of miR-374a-5p predicted based on starbase, TargetScan, and miRDB; (**B**) RIP assay confirmed that three mRNAs and miR-374a-5p were enriched in LoVo cells. (**C**) GEPIA database analysis of ESCO2 in CRC. (**D**) RT-qPCR to detect ESCO2 in CRC tissues. (**E**) Western blot to detect ESCO2 in CRC cell lines. (**F**) Potential binding sites of miR-374a-5p and ESCO2 predicted based on starbase. (**G**) Dual luciferase reporting assay to explore the targeting relationship between miR-374a-5p and ESCO2. duced miR-374a-5p expression. CCK-8 assay and colony formation assay showed that si-circMETTL15 and miR-374a-5p mimic inhibited cell proliferation rate and the number of colonies, but the effects of si-circMETTL15 were reversed by knockdown of miR-374a-5p (Fig. 4B, C). Flow cytometry showed that si-circMETTL15 and miR-374a-5p mimic increased the proportion of G0/G1 phase cells but reduced the proportion of G0/G1 phase cells after knockdown of miR-374a-5p (Fig. 4D). In addition, si-circMETTL15 and miR-374a-5p mimic promoted apoptosis rates, while the effects of si-circMET-TL15 were reversed by silencing miR-374a-5p (Fig. 4E).

Transwell assay showed that si-circMETTL15 and miR-374a-5p mimic reduced the number of cells that invaded and migrated, while silencing miR-374a-5p reversed the effects of si-circMETTL15 (Fig. 4F). Western blot evaluated that si-circMETTL15 and miR-374a-5p mimic inhibited protein expression of N-cadherin and Ki-67 and promoted protein expression of cleaved caspase-3 and E-cadherin. However, knockdown of miR-374a-5p prevented changes in these proteins (Fig. 4G). These findings indicated that overexpression of miR-374a-5p inhibited the proliferation, invasion, and migration of LoVo cells, promoted apoptosis, increased the proportion of

(N=3).

G0/G1 phase cells, and circMETTL15 affected the proliferation, apoptosis, cell cycle, invasion, migration, and EMT processes of CRC cells by regulating miR-374a-5p.

miR-374a-5p serves as a regulator of ESCO2 expression

To explore downstream targets regulated by miR-374a-5p, starbase, TargetScan and miRDB predicted seven overlapping candidate downstream genes (Fig. 5A). Three were identified to be enriched with miR-374a-5p by RIP screening (Fig. 5B), among which ESCO2 was found to be upregulated in CRC by TCGA database analysis (Fig. 5C). ESCO2 upregulation was also demonstrated in CRC patients and cell lines (Fig. 5D, E). Sub-

Figure 8. Knockdown of circMETTL15 inhibits CRC tumorigenesis *in vivo*
(**A**) Representative images of tumors. (**B–C**) Tumor volume and weight. (**D**) IHC staining to measure ESCO2 and Ki-67 expression in tumors; data are expressed as mean ± S.D. (n=5).

sequently, the targeting relationship between ESCO2 and miR-374a-5p was confirmed by dual luciferase reporter experiments (Fig. 5F, G). Furthermore, ESCO2 expression reduced accordingly when miR-374a-5p was overexpressed (Fig. 5H).

Knockdown of ESCO2 inhibits CRC cell proliferation, invasion, migration, and EMT and promotes apoptosis

Subsequently, the effects of ESCO2 on the biological behavior of LoVo cells were examined. Western blot assay showed that transfection of si-ESCO2 decreased ESCO2 expression in LoVo cells (Fig. 6A). CCK-8 and colony formation experiments showed that knockdown of ESCO2 inhibited cell proliferation rate and colony-forming ability (Fig. 6B, C). Flow cytometry showed that knockdown of ESCO2 resulted in an increased proportion of cells arrested in the G0/G1 phase (Fig. 6D) and resulted in increased apoptosis (Fig. 6E). Transwell assay showed that the invasion and migration abilities of cells were reduced after ESCO2 knockdown (Fig. 6F). Western blot analysis showed that ESCO2 inhibition decreased N-cadherin and Ki-67 expression and increased cleaved caspase-3 and E-cadherin expression (Fig. 6G). The above data indicated that knockdown of ESCO2 effectively inhibited CRC proliferation, invasion, migration, and EMT and promoted apoptosis.

circMETTL15 affects CRC cell proliferation, cell cycle, apoptosis, invasion, migration, and EMT processes by regulating miR-374a-5p/ESCO2 axis

To explore whether the miR-374a-5p/ESCO2 axis is involved in the process of circMETTL15 regulating the biological behavior of CRC cells, LoVo cells were subjected to a co-transfection design with pcDNA 3.1 overexpression vector targeting circMETTL15 and si-ESCO2. pcDNA 3.1 overexpression vector targeting circMETTL15 promoted circMETTL15 and ESCO2 expression

and suppressed miR-374a-5p expression, while si-ESCO2 made ESCO2 expression partially recovered (Fig. 7A, B). CCK-8 and colony formation assays showed that overexpression of circMETTL15 promoted cell proliferation rate and cell cloning ability, but knockdown of ESCO2 reversed this phenomenon (Fig. 7C, D). Flow cytometry showed that overexpression of circMETTL15 reduced the proportion of cells arrested in G0/G1 phase, while knockdown of ESCO2 increased the proportion of G0/G1 phase cells (FIG. 7E). Annexin V-FITC/PI apoptosis kit tests showed that the overexpression of circMETTL15 reduced apoptosis rate, while knockdown of ESCO2 reversed this effect (Fig. 7F). Transwell assay showed that overexpression of circMETTL15 enhanced cell invasion and migration, but knockdown of ESCO2 reduced the number of invasion and migration cells (Fig. 7G). In addition, overexpression of circMETTL15 promoted expression of N-cadherin and Ki-67 and inhibited expression of cleaved caspase-3 and E-cadherin, but knockdown of ESCO2 prevented changes in these proteins (Fig. 7H). These data suggest that circMETTL15 promotes LoVo cell proliferation, invasion, migration, and EMT and reduces apoptosis by regulating the miR-374a-5p/ESCO2 axis.

Knockdown of circMETTL15 inhibits CRC tumorigenesis *in vivo*

At last, LoVo cells stably knocking down circMETTL15 were implanted into nude mice to explore the effect of circMETTL15 on the growth of CRC tumors *in vivo*. CircMETTL15 depletion suppressed tumor volume and weight (Fig. 8A–C). IHC staining showed that knockdown of circMETTL15 decreased ESCO2 expression and Ki-67 expression in tumors (Fig. 8D).

DISCUSSION

Late detection is the main reason for annual mortality in CRC (Ameli-Mojarad *et al.*, 2021), therefore, the search for an optimal biomarker for disease diagnosis and prognosis is necessary for identifying and treating CRC cases. Molecular biology and genomics have emphasized the significance of non-coding RNAs in tumor development (Chu *et al.*, 2021). Therefore, we attempted to investigate the effects of circMETTL15 involved in CRC, as well as related molecular mechanisms. Further experiments demonstrated that silence of circMETTL15 by suppressing miR-374a-5p and promoting ESCO2 expression could effectively inhibit the malignant behavior of CRC.

circRNAs are more suitable as new biomarkers for CRC and have potential clinical value in the early diagnosis and prognostic assessments of CRC (C. Lin *et al.*, 2022; Radanova *et al.*, 2021). For example, circ_001659 has a good predictive value and probability ratio for the diagnosis of CRC and confers pro-tumor influence on CRC development (He *et al.*, 2021) and circMYLK is associated with poor prognosis and some unfavorable clinical features of CRC patients (Huang & Dai, 2021). Similarly, our findings suggested that a higher abundance of circMETTL15 was correlated with tumor size, TNM stage, lymph node metastasis, and poor overall survival. The results indicated that circMETTL15 may be a prognostic or diagnostic biomarker in CRC, which needs to be verified by detecting circMETTL15 expression in CRC serum in subsequent studies. In a recent study, circMETTL15 is highly expressed in lung cancer and regulates malignant progression and immune escape

(Zhang *et al.*, 2022). The results of this study further support the role of circMETTL15 as a cancer-promoting factor, which promotes ESCO2 expression by binding miR-374a-5p, thus promoting CRC development. The study speculates that circMETTL15 also has the function of regulating immune checkpoint in CRC, and it may be feasible to employ circMETTL15 as a new target for immunotherapy, but this needs to be explored in subsequent studies.

miRNAs have been widely recognized as key regulators in cancers (Yamamoto & Mori, 2016). According to the ceRNA network, circRNAs can bind to miRNAs, thereby reducing the biological functions of miRNAs (Jorgensen & Ro, 2022). The study predicted and then verified that miR-374a-5p was a downstream miRNA of circMETTL15 in CRC. miR-374a-5p is considered a tumor oncogenic factor in ovarian cancer (Hao, Huang, & Han, 2020), triple-negative breast cancer (Son *et al.*, 2019), gastric cancer (Ji *et al.*, 2019), whereas a tumor suppressor in non-small cell lung cancer (Guo *et al.*, 2021) and esophageal squamous cell carcinoma (Chen *et al.*, 2019). Notably, it is recorded that miR-374a-5p is downregulated in CRC and is related to patients' survival rate (Slattery *et al.*, 2017; Slattery *et al.*, 2015). The study continuously explored miR-374a-5p in CRC and, as expected, miR-374a-5p could suppress the malignant phenotype of CRC cells while miR-374a-5p downregulation rescued the effect of circMETTL15 silencing on the biological behavior of CRC cells.

For this study, the downstream target (ESCO2) of miR-374a-5p was screened, which was upregulated in CRC. ESCO2, a member of the Eco1 family, contributes to sister chromatid cohesion during cell cycle progression (Wang & Liu, 2020). It is well known that different states of cohesin are associated with different phases of the cell cycle (Alomer *et al.*, 2017) and ESCO2 is involved in cohesion-mediated DNA repair (Rahman, Jones, & Jallepalli, 2015). Because of this, ESCO2 has received increasing attention in cancer development. It is noted that ESCO2 promotes lung adenocarcinoma (Zhu *et al.*, 2021) and gastric cancer (Chen *et al.*, 2018). Notably, ESCO2 is recently reported as an epigenetic regulator to suppress tumor metastasis in CRC (Guo *et al.*, 2018). Based on this, a functional rescue experiment was performed to reveal that ESCO2 knockdown rescued the promotion of circMETTL15 overexpression on the malignant progression of CRC cells.

However, how ESCO2 interacts with other epigenetic regulators or pathways to influence the development and progression of CRC has not been thoroughly investigated. In the follow-up experiments, we should further carry out multi-center trials and animal experiments to clarify the therapeutic effect and mechanism of circMETTL15 on CRC. In addition, multicenter trials and animal experiments are needed to elucidate the role of circMETTL15 in CRC.

CONCLUSION

In conclusion, this study suggests that circMETTL15 sponges miR-374a-5p to regulate ESCO2 and promote CRC malignant behavior. These data provide new molecular targets for the development of CRC-targeted drugs and future combination therapies. However, the results of this study have so far only been verified in LoVo cells and animal experiments. Therefore, it is not suitable for clinical trials. More basic experiments (such as validation in more CRC cell lines) are needed in the

future to further explore the influence of the circMET-TL15/miR-374a-5p/ESCO2 axis on CRC biological behavior.

Recent studies on non-invasive biomarkers useful in biliary atresia – a literature review

Anna Lew-Tusk[1]✉, Marta Pęksa[2] and Teresa Stachowicz-Stencel[3]

[1]Department of Neonatology and Neonatal Intensive Care Unit, St Wojciech Hospital, Gdańsk, Poland; [2]Department of Obstetrics, Medical University of Gdansk, Gdańsk, Poland; [3]Department of Pediatrics, Hematology and Oncology, Medical University of Gdansk, Gdańsk, Poland

The aim of this review is to specify new potential reliable and non-invasive methods for the diagnosis of biliary atresia (BA) that could shorten the way to diagnose BA, and finally the surgical treatment. Apart from the biomarkers that have been proven helpful and are used nowadays in neonatal wards, there are several new potential biomarkers that researchers have found to be helpful in the diagnosis of biliary atresia. Circulating microRNAs, matrix metalloproteinase-7, stool proteins, interleukin-33, Th17-associated cytokines, urinary metabolomics, anti-smooth muscle antibodies, heat shock proteins 90 and positive biliary epithelial cells CD56 are among those presented in this summary. These markers may play a new significant role in BA diagnosis. The described methods include Nomogram, Circulating microRNAs (miRNAs), Matrix metalloproteinase-7 (MMP-7), Stool proteins, Interleukin-33 (IL-33), Th17-associated cytokines, Alpha-aminoadipic acid and N-acetyl-d-mannosamine in urine, Anti-smooth muscle antibodies (ASMA), Heat shock proteins 90 (HSP90), Positive biliary epithelial cells CD56.

Abbreviations: ALP, alkaline phosphatase; ALT, Alanine transaminase; ASMA, Anti-smooth muscle antibodies; AST, aminotransferase; AUC-ROC, the area under the receiver operating characteristic curve; BA, biliary atresia; DB, direct bilirubin; GC–MS, gas chromatography–mass spectrometry metabolomics; GGT, gamma-glutamyl transpeptidase; HSP90, Heat shock proteins; IHS, infantile hepatitis syndrome; IIF, indirect immunofluorescence; IL-33, Interleukin-33; MIP3a, macrophage inflammatory protein-3alpha ; MMP-7, Matrix metallopro-teinase-7; MRCP, magnetic resonance cholangiopancreatography; OPLS-DA, orthogonal partial least squares discriminant analysis; TB, total bilirubin

INTRODUCTION

Biliary atresia (BA) (ORPHA:244283; OMIM: 210500) is an uncommon infancy fibroinflammatory obliterative cholangiopathy that affects extrahepatic and intrahepatic biliary ducts. It is associated with obstructive jaundice, pale stools and hepatomegaly, and leads to severe cholestasis and fatal biliary cirrhosis. The etiology of BA remains elusive. If not treated in time with hepatoportoenterostomy which restores bile flow (Kasai procedure KPE – the primary treatment of BA), it leads to liver failure within 2 years (Basset *et al.*, 2008; Chardot, 2006; Sokol *et al.*, 2007; Feldman *et al.*, 2015). BA remains the most common cause of a liver transplant in young children. It affects approximately 1 in 5000 to 25 000 live

births. It is more common in the Asia-Pacific region, especially in South China where the prevalence is about 1/5000 (Chen *et al.*, 2019).

An early diagnosis is highly problematic due to unspecific symptoms which can mimic other cholestatic diseases (non-BA). There are no reliable and specific biomarkers that are recommended for routine clinical use. Currently, the gold standard for BA diagnosis is an intraoperative cholangiogram which is highly invasive. Liver biopsy with 96.6% accuracy is the most reliable method (Chen *et al.*, 2016). The longer it takes to diagnose chronic cholestasis, the higher the risk of liver fibrosis. Because the success of Kasai portoenterostomy depends, among others, on age at the time of surgery, due to delayed diagnosis many infants with BA lose the chance for proper treatment. Also, a late diagnosis worsens the outcomes of other cholestasis-associated diseases like hypopituitarism, galactosaemia and tyrosinaemia.

The investigation of biliary atresia requires taking the following blood tests: gamma-glutamyl transpeptidase (GGT), also combined with total bilirubin, direct bilirubin, alkaline phosphatase, and aminotransferase (AST). The diagnosis is also based on clinical evaluation, hepatomegaly, stool colour, duodenal juice colour, bile acid in duodenal juice, ultrasonography (the gallbladder triad, the triangular cord sign or strip-apparent hyperechoic foci), hepatobiliary scintigraphy, MRCP and liver biopsy (Dong *et al.*, 2018).

NOMOGRAM

In the Dong and others research, bile acid level in duodenal juice and hepatobiliary scintigraphy showed the highest (100%) sensitivity for diagnosing BA (Dong Ch *et al.*, 2018). Ultrasonography (triangular cord sign or presence of strip-apparent hyperechoic foci) showed the highest specificity (99.5%). The colour of the stool is also pathognomic. High levels of bilirubin alter the hue of the stool and turn it into light yellow. The diagnostic accuracy by feces color was 84.3% with a sensitivity of 96.1% and specificity of 74.8% in Dong's and others research (Dong Ch *et al.*, 2018). All of the known differential diagnosis methods are useful. Gamma-glutamyl transpeptidase (GGT) is used in combination with other biomarkers of BA cholestasis (Chen *et al.*, 2016; Liu *et al.*, 1998; Cabrera-Abreu *et al.*, 2002; Rendon-Macias *et al.*, 2008; Tang *et al.*, 2007; Maggiore *et al.*, 1991). Younger infants with BA (age <30 days) proved to have significantly higher GGT levels than older patients (Dong Ch *et al.*, 2018). The researchers demonstrated that in a 2-year treatment, 53.7% of patients survived with their native liver, while the remaining patients needed liver

transplantation. Sira and others reported that the serum activity of GGT had a sensitivity of 76.7% and specificity of 80% for the diagnosis of BA (Sira *et al.*, 2012). Nonetheless, the GGT level was also increased in the serum of infants on the day of birth or varied depending on age (Dong Ch *et al.*, 2018). In the Dong's and others research, carried out in a large Chinese children's hospital on 1728 patients, to confirm BA intraoperative cholangiography and liver biopsy for histological assessment were used (Dong R *et al.*, 2018). 1512 patients were diagnosed with BA and 216 patients were confirmed to have non-BA cholestasis. 80% of non-BA patients were male, however, there was no statistical difference in gender in the BA group (51% male, 49% female). The research also included weight, age and the levels of: total bilirubin (TB), direct bilirubin (DB), alkaline phosphatase (ALP), and gamma-glutamyl transpeptidase (GGT), AST and ALT (Alanine transaminase). There was no significant difference in TB, AST and ALT levels. Patients' age also did not show any notable influence on results. The non-BA group presented higher alkaline phosphatase levels (ALP). Gender, weight, DB, ALP, and GGT showed a good prediction with the AUC-ROC curve (the area under the receiver operating characteristic curve) >0.8 (a value close to 1 is considered perfect discrimination). Rui Dong and others (Dong R *et al.*, 2018) created a nomogram based on those factors (gender, weight, DB, ALP, and GGT) allowing to predict BA.

Nomogram based on various factors (gender, weight, DB, and GGT) proved helpful in diagnosing BA.

The nomogram demonstrated a good discriminative ability with a sensitivity of 85.7% and specificity of 80.3%. It proveduseful in diagnosing BA and, additionally, to have the potential for clinical application (Dong R *et al.*, 2018).

CIRCULATING MICRORNAS (miRNAs)

Zahm and others (Zahm *et al.*, 2011) hypothesized that unique miRNAs may serve as a new class of biomarkers that could help to distinguish BA from other forms of neonatal cholestasis and therefore become a new diagnostic biomarker of BA. Goldschmidt's analysis says that circulating MicroRNA as the miR-21 and miR-29a cluster may be used as markers of liver diseases in children (Goldschmidt *et al.*, 2016). MicroRNAs are short non-coding parts of RNAs which are necessary for organ development (Thai *et al.*, 2007; Lynn *et al.*, 2007; Hand *et al.*, 2009). MiRNAs are dysregulated in many pathologies including BA. Increased levels of circulating miRNAs can suggest specific tissue damage (Morimura *et*

al., 2011; Laterza *et al.*, 2009; Zahm *et al.*, 2011). Zahm et al. proved that a cluster of miRNAs (miR-200b/429) is elevated in BA patients' sera compared to cholestatic control samples. The researchers used serum samples obtained from patients with confirmed BA (by cholangiography, operative exploration, and/or histology) and extrahepatic bile duct tissue from mouse liver. 11 miRNAs were selected for further analysis out of which the miR-200b showed significant alterations. To prove the importance of miR-200b, they measured levels of miR-200a and miR-429 (which are co-transcribed with miR-200b from the miR-200b/429 locus (Zahm *et al.*, 2012)). They were both altered in the sera of BA patients. The AUC values 0.8 for the miR-200b/429 cluster with a sensitivity of 71% and specificity of 92%. Adam M. Zahm et al. also discovered that cholangiocytes serve as the source of miR-200b/429 cluster in biliary atresia. Detecting elevated levels of miR-200b/429 in serum can be useful not only in distinguishing BA from non-BA patients, but also in predicting survival after KPE. The miR-200b/429 cluster classifies correctly 85% of patients (Zahm *et al.*, 2012). Because not all samples are correctly classified, further research is needed. Nevertheless, elevated circulating miR-200b/429 levels may prove useful in BA diagnostics. Another microRNA analysis done by Zahm and others (Zahm *et al.*, 2011) showed that circulating miR-4429 and miR-4689 can play a certain role in diagnosing BA. The AUC of miR-4429 was 0.789 with a sensitivity of 83.3% and a specificity of 80.0%, and the AUC of miR-4689 was 0.722 with a sensitivity of 66.7% and specificity of 80.0% for the prediction of BA (Zahm *et al.*, 2012).

MATRIX METALLOPRO-TEINASE-7 (MMP-7)

MMP-7 (also known as matrilysin (Hugh, 2017)) is a zinc-dependent endopeptidase that breaks down the extracellular matrix and its expression can correlate with BA-related liver fibrosis (Yang *et al.*, 2018; Jiang *et al.*, 2019). The researchers have recently discovered that an altered level of MMP-7 in the serum of a cholestatic patient can be associated with biliary atresia (Yang *et al.*, 2018; Jiang *et al.*, 2019). To prove the diagnostic value of MMP-7, Yang and others (Yang *et al.*, 2018) tested 135 infants with cholestasis (75 with BA and 60 non-BA) and a 54 control group at three pediatric centers. The results showed that MMP-7 levels in BA patients sera were significantly higher than in non-BA cases. Serum levels of MMP-7 in a non-cholestatic group had a median of 2.86 ng/mL, the non-BA group was circa 11.47 ng/mL and BA patients had an average with a median of 121.1 ng/mL, that is 10-times higher than in others. Yang and others (Yang *et al.*, 2018) have also compared GGT and MMP-7 levels in the sera of BA- neonates. The AUC of MMP-7 was 0.9900 and the AUC for GGT was 0.7186. For GGT, the sensitivity was 64.00% and the specificity was 71.67%. In comparison, the sensitivity and the specificity of MMP-7 were respectively 98.67% and 95.00%. The negative predictive value of MMP-7 was 98.28% (Yang *et al.*, 2018). The number needed to misdiagnose (NNM) was also calculated and for MMP-7 it was 25 (which means that 1 out of 25 patients was misdiagnosed). For GGT, the NNM was 3 (so 1 out of 3 was misdiagnosed). Combining MMP-7 and GGT with an AUC of 0.9898 does not increase diagnostic accuracy (Hugh, 2017; Yang *et al.*, 2018). Lertudomphonwanit et al. investigated samples of 35 BA patients and 35 cases with intrahepatic cholestasis. Serum levels of MMP7 and

GGT were different in these two groups and the researchers estimated that 19.1 infants could be diagnosed with BA with the MMP7 plus GGT as a biomarker (Lertudomphonwanit *et al.*, 2017; Hugh, 2017). Jiang and others (Jiang *et al.*, 2019) diagnosed 288 patients with jaundice. The median of MMP-7 in BA group sera was 38.89 ng/mL and in non-BA: 4,4 ng/mL. The sensitivity, specificity, positive predictive value and negative predictive value were 95.19%, 93.07%, 97.27%, and 91.43%, respectively. The accuracy was improved when MMP-7 was combined with GGTP. Based on this data, alterations in the serum MMP-7 levels may be helpful in the diagnosis of biliary atresia. It also correlates with liver fibrosis, therefore it can be potentially used as a therapeutic target or a prognostic biomarker (Hugh, 2017; Yang *et al.*, 2018; Jiang *et al.*, 2019). Another study by Wu et al. was based on a group of 100 neonates including 36 with BA. The serum level of MMP-7>1.43 ng/mL for predicting biliary atresia has a median of 10.26 ng/mL for BA (Yang *et al.*, 2018; Harpavat, 2019). They also observed that serum MMP-7 levels may rise with age, as liver damage proceeds, and that MMP-7 is a less useful serum marker in neonates due to its correlation with other liver diseases. There is pressure to include the MMP-7 level in the prognostic algorithm. However, the usefulness of this marker has limitations: the values of the MMP-7 level can vary depending on the type of immunosorbent assay kits used (Yang *et al.*, 2018; Harpavat, 2019). In comparison, the median serum MMP-7 levels were 38.89 ng/mL for the BA group and 4.4 ng/mL for the non-BA group in the Yang *et al.* research. Hence, the role of MMP-7 as a reliable biomarker remains controversial. The confirmation of the diagnostic utility of serum MMP-7 levels may be an objective for therapeutics.

STOOL PROTEINS

There are two kinds of stool tests: Sudan III staining of stool fat and measurement of duodenal bile acid. Steatorrhea in a stool is patognomic for BA patients as well as acholic feces (Okajima *et al.*, 2016). Detection of steatorrhea in Sudan III straining is an easy-to-obtain and rapid examination. Gu et al. have published their research where they claim that the fat content of a stool may be helpful especially when feces are non-acholic (Gu *et al.*, 2015). They have examined 313 230 infants, 34 with biliary atresia. The stool colour card screening showed 76.5% sensitivity and 99.9% specificity in this research. Lien et al.'s analysis also shows that stool colour card is useful in detecting BA patients. The research includes babies born before 2002 – the beginning of using the stool colour card in Taiwan, and after 2002. The analysis conclusion was that the stool colour card screening program allows to implement earlier Kasai operation (Lien *et al.*, 2010).

Another research concerned an analysis of proteins using data-independent acquisition mass spectrometry (DIA–MS) (Watanabe *et al.*, 2020). The assumption was that because of the obstruction of the normal flow of bile juice, BA patients' stool contains fewer proteins that are produced in the biliary tract. Also, some specific proteins that originate from the biliary tract are possibly absent or reduced compared to the non-BA patients (Watanabe *et al.*, 2020). The researchers examined four patients with BA and three others with non-BA cholestasis. They proved that 49 proteins were higher and 54 proteins lower in the stool of BA patients. The analysis

showed that proteins RBP4, SHMT2, HMGCS1, ADH6, ALDH1A1, ACADS, ADK, KHK, ACAA2, PSAT1, AMACR, and PTGR1 are lower in stool samples of BA-patients (Watanabe *et al.*, 2020). And conversely: the CEACAM1, CEACAM5, and CEACAM8 were significantly higher in patients with BA (Watanabe *et al.*, 2020). CHI3L1 is correlated with worse BA outcome (Watanabe *et al.*, 2020). The measurement of those dominant proteins in the stool of BA patients could be of assistance in the early diagnosis of the disease. Watanabe et al. emphasized that the research needs evaluation on a larger cohort.

INTERLEUKIN-33 (IL-33)

A specific cytokine involved in the pathogenesis of liver fibrosis and severe inflammation (Tan *et al.*, 2018). It is released in the course of cell death (Rinella, 2015; Zhang *et al.*, 2015). It is assumed that IL-33 assists as an "alarm signal" released by stressed hepatocytes (Heymann *et al.*, 2016). In the following research, Ola G. Behairy et al. observed 60 infants with cholestasis (BA and non-BA) and 30 healthy ones. BA diagnosis was based on surgical cholangiography. Cholestasis was recognized when conjugated bilirubin was 20% of the total bilirubin or when total bilirubin exceeded 17 mg/dL. The level of IL-33 in the serum was measured and the results showed that the IL-33 gene expression in the BA group was markedly upregulated. The median in the BA group was 48.0 pg/mL and in the non-BA group with cholestasis it was 17.3 pg/mL (Behairy *et al.*, 2020), while at the same time, healthy infants presented a 7.3 pg/mL average. There was also a gradual increase in the serum IL-33 level in BA and non-BA group with fibrosis stage (Behairy *et al.*, 2020) with the cut-off level determined at 20.8 pg/mL (specificity of 95% and sensitivity of 96.7%) (Behairy *et al.*, 2020). Still, jaundice, ascites and stool colour were the most visible symptoms in both cholestatic patient groups. Significantly, the aminotransferases and total leucocytic count levels were higher in the non-BA group, and gamma-glutamyl transferase, total protein, alkaline phosphatase and total and direct bilirubin levels were higher in the BA cohort (Behairy *et al.*, 2020). The total protein showed the highest level in the group of healthy infants, whereas the total leucocytic count was the lowest. The role of IL-33 in the diagnostics of biliary atresia is indisputable. Its serum concentration correlates with the levels of aminotransferases, as well as total and direct bilirubin levels (Behairy *et al.*, 2020). Another analysis made by Liu and others (Liu *et al.*, 2019) consists of 36 BA patients and 8 patients as a control group. The expression level of IL-33 was increased in BA patients compared to the control group (3.9 ± 0.5 *vs.* 1.0 ± 0.3). The result of the analysis was that the IL-33/ST2 receptor signaling axis is activated in BA patients. IL-33 exacerbates inflammatory reactions and drives liver fibrosis (Li *et al.*, 2014). Measuring serum interleukin-33 levels may have a diagnostic value in infants with biliary atresia as a reliable, non-invasive and fast tool.

Th17-ASSOCIATED CYTOKINES

Those cytokines are the ones that play an important role in the immune-mediated injury against intrahepatic bile duct epithelial cells (Chen *et al.*, 2019). Chen and colleagues conducted a study of 31 BA-infants and 45 non-BA infants with cholestasis. They tested 25 Th17-associated cytokines in those groups. They observed a

different gene expression of cytokines: IL-17F, IL-10, macrophage inflammatory protein-3alpha (MIP3a), IL-22, IL-13, IL-33, IL-6, IL-17E, IL-27, IL-31, TNF-a and TNF-b in BA patients (Chen *et al.*, 2019). The highest AUC showed MIP3a in comparison to the others (Chen *et al.*, 2019). MIP3a – cysteine motif chemokine ligand 20 (CCL20) used alone or in combination with other biomarkers may become useful in BA diagnosis. MIP3a overexpression is related to inflammatory damage in bile ducts and to the development of BA (Chen *et al.*, 2019). For validation, Chen and others studied another group of 68 cholestatic patients (30 BA and 38 non-BA). BA was diagnosed by intraoperative cholangiography. In both studies, BA samples showed clay stool and higher GGT levels. 12 following cytokines showed a significant difference in concentrations between BA and non-BA infants: IL-17F, IL-10, MIP3a, IL-22, IL-13, IL-33, IL-6, IL-17E, IL-27, IL-31, TNF-a and TNF-b (Chen *et al.*, 2019). MIP3a showed better results in the diagnosis of BA than the other cytokines. Furthermore, the AUCs of MIP3a, IL-13 and TNFa were higher than 0.8. The sensitivity and the specificity of MIP3a were 90.40% and 80.0%. The AUC of GGT was 0.802 and clay stool showed an AUC of 0.792. The researchers went further and investigated if combining the marker with clay stool and GGT would increase the diagnostic value compared to the marker alone. Their research showed that the AUC of clay stool + GGT, clay stool + MIP3a, GGT + MIP3a and clay stool + GGT + MIP3a was 0.824, 0.918, 0.880 and 0.892 respectively (Chen *et al.*, 2019). A combined test would increase the diagnostic specificity. This finding indicates that a single MIP3a plus a single biomarker increases the diagnostic accuracy of BA (Chen *et al.*, 2019).

ALPHA-AMINOADIPIC ACID AND N-ACETYL-D-MANNOSAMINE IN URINE

Metabolomics can aid in understanding the disease mechanisms and identifying biomarkers for the diagnosis and, furthermore, monitoring the disease (Mamas *et al.*, 2011; Vinayavekhin *et al.*, 2010). By analyzing the urine we can observe the underway metabolic processes. Urine is an excellent material for discovering new biomarkers because it can be obtained non-invasively. Li and others (Li *et al.*, 2014) characterized urinary metabolomic profiles in infants with BA and infantile hepatitis syndrome (IHS). The levels of identified metabolites were further measured using the human metabolome database to determine if they were endogenous or exogenous. A urinalysis from an infant is simple because of its restricted diet. The research was based on 25 BA patients, 38 IHS patients, and on 38 healthy ones. The researchers used gas chromatography-mass spectrometry metabolomics (GC–MS) and orthogonal partial least squares discriminant analysis (OPLS-DA) for testing. In the analysis, total bilirubin, GGT and alkaline phosphatase were significantly higher in BA patients compared to IHS. 41 urine metabolites demonstrated a different expression between BA *vs.* NC, IHS vs. NC, and BA *vs.* IHS (Li *et al.*, 2018). The most notable differences showed N-acetyl-d-mannosamine and alpha-aminoadipic acid obtained from the urine of children with BA. The alpha-aminoadipic acid level was significantly increased in IHS (Li *et al.*, 2018). Alpha-aminoadipic acid's AUC was 0.95 in distinguishing BA from IHS in the training set, and 0.88 in distinguishing BA from IHS in the test set. N-acetyl-D-mannosamine had an AUC of 0.91 for distinguishing BA from

IHS in the training set, and 0.94 in the test set (Li *et al.*, 2018). After using the permutation test, the researchers presumed that alpha-aminoadipic acid and D-man-nosamine may be useful in BA diagnosis. On the other hand, 19 metabolites showed the same trend in BA *vs.* NC and IHS *vs.* NC (ex. lysine, leucine and tyrosine, tyrosine metabolite-hydroxyphenyllactic acid, ornithine, glutamine and glycocyamine), which suggests that those two diseases may have the same metabolic mechanism (Chen *et al.*, 2019). Li *et al.* study showed that the level of adenine was also increased, and the xanthine level was reduced in BA and IHS infants. They also found that Myo-inositol and glucuronic acid were elevated in BA and IHS patients. According to the study, urinary metabolites may be useful as potential biomarkers for a differential diagnosis of BA and IHS, but it still needs to be validated in further studies.

ANTI-SMOOTH MUSCLE ANTIBODIES (ASMA)

The study of Rafeey and others (Rafeey *et al.*, 2021) included 18 BA patients and 12 patients with neonatal hepatitis. The research showed a higher expression of anti-smooth muscle antibodies (ASMA) in the sera of BA patients. ASMA is detected by indirect immunofluorescence (IIF), fibroblasts, or HEp-2 cells. The conclusion was that ASMA levels were higher in neonatal hepatitis samples but not statistically significant in BA (the sensitivity and specificity were respectively 66.7% and 75%) (Rafeey *et al.*, 2021), whereas GGT and ALP levels were significantly increased in the sera of BA patients (for GGT, the sensitivity and specificity were 88.9%, 66.7% and for ALP the sensitivity and specificity were 77.8% and 75%). The study showed that ASMA may be useful for the differentiation of BA from neonatal hepatitis, however, it still needs to be further evaluated.

HEAT SHOCK PROTEINS 90 (HSP90)

HSP 90 are proteins involved in the folding and unfolding of other proteins (Dong R *et al.*, 2013). Their level is higher in response to stress (De Maio, 1999). Another HSP protein – HSP 47 has been linked to fibrosis in BA (Deng *et al.*, 2011). Cholangiocytes or hepatocytes secrete proteins in response to cholestatic diseases such as BA (De Maio, 1999). Cholangiocytes affect the bile composition (Dong R *et al.*, 2013). Following that thought, Dong *et al.* have looked for a protein that plays a crucial role in biliary atresia pathogenesis. They used liver tissue obtained by biopsy of 20 BA patients and 12 non-BA cholestatic infants (Dong R *et al.*, 2013). In the study, two-dimensional electrophoresis was used to reveal 15 proteins highly upregulated in BA. From among that group, nine were elevated and six were downregulated in the liver tissues of BA patients. Among 19 proteins, the HSP90 level was significantly higher. The mean level of HSP90 in BA patients was significantly lower than in non-BA cholestatic patients (Dong R *et al.*, 2013). To confirm those results, mass spectrometric identification and immunoblotting analysis of HSP90 were used. Dong and others (Dong *et al.*, ????) suggest that HSP 90 could play a protective role during cholestasis and may serve as a prognostic marker for NC compared to BA. Yet, further analyses need to be conducted on a larger cohort of patients.

POSITIVE BILIARY EPITHELIAL CELLS CD56

cells that play an important role in morphogenesis, re-modeling, and migration in several organs through cell–cell and cell–matrix interactions (Sira *et al.*, 2012). In Sira et al. research, 30 infants with BA and 30 infants with non-BA cholestasis were included. CD56-positive cells were found in the epithelium of bile ducts and duct-ules where their level was significantly higher in the BA group (83.3%) than in the non-BA group (6.7%) (Sira *et al.*, 2012). BA patients with biliary causes compared to the non-BA group had a significantly higher CD56 stain-ing in the biliary epithelium than in the BA group. The results showed that the CD56 cells were highly elevated in the sera of BA patients. Simultaneously, CD56 natu-ral killer cells were significantly elevated in the non-BA group. The research concluded that CD56 immunostain-ing could be helpful in differentiating patients with BA.

SUMMARY

Biliary atresia is a cause of chronic cholestasis in neo-nates and if untreated leads to liver failure. BA has to be managed operatively as soon as it is possible. Because of a lack of non-invasive markers, the worth of a reli-able and easy-to-obtain biliary atresia marker is invalu-able. New discoveries allow us to have a new picture of diagnosing BA. Plenty of studies showed the diagnostic validity of laboratory investigations in the differentiation of BA from other cases of cholestasis. Circulating mi-croRNAs with their 92% specificity (Zahm *et al.*, 2012) have a great value in diagnosing BA. Levels of the miR-200b/429 cluster were elevated in BA patients in com-parison to cholestatic controls. Nevertheless, future work on a larger cohort is needed. Matrix metallopro-teinase-7 (MMP-7), as noted in several reports, still needs more evaluation because its level depends on the patient's age and the type of laboratory kit used. Stool proteins and alpha-aminoadipic acid, and *N*-acetyl-D-mannosamine obtained from urine may be the future of BA diagnos-tics. The sample is easy to obtain and there is no need to keep it sterile. It is especially worth it when it comes to developing countries. The research shows that Inter-leukin-33 (IL-33) along with gamma-glutamyl transferase, total protein, alkaline phosphatase and total and direct bilirubin can be useful in diagnosing BA (Behairy *et al.*, 2020). In the study diagnostic accuracy of Anti-smooth muscle auto-antibody (ASMA) was evaluated. Compared with the accuracy rates of invasive procedures ASMA may be a useful marker for the differentiation of BA from non-BA patients. Heat shock protein 90 (HSP90) needs tissue from a liver biopsy to evaluate the result which makes it hard to determine. The nomogram pre-sented in Chen Dong and others research (Dong Ch *et al.*, 2018) is a good way to deduce the probability of biliary atresia using gender, weight, GGT, ALP and di-rect bilirubin levels. Bile acid level in duodenal juice and hepatobiliary scintigraphy showed the highest (100%) sensitivity for diagnosing BA (Dong Ch *et al.*, 2018). On the basis of all the above-mentioned findings, we may conclude that an easier diagnostics of biliary atresia in newborns is within range of our hospital capabilities. Clearly, some medical research will still require more comprehensive verification. Rapid and accurate diagnos-tics with possible avoidance of liver biopsy is crucial in the case of cholestasis of an unknown nature, therefore every additional parameter achieved in a non-invasive way, straight from a laboratory, would be of life impor-

tance. In the opinion of the authors, in clinical practice, the Stool Proteins method seems to be the most promis-ing and practical thanks to its simplicity and fully non-invasive character.

Circular RNA LPAR3 targets JPT1 *via* microRNA-513b-5p to facilitate glycolytic activation but repress prostate cancer radiosensitivity

Yuan Yuan Chen[1], Li Ping Luo[1]✉ and Ke Chong Deng[2]✉

[1]Department of Oncology, Wuhan Wuchang Hospital Affiliated to Wuhan University of Science and Technology, Wuhan City, Hubei Province, 430063, China; [2]Department of Emergency, Wuhan Wuchang Hospital Affiliated to Wuhan University of Science and Technology, Wuhan City, Hubei Province, 430063, China

A great many circular RNAs (circRNAs) are considered key modulators of human malignancies. However, the function of circRNA lysophosphatidic acid receptor 3 (LPAR3) in the radioresistance of prostate cancer (PCa) cells is still uncertain. circLPAR3, microRNA (miR)-329-3p, and JPT1 expression in PCa tissues and cells were detected by real-time quantitative PCR or western blot. Cell proliferation was detected by CCK-8 (cell proliferation assay) and colony formation assay, apoptosis was by flow cytometry, and migration and invasion ability were by Transwell assay. Cell glycolysis was analyzed by glucose uptake, lactate production, and ATP metabolism. Under different doses of radiation, the radiosensitivity of PCa cells was detected by colony formation assay. The relationship between circLPAR3, miR-513b-5p, and JPT1 was confirmed by dual luciferase reporter gene detection and RIP assay. The data presented that circLPAR3 and JPT1 expression was elevated in PCa, while miR-513b-5p expression was reduced. Repression of circLPAR3 depressed cell advancement, and restrained glycolysis, but enhanced the radiosensitivity of PCa cells. CircLPAR3's target miRNA was miR-513b-5p which targeted JPT1. Elevated JPT1 reversed the repressive effects of circLPAR3 knockdown or miR-513b-5p overexpression on PCa advancement, glycolysis, and radiosensitivity. In summary, the knockdown of circLPAR3 reduces glycolysis, but promotes PCa radiosensitivity *via* the miR-513b-5p/JPT1 axis, discovering a novel mechanism in PCa progression.

Abbreviations: circRNA, circular RNA; JPT1, Jupiter microtubule associated homolog 1; LC, lung cancer; LPAR3, lysophosphatidic acid receptor; miRNAs, MicroRNAs; PCa, prostate cancer

INTRODUCTION

Prostate cancer (PCa) is a common cancer among men worldwide, and its mortality rate ranks 2nd among men's cancers (Wu *et al.*, 2019). Recently, the incidence rate of PCa in China has manifested an upward trend (Zhou *et al.*, 2021). In addition to surgical resection, radiotherapy is another treatment approach that can cure PCa (Li *et al.*, 2020). Nevertheless, owing to radioresistance, the effectiveness of radiotherapy is unsatisfactory. Therefore, it is vital to explore a way to promote radiosensitivity.

Circular RNA (circRNA) is an endogenous non-coding RNA transcribed by RNA polymerase II, and featured by linking the 3' with 5' ends *via* exon or intron cycles (Kong *et al.*, 2017). Studies have clarified that circRNA is crucial in various biological processes like apoptosis, cell vascularization, and cell invasion (Yuan *et al.*, 2019). For instance, circRNA La-related RNA-binding protein 4 (LARP4) represses cell migration and invasion of PCa *via* targeting FOXO3A (Weng *et al.*, 2020).. circRNA is differentially manifested in cancers and could serve as a latent modulator of tumorigenesis or cancer advancement. For instance, circ-membrane bound O-acyltransferase domain containing 2 accelerates PCa advancement *via* the miR-1271-5p/mTOR axis (Shi *et al.*, 2020). CircRNA lysophosphatidic acid receptor 3 (LPAR3), a novel circRNA discovered recently, has been testified to be aberrantly manifested in several human cancers, like esophageal cancer (Shi *et al.*, 2020) and ovarian cancer (Xu *et al.*, 2020). However, its expression and function in PCa are not yet distinct.

MicroRNAs (miRNAs) are a set of short endogenous non-coding RNAs that could control approximately 30–50% of human protein-coding genes and molecular signaling pathways in cells (Porzycki *et al.*, 2018). Accumulating evidence clarify that miRNAs are differentially expressed in cancers and impact cell growth, differentiation and apoptosis processes (Ghafouri-Fard *et al.*, 2020). miRNA expression has become a latent biomarker for PCa diagnosis and prognosis (Nayak *et al.*, 2020). For instance, miR-424/572 in recurrent PCa specimens are novel biomarkers for predicting PCa progression (Suer *et al.*, 2019). MiR-215-5p reduces the metastasis of PCa *via* targeting phosphoglycerate kinase 1 (Chen *et al.*, 2020). MiR-513b-5p is dysregulated in multiple human cancers, like lung cancer (LC) (Cai *et al.*, 2020), hepatocellular carcinoma (Jin *et al.*, 2021) and breast cancer (Lin *et al.*, 2020). However, no research is presented to manifest what effects miR-513b-5p has on PCa.

In this study, we discovered the expression of circLPAR3 was more highly expressed in PCa samples than in controls. Therefore, we knock down circLPAR3 expression to identify its potential roles and explore possible mechanisms in carcinogenesis of PCa. Here, we demonstrated that circLPAR3 acted as a miR-513b-5p sponge to up-regulated Jupiter microtubule associated homolog 1 (JPT1). The research suggests that a novel circRNA may serve as a new biomarker for the early diagnosis and treatment of PCa.

MATERIALS AND METHODS

Sample collection

Tumors and normal tissues adjacent to cancer were harvested from 58 patients with PCa in The Affiliated Hospital of Jiaxing University and stored in liquid nitrogen. Approval of this study was obtained from the Ethics Committee of The Affiliated Hospital of Jiaxing University and written informed consent was gained from each patient (Approval number: JX20156211).

Cell culture

PCa cell lines PC-3, LNCaP, VCaP, DU145 and human normal prostate epithelial cell line RWPE-1 were purchased from ATCC (MA, USA). PC3 cells were cultured in FK12 medium (Gibco, CA, USA), LNCaP cells were in RPMI-1640 medium (Gibco), VCaP cells were in 90% Dulbecco's modified Eagle's medium (Gibco), DU145 cells were in Eagle's Minimum Essential Medium; and RWPE-1 cells were in Keratinocyte Serum-Free Medium Kit (Invitrogen, CA, USA). The mediums for PC cell culture were supplemented with 10% fetal bovine serum (Gibco).

Cell transfection

For the inhibition of circLPAR3 and JPT1, shRNA sequences targeting circLPAR3 and JPT1-specific siRNA (si-JPT1) sequences were synthesized by GenePharma. For miRNA overexpression, miR-513b-5p mimic was obtained from GenePharma. Gene overexpression vector (pcDNA-JPT1) and control vector (pcDNA) were purchased from Nanjing Jinrui Biotechnology Co., Ltd. After 24 h of cell culture, plasmids were transfected using Lipofectamine 3000 Transfection Reagent (Invitrogen).

RNase R treatment test

RNase R (6 units, Geneseed Biotech) was added to every 2 g RNA. After RNase R treatment, reverse transcription-quantitative polymerase chain reaction (RT-qPCR) was applied to detect circLPAR3 and LPAR3 in LNCaP cells PMID: 34913472.

Actinomycin D test

The actinomycin D test was performed with LNCaP cells incubated with actinomycin D (2 mg/mL; Sigma-Aldrich, Tokyo, Japan) for 0, 4, 8, 12 and 24 h PMID: 34913472.

Cell counting kit (CCK-8) assay

About 3×10^3 cells were seeded in each well of a 96-well plate and detected proliferation at 24, 48 and 72 hours by CCK-8 (Dojindo, Haidian, Beijing, China). The absorbance at 450 nm was recorded at each time point, and the cell proliferation curve was drawn.

X-ray exposure

X-ray generator (Varian, Palo Alto, CA, USA) was applied to radiation management at a fixed rate of 4 Gy/min.

Colony formation and survival analysis

Approximately 140 transfected cells were incubated in each well of a 6-well plate for 14 to 21 days. Then the staining with 0.5% crystal violet (Yeasen) was observed under an inverted microscope (×40; Leica, Germany). For survival analysis, 200 cells were seeded on a 6-well plate and irradiated at 0, 2, 4, 6, and 8 Gy X-ray or not. Subsequently, a colony formation test was performed as described above.

Flow cytometry

Cells were treated with double-staining with fluorescein isothiocyanate-labeled annexin V (Invitrogen) and propidium iodide and then detected on a FACS Calibur flow cytometer (Becton Dickinson, San Jose, CA, USA) equipped with Cell Quest software (Becton, Franklin Lakes, NJ, USA) PMID: 31733095.

Migration and invasion test

A 24-well transwell chamber (Millipore, Billerica, MA, USA) with an 8 μm polycarbonate membrane was used to perform migration tests on LNCaP cells. Briefly, LNCaP cells (5×10^5 cells/well) were added into the upper chamber with 200 μL of serum-free medium, and the complete medium was added into the lower chamber as a chemoattractant. After 24 h, the migrating submembrane cells were fixed with 95% ethanol for staining with crystal violet (Beyotime, Shanghai, China) and imaging under the microscope (Leica). Image Lab software 5.2 (Bio-Rad, Hercules, CA, USA) was used for data analysis. The 24-well transwell was pre-covered with Matrigel (BD Biosciences) and was needed for invasion detection PMID: 31387394.

Glucose consumption, lactate production and adenosine triphosphate (ATP) levels

A glucose determination kit (Sigma), lactic acid colorimetric/fluorescence determination kit (BioVision) and CellTiter Glo Luminescent Cell survival Assay (Promega) were put to detect glucose consumption, lactate production and ATP levels (Zheng *et al.*, 2020).

qPCR

Total RNA was isolated from PC tissues and cells using TRIzol (Invitrogen). To measure miRNA expres-

Table 1. Fluorescence quantitative PCR primer sequence

sion, RNA was reverse transcribed into cDNA using the TaqMan miRNA Reverse Transcription Kit (Applied Biosystems) and then quantified by real-time PCR using TaqMan Universal PCR Master Mix and TaqMan RNA Detection (Applied Biosystems). To measure circRNA expression, RNA was reverse transcribed into cDNA using PrimeScript RT Reagent (Takara) and then quantified by SYBR Premix Ex Taq (Takara). U6 and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) were used as the internal reference. The $2^{-\Delta\Delta Ct}$ method was put into use to calculate the relative miR-513b-5p and the target gene. RT-qPCR primer sequence was manifested in Table 1 PMID: 34515615.

Western blot analysis

Total protein was extracted from cell lysis buffer (Sangon Biotech), separated on 12% sulfate-polyacrylamide gel, and electroblotted onto a polyvinylidene fluoride membrane (Millipore, Billerica, MA, USA). Using primary antibodies JPT1 (ab126705; 1:1000; Abcam) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (ab8245; 1:1000; Abcam), the membrane was incubated overnight. Added with the secondary antibody (1:2000, Promega), the membrane was analyzed by Odyssey Infrared Imaging System (LI-COR, Lincoln, NE, USA) PMID: 31624242.

The luciferase activity assay

Co-transfection of circLPAR3/JPT1-wild/mutant types (WT/MUT), miR-513b-5p mimic or miR-NC was conducted in LNCaP cells (Thermo Fisher Scientific) with Lipofectamine 3000. After 48 h, the relative activity of luciferase was detected *via* the dual Glo luciferase detection system (Promega, Shanghai, China).

RNA binding protein immunoprecipitation (RIP) assay

RNA immunoprecipitation kit (Millipore, Bedford, MA, USA) was carried out for RIP detection. LNCaP cells at a density of 5×10^5 cells/plate were treated with

ice-cold radioimmunoprecipitation (RIPA) lysis buffer (Beyotime, Shanghai, China), incubated with protein A/G beads containing Anti-Argonaute 2 (anti-Ago2) or anti-Immunoglobulin G (anti-IgG). circLPAR3, miR-513b-5p and JPT1 were examined by RT-qPCR. N=3 (Du *et al.*, 2020).

Statistical analysis

SPSS 21.0 (SPSS, Inc, Chicago, IL, USA) statistical software was applied to analyze the data. After the Kolmogorov-Smirnov test, the data were normally distributed and manifested as mean ± standard deviation (S.D.). The two-group comparison was conducted *via* t-test, while the comparison among multiple groups was *via* one-way analysis of variance (ANOVA), and Fisher's least significant difference t-test (LSD-t). Enumeration data reported as rate or percentage were compared by chi-square test. *P* was a two-sided test; *P*<0.05 emphasized obvious statistical meaning.

RESULTS

We aimed to investigate circLPAR3 expression in PCa and its underlying molecular mechanism of regulating PCa progression by targeting JPT1 through miR-513b-5p. By collecting PCa clinical specimens and culturing PCa cells *in vitro*, we determined the relative expression levels of circLPAR3, miR-513b-5p and JPT1, and further verified their targeting relationship and interaction relationship. Our experiments found that circLPAR3 promoted glycolytic activation by targeting JPT1 through miR-513b-5p and inhibited PCa radiosensitivity. Therefore, our data are the first to investigate the function and mechanism of circLPAR3 in PCa, providing new insights into the pathogenesis of PCa.

Elevated circLPAR3 suggests an unpleasing into bad for PCa patients

CircRNAs are considered to be a promising marker for cancer diagnosis and prognosis. It has been report-

ed that circLPAR3 promotes the migration, invasion and metastasis of esophageal cancer PMID: 32495982. However, the role of circLPAR3 in PCa is still unclear. We first explored the properties of circLPAR3: actinomycin D (Fig. 1A) and RNase R experiments (Fig. 1B) manifested that circLPAR3 was much larger than the linear transcript. circLPAR3 expression in PCa patient specimens was clearly elevated (Fig. 1C). In PCa cell lines, it was discovered that circLPAR3 in PCa cells was enhanced (Fig. 1D). Subsequently, we divided circLPAR3 into high expression and low expression according to the median expression level of circLPAR3 in clinical patients, and analyzed the clinicopathological characteristics of PCa patients, and found that circLPAR3 expression was associated with high Gleason score, advanced pathological T stage and distant metastases (Table 2). The survival analysis calculated by Kaplan Meier affirmed that PCa patients with elevated circLPAR3 had a lower survival rate than those with reduced circLPAR3 (Fig. 1E). All in all, the results affirmed that circLPAR3 suggested an unpleasing prognosis for PCa patients.

Silenced circLPAR3 weakens cell advancement and glycolysis, but enhances radiosensitivity

In order to immediately examine the functional role of circLPAR3 in PCa progression, the introduction of sh-circLPAR3 clearly reduced circLPAR3 (Fig. 2A). It was worth noting that knockdown of circLPAR3 repressed cell advancement (Fig. 2B–F). Glycolysis, characterized by enhanced glucose uptake and lactate accumulation, is a common feature of cancer cells PMID: 34237309. In the meantime, it was manifested that repressingcircLPAR3 restrained glucose uptake, lactate production and ATP levels (Fig. 2G–I). To

improve the radiotherapy effect of PCa and improve the radiosensitivity, it is a hot research topic to understand the mechanism of cellular radioresistance PMID: 33033519. It was also determined whether circLPAR3 could impact the radiosensitivity of LNCaP cells *in vitro*. Moreover, with the application of sh-circLPAR3, the cell survival rate was clearly decreased after radiation exposure (Fig. 2J), revealing that circLPAR3 silencing enhanced cell radiosensitivity. The above data clarified silenced circLPAR3 weakened cell advancement with glycolysis but enhanced radiosensitivity *in vitro*.

CircLPAR3 absorbs miR-513b-5p in PCa cells

CircRNAs are involved in the regulation of miR sponges in PCa cells PMID: 34515615. Interestingly, the starBase database predicted a latent binding site between circLPAR3 and miR-513b-5p (Fig. 3A). For verifying whether circLPAR3 could adsorb miR-513b-5p, an experiment was implemented. It was discovered that miR-513b-5p mimic was available to reduce the luciferase activity of the circLPAR3-WT reporter plasmid, while had no clear effect on that of the MUT one (Fig. 3B). Then it was clarified that compared to the control IgG, circLPAR3 and miR-513b-5p were rich in microribonucleoprotein consisting of Ago2 (Fig. 3C). Moreover, reduced miR-513b-5p was detected in PCa (Fig. 3D, E) and was negatively linked with circLPAR3 expression in PCa samples (r=−0.637, Fig. 3F). In cells silencing circLPAR3, miR-513b-5p was found to be up-regulated (Fig. 3G). In general, circLPAR3 adsorbed miR-513b-5p and negatively modulated its levels in PCa cells.

MiR-513b-5p reduces PCa cell growth and glycolysis and promotes cellular radiosensitivity

Altered miRNA expression has been shown to play an important role in PCa invasion and metastasis PMID:34461437, while the expression of miR-513b-5p in PCa is unclear. It was confirmed that miR-513b-5p expression was elevated after miR-513b-5p mimic transfected into LNCaP cells (Fig. 4A). Subsequently, functional test data manifested that up-regulated miR-513b-5p repressed cell progression with glycolysis, but enhanced radiosensitivity *in vitro* (Fig. 4B–J). The above data confirmed that miR-513b-5p restrained growth and glycolysis, and promoted cellular radiosensitivity of PCa cells.

JPT1 is the immediate target of miR-513b-5p

As manifested in Fig. 5A, JPT1 was predicted to be miR-513b-5p's target on StarBase. The miR-513b-5p-transfected JPT1 3'untranslated region (UTR)-WT group produced reduced luciferase activity. At the same time, for verifying whether the predicted binding site of JPT1 with miR-513b-5p was necessary for the two's binding, mutation of the JPT1 binding site was conducted to construct the JPT1 3'UTR-MUT reporter plasmid. When co-transfection with miR-NC/513b-5p,

the luciferase activity of the JPT1 3'UTR-MUT group was not impacted (Fig. 5B), suggesting that miR-513b-5p immediately interacted with JPT1. The other experiment also manifested miR-513b-5p was available to combine with JPT1 (Fig. 5C). JPT1 mRNA was clearly up-regulated in cancer tissues and PCa cells than normal tissues adjacent to cancer, and RWPE-1 cells (Fig. 5D, E). It was also discovered that JPT1 and miR-513b-5p were negatively linked (r = -0.616, Fig. 5F). In the meantime, in cells with up-regulated miR-513b-5p, it was found that JPT1 expression was suppressed (Fig. 5G). In summary, miR-513b-5p directly interacted with JPT1 in PCa cells.

Inhibition of JPT1 inhibits cell growth and glycolysis and promotes radiosensitivity *in vitro*

To further examine the functional role of JPT1 in PCa, we knocked down JPT1 in cells (Fig. 6A). Responded to inhibition of JPT1, cell growth and glycolysis were suppressed and radiosensitivity was induced (Fig. 6B–J). Collectively, inhibition of JPT1 inhibits cell growth and glycolysis, and promotes radiosensitivity *in vitro*.

Figure 5. JPT1 is the immediate target of miR-513b-5p
(**A**)Prediction of the binding area between JPT1 and miR-513b-5p using the StarBase database. (**B**) The luciferase activity assay to detect the interaction between miR-513b-5p and JPT1 target protein. (**C**) RIP test to evaluate the binding of miR-513b-5p to JPT1. (**D, E**) RT-qPCR to detect JPT1 mRNA in PCa tissues and cells, n=58. (**F**) Pearson to analyze the linear relationship between miR-513b-5p and JPT1, n=58. (**G, H**) RT-qPCR and Western blot to detect JPT1 in PCa cells after up-regulated miR-513b-5p. N=3; The data in the figure were all measurement data, the manifestation of which was as mean ± S.D. *vs. RWPE-1 cells, $P<0.05$; +vs. the miR-NC, $P<0.05$

Overexpression of JPT1 reversed the role of downregulated circLPAR3 or upregulated miR-513b-5p on cancer cell growth

For determining the influence of miR-513b-5p on PCa development and the possible mechanism, a rescue experiment was conducted by transfection with sh-circLPAR3 + pcDNA-NC, sh-circLPAR3 + JPT1, miR-513b-5p + pcDNA-NC or miR-513b-5p + JPT1 in LNCaP cells (Fig. 7A). The experiment clarified that elevated JPT1 reversed the repressive effects of silenced circLPAR3 or up-regulated miR-513b-5p on PCa advancement with glycolysis, and radiosensitivity (Fig. 7B–J). All in all, overexpression of JPT1 reversed the inhibition of circLPAR3 or upregulated miR-513b-5p on cancer cell growth.

DISCUSSION

At present, PCa has surpassed LC to become the most prevalent malignant tumor in American men. Although the overall survival rate of PCa patients has been improved owing to crucial advances in early screening and cancer management programs, the pathogenesis of PCa is still ambiguous yet (Wang *et al.*, 2019). CircRNA has been proven to be a critical modulator of human

cancer, and it can perform its functions *via* cooperating with its host gene (Liu *et al.*, 2020). In this study, it was discovered for the first time that circLPAR3 was elevated in PCa patients, and PCa patients with upregulated circLPAR3 had a lower survival rate. This result suggested circLPAR3 could be applied as a latent biomarker for poor prognosis. Hence, exploring the function of circRNA in PCa can be a breakthrough to understand the pathogenesis of PCa.

A study has clarified that the reprogramming of cell metabolism is closely implicated in tumorigenesis and can be applied to cancer treatment (Xia *et al.*, 2020). Because cancer cells have a strong ability to reproduce, hypoxia frequently shows up during tumor growth (Wang *et al.*, 2019). As we all know, normal cells generally produce energy through mitochondrial oxidative phosphorylation, while quick cancer cell proliferation requires more energy. Therefore, the metabolic pathway of hypoxic cancer cells must be different from the normal metabolic pathway. It is reported that hypoxia facilitates the development of tumor cells to produce the inefficient pathways of ATP, making them inclined to gain energy *via* the glucose-dependent glycolysis pathway, which is necessary to maintain the rapid growth of tumors, also known as the Warburg effect (Dyshlovoy *et al.*, 2020). Hence, repressing the activation of

Figure 6. Inhibition of JPT1 inhibits cell growth and glycolysis, and promotes radiosensitivity *in vitro*
(**A**) circLPAR3-shRNA lentiviral transfection efficiency; (**B**) CCK-8 and (**C**) plate clone to detect cell proliferation ability after repressing circLPAR3; (**D**) Flow cytometry to detect cell apoptosis after depressing circLPAR3; (**E, F**) Transwell detection of cell migration and invasion abilities after restrained circLPAR3; (**G–I**) Glucose uptake, lactate production and ATP metabolism analysis of cell glycolysis; (**J**) Under radiation (0, 2, 4, 6 and 8 Gy) irradiation, colony formation assay to analyze the survival of the transduced cells. N=3; The data in the figure were all measurement data, the manifestation of which was as mean ± S.D. %*vs.* the si-NC, *P*<0.05.

glycolysis is an effective treatment to prevent PCa. Numerous studies have clarified that circRNA is available to impact the glycolysis of cancer cells. For instance, circDENND4C accelerates the advancement with glycolysis of colorectal cancer cells *via* the miR-760/GLUT1 axis (Zhang *et al.*, 2020). Circ_0057553/miR-515-5p controls PCa cell advancement with glycolysis *via* targeting YES1 (Zhang *et al.*, 2020). In the meantime, in this study, it was discovered that circLPAR3 expression was also elevated in PCa cells. Knockdown of circLPAR3 clearly repressed cell advancement with glycolysis. Additionally, at the clinical level, radiation therapy is the most familiar and ideal cure way for PCa (Miszczyk *et al.*, 2021). However, because cancer cells have different repair abilities after radiation, radioresistance has always been a challenge for cure (Ihara *et al.*, 2019). It came out that the silencing of circLPAR3 clearly enhanced radiosensitivity.

Former studies have manifested that circRNA is available to be applied as a competitive endogenous RNA (ceRNA) of miRNA to adsorb miRNA to modulate mRNA gene expression (Shu *et al.*, 2019). For instance, circ CCNB2 knockdown depresses autophagy of PCa cells *via* targeting the miR-30b-5p/KIF18A axis and makes PCa sensitive to radiation (Cai *et al.*, 2020). In this study, it was confirmed that miR-513b-5p was a circLPAR3's target. Former stud-

ies have testified that miR-513b-5p is crucial in various human cancers, like embryonic testicular cancer (Wang *et al.*, 2017), breast cancer (Muti *et al.*, 2018) and pancreatic cancer (Li *et al.*, 2021). In the research, it was discovered the reduction of miR-513b-5p in PCa; Up-regulated miR-513b-5p repressed cell progression with glycolysis but enhanced radiosensitivity *in vitro*. As far as we know, this is the first study on miR-513b-5p in PCa.

Next, it was further figured out the downstream target genes of miR-513-5p. JPT1 is a protein-coding gene that impacts cell apoptosis and signal transduction (Bateman *et al.*, 2020). A previous study has clarified that JPT1 is linked with the progression of PCa (Cheng *et al.*, 2021). However, since there is very little research on JPT1, further studies are required to figure out the molecular mechanism of its action. In the research, it was discovered that JPT1 mRNA was clearly up-regulated in PCa. Moreover, elevated JPT1 reversed the effect of knocking down circLPAR3 or up-regulating miR-513b-5p on PCa cells, facilitating the advancement with glycolysis, but repressing radiosensitivity. All in all, JPT1 involves in circLPAR3/miR-513b-5p axis-regulated PCa cell growth and metastasis.

However, this research still has some limitations. First, owing to limited conditions, the sample size an-

Figure 7. Overexpression of JPT1 reversed the role of downregulated circLPAR3 or upregulated miR-513b-5p on cancer cell growth.
(**A**) qPCR to detect transfection efficiency; (**B**) CCK-8 method and (**C**) plate clone to detect cell proliferation. (**D**) Flow cytometry to detect cell apoptosis; (**E**) Transwell method to detect cell migration and invasion. (**F–I**) Glucose uptake, lactic acid production and ATP metabolism analysis of cellular glycolysis; (**J**) Under different doses of radiation, the survival rate of PCa cells detected by colony formation experiments. N=3; The data in the figure were all measurement data, the manifestation of which was as mean ± S.D. ^*vs.* the sh-circLPAR3+pcDNA-NC, $P<0.05$; &*vs.* the miR-513b-5p+pcDNA-NC, $P<0.05$.

alyzed is limited. Secondly, *in vivo* animal experiments were not further conducted to verify the influence of the circLPAR3/miR-513b-5p/JPT1 axis on PCa *in vivo*. Finally, further exploration of the downstream target genes of JPT1 was not implemented. We hope that these issues can be further figured out in later studies.

CONCLUSION

In conclusion, the research has discovered a new mechanism of action of circRNA in PCa. It is found that circLPAR3 performs as a sponge of miR-513b-5p in PCa to restrain PCa cell glycolysis and accelerate radiosensitivity, while upregulation of JPT1 reverses this ef-

fect. The results indicate the circLPAR3/miR-513b-5p/JPT1 axis is supposed to be a latent prognostic and therapeutic target to improve the diagnosis and treatment of PCa.

Vitamin D deficiency (VDD) causes a wide range of health problems, including anemia in infants. If not treated promptly, it may create serious issues for infants with long-term impacts. Therefore, a satisfactory solution to this problem is required. This investigation was to explore the correlation between the blood 25-hydroxyvitamin D (25(OH)D) levels and childhood anemia. In this investigation, a cross-sectional examination was performed on 2,942 babies ranging in age from 2 to 36 months and classified into three cohorts: VDD (Vitamin D deficiency), VDI (Vitamin D insufficiency), and VDS (Vitamin D sufficiency). Multiple-variables and multinomially-related logistic regressions for examining the anemia status-vitamin D (Vit-D) relationship of the baseline as the interpretable visual quality models were examined. The median serum 25(OH)D level in 2,942 infants was 24.72±4.26 ng/l, with 661 cases (22.5%) of VDD and 1710 cases of deficiency (58.1%), and a noticeable seasonal variation (_p_<0.05). Anemia was present in 28.5% of the VDD group compared with 3.3% in vit-D sufficient infants (_p_<0.0001). Lower levels of 25(OH)D were found to be associated with an increased risk of anemia in a multiple-variable regression analysis. In healthy children, low 25(OH)D levels were associated with increased risk of anemia. Biologically inspired, primary care physicians should assess Vit-D levels and place a greater emphasis on adequate supplementation for deficiency prevention.

Keywords: Low 25(OH)D; childhood anemia; healthy children; vitamin D

INTRODUCTION

Anemia is a pervasive issue in pediatrics and is an important part of standard care for all pediatric patients. If not treated in time, it can cause significant problems for children, and the effects can be long lasting (Khan, 2018). The hemoglobin (Hb) level in these patients is too low to meet cellular oxygen demands (D'Souza, 2020). It is necessary to employ better tactics, like the targeted screening of high-risk children, such as iron insufficiency and VDD. VDD refers to a highly frequent nutrition-related deficiency globally, especially in young children (Laway _et al._, 2014). The effect of 25(OH)D, a key circulation vitamin D (vit-D) state, on calcium absorption and bone metabolic processes is noteworthy (Uberti _et al._, 2016; Alyasin _et al._, 2011). It has been progressively found to that decreased vit-D extents display relationships to diabetes mellitus (Sharma _et al._, 2015), hypertension, cancer and the maintenance of immune homeostasis (Atkinson _et al._, 2014). Existing studies show that serum 25(OH)D, which has long been thought to be the greatest indication of overall vit-D status, has a relationship with Hb level (Alyasin _et al._, 2011), but the studies either used small sample sizes or focused primarily on women, the elderly, or adults in a healthcare setting (Shin & Shim, 2013; Yoo & Cho, 2015). In addition, lower 25 (OH)D extents have displayed an individual associating process to anemia in adults exhibiting chronic diseases (e.g., heart failing state, end-stage renal disease and diabetes) (Ernst _et al._, 2015; Holick, 2007), even among healthy adults (Yazici _et al._, 2018). However, this association has not been explored in infants with health conditions. It is generally considered that vit-D impacts proliferating and differentiating processes of stem cells in marrow of bone and may impact red cell proliferating process (Uberti _et al._, 2016). For this reason, VDD may have an influence on Hb metabolism and induce anemia (Balasubramanian, 2011). Nevertheless, the likely relating characteristic of the VDD and anemia is still unclear. Thus, our intention was to assess the degree of vit-D in Zhang Jiagang's common children. Furthermore, the current investigation revealed the components that might be impacting VDD, the associations between feeding category, Hb extents, anemia status, and VDD, and the connection between the blood 25-hydroxyvitamin D level and childhood anemia.

MATERIALS AND METHODS

This experiment was performed at the Zhang Jiagang Maternity and Child Health Care Hospital in China from 2011 to 2016. This experiment was approved by the ethical committee of the Zhang Jiagang Maternity and Child Health Care Hospital, China. (Reg. No. 38563/2010/VIT-D/11.07.2010), and written informed consent was obtained from each participant. Totally, 2,942 infants

were chosen from the Child Health Care outpatient department at Zhang Jiagang Maternity and Child Health Care in China.

Inclusion criteria

1. Infants age limit from 2 months to 3 years. 2. Experimental duration August 2011 to November 2016.

Exclusion criteria

1. Systemically-related illness, 2. covering celiac disease, 3. liver, kidney disorders, rickets, joint pain, malnutrition, hypothyroidism, 4. hematologically-related disorders (e.g., anemia, G-6PD deficiency and thalassemia) besides iron insufficiency anemia received the exclusion. Feeding figures received the grouping process to 3 types specific to formula, cow's milk, and breast milk applications.

Anemia

Anemia is brought on by disruptions in the Hb production process. Anemia received the definition of Hb less than 110 mg/dL for males and females. Mild anemia = Hb 100 to 109 mg/dL; Moderate anemia = Hb 70 to 99 mg/dL; Severe anemia = Hb <70 mg/dL (Molloy *et al.*, 2017).

Further children were grouped as VDD was classified as serum 25(OH) D extents<20 ng/mL, VDI as 25(OH) D extents between 20 and 30 ng/mL, VDS as >30 ng/mL, VDS intoxication as >150 ng/mL (Balasubramanian, 2011; Holick *et al.*, 2015).

ELISA analysis

Serum 25(OH)D levels were determined by ELISA (Immunodiagnostic Systems Ltd., Beijing Bohui Innovation Technology) according to the manufacturer's instructions. In the first analytical phase, calibrators and specimens of blood are diluted with biotin-labeled 25(OH)D and added to microplate wells coated with monoclonal anti-25(OH)D antibodies. During the incubation, an unknown quantity of 25(OH)D in the blood sample competes with a known amount of biotin-labeled 25(OH)D for antibody binding sites in the microplate wells. Washing removes unbound 25(OH)D. A second incubation with peroxidase-labelled streptavidin is used to identify bound biotin-labelled 25(OH)D. The attached peroxidase induces a colour response in a third incubation with the peroxidase substrate tetramethylbenzidine (TMB). To halt the process, an acidic stopping solution is introduced. The intensity of the colour is related to the concentration of 25(OH)D. The intraassay CVs were 4.9% at a 25(OH)D mean concentration of 27.0 nmol/L, 6.9% at a 25(OH)D mean concentration of 61.5 nmol/L, and 3.2% at a 25(OH)D mean concentration of 160.3 nmol/L.

Haemoglobin (Hb) determination

The Hb was determined using the spectrophotometric cyanmethaemoglobin (HiCN) method by the XK-2 analysing tool. This approach is to convert haemoglobin to cyanmethemoglobin by adding potassium cyanide and ferricyanide, and then measure the absorbance at 540 nm in a photoelectric calorimeter against a reference solution. The test was carried out exactly as described by Bhaskaram and others (Bhaskaram *et al.*, 2003).

Statistical Analysis

Overall, statistically-related processes were carried out by SPSS,12.0 Ver software. The information had the expression "proportions" or "mean ± standard deviation. The key features were evaluated within the groups using *t*-testing methods. The chi-square and Fisher's test methods were utilised to effectively assess the categorical data. The Pearson correlation assay was undertaken to assess the connection among 25(OH)D and Hb levels. Multiple logistic regression analysis techniques were employed to assess the baseline anemia conditions of the different vit-D groups. The regulations for the mothers' years of schooling, family income, sex, season, and child age based on the models were mentioned. The multinomial logistic regression studies for measuring the relationship between VDD and various anemia (moderate and mild) in contrast to non-anemia at baseline were

also employed. A *p* value of <0.05 exhibited statistics-related significance.

RESULTS

The characteristics of study population characteristics

The features of the investigated participant are demonstrated in Table 1. Among the total 2 942 infants enrolled here. Among these, 1541 (52.4%) were men and 1401 (47.6%) were girls. In this, 594 (20.2%) were below 6 months of age, whereas 318 (10.8%), 1094 (37.2%) and 936 (31.8%) from 6–12, 12–24, and 24–36, respectively. In infants <6 month, 95.5% were breastfed, whereas 4.5% received Breast milk and formula. In 6-12 months, 71.1% were breastfed and 20.4% were received Breast milk and formula, 8.5% received only formula. In 12–24 months, 43.6% were breastfed only, 45.9% were received only breast milk and formula and 10.5% received only formula. In 24–36 months, 1.6% were only breastfed and 75.4% were received breast milk and formula, 22% received only formula. The 25(OH)D deficiency levels <20 ng/mL showed 27.6% in the below 6 month. The 25(OH)D deficiency levels of <0 ng/mL were noted 27.6% in the below six months babies, 39.3% in 6–12 months, 27.2% in 12 to 24 months and 7.9% in 24 to 36 months. The 71.7% of below 6 months babies were showed 25(OH)D insufficiency levels of 20–30 ng/mL, 58.8% showed by 6–12 months babies, 58.5% were showed by 12 to 24 months, 48.8% showed in 24 to 36 months. In the study, 71.7%, 58.8%, 58.5%, and 48.8% of babies as follows: below 6 months, 6–12 months, 12–24 months, and 24–36 months showed 25(OH)D insufficiency levels (20–30 ng/mL). In the study, 0.7%, 1.9%, 14.2%, and 43.3% of babies as follows: below 6 months, 6–12 months, 12–24 months, and 24–36 months showed 25(OH)D sufficiency (levels >30 ng/mL). No 25(OH)D intoxication levels >150 ng/mL were reported in this study. In the study, 66.2%, 66%, 54.2%, and 32.8% babies as follows: below 6 months, 6–12 months, 12–24 months, and 24–36 months showed Anemia (Hb <110 mg/dL).

The associating process of VDD presence and breastfeeding exhibited statistics-related significance

In the tested babies, 22.5% showed by VDD, 58.1% expressed by VDI and 19.4% showed by VDS (Table 2). Mean age of the children who in VDD cohort was 11.58±7.98 months, while it in VDI group reached 19.40±9.64 months and in the VDS group

was 27.77±8.55 months. The male (%) in the VDD was 50.5%, 49.0% in VDI and in VDS 67.4%. the female (%) in the VDD was 49.5%, 51.0% in VDI and in VDS 32.6%. The rate of exclusive breast feeding in the three cohorts was 39.0%, 21.8% and 65.1%. For this reason, the associating process of VDD presence and breastfeeding exhibited statistics-related significance (*p*<0.05). The significant diversification between Hb extents is among 3 cohorts. Among children VDD, 28.5% of infants were with Hb <110 mg/dL and mean Hb as 112.54±10.67 mg/dL. However, 8.2% of overall in the VDI cohort exhibiting mean Hb as 118.63±8.52 mg/dL and 3.3% of overall in the VDS cohort exhibiting mean Hb as 122.77±8.21 mg/dL (*p*<0.001). Thus, in vit-D deficient cohort, cases number exhibiting low Hb extents (<110 mg/dL) was higher in comparison with vit-D sufficient cohort (Fig. 1).

Anemia condition of different patients

Table 3 lists the anemia condition for different levels of vit-D. About 95.2% of the recruited infants had Mild anemia, covering 73.4% Moderate anemia and 17.6% sever anemia. When confounders (the mothers' years of schooling, family income, sex, season, and infant age) were controlled for, no connections were noted between vit-D and anaemia condition; however, moderate anaemia had a higher risk in 25(OH)D 30 mg/mL infants than in 25(OH)D 30 mg/mL infants [relative risk (RR), 1.59; 95% confidence interval (CI), 1.09-2.31]. The frequency of mild anaemia showed a weak correlation with vit-D status (RR, 1.04; 95% CI, 0.97–1.29). In Fig. 2, the authors also analyzed case number with 25(OH)D deficiency, insufficiency and sufficiency and the extents of 25(OH)D in line with seasons. The number of cases with vit-D levels of <30 ng/mL in the autumn (September to November) was 536 (76.9%), 625 (74.4%) in the summer

Figure 1. The Ratio of anaemia in VDD was significantly higher than that in VDI and VDS, *p*<0.05*.
VDD, vitamin D deficiency. VDI, vitamin D insufficiency. VDS, vitamin D sufficiency.

Table 3. Prevalence of anemia in different levels of 25 (OH)D children

Variable	25(OH)D<30 mg/mL (n=2371)	25(OH)D≥30 mg/mL (n=571)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)*
Mild anemia (Hb<110mg/dL)	1264 (53.3)	239 (41.9)	1.23 (0.45, 1.68)	1.23 (0.12, 1.35)
Subgroup				
			Unadjusted OR (95% CI)	Adjusted OR (95% CI)**
Anemia (Hb 70-99 mg/dL)	367 (15.5)	12 (2.1)	1.53 (1.11, 2.09)	1.59 (1.09, 2.31)
Moderate anemia (Hb 100-109 mg/dL)	897 (33.6)	227 (39.8)	1.06 (0.73, 1.55)	1.04 (0.97, 1.29)

*ORs were calculated by using logistic regression and adjusted for age of the child, season, sex, family income and mothers' years of schooling.
**ORs were calculated by using multinomial logistic regression and adjusted age of the child, season, sex, family income and mothers' years of schooling.

Table 4. Factors associated with vitamin D deficiency

Variable	Odds ratio	95 % CI
Male	0.89	0.72-3.36
Female	0.81	0.66-3.27
Age (<12 Mo)	1.88*	0.65-6.06
Breast feeding	0.78	0.45-1.57
Serum mean Hb level	1.51*	1.02-2.84
Vitamin D tested in winter/spring	3.22*	1.13-4.57

*p value <0.001; VDD, vitamin D deficiency.

(June to August), 453 (87.3%) in the winter (December to February), and 757 (85.4%) in the spring (March to May). The average serum 25(OH)D level was significantly lower in spring/winter than in summer/autumn (25.28±4.31 v/s 23.78±4.34 ng/mL, $p<0.01$). The winter season exhibited the maximum VDD ratio (31.6%), and the spring season achieved the maximum VDI ratio (62.4%). The lone risk element for VDD determined by multiple-variable logistic regression was 25OHD in the winter or spring [odds ratio, 3.22; 95% CI, 1.13 to 4.57]. Several factors related to sex and breastfeeding that were seen in the univariate research had no independent relationship with VDD (Table 4). The risk element in terms

Figure 2. The levels of 25(OH)D status increased from spring to summer and then decreased in autumn and winter.
VDD, vitamin D deficiency. VDI, vitamin D insufficiency. VDS, vitamin D sufficiency.

of VDD developing process was evident in babies with anemia ($p<0.001$) and if 25(OH) D extents received the testing process in winter/spring ($p<0.001$).

DISCUSSION

The present work suggests that in a large, group-related Zhang Jiagang infants cohort with health condition, lower 25(OH)D extents displayed associations to elevated anemia risk. The identified associating process of vit-D condition and anemia was determined by other elements probably inducing anemia risk such as the mothers' years of schooling, family income, sex, season and age of infants. In the present work 28.5% and 8.2% of the infants achieved Hb <110 mg/dL in the vit-D deficient cohort (VDD and VDI), but merely 3.3% of the infants achieved Hb <110 mg/dL in the vit-D sufficient cohort. vit-D is vital nutrient required by an infant to grow and develop (Harinarayan & Joshi, 2009). The experts recommended that all only breastfeeding-based infants were required to undergo 400 IU per day of vit-D supplementing processes, which should be initiated several days after birth. No diversification received the identification in mean extents of vit-D in sex. However, the vit-D adequacy ratios of boy were slightly higher than in girls, which may be related to boys spending more time outdoors than girls. The authors further identified a noticeable correlating characteristic of <6 months age and VDD. Such correlating characteristic is likely to result from declined vit-D stores in such age cohort, breastfeeding almost exclusively and increased vit-D requirements and/or insufficient sun exposure. Balasubramanian and others (Balasubramanian et al., 2011) suggest that a greater risk of VDD received the identification in infants having undergone exclusive breastfeeding process with no adequate vit-D supplementing process and appropriate exposure to sunlight. Furthermore, only a small number of breastfed infants get vit-D supplements since very few mothers follow their physician's suggestion for vit-D supplement because they think breast milk may provide critical nutrients (Yoon et al., 2012). The majority of them prefer to buy health supplements like fish glycerides and DHA online. They consider that the vit-D presented by the hospital is easy to poison, and only part of the mother will take vit-D supplements during pregnancy.

The relating characteristic between VDD and anemia identified here complies with several recently conducted

researched on a range of groups (Alyasin *et al.*, 2011; Ernst *et al.*, 2015; Htet *et al.*, 2014). Several potential mechanisms could explain the associating characteristic of VDD and anemia in healthy infants. Major possibility is that VDD in infants is suggested displaying relationship to lifestyle and nutrition-related elements covering reduced milk intake and obesity as aforesaid. Inadequate 25(OH)D levels decrease local calcitriol synthesis in the bone marrow, resulting in decreased erythropoiesis (Sim *et al.*, 2010). Calcitriol could reduce cytokine producing process, thereby reducing inflammation-related milieu and anemia. The abundance of vitamin D receptors and vit-D in bone marrow seem to trigger erythroid precursors. High levels of 25(OH)D in hematopoietic tissues have been linked to erythroid progenitor cell paracrine activation. Moreover, there is considerable evidence that inflammatory cytokines affect erythropoiesis. Immunomodulation-related influences exerted by vit-D are likely to critically impact its role to prevent anemia by the modulating process related to systemically-related cytokine producing process, probably suppressing particular inflammation-related channels facilitating anemia progression. Furthermore, because of anemia people are commonly tired and less probably going externally for obtaining adequate sun exposing to generate vit-D. Anemia may also in turn contribute to VDD.

The season-related varying process acted as a single predicting element for VDD among infants subjected to anemia, abiding by existing works (Jin *et al.*, 2013). Given vit-D is primarily sourced by skin casually exposed to sunlight. 7-dehydrocholesterol (7-DHC) is isomerized to pre-vitamin D3 in the exposing process of the UVB (290 to 315 nm) part pertaining to sun photolyzes. When the relevant forming process is achieved, pre-vitamin D3 will undergo thermally isomerizing process for synthesize vit-D3. Solar UVB radiation amount accessing into the biosphere refers to one function pertaining to wavelength and ozone amount traveled by solar radiating process via the air, one function pertaining to the solar zenith angle, is determined by day time, season as well as latitude. Because the sun largely drives the vit-D synthesising process in the body, it was reported that VDD was more common; serum 25(OH)D extent was noticeably low in the spring/winter season than in the autumn/summer season. This is most likely due to summer/autumn sun exposure is adequate illumination than winter/spring and children outdoor time is longer. Human skin can be exposed to ultraviolet B radiation to produce more vit-D. Moreover, as suggested from recently conducted researches, genetically-related predisposition is likely to critically impact susceptible characteristic to VDI, and both vit-D uptake via diet and supplementing processes and skin-forming process when solar exposure is achieved may be determined by single genetically-related varying processes (Anastasiou *et al.*, 2017). The present multiple-variables-based logistic study suggested that season-based varying process in 25(OH)D acted as the merely noticeable single risk element in terms of VDD. For this reason, the present work demonstrates the season-based varying process is the primary risk component of VDD in Infants with anemia. Accordingly, the significance of sunshine and the requirement for vit-D supplement, especially throughout the winter and spring, are stressed. More research is required to explore the relationship among blood 25-hydroxyvitamin D levels and childhood anaemia.

CONCLUSION

To be specific, the present work on Zhang Jiagang infants suggested the correlative characteristics between anemia severity and VDD. For presenting the optimal nutritional condition for infants, breastfeeding continues to be worth recommending. However, educational efforts are required publicly and those breastfed in an exclusive manner (even under asymptomatic child) for increasing abidance by vit-D supplementing requirements.

Limitations

The present work showed several limitations. Subjects had varying ages; thus, their dietary intake and habits of feeding were likely to vary, probably causing a memory bias. It is better to compare plasma Hb and ferritin extents in the same patients, complying with the vital elements in Hb synthesis. It will be better to demonstrate the relationship to vit-D condition and categories of anemia and the strength of association differs among types of anemia. Considerable trials under randomization-based controlling should be conducted for determining if enhancing vit-D condition is capable of reducing anemia severity in normal groups.

Hexafluoro-2-propanol represses colorectal cancer proliferation by regulating transaminases

Zhongxin Shao[1‡], Lu Sun[2‡] and Wenxin Lin[1✉]

Hexafluoro-2-propanol (HFIP) is a metabolite of sevoflurane used as part of the general anaesthesia technique. This study aims to investigate the effect of HFIP in colorectal cancer (CRC) and the regulation of associated genes. The differential expressed genes (DEGs) with HFIP treatment were analysed based on GEO dataset GSE56256. Due to the restricted number of studies performing RNA-Seq in CRC with HFIP treatment, we selected a CRC patient cohort (GSE23878) to obtain DEGs that were compared with DEGs from GSE56256. The DEGs with opposite expression patterns in these two GEO datasets indicate that the genes mediate the function of HFIP, thereby repress the progression of CRC. The DEGs from these two GEO datasets were analysed independently. We obtained 10 up-regulated genes in GSE23878 (CRC patient cohort) were also down-regulated in GSE56256 (HFIP cohort), therefore, these 10 genes may function as tumor suppressors in CRC and may be involved in the function of HFIP. STRING analysis demonstrated an interaction in GPT2, PSAT1 and SLC7A11. The high expression of GPT2, PSAT1 and SLC7A11 were confirmed in TCGA-COAD datasets and in CRC cells. HFIP treatment repressed GPT2, PSAT1 and SLC7A11, which resulted in an inhibited proliferation and colony formation ability of DLD-1 and HCT-116 cells. Silencing GPT2, PSAT1 and SLC7A11 showed similar effect compared to HFIP treatment. Overexpression of GPT2, PSAT1 and SLC7A11 abrogated the effect of HFIP. In conclusion, the sevoflurane metabolite HFIP plays a cancer suppression role depending on cell proliferation in colorectal cancer through the down-regulation of GPT2, PSAT1 and SLC7A11 expression.

INTRODUCTION

Sevoflurane is a commonly used anaesthetic because of the safety with fewer side effects compared with other inhalation anaesthetics (Kanaya *et al.*, 2014). Studies confirmed that volatile anaesthetics influence cancer cells and show potential regulatory effect on a variety of tumours (Sumi *et al.*, 2019; Zhao *et al.*, 2020). During the metabolism of sevoflurane, water-soluble hexafluoro-2-propanol (HFIP) presents as a primary metabolite of sevoflurane (Buratti *et al.*, 2002). Previous researches have shown that HFIP attenuates inflammation *in vitro* by repressing related inflammatory mediators (Urner *et al.*, 2015). However, few studies investigated the effect of HFIP on cancer progression especially on colorectal cancer, therefore, we demonstrated the function of HFIP in colorectal cancer cells and aimed to illustrate the potential molecular mechanisms.

The growth of mammalian cells is supported by nutrient sources including glucose and glutamine, which are involved in energy production and are related to cancer progression (Hosios *et al.*, 2016). Most cancer cells proliferate depending on glutamine. Glutamine starvation results in growth inhibition. GPT2 is a type of glutamic pyruvate transaminase catalysing the reversible transamination between alanine and α-ketoglutarate (AKG) generating pyruvate and glutamate (Welch, 1975). Previous studies have shown that GPT2, PSAT1 and SLC7A11 are involved in the progression of different cancers: GPT2 is highly expressed in cancers, such as breast cancer and pancreatic cancer (Cao *et al.*, 2017). Therefore, GPT2 is a potential biomarker and target in cancer therapy. PSAT1 was identified highly expressed in various cancers including colorectal cancer and non-small cell lung cancer (Qian *et al.*, 2017; Lodovichi *et al.*, 2019). Studies demonstrated that PSAT1 is involved in serine biosynthesis and mediates cell cycle progression, which implies a promising target for anticancer therapy. In the regulation of nutrient dependency of cancer cells, SLC7A11 plays emerging roles which maintain redox homeostasis (Koppula *et al.*, 2018). In colorectal cancer stem cells (CSCs), SLC7A11 has a higher level compared to colorectal cancer cells. Repression of SLC7A11 sensitizes colorectal CSCs to ferroptosis and chemotherapy drugs (Xu *et al.*, 2020). Furthermore, repression of SLC7A11 inhibits metastasis of pancreatic cancer by blocking the PI3K/Akt signaling pathway (Zhang *et al.*, 2021). The pro-death functions of SLC7A11 happen under glucose starvation (Karunakaran *et al.*, 2008). Overexpression of SLC7A11 confers resistance to MEK and BRAF inhibitors in *BRAF*[V600E] mutant melanoma via increasing intracellular GSH contents (Wang *et al.*, 2018). Cancer cells employ up-regulated SLC7A11 to mediate cystine uptake, which results in better capabilities of cancer cells to survive in oxidative stress conditions (Koppula *et al.*, 2018). SCL7A11 provides a novel and effective therapeutic strategy for cancer treatment.

In our study, the regulation of GPT2, PSAT1 and SLC7A11 by HFIP was investigated in colorectal cancer. This study showed that HFIP repressed colorectal cancer proliferation *via* regulating glutamine metabolism related genes.

MATERIAL AND METHODS

Cell culture and treatment

Human colorectal cancer cell lines DLD-1, HCT-116 and RKO were obtained from ATCC. Human colon epithelium cell HCoEpiC was purchased from National Collection of Authenticated Cell Culture. Cells were cultivated in McCoy's 5A medium containing 10% fetal bovine serum (FBS), penicillin 100 units/ml and streptomycin 100 ug/ml with 5% CO_2 in 37°C. HFIP (105528) was purchased from Sigma Aldrich and dissolved in DMSO to a stock concentration of 100 mM. Working concentration of 50 mM was achieved by diluting HFIP stock solution with HBSS. Before different experiments cells were treated with HFIP for 12 h.

Transfection

GPT2, PSAT1 and SLC7A11 pcDNA3.1 overexpressing vectors were designed and constructed by BGI (Beijing, China). Specific siRNAs of GPT2, PSAT1 and SLC7A11 were purchased from QIAGEN (Germany). For transfection, cells were seeded into 6-well plate at the density of 5×10^5 cells/well and cultivated to at least 70% confluence. Vectors were transfected with Lipofectamine 2000, and siRNAs were transfected with Lipofectamine RNAiMAX (Thermo Fisher, USA) at 1:1 ratio (v/v) according to the protocol provided by the manufacturer. The final concentration of vector and siRNA were 2 μg/ml and 25 nM, respectively.

RNA isolation and quantitative real-time PCR (q-PCR)

Total RNAs were isolated and purified by High Pure RNA Isolation Kit (Roche, Switzerland) based on the instruction of the kit. 100 ng of isolated RNA was used for reverse transcription with verso cDNA synthesis kit (Thermo Fisher, USA). Q-PCR was performed with SYBR® Premix Ex Taq™ (RR420A; Takara) in Roche LightCycler 480 system. The data were normalized to GAPDH and calculated using $2^{-\Delta\Delta Ct}$ value. Primers used in q-PCR were listed in Table 1.

Table 1.. Primers used in q-PCR analysis

Genes	Sequence 5'-3'
GPT2 F	GTGATGGCACTATGCACCTAC
GPT2 R	TTCACGGATGCAGTTGACACC
PSAT1 F	TGCCGCACTCAGTGTTGTTAG
PSAT1 R	GCAATTCCCGCACAAGATTCT
SLC7A11 F	TCTCCAAAGGAGGTTACCTGC
SLC7A11 R	AGACTCCCCTCAGTAAAGTGAC
GAPDH F	CTGGGCTACACTGAGCACC
GAPDH R	AAGTGGTCGTTGAGGGCAATG

Western blot

Total protein was isolated from colorectal cancer cells after different treatments by applying RIPA lysis buffer. Protein concentrations of each group were quantified with BCA kit based on the instructions. Total 40 μg of protein was loaded onto 10% sodium dodecyl sulfate polyacrylamide gel (SDS-PAGE). Electrophoresis conditions were 120 V for 120 min. It was then transferred to a polyvinylidene difluoride membrane (300 mA, 90 min).

Membranes were blocked by 5% milk in 1×TBST and then incubated with primary antibodies GPT2 (1:1000, Life, USA), PSAT1 (1:1000, Santacruz, USA), SLC7A11 (1:1000, Abcam, USA) and β-actin (1:2000, Abcam, USA) overnight at 4°C.

MTT assay

For cell proliferation rate, after different treatments, cells were seeded in 96-well plates in 100 μl of medium. Three parallel wells were assigned for each time points. MTT solution (5 mg/ml) was added to each well and incubation continued for 4 hours. It was followed by removing medium and washing with PBS twice. Afterwards, 150 μl DMSO was added into each well and then plate was shaken for 10 min. OD values were measured at 490 nm wavelength.

Colony formation assay

After different treatments, cells were seeded into 6-well pate at the density of 500 cells/well and cultivated to 3 weeks until cell colonies could be observed by eye. Cells were fixed with methanol for 15 min and then stained with crystal violet for 30 min. After staining, cells were washed under running water and taken pictures of by camera. Colony numbers were counted by using Image J software.

Bioinformatic analysis

GSE56256 and GSE23878 were obtained from GEO database (https://www.ncbi.nlm.nih.gov/geo/), and the download data format was MINIML. GSE56256 includes two groups of lipopolysaccharides (LPS)/HFIP treated endothelial cells and three groups of LPS treated endothelial cells (Urner et al., 2015). The array profiling was performed on the platform of Agilent-028004 SurePrint G3 Human GE 8x60K Microarray. GSE23878 contains 35 colorectal cancer patient samples and 24 normal samples (Uddin et al., 2011). The cDNA microarray was performed on the [HG-U133_Plus_2] Affymetrix Human Genome U133 Plus 2.0 Array. Limma package (version: 3.40.2) of R software was used to study the differential expression of mRNAs. The adjusted P-value was analysed to correct for false positive results in GEO datasets. "Adjusted $P<0.05$ and $|Log_2[Fold\ Change]| >1$" were defined as the thresholds for the screening of differential expression of mRNAs. To further confirm the underlying function of potential targets, the data were analyzed by functional enrichment. To better understand the carcinogenesis of mRNA, ClusterProfiler package (version: 3.18.0) in R was employed to analyze the GO function of potential targets and enrich the KEGG pathway. The box plot is implemented by the R software package ggplot2; PCA graphs are drawn by R software package ggplot2; the heat map is displayed by the R software package heatmap. All the above analysis methods and R package were implemented by R foundation for statistical computing (2020) version 4.0.3.

Statistics

SPSS 21.0 was used to calculate all the values (means ± standard error of the mean). Statistical analyses were analysed with Student's t test in two-groups comparison. One-way analysis of variance (ANOVA) test was used to verify the significance among experimental groups. The statistical significance was $P<0.05$. All experiments were performed in triplicate.

RESULTS

Analysis of differentially expressed genes with HFIP treatment

Since few studies performed next generation analysis of HFIP treatment in colorectal cancer cells or patients, here we selected a GEO dataset GSE56256 which investigated that HFIP as an anti-inflammation reagent in li-popolysaccharides (LPS) induced inflammatory response in lung cancer. Therefore, we could obtain genes that are regulated by HFIP. We compared the duplicate of LPS-HFIP co-treatment groups to the triplicate of LPS treatment groups. A total of 5583 genes were down-regulated with $Log_2[Fold Change] < -1$ while a total of 54 genes were up-regulated with f $Log_2[Fold Change] > 1$ after HFIP treatment (Fig. 1A and 1B). From the results, DEGs were mainly enriched in down-regulated group. Next, DEGs were put into KEGG signalling pathway

Figure 1. Analysis of differential expressed genes with HFIP treatment.
(**A**) Volcano plot of differentially expressed genes with |$Log_2[Fold Change]$|> 1 after HFIP treatment compared to LPS treatment only (GSE56256). Down regulated genes were represented by blue dots and up-regulated genes were represented by red dots. (**B**) Heat map of differentially expressed genes after HFIP treatment compared to LPS treatment only (GSE56256). Down regulated genes were marked with blue bars and up-regulated genes were marked with red bars. (**C**) Kyoto Encyclopedia of Genes and Genomes (KEGG) and gene ontology (GO) analysis of up-regulated genes after HFIP treatment in GSE56256. (**D**) KEGG and GO analysis of down-regulated genes after HFIP treatment in GSE56256.

(**B**) Heat map of differentially expressed genes in colorectal cancer patients (GSE23878). Down regulated genes were marked with blue bars and up-regulated genes were marked with red bars. (**C**) Venn diagram showed overlapped genes of HFIP down-regulated genes selected from GSE56256 and up-regulated genes in colorectal cancer patients from GSE23878. (**D**) STRING database analysis of selected 10 common DEGs. (**E**) and (**F**) Unpaired and paired analysis of GPT2, PSAT1 and SLC7A11 in TCGA-COAD dataset. (**G**) q-PCR analysis of GPT2, PSAT1 and SLC7A11 in three indicated CRC cell lines (n=3) compared to HCoEpiC cell, normalized to *GAPDH*. (**H**) Western blot analysis of GPT2, PSAT1 and SLC7A11 in three indicated CRC cell lines compared to HcoEpiC cell, normalized to β-actin. The quantification of western blot was also presented (n=3). *$P<0.05$, **$P<0.01$, ***$P<0.001$.

and gene ontology (GO) analysis. Both KEGG analysis and GO analysis results demonstrated that the up-regulated genes were mainly enriched in pathways and biological processes involving cell cycle, DNA replication (Fig. 1C). For down-regulated genes, they were mainly enriched in chemokine signalling and immune cell func-

tions (Fig. 1D). The above analysis indicates that HFIP treatment reduces inflammation response. Since the chronic inflammation is a significant causal factor in the development of colorectal cancer, our results imply that HFIP has a potential protective effect in colorectal cancer treatment.

Table 2. 10 common DEGs up-regulated in GSE23878 and down-regulated in GSE56256

Gene symbol	Description
STC2	stanniocalcin 2
CLDN1	claudin 1
CTHRC1	collagen triple helix repeat containing 1
PSAT1	phosphoserine aminotransferase 1
HS6ST2	heparan sulfate 6-O-sulfotransferase 2
MMP10	matrix metallopeptidase 10
HKDC1	hexokinase domain containing 1
SLC7A11	solute carrier family 7 member 11
SIX4	SIX homeobox 4
GPT2	glutamic--pyruvic transaminase 2

HFIP potentially regulates transaminases in colorectal cancer

Since inflammation is one of the factors of arising colorectal cancer, we would like to know whether the genes regulated by HFIP in endothelial cells of the lung are also involved in the progression of colorectal cancer. Due to the restricted number of studies performing RNA-Seq in colorectal cancer with HFIP treatment, we selected a colorectal cancer patient cohort (GSE23878) to obtain DEGs that were compared with DEGs from GSE56256. The DEGs from these two GEO datasets were analysed independently. The DEGs with opposite expression patterns in these two GEO datasets may indicate the genes that mediate the function of HFIP, thereby repress the progression of colorectal cancer. GSE23878 contains 35 colorectal cancer samples and 24 normal samples. A total of 150 genes were up-regulated with Log_2[Fold Change] >1 while a total of 610 genes were down-regulated with Log_2[Fold Change] <-1 (Fig. 2A and 2B). Since HFIP is supposed to have a repression effect in cancers, it is intriguing to compare the genes downregulated by HFIP in GSE56256 to the genes up-regulated in colorectal cancer samples in GSE23878. Finally, we obtained 10 genes that overlapped (Fig. 2C) and were listed in Table 2, indicating that these 10 genes may serve as tumor suppressors and mediate the function of HFIP in colorectal cancer. Next, all the 10 genes were analysed *via* STRING database to get the potential protein interaction network. As presented in Fig 2D, only GPT2, PSAT1 and SLC7A11 showed interactions in those 10 genes. GPT2 and PSAT1 are transaminases and SLC7A11 is a cysteine/glutamate transporter (Welch, 1975; Qian *et al.*, 2017; Koppula *et al.*, 2018), which are associated with glutamine metabolism. Furthermore, GPT2, PSAT1 and SLC7A11 contribute to the cancer progression. Interestingly, GPT2, PSAT1 and SLC7A11 were validated to be highly expressed in colorectal cancer from the data of TCGA-COAD dataset (Fig. 2E and 2F). In addition, q-PCR analysis indicated a higher expression level of GPT2, PSAT1 and SLC7A11 in DLD-1, HCT-116 and RKO cells compared to a normal cell line HCoEpiC (Fig. 2G). Western blot also showed similar results (Fig. 2H). Therefore, GPT2, PSAT1 and SLC7A11 serve as oncogenes independent of tissue context. Collectively, HFIP potentially regulates glutamine metabolism in colorectal cancer through mediating GPT2, PSAT1 and SLC7A11.

HFIP represses proliferation of colorectal cancer cells

The effect of HFIP on colorectal cancer cells was investigated in the following studies. The proliferation rate of DLD-1 cells was repressed by HFIP treatment, which was concentration dependent (Fig. 3A). 20 mM HFIP repressed colony formation capability of DLD-

Figure 3. HFIP represses proliferation of colorectal cancer cells.
(**A**) MTT assay showed relative proliferation rate of DLD-1 cells after treated by HFIP with indicated concentration. Proliferation rate was compared to untreated group. (**B**) Colony formation assay was performed in DLD-1 and HCT-116 cells treated with 20 mM HFIP compared to untreated group. (**C**) Western blot analysis of GPT2, PSAT1 and SLC7A11 in DLD-1 cell treated with 20 mM HFIP compared to untreated group. (**D**) MTT assay showed relative proliferation rate of DLD-1 cells after treated by GPT2, PSAT1 or SLC7A11 siRNA. Proliferation rate was compared to scrambled siRNA group. (**E**) Colony formation assay was performed in DLD-1 cell after treated by GPT2, PSAT1 or SLC7A11 siRNA. Proliferation rate was compared to scrambled siRNA group. *$P<0.05$, **$P<0.01$.

Figure 4. GPT2, PSAT1 and SLC7A11 are required for HFIP effect.
(**A**) Western blot analysis of GPT2, PSAT1 and SLC7A11 in DLD-1 cell treated with 20 mM HFIP together with overexpression vectors. (**B**) MTT assay showed relative proliferation rate of DLD-1 and HCT-116 cells treated with 20 mM HFIP together with overexpression vectors. (**C**) Colony formation assay was performed in DLD-1 cell treated with 20 mM HFIP together with overexpression vectors. *$P<0.05$, **$P<0.01$.

1 and HCT-116 cells (Fig. 3B). Above results demonstrated that HFIP suppressed proliferation of colorectal cancer cells. Since GPT2, PSAT1 and SLC7A11 are supposed to be repressed by HFIP in bioinformatic analysis and the expression of these genes was validated in colorectal cancer cells, next we further validated that HFIP treatment significantly repressed the protein level of GPT2, PSAT1 and SLC7A11 compared to control group in DLD-1 cells (Fig. 3C). In addition, silencing GPT2, PSAT1 and SLC7A11 repressed DLD-1 cell proliferation rate (Fig. 3D) and inhibited DLD-1 cell colony formation ability (Fig. 3E). Taken together, HFIP treatment and GPT2/PSAT1/SLC7A11 silence repressed proliferation of colorectal cancer cells, in which the effect of HFIP is potentially mediated by GPT2/PSAT1/SLC7A11.

GPT2, PSAT1 and SLC7A11 are required for HFIP function

As GPT2, PSAT1 and SLC7A11 were validated to be down-regulated by HFIP, here we investigated whether GPT2, PSAT1 and SLC7A11 are required for HFIP function. DLD-1 cells were treated with HFIP and co-transfected with one of the GPT2, PSAT1 and SLC7A11 overexpression vectors. The protein level of GPT2, PSAT1 and SLC7A11 stayed at a high level by co-transfected with overexpression vector and treated with HFIP (Fig. 4A). In both DLD-1 and HCT-116 cells, ectopic expressing GPT2, PSAT1 or SLC7A11 abrogated the effect of HFIP treatment on cell proliferation rate repression. The strongest abrogation effect was observed in the common overexpressing GPT2, PSAT1 and SLC7A11

(Fig. 4B). Similarly, GPT2, PSAT1 or SLC7A11 overexpression abrogated the effect of HFIP on reducing DLD-1 cell colony formation ability (Fig. 4C). Above results indicated that GPT2, PSAT1 and SLC7A11 mediated the effect of HFIP in colorectal cancer cells.

DISCUSSION

In this study, we investigated the function of sevoflurane metabolite HFIP on repressing colorectal cancer cell proliferation. Two transaminases and one cysteine/glutamate transporter were inhibited by HFIP treatment, which mediates the effect of HFIP. Previous studies identified that HFIP is a water soluble primary metabolite of the volatile anaesthetic sevoflurane (Buratti *et al.*, 2002), which is associated with attenuating inflammation through repressing inflammatory mediators (Urner *et al.*, 2015). In line with these conclusions, analysis in RNA-seq data from GSE56256 revealed that HFIP treatment represses more 5000 genes in LPS induced inflammatory response cases. Among those HFIP repressing genes, many genes are mainly enriched in signalling pathway and biological process involving cytokine-cytokine receptor interaction and immunocyte proliferation, which provides the evidence that HFIP has an effect on inflammation.

Since inflammation plays a pivotal role in tumorigenesis *via* multiple molecular mechanisms, here we explored the effect of HFIP on colorectal cancer, which is at a high risk for the patients with inflammatory bowel disease (Herszenyi *et al.*, 2015). Since few studies performed Micro-array analysis in colorectal cancer patients

Figure 5. The regulation model of HFIP in colorectal cancer.
GPT2, PSAT1 and SLC7A11 were screened from two independent patient cohorts. HFIP repressed proliferation of colorectal cancer cells through down-regulating GPT2, PSAT1 and SLC7A11 expression, which are involved in glutamine metabolism of colorectal cancer.

with HFIP treatment, we endeavoured an alternative way to find the tumor suppressive genes that are involved in the function of HFIP: We performed differentially expressed gene analysis in a colorectal cancer patient cohort (GSE23878) to obtain DEGs that were compared with DEGs from GSE56256. The DEGs from these two GEO datasets were analysed independently. The DEGs with opposite expression patterns in these two GEO datasets indicate the genes that mediate the function of HFIP, thereby repress the progression of CRC. We obtained 10 up-regulated genes in GSE23878 (CRC patient cohort) that were also down-regulated in GSE56256 (HFIP cohort). Since the two GEO datasets are from different tissues, we exclude the context specificity of the 10 genes. Among those 10 genes, GPT2, PSAT1 and SLC7A11 showed connections with each other, which implies that these three genes play critical roles as a network in HFIP function. Actually, GPT2, PSAT1 and SLC7A11 are involved in glutamine metabolism in cancer progression dependent on proliferation and cell growth (Cao *et al.*, 2017; Qian *et al.*, 2017; Koppula *et al.*, 2018). Indeed, altered cellular energetics is an established hallmark of cancer. Glutamine normally provides carbon and nitrogen for biosynthesis involved in cancer survival and proliferation. SLC7A11 functions as a cysteine/glutamate transporter, while GPT2 and PSAT1 are transaminases that convert glutamine to AKG. Here we confirmed that HFIP treatment repressed proliferation of colorectal cancer cells. Meanwhile, silencing GPT2, PSAT1 and SLC7A11 also inhibited cell proliferation. Therefore, we suppose that the effect of HFIP on cell proliferation repression is mediated by GPT2, PSAT1 and SLC7A11. In addition, glutamine can be transported into cells by the SLC7A11, and it is possible that SLC7A11 takes first place in the response to HFIP treatment.

Furthermore, Overexpression of GPT2, PSAT1 and SLC7A11 abrogated the effect of HFIP on repressing colorectal cancer cells, which demonstrates that GPT2, PSAT1 and SLC7A11 are necessary for HFIP function. Notably, common overexpressing of GPT2/PSAT1/SLC7A11 showed the strongest effect on the abrogation of HFIP function. Therefore, GPT2, PSAT1 and SLC7A11 may have a synergetic effect and mediate HFIP effect together.

In conclusion, HFIP represses proliferation of colorectal cancer cells through down-regulating GPT2, PSAT1 and SLC7A11 expression, which are involved in glutamine metabolism of colorectal cancer, summarized in Fig. 5.

Circular RNA CSPP1 motivates renal cell carcinoma carcinogenesis and the Warburg effect by targeting RAC1 through microRNA-493-5p

Dong Zhang, XiaoJie Yang, QiDong Luo, DeLai Fu, HongLiang Li, Peng Zhang✉ and Chong Tie

Department of Urology, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an City, Shaanxi Province, 710004, China

Circular RNAs (circRNAs) take on regulatory roles in renal cell carcinoma (RCC). The research's goal was to figure out circ-CSPP1's role and molecular mechanism in RCC. The results clarified that circ-CSPP1 expression was enhanced in RCC. Down-regulating circ-CSPP1 refrained the proliferation, migration, invasion, and Warburg effect (aerobic glycolysis), but accelerated apoptosis of RCC cells. The luciferase activity assay exhibited that circ-CSPP1 could perform as an endogenous sponge for miR-493-5p. Elevating miR-493-5p repressed RCC progression. The bioinformatics website starBase confirmed that ras-related C3 botulinum toxin substrate 1 (RAC1) was a target gene of miR-493-5p. Circ-CSPP1 up-regulated RAC1 by sponging miR-493-5p, and elevating RAC1 could turn around the effect of down-regulating circ-CSPP1 on RCC cells. Taken together, circ-CSPP1 is identified as a novel RCC-promoting RNA that could serve as a latent therapeutic target for RCC therapy.

INTRODUCTION

Renal cell carcinoma (RCC) is a class of diversified malignant neoplasms of the renal cortex with diverse clinical, morphological, and genetic features (Rysz *et al.*, 2021). Though clinical interventions like chemotherapy, surgery, and radiotherapy have made great progress, RCC patients' prognosis is still unpleasing. Therefore, it is imperative to develop new therapeutic strategies considering the biological characteristics of RCC cells. It is well known that metabolic reprogramming, a recognized hallmark of cancer, achieves tumor cell proliferation and survival by changing bioenergetic and biosynthetic pathways. Tumor cells having glycolysis high rates (Warburg effect) is a phenomenon that has been extensively studied in RCC (Emberley *et al.*, 2021). Therefore, figuring out the regulatory mechanism of the Warburg effect is likely to be beneficial for the development of effective RCC treatments.

Circular RNAs (circRNAs), a class of covalently closed endogenous RNAs without a 5' cap or 3' poly(A) tail, are cell-specific, tissue-specific, and developmental stage-specific (Huang *et al.*, 2020). For a long time, circRNAs have been regarded as waste products of splicing errors. Recent studies have discovered circRNAs can perform as gene regulators in diversified physiological and pathological processes and can regulate tumorigenesis and cancer progression (Li *et al.*, 2020). Meanwhile, circRNAs have also been clarified to exert biological functions by performing as miRNA sponges or protein sponges (van Zonneveld *et al.*, 2021). Therefore, circRNAs have been identified as latent biomarkers for tumor diagnosis (Zhu *et al.*, 2021). Circ-CSPP1 is a newly identified circRNA that has been confirmed to take on a momentous role in tumorigenesis (Xue, 2020; Sun *et al.*, 2020). However, its role in RCC and its latent mechanisms remain uncertain.

MicroRNAs (miRNAs) are a class of single-stranded non-coding RNAs that post-transcriptionally control gene expression (Bushati *et al.*, 2007). miRNA dysregulation is the key to the pathogenesis of diversified diseases, including cancer (Ali Syeda *et al.*, 2020) and can function as latent oncogenes or tumor suppressor genes (Iorio *et al.*, 2012). For instance, miR-133b impacts cell proliferation, chemosensitivity, and invasion of RCC cells by refraining the ERK signaling pathway (Xu *et al.*, 2020). A former study clarified that miR-493-5p expression is reduced in hepatocellular carcinoma (HCC) (Yang *et al.*, 2021). However, miR-493-5p's functions in RCC and its interaction with circ-CSPP1 remain ambiguous.

Ras-related C3 botulinum toxin substrate 1 (RAC1) is also commonly present in mammalian tissues and cells as a multiplex regulator of epithelial differentiation and is involved in apoptosis-related pathways through the production of reactive oxygen species (Lee *et al.*, 2012). RAC1 has been implicated in multiple cellular processes, such as cell proliferation, tumor metastasis, and epithelial-mesenchymal transition (Yoon *et al.*, 2017). The same pathways shared by circRNAs, miRNAs, and RAC1 suggest that they might function coordinately to orchestrate tumorigenesis. RAC1 has been reported to contribute to the tumorigenesis of RCC (Zhang, 2022; Shan *et al.*, 2017). Thus, RAC1 could be the target gene of miRNAs to regulate the tumorigenesis of RCC.

This study was conducted to figure out the biological characteristics and latent mechanisms of circ-CSPP1 in RCC progression and Warburg effect. Circ-CSPP1 motivated RCC progression and the Warburg effect by targeting miR-493-5p to control RAC1, suggesting that circ-CSPP1 may offer a novel biomarker and latent therapeutic target for RCC.

MATERIALS AND METHODS

Clinical sample collection

The research was approved by the Ethics Committee of The Second Affiliated Hospital of Xi'an Jiaotong University (Approval number.201803XAHT), and informed consent was obtained from each subject before sample collection. Forty pairs of RCC tumor tissues and adjacent normal tissues were harvested from patients in the urology department at The Second Affiliated Hospital of Xi'an Jiaotong University, and two pathologists independently made a definite pathological diagnosis. Adjacent normal tissue was harvested at least 3 cm from the tumor site. Tissues were kept in liquid nitrogen. Clinical data including clinical stage, age, gender, tumor stage, lymph node metastasis, and distant metastasis were recorded.

Cell culture

RCC cell lines (786-O, ACHN, CAKI-1, and OSRC2) and human normal kidney cell line (HK-2) were bought from the Chinese Academy of Sciences (Shanghai, China). Cells were cultured in Roswell Park Memorial Institute (RPMI) 1640 medium plus 10% fetal bovine serum (Gibco, Carlsbad, CA, USA), 100 units (U)/ml penicillin, and 100 U/ml streptomycin (Gibco).

Cell transfection

Transfection of miRNA mimics, inhibitors, small interfering RNAs (siRNAs), and plasmids was done with Lipofectamine 3000 (Invitrogen, Carlsbad, CA) in the light of the manufacturer's instructions. MiR-493-5p mimic, miR-493-5p inhibitor, circ-CSPP1 siRNA (si-circ-CSPP1), RAC1 siRNA (si-RAC1) and their negative controls (NCs) were bought from GenePharma (Shanghai, China). pcDNA 3.1 circRNA mini vector was utilized to elevate circ-CSPP1 expression in RCC cells.

Cell counting kit (CCK)-8 assay

Transfected cells were seeded in 96-well plates (Gibco BRL, Gaithersburg, MD, USA). Measurement of optical density at 450 nm was done with a microplate reader (Millipore, Billerica, MA, USA) (Chen *et al.*, 2020).

Colony formation assay

Transfected cells were seeded in 6-well plates and cultivated for colony formation assay. The colonies were fixed with 4% formaldehyde (Macklin, Shanghai, China), and then staining with 0.3% crystal violet was implemented. Counting and analyzing visible colonies were done by Image J software 1.8.0 (Wang *et al.*, 2020).

Flow cytometry

Apoptosis was tested by Annexin V- fluorescein isothiocyanate/propidium iodide (PI) apoptosis detection kit (Invitrogen). Briefly, double-staining was done with Annexin V and PI, and then the apoptosis rate was examined via FACSCalibur (Becton Dickinson) and FlowJo 10.0 software (Lin *et al.*, 2020).

Transwell assays

For cell invasion assay, transfected cells were seeded into 24-well transwell chambers with Matrigel. After incubation, non-invasive cells were wiped off, invasive cells were fixed with paraformaldehyde, and then staining with crystal violet was implemented. Counting and photographing stained cells in each well were conducted under an inverted microscope (Olympus, Japan). As for the migration experiment, cells were seeded into the upper chamber without Matrigel, and other steps were similar to the cell invasion experiments.

Lactate production, glucose uptake, and ATP

Quantification of glucose levels was done using a glucose assay kit (Sigma-Aldrich, St. Louis, MO, USA). Measurement of lactate levels was implemented using a lactate assay kit (BioVision, Mountain View, CA, USA). ATP levels were tested by the CellTiter-Glo fluorescent cell viability assay (Promega, Madison, MI, USA).

Reverse transcription quantitative polymerase chain reaction (RT-qPCR)

Total RNA was extracted from tissues or cells using the RNeasy Mini Kit (QIAGEN, Hilden, Germany) according to the manufacturer's protocol. cDNA was generated using the Promega reverse transcription kit. RT-qPCR was carried out in the ABI7500 system using the SYBR Green method. Relative gene expression was determined by the $2^{-\Delta\Delta ct}$ method. The primers were clarified in Table 1 (Cao *et al.*, 2020).

Western blot

RIPA lysis buffer (Beyotime) was used to extract total protein. Proteins were separated by 12% Sodium dodecyl sulfate-polyacrylamide gel electrophoresis and electro-blotted onto polyvinylidene fluoride membranes. The membranes were incubated with primary antibodies RAC1 (05-389, 1:1000, MilliporeSigma) and GAPDH (2118, 1:1000, Cell Signaling Technology). Bands were visualized via enhanced chemiluminescence (Millipore) after incubation with the HRP-conjugated secondary antibody. Relative band intensities were quantified by the ChemiDoc XRS imaging system (Liu *et al.*, 2020).

(**A, B**) RT-qPCR to test circ-CSPP1 in RCC tissues and adjacent tissues (n=40), and RCC cell lines; (**C**) Kaplan-Meier survival analysis. Measurement data were shown as mean ± S.D.

Luciferase activity assay

After predicting the binding sites of circ-CSPP1 and RAC1 3'UTR in miR-493-5p, pmirGLO reporter vector (Promega) was utilized to construct circ-CSPP1 and RAC1 3'UTR wild-type (WT) and Mutant (MUT) reporter vectors. A549 cells were incubated with miR-545-5p mimic or mimic NC with the reporter vectors. Then cell luciferase activity was tested by the dual luciferase reporter gene detection kit (Promega) (Yuan *et al.*, 2021).

Statistics

All data were processed by SPSS 21.0 statistical software (SPSS, Inc, Chicago, IL, USA). Measurement data were shown as mean ± standard deviation (S.D.). For the measurement data obeyed a normal distribution, a t-test was used for comparison between the two groups, and a one-way analysis of variance and the Bonferroni post-hoc test were used for comparison among multiple groups. To evaluate the relationship between circ-CSPP1 and the survival prognosis of RCC patients, the Kaplan-Meier method was used for survival analysis, and a log-rank test was used to determine that the difference between high and low expression curves was statistically

significant. Pearson correlation analysis in clinical samples was conducted. $P<0.05$ emphasized obvious statistical meaning.

RESULTS

Circ-CSPP1 is elevated in RCC and is associated with poor prognosis

Circ-CSPP1 was up-regulated in RCC tissues (Fig. 1A). Endogenous circ-CSPP1 was elevated in RCC cell lines, and highest in ACHN cells (Fig. 1B). Therefore, ACHN cells were chosen for subsequent experiments. The 40 patients were divided into two groups according to circ-CSPP1 expression, and circ-CSPP1 was associated with distant metastasis, clinical stage, and tumor stage (Table 2). Meanwhile, it came out that clinical stage, tumor stage, distant metastasis, and circ-CSPP1 were independent predictors of overall survival (OS) of RCC patients (Table 3). Kaplan-Meier survival analysis exhibited that RCC patients with higher circ-CSPP1 expression had poor OS (Fig. 1C). These results suggested

Table 2. The link between circ-CSPP1 and clinicopathological features of RCC

Characteristics	Number	circ-CSPP1		P

that circ-CSPP1 is elevated in RCC and is associated with poor prognosis.

Circ-CSPP1 motivates RCC progression and glycolysis

For studying the biological function of circ-CSPP1 in RCC, si-circ-CSPP1, pcDNA3.1-circ-CSPP1, and corresponding NCs were introduced into ACHN cells, and the transfection efficiency was verified (Fig. 2A). The results clarified that repression of circ-CSPP1 restrained cell proliferation, invasion, and migration, and induced apoptosis, but elevation of circ-CSPP1 had the opposite effect (Fig. 2B–F). Meanwhile, Warburg effect correlation analysis clarified that suppressing circ-CSPP1 reduced lactate production, glucose uptake, and ATP, while up-regulation of circ-CSPP1 resulted in the opposite results (Fig. 2G–I). In addition, similar results were found in KAKi-1 cells (Supplementary Fig. 1A–I at https://ojs.ptbioch.edu.pl/index.php/abp). These data suggested that circ-CSPP1 motivated RCC progression and glycolysis.

Circ-CSPP1 adsorbs miR-493-5p in RCC

The targeting sites for circ-CSPP1 and miR-493-5p were predicted by starBase (Fig. 3A). Luciferase activity assay was performed to testify the binding relationship between circ-CSPP1 and miR-493-5p, and it came out that circ-CSPP1-WT with miR-493-5p mimic reduced luciferase activity, indicating that circ-CSPP1 could combine with miR-493-5p (Fig. 3B). As expected, depression of circ-CSPP1 elevated miR-493-5p expression in ACHN cells, whereas upregulating circ-CSPP1 suppressed miR-493-5p expression (Fig. 3C). Moreover, it was discovered that circ-CSPP1 was inversely correlated with miR-493-5p expression in RCC tissues (Fig. 3D–E). Taken together, these findings suggested that circ-CSPP1 adsorbed miR-493-5p in RCC.

MiR-493-5p represses RCC progression and glycolysis

For studying miR-493-5p's biological function in RCC, miR-493-5p mimic, miR-493-5p inhibitor and corresponding NCs were introduced into ACHN cells, and the transfection efficiency was testified (Fig. 4A). It turned out that elevating miR-493-5p refrained cell progression while repressing miR-493-5p had the opposite effect (Fig. 4B–F). The Warburg effect correlation analysis clarified that elevation of miR-493-5p reduced ATP, glucose uptake and lactate production, while depression of miR-493-5p caused the opposite results (Fig. 4G–I). These results suggested that miR-493-5p depressed RCC progression and glycolysis.

RAC1 is miR-493-5p's downstream target in RCC

starBase was applied for predicting that miR-493-5p had a targeted binding site with RAC1 (Fig. 5A). RAC1 expression was elevated in RCC tissues (Fig. 5B), and miR-493-5p was inversely linked with RAC1 expression in RCC tissues (Fig. 5C). Furthermore, it was found that miR-493-5p mimic could reduce RAC1 expression, whereas miR-493-5p inhibitor could elevate RAC1 expression (Fig. 5D). In the luciferase activity assay, it was found that the luciferase activity was suppressed after introduction of RAC1-WT and miR-493-5p mim-

ic (Fig. 5E). All in all, RAC1 was miR-493-5p's downstream target in RCC.

Circ-CSPP1 accelerates RCC progression and glycolysis through the miR-493-5p/RAC1 axis

After verifying that RAC1 is the target of miR-493-5p, we investigated whether circ-CSPP1 accelerates the development of RCC by controlling the miR-493-5p/RAC1 axis. It was found that upregulation of circ-CSPP1 elevated RAC1 expression, and repression of RAC1 restored RAC1 expression following upregulation of circ-CSPP1 (Fig. 6A). It turned out that repression of RAC1 abolished the motivation of cell proliferation by elevation of circ-CSPP1 (Fig. 6B, C). Likewise, the repressive effect of up-regulated circ-CSPP1 on apoptosis was abolished by down-regulated RAC1 (Fig. 6D). Moreover, RAC1 repression attenuated the promoting effect of circ-CSPP1 upregulation on cell invasion and migration (Fig. 6E, F). Also, repression of RAC1 could turn around the motivation of cellular glycolysis by up-regulation of circ-CSPP1 (Fig. 6G-I). Taken together, these data suggested that circ-CSPP1 motivated RCC progression and glycolysis through the miR-493-5p/RAC1 axis.

DISCUSSION

CircRNAs are extensively studied cancer markers recently (Yan *et al.*, 2021). More studies have shown that circRNA takes on a crucial role in the genesis and progression of diversified tumors. For example, hsa_circ_0065217 is elevated in RCC and motivates RCC growth and metastasis *via* controlling the miR-214-3p-ALPK2 axis (Zhang *et al.*, 2021). Circ_001842 is elevated in RCC and exerts an oncogenic role in RCC *via* a miR-502-5p-dependent SLC39A14 mechanism (Zeng *et al.*, 2020). Our research revealed that circ-CSPP1 was upregulated in RCC tissues, and RCC patients with high circ-CSPP1 expression had a poor prognosis, suggesting that circ-CSPP1 may be a prognostic biomarker for RCC patients. Meanwhile, circ-CSPP1 silencing restrained RCC cell progression *in vitro*, while elevation of circ-CSPP1

Figure 6. Circ-CSPP1 accelerates RCC progression and glycolysis through the miR-493-5p/RAC1 axis.
(**A**) RT-qPCR and Western blot to test RAC1; (**B–C**) CCK-8 and clone formation assay to examine cell proliferation; (**D**) Flow cytometry to detect cell apoptosis; (**E–F**) Transwell to detect cell migration and invasion; (**G–I**) ATP, glucose uptake and lactate production. Measurement data were shown as mean ± S.D. *vs. the pcDNA3.1-circ-CSPP1+si-NC, $P<0.05$.

showed opposite results. These data suggested that circ-CSPP1 motivated the progression of RCC.

It is well known that mammalian cells generate energy through oxidative phosphorylation under aerobic conditions, and during tumorigenesis, cancer cells must rewire their metabolism to maintain survival and reproduction (Urbano *et al.*, 2021). Most cancer cells utilize the Warburg effect to support anabolic growth and tumorigenesis, namely aerobic glycolysis, a metabolic mode that is favored even in the presence of oxygen (Lundø *et al.*, 2020). Warburg effect was found to be beneficial for cancer cell progression and was involved in immune responses (Samec, 2020; Icard *et al.*, 2018). Recent studies have shown that circRNAs can modulate tumor phenotypes, such as metastasis and the Warburg effect. For example, circFOXP1 motivates RCC progression and Warburg effect by sponging miR-423-5p to upregulate U2AF2 (Fang *et al.*, 2021). This study identified a novel circRNA as a regulator of the Warburg effect. The results clarified that downregulation of circ-CSPP1 suppressed the Warburg effect in RCC cells.

Several studies have shown that circ-CSPP1 performs as an oncogene in diversified human cancers and exerts its biological functions by adsorbing miRNAs. For example, circ-CSPP1 is elevated in cervical cancer (CC), and circ-CSPP1 knockdown suppresses CC tumor

growth and migration via downregulating ITGB1, PI3K and Akt expression by sponging miR-361-5p (Yang *et al.*, 2020). Circ-CSPP1 is upregulated in ovarian cancer (OC), and silencing circ-CSPP1 represses OC cell biological functions via upregulating miR-1236-3p (Li *et al.*, 2019). Here, it was confirmed that circ-CSPP1 was a decoy of miR-493-5p. Furthermore, repressing miR-493-5p turned around the effect of circ-CSPP1 silencing on RCC cell progression and Warburg effect, while elevating miR-493-5p turned around the effect of upregulating circ-CSPP1 on RCC progression and Warburg effect in HCC. These results suggested that circ-CSPP1 controlled RCC progression and the Warburg effect via performing as a sponge for miR-493-5p.

MiRNAs control gene expression by combining with mRNAs' 3'-UTR, thereby regulating diversified aspects of cellular activity (Huang *et al.*, 2011). Here, RAC1 was a target of miR-493-5p. RAC1 is a highly conserved rho family small GTPase that is essential for diversified cellular and developmental processes (Banka *et al.*, 2022). RAC1 is elevated in different types of tumors, including RCC, and motivates tumorigenesis by participating in tumor cell biological behaviors (Liang *et al.*, 2021; Goka *et al.*, 2020). This study also confirmed that RAC1 was elevated in RCC tissues, and its expression was up-regulated by elevation of circ-CSPP1 but refrained by upreg-

ulation of miR-493-5p. Moreover, repression of RAC1 clearly turned around the effect of circ-CSPP1 elevation on RCC cell progression and the Warburg effect. These results suggested that circ-CSPP1 motivated RCC progression and glycolysis through miR-493-5p/RAC1 axis.

However, the research still takes on several limitations. Although the role of circ-CSPP1 in RCC progression has been partially elucidated, the study had a small sample size, and more tissue samples are still needed to further examine circ-CSPP1 expression trend in RCC. Also, further animal experiments are required to validate the effect of the circ-CSPP1/miR-493-5p/RAC1 axis on RCC tumor growth *in vivo*. Moreover, the Crabtree effect (inhibitory effect of high glucose on mitochondrial oxidative phosphorylation) may also exist in cancer cells. In other words, under the condition of high glucose concentration, glycolytic metabolism is dominated in cells while aerobic respiration is inhibited, thus generating lactic acid (Diaz *et al.*, 2011; Redman *et al.*, 2013). The Crabtree effect is similar to the Warburg effect, the only difference being that the Crabtree effect is caused by high concentrations of glucose (Hammad *et al.*, 2016), therefore, in future studies, exogenous glucose concentration will be a parameter that needs to be designed more precisely to exclude the interference of Crabtree effect as much as possible.

CONCLUSION

All in all, circ-CSPP1 motivates RCC progression and the Warburg effect by acting as a miR-493-5p sponge to upregulate RAC1. The study findings suggest that circ-CSPP1 may serve as a hopeful diagnostic and therapeutic target for RCC.
